A transmit buffer empty interrupt request when transmission starts is generated by setting the SPE and SPTIE bits to 1 at the same time or by setting the SPE bit to 1 after setting the SPTIE bit to 1.

Note that a transmit buffer interrupt is generated when the SPTIE bit is 1 even if the RSPI function is disabled (the SPTIE bit is changed to 0).

SPE Bit (RSPI Function Enable)

The SPE bit enables or disables the RSPI function.

When the SPSR.MODF flag is 1, the SPE bit cannot be set to 1. For details, refer to section 44.3.8, Error Detection.

Setting the SPE bit to 0 disables the RSPI function, and initializes a part of the module function. For details, refer to section 44.3.9, Initializing RSPI. Furthermore, a transmit buffer empty interrupt request is generated by the state of the SPE bit changing from 0 to 1 or from 1 to 0.

SPRIE Bit (RSPI Receive Buffer Full Interrupt Enable)

If the RSPI has detected a receive buffer full write after completion of a serial transfer, the SPRIE bit enables or disables the generation of an RSPI receive buffer full interrupt request.

44.2.2 RSPI Slave Select Polarity Register (SSLP)

Address(es): RSPI0.SSLP 000D 0101h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	SSL3P	SSL2P	SSL1P	SSL0P
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SSL0P	SSL0 Signal Polarity Setting	0: SSL0 signal is active low 1: SSL0 signal is active high	R/W
b1	SSL1P	SSL1 Signal Polarity Setting	0: SSL1 signal is active low 1: SSL1 signal is active high	R/W
b2	SSL2P	SSL2 Signal Polarity Setting	0: SSL2 signal is active low 1: SSL2 signal is active high	R/W
b3	SSL3P	SSL3 Signal Polarity Setting	0: SSL3 signal is active low 1: SSL3 signal is active high	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

If the contents of SSLP are changed while the SPCR.SPE bit is 1, subsequent operations should not be performed.

44.2.3 RSPI Pin Control Register (SPPCR)

Address(es): RSPI0.SPPCR 000D 0102h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	MOIFE	MOIFV	—	—	SPLP2	SPLP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SPLP	RSPI Loopback	0: Normal mode 1: Loopback mode (data is inverted for transmission)	R/W
b1	SPLP2	RSPI Loopback 2	0: Normal mode 1: Loopback mode (data is not inverted for transmission)	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	MOIFV	MOSI Idle Fixed Value	0: The level output on the MOSIA pin during MOSI idling corresponds to low 1: The level output on the MOSIA pin during MOSI idling corresponds to high	R/W
b5	MOIFE	MOSI Idle Value Fixing Enable	0: MOSI output value equals final data from previous transfer 1: MOSI output value equals the value set in the MOIFV bit	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

If the contents of SPPCR are changed while the SPCR.SPE bit is 1, subsequent operations should not be performed.

SPLP Bit (RSPI Loopback)

The SPLP bit selects the mode of the RSPI pins.
When the SPLP bit is set to 1, the RSPI shuts off the path between the MISOA pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIA pin and the shift register if the SPCR.MSTR bit is 0, and connects (inverts) the input path and output path for the shift register (loopback mode).

SPLP2 Bit (RSPI Loopback 2)

The SPLP2 bit selects the mode of the RSPI pins.
When the SPLP2 bit is set to 1, the RSPI shuts off the path between the MISOA pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIA pin and the shift register if the SPCR.MSTR bit is 0, and connects the input path and output path for the shift register (loopback mode).

MOIFV Bit (MOSI Idle Fixed Value)

If the MOIFE bit is 1 in master mode, the MOIFV bit determines the MOSIA pin output value during the SSL negation period (including the SSL retention period during a burst transfer).

MOIFE Bit (MOSI Idle Value Fixing Enable)

The MOIFE bit fixes the MOSIA output value when the RSPI in master mode is in an SSL negation period (including the SSL retention period during a burst transfer). When the MOIFE bit is 0, the RSPI outputs the last data from the previous serial transfer during the SSL negation period to the MOSIA pin. When the MOIFE bit is 1, the RSPI outputs the fixed value set in the MOIFV bit to the MOSIA pin.

44.2.4 RSPI Status Register (SPSR)

Address(es): RSPI0.SPSR 000D 0103h

	b7	b6	b5	b4	b3	b2	b1	b0
	SPRF	—	SPTEF	—	PERF	MODF	IDLNF	OVRF
Value after reset:	0	0	1	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	OVRF	Overrun Error Flag	0: No overrun error occurs 1: An overrun error occurs	R/(W) *1
b1	IDLNF	RSPI Idle Flag	0: RSPI is in the idle state 1: RSPI is in the transfer state	R
b2	MODF	Mode Fault Error Flag	0: No mode fault error occurs 1: A mode fault error occurs	R/(W) *1
b3	PERF	Parity Error Flag	0: No parity error occurs 1: A parity error occurs	R/(W) *1
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	SPTEF	Transmit Buffer Empty Flag	0: Transmit buffer has valid data 1: Transmit buffer has no valid data	R/(W) *2
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	SPRF	Receive Buffer Full Flag	0: Receive buffer has no valid data 1: Receive buffer has valid data	R/(W) *2

Note 1. Only 0 can be written to clear the flag after reading 1.
Note 2. The write value should be 1.

OVRF Flag (Overrun Error Flag)

The OVRF flag indicates the occurrence of an overrun error. In master mode (when the SPCR.MSTR bit is 1) and when the RSPCK clock auto-stop function is enabled (the SPCR2.SCKASE bit is 1), an overrun error does not occur; accordingly this flag does not become 1. For details, refer to section 44.3.8.1, Overrun Error.

[Setting condition]

- When the next serial transfer ends while the SPCR.TXMD bit is 0 and the receive buffer is full.

[Clearing condition]

- When SPSR is read while the OVRF flag is 1, and then 0 is written to the OVRF flag.

IDLNF Flag (RSPI Idle Flag)

The IDLNF flag indicates the transfer status of the RSPI.

[Setting condition]

Master mode

- Condition 1 and condition 2 are not satisfied in master mode under the [Clearing condition] below.

Slave mode

- The SPCR.SPE bit is 1 (enables the RSPI function)

[Clearing condition]

Master mode

- The following 1 is satisfied (condition 1) or all of the following 2 to 4 are satisfied (condition 2).

1. The SPCR.SPE bit is 0 (disables the RSPI function)
2. The transmit buffer (SPTX) is empty (data for the next transfer is not set)
3. The SPSSR.SPCP[2:0] bits are 000b (beginning of sequence control)

4. The RSPI internal sequencer has entered the idle state (status in which operations up to the next-access delay have finished)

Slave mode

- The SPCR.SPE bit is 0 (disables the RSPI function)

MODF Flag (Mode Fault Error Flag)

Indicates the occurrence of a mode fault error.

[Setting condition]

Multi-master mode

- When the input level of the SSLAi pin changes to the active level while the SPCR.MSTR bit is 1 (master mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), the RSPI detects a mode fault error

Slave mode

- When the SSLAi pin is negated before the RSPCK cycle necessary for data transfer ends while the SPCR.MSTR bit is 0 (slave mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), the RSPI detects a mode fault error

The active level of the SSLAi signal is determined by the SSLP.SSLiP bit (SSLi signal polarity setting bit).

[Clearing condition]

- When SPSR is read while the MODF flag is 1, and then 0 is written to the MODF flag

PERF Flag (Parity Error Flag)

Indicates the occurrence of a parity error.

[Setting condition]

- When a serial transfer ends while the SPCR.TXMD bit is 0 and the SPCR2.SPPE bit is 1, the RSPI detects a parity error

[Clearing condition]

- When SPSR is read while the PERF flag is 1, and then 0 is written to the PERF flag

SPTEF Flag (Transmit Buffer Empty Flag)

Indicates whether the transmit buffer (SPTX) in the RSPI data register has valid data.

[Setting condition]

- When the SPCR.SPE bit is 0 (disables the RSPI function)
- When data is transferred from the transmit buffer to the shift register

[Clearing condition]

- When the number of frames of transmit data specified by the SPDCR.SPFC[1:0] bits is written to the SPDR register

The SPDR register can be set only when the SPTEF flag is 1. The data in the transmit buffer is not updated when the SPDR register is set while the SPTEF flag is 0.

SPRF Flag (Receive Buffer Full Flag)

Indicates whether the receive buffer (SPRX) in the RSPI data register has valid data.

[Setting condition]

- When the number of frames of receive data specified by the SPDCR.SPFC[1:0] bits is transferred from shift register to the receive buffer (SPRX) while the SPCR.TXMD bit is 0 (full duplex) and the SPRF flag is 0.
  Note that the SPRF flag does not become 1 when the OVRF flag is 1.

[Clearing condition]

- When all of the received data are read from the SPDR register

44.2.5 RSPI Data Register (SPDR)

- When accessing in longword size

Address(es): RSPI0.SPDR 000D 0104h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

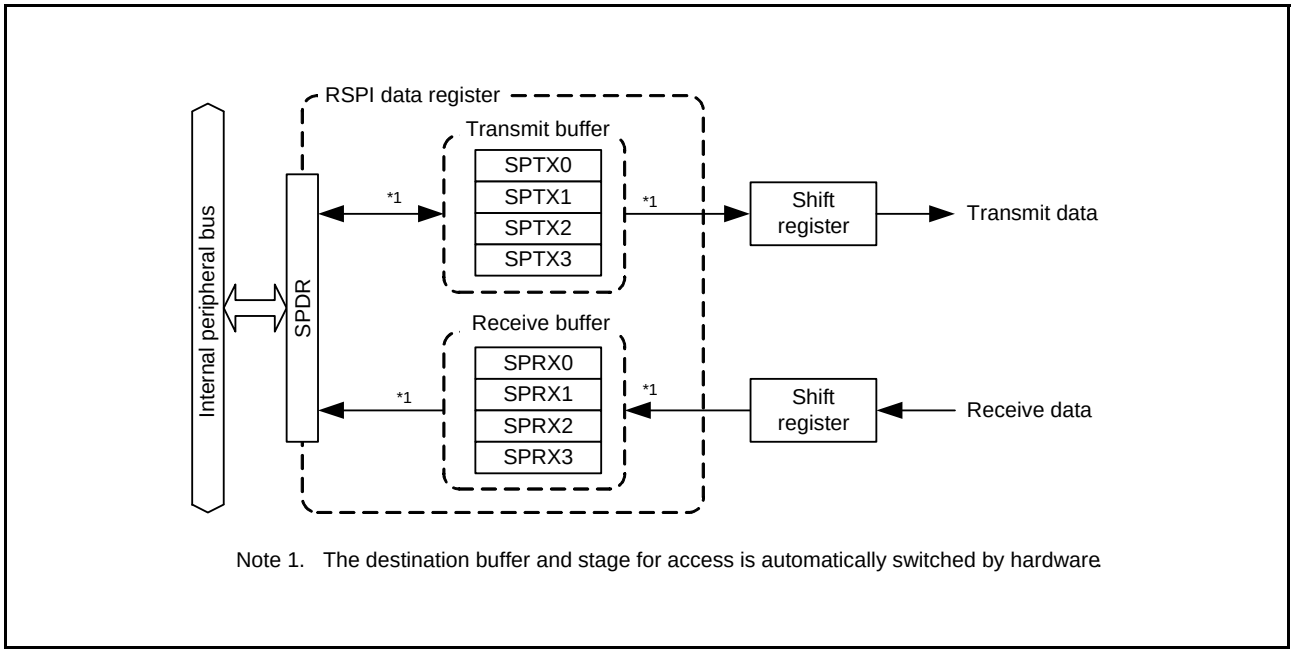
- When accessing in word size

Address(es): RSPI0.SPDR.H 000D 0104h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	H															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SPDR is the interface with the buffers that hold data for transmission and reception by the RSPI.
When accessing in longwords (the SPLW bit is 1), access SPDR in 32-bit units.
When accessing in words (the SPLW bit is 0), access SPDR.H in 16-bit units.
The transmit buffer (SPTX) and receive buffer (SPRX) are independent but are both mapped to SPDR. Figure 44.2 shows the Configuration of SPDR.



Note 1. The destination buffer and stage for access is automatically switched by hardware.

Figure 44.2 Configuration of SPDR

The transmit and receive buffers each have four stages. The number of stages to be used is selectable by the number of frames specification bits in the RSPI data control register (SPDCR.SPFC[1:0]). The eight stages of the buffer are all

mapped to the single address of SPDR.
Data written to SPDR are written to a transmit-buffer stage (SPTXn) (n = 0 to 3) and then transmitted from the buffer. The receive buffer holds received data on completion of reception. The receive buffer is not updated if an overrun is generated.
Furthermore, if the data length is other than 32 bits, bits not referred to in SPTXn (n = 0 to 3) are stored in the corresponding bits in SPRXn. For example, if the data length is 9 bits, received data are stored in the SPRXn[8:0] bits and the SPTXn[31:9] bits are stored in the SPRXn[31:9] bits.

(1) Bus Interface

SPDR is the interface with 32-bit wide transmit and receive buffers, each of which has four stages, for a total of 32 bytes. In other words, the 32 bytes are mapped to the 4-byte address space for SPDR. Furthermore, the unit of access for SPDR is selected by the SPDCR.SPLW bit.
Data for transmission should be flush with the LSB end of the register. Received data are stored flush with the LSB end. Operations involved in writing to and reading from SPDR are described below.

(a) Writing

Data written to SPDR are written to a transmit buffer (SPTXn). This is not influenced by the value of the SPDCR.SPRDTD bit unlike when reading from SPDR.
The transmit buffer includes a transmit buffer write pointer which is automatically updated to indicate the next stage each time data are written to SPDR.
Figure 44.3 shows the configuration of the bus interface with the transmit buffer in the case of writing to SPDR.

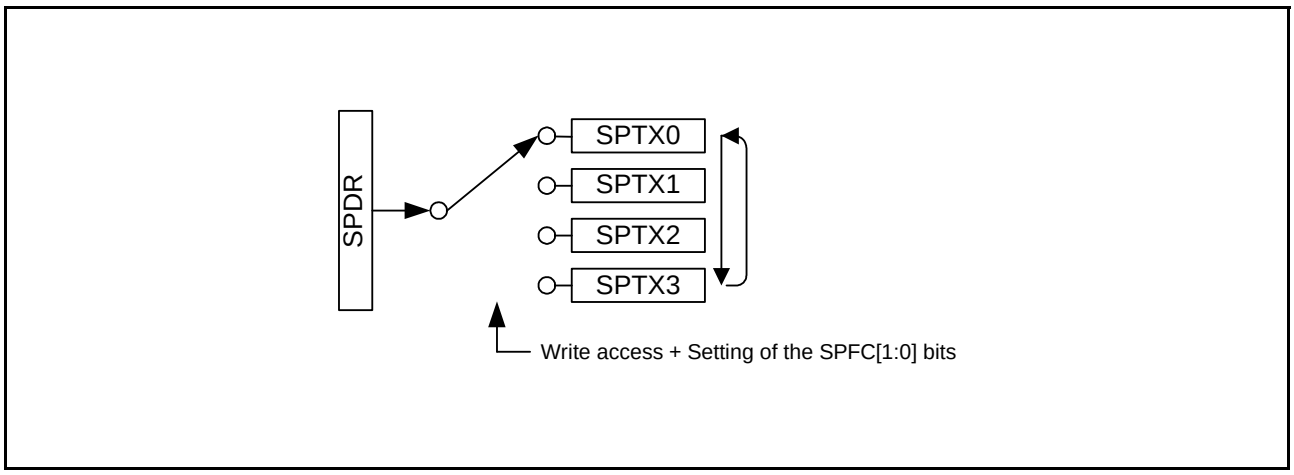


Figure 44.3 Configuration of SPDR (Writing)

The sequence for switching the transmit buffer write pointer differs with the setting of the number of frames specification bits in the RSPI data control register (SPDCR.SPFC[1:0]).

- Settings of the SPFC[1:0] bits and sequence of switching the pointer among SPTX0 to SPTX3.
  When the SPFC[1:0] bits are 00b: SPTX0 → SPTX0 → SPTX0 → …
  When the SPFC[1:0] bits are 01b: SPTX0 → SPTX1 → SPTX0 → SPTX1 → …
  When the SPFC[1:0] bits are 10b: SPTX0 → SPTX1 → SPTX2 → SPTX0 → SPTX1 → …
  When the SPFC[1:0] bits are 11b: SPTX0 → SPTX1 → SPTX2 → SPTX3 → SPTX0 → SPTX1 → …

When 1 is written to the RSPI function enable bit in the RSPI control register (SPCR.SPE) while the bit's current value is 0, SPTX0 will be the destination the next time writing proceeds.
When writing to the transmit buffer (SPTXn) after generation of the transmit buffer empty interrupt (after the SPSR.SPTEF flag becomes 1), write the number of frames set by the number of frames specification bits (SPFC[1:0]) in

the RSPI data control register (SPDCR). Even if the number of frames is written to the transmit buffer (SPTXn), the value of the buffer is not updated after completion of the writing and before generation of the next transmit buffer empty interrupt (while the SPSR.SPTEF flag is 0).

(b) Reading

SPDR can be read to read the value of a receive buffer (SPRXn) or a transmit buffer (SPTXn). The setting of the RSPI receive/transmit data select bit in the RSPI data control register (SPDCR.SPRDTD) selects whether reading is of the receive or transmit buffer.

The sequence of reading the SPDR register is controlled by independent pointers, receive buffer read pointer and transmit buffer read pointer.

Figure 44.4 shows the configuration of the bus interface with the receive and transmit buffers in the case of reading from SPDR.

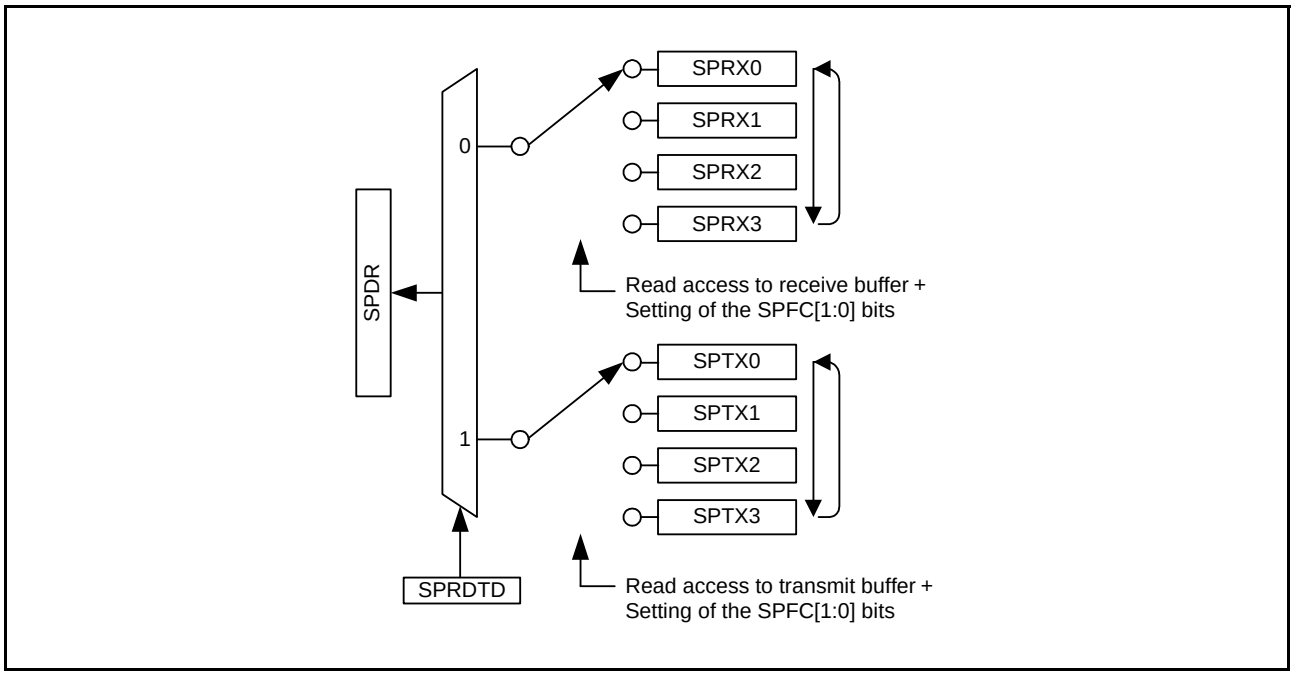

Figure 44.4 Configuration of SPDR (Reading)

Reading the receive buffer switches the receive buffer read pointer to the next buffer automatically.

The sequence of switching the receive buffer read pointer is the same as that for the transmit buffer write pointer. However, when 1 is written to the RSPI function enable bit in the RSPI control register (SPCR.SPE) while the bit's current value is 0, SPRX0 will be indicated by the buffer read pointer the next time reading proceeds.

The transmit buffer read pointer is updated when writing to SPDR, and not updated when reading from the transmit buffer. When reading from the transmit buffer, the value most recently written to SPDR is read. However, after generation of the transmit buffer empty interrupt, the values read from the transmit buffer are all 0 in the interval after completion of writing the number of frames of data specified in the number of frames specification bits (SPDCR.SPFC[1:0]) and before generation of the next buffer empty interrupt (while the SPSR.SPTEF flag is 0).

44.2.6 RSPI Sequence Control Register (SPSCR)

Address(es): RSPI0.SPSCR 000D 0108h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SPSLN[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SPSLN[2:0]	RSPI Sequence Length Specification	b2 b0 Sequence Length — Referenced SPCMD0 to SPCMD7 (No.) 0 0 0: 1 — 0→0→… 0 0 1: 2 — 0→1→0→… 0 1 0: 3 — 0→1→2→0→… 0 1 1: 4 — 0→1→2→3→0→… 1 0 0: 5 — 0→1→2→3→4→0→… 1 0 1: 6 — 0→1→2→3→4→5→0→… 1 1 0: 7 — 0→1→2→3→4→5→6→0→… 1 1 1: 8 — 0→1→2→3→4→5→6→7→0→… The order in which the SPCMD0 to SPCMD7 registers are to be referenced is changed according to the sequence length that is set in these bits. The relationship among the setting of these bits, sequence length, and SPCMD0 to SPCMD7 registers referenced by the RSPI is shown above. However, the RSPI in slave mode references SPCMD0.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SPSCR sets the sequence length when the RSPI operates in master mode. When changing the SPSCR.SPSLN[2:0] bits while both the SPCR.MSTR and SPCR.SPE bits are 1, the bits should be changed while the SPSR.IDLNF flag is 0.

SPSLN[2:0] Bits (RSPI Sequence Length Specification)

The SPSLN[2:0] bits specify a sequence length when the RSPI in master mode performs sequential operations. The RSPI in master mode changes SPCMD0 to SPCMD7 registers to be referenced and the order in which they are referenced according to the sequence length that is set in the SPSLN[2:0] bits.
In slave mode, SPCMD0 is referred.

44.2.7 RSPI Sequence Status Register (SPSSR)

Address(es): RSPI0.SPSSR 000D 0109h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	SPECM[2:0]			—	SPCP[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SPCP[2:0]	RSPI Command Pointer	b2 b0 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
b3	—	Reserved	This bit is read as 0.	R
b6 to b4	SPECM[2:0]	RSPI Error Command	b6 b4 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
b7	—	Reserved	This bit is read as 0.	R

SPSSR indicates the sequence control status when the RSPI operates in master mode.
Any writing to SPSSR is ignored.

SPCP[2:0] Bits (RSPI Command Pointer)

The SPCP[2:0] bits indicate SPCMDm that is currently pointed to by the pointer during sequence control by the RSPI. For the RSPI's sequence control, refer to section 44.3.10.1, Master Mode Operation.

SPECM[2:0] Bits (RSPI Error Command)

The SPECM[2:0] bits indicate SPCMDm that is specified by the SPCP[2:0] bits when an error is detected during sequence control by the RSPI. The RSPI updates the SPECM[2:0] bits only when an error is detected. If both the SPSR.OVRF and SPSR.MODF flags are 0 and there is no error, the values of the SPECM[2:0] bits have no meaning. For the RSPI's error detection function, refer to section 44.3.8, Error Detection. For the RSPI's sequence control, refer to section 44.3.10.1, Master Mode Operation.

44.2.8 RSPI Bit Rate Register (SPBR)

Address(es): RSPI0.SPBR 000D 010Ah

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

SPBR sets the bit rate in master mode. If the contents of SPBR are changed while both the SPCR.MSTR and SPCR.SPE bits are 1, subsequent operations should not be performed.

When the RSPI is used in slave mode, the bit rate depends on the bit rate of the input clock (bit rate satisfying the electrical characteristics should be used) regardless of the settings of SPBR and the SPCMDm.BRDV[1:0] bits (bit rate division setting bits).
The bit rate is determined by combinations of the SPBR setting and the SPCMDm.BRDV[1:0] bit setting. The equation for calculating the bit rate is given below. In the equation, n denotes an SPBR setting (0, 1, 2, …, 255), and N denotes a BRDV[1:0] bit setting (0, 1, 2, 3).

$$\text{Bit rate} = \frac{f(PCLK)}{2 \times (n + 1) \times 2^{N}}$$

Table 44.3 lists examples of the relationship among the SPBR settings, the BRDV[1:0] settings, and bit rates.
Use the bit rate that meets electrical characteristics based on the AC specifications of the target device.

Table 44.3 Relationship among SPBR Settings, BRDV[1:0] Settings, and Bit Rates

SPBR (n)	BRDV[1:0] Bits (N)	Division Ratio	Bit Rate							
			PCLK = 32 MHz	PCLK = 36 MHz	PCLK = 40 MHz	PCLK = 50 MHz	PCLK = 60 MHz	PCLK = 80 MHz	PCLK = 100 MHz	PCLK = 120 MHz

44.2.9 RSPI Data Control Register (SPDCR)

Address(es): RSPI0.SPDCR 000D 010Bh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	SPLW	SPRDTD	—	—	SPFC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	SPFC[1:0]	Number of Frames Specification	b1 b0 0 0: 1 frame 0 1: 2 frames 1 0: 3 frames 1 1: 4 frames	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	SPRDTD	RSPI Receive/Transmit Data Select	0: SPDR values are read from the receive buffer 1: SPDR values are read from the transmit buffer (but only if the transmit buffer is empty)	R/W
b5	SPLW	RSPI Longword Access/ Word Access Specification	0: SPDR is accessed in words 1: SPDR is accessed in longwords	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Up to four frames can be transmitted or received in one round of transmission or reception activation. The amount of data in each transfer is controlled by the combination of the SPCMDm.SPB[3:0] bits, the SPSCR.SPSLN[2:0] bits, and the SPDCR.SPFC[1:0] bits.
When changing the SPDCR.SPFC[1:0] bits while the SPCR.SPE bit is 1, the bits should be changed while the SPSR.IDLNF flag is 0.

SPFC[1:0] Bits (Number of Frames Specification)

The SPFC[1:0] bits specify the number of frames that can be stored in SPDR (per transfer activation). Up to four frames can be transmitted or received in one round of transmission or reception, and the amount of data is determined by the combination of the SPSCR.SPSLN[2:0] bits, and the SPDCR.SPFC[1:0] bits. Furthermore, the setting of the SPFC[1:0] bits adjusts the number of frames for generation of RSPI receive buffer full interrupt, and start of transmission or generation of transmit buffer empty interrupts.
When the number of frames of transmit data specified by SPFC[1:0] bits is written to the SPDR register, the SPSR.SPTEF flag becomes 0 and transmission starts. Then, when the specified number of frames of transmit data has been transferred to the shift register, the SPTEF flag becomes 1 and the RSPI transmit buffer empty interrupt is generated.
When the number of frames specified by the SPFC[1:0] bits are received, the SPSR.SPRF flag becomes 1 and the RSPI receive buffer full interrupt is generated.
Table 44.4 lists the frame configurations that can be stored in SPDR and examples of combinations of settings for transmission and reception. If combinations of settings other than those shown in the examples are made, subsequent operations should not be performed.

Table 44.4 Settable Combinations of SPSLN[2:0] Bits and SPFC[1:0] Bits

Setting	SPSLN[2:0]	SPFC[1:0]	Number of Frames in a Single Sequence	Number of Frames at which Transmit Buffer or Receive Buffer Status Becomes “Has Valid Data”
1-1	000b	00b	1	1
1-2	000b	01b	2	2
1-3	000b	10b	3	3
1-4	000b	11b	4	4

4	011b	11b	4	4
5	100b	00b	5	1
6	101b	00b	6	1
7	110b	00b	7	1
8	111b	00b	8	1

SPRDTD Bit (RSPI Receive/Transmit Data Select)

The SPRDTD bit selects whether the SPDR reads values from the receive buffer or from the transmit buffer.
If reading is from the transmit buffer, the value written to SPDR register immediately beforehand is read.
When reading the transmit buffer, do so before writing of the number of frames set in the SPFC[1:0] bits is finished and after generation of the transmit buffer empty interrupt (While the SPSR.SPTEF flag is 1).
For details, refer to section 44.2.5, RSPI Data Register (SPDR).

SPLW Bit (RSPI Longword Access/Word Access Specification)

The SPLW bit specifies the access width for SPDR. Access to the SPDR register in words when the SPLW bit is 0 and in longwords when the SPLW bit is 1.
Also, when the SPLW bit is 0, set the SPCMDm.SPB[3:0] bits (RSPI data length setting bits) to 8 to 16 bits. When 20, 24, or 32 bits is specified, operations should not be performed.

44.2.10 RSPI Clock Delay Register (SPCKD)

Address(es): RSPI0.SPCKD 000D 010Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SCKDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SCKDL[2:0]	RSPCK Delay Setting	b2 b0 0 0 0: 1 RSPCK 0 0 1: 2 RSPCK 0 1 0: 3 RSPCK 0 1 1: 4 RSPCK 1 0 0: 5 RSPCK 1 0 1: 6 RSPCK 1 1 0: 7 RSPCK 1 1 1: 8 RSPCK	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SPCKD sets a period from the beginning of SSLAi signal assertion to RSPCK oscillation (RSPCK delay) when the SPCMDm.SCKDEN bit is 1. If the contents of SPCKD are changed while both the SPCR.MSTR and SPCR.SPE bits are 1, subsequent operations should not be performed.

SCKDL[2:0] Bits (RSPCK Delay Setting)

The SCKDL[2:0] bits set an RSPCK delay value when the SPCMDm.SCKDEN bit is 1.
When using the RSPI in slave mode, set the SCKDL[2:0] bits to 000b.

44.2.11 RSPI Slave Select Negation Delay Register (SSLND)

Address(es): RSPI0.SSLND 000D 010Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SLNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SLNDL[2:0]	SSL Negation Delay Setting	b2 b0 0 0 0: 1 RSPCK 0 0 1: 2 RSPCK 0 1 0: 3 RSPCK 0 1 1: 4 RSPCK 1 0 0: 5 RSPCK 1 0 1: 6 RSPCK 1 1 0: 7 RSPCK 1 1 1: 8 RSPCK	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

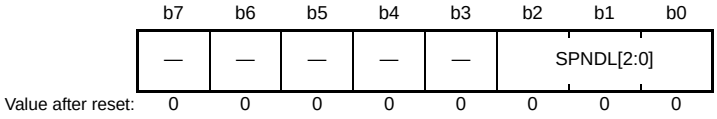
SSLND sets a period (SSL negation delay) from the transmission of a final RSPCK edge to the negation of the SSLAi signal during a serial transfer by the RSPI in master mode. If the contents of SSLND are changed while both the SPCR.MSTR and SPCR.SPE bits are 1, subsequent operations should not be performed.

SLNDL[2:0] Bits (SSL Negation Delay Setting)

The SLNDL[2:0] bits set an SSL negation delay value when the RSPI is in master mode.
When using the RSPI in slave mode, set the SLNDL[2:0] bits to 000b.

44.2.12 RSPI Next-Access Delay Register (SPND)

Address(es): RSPI0.SPND 000D 010Eh



Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SPNDL[2:0]	RSPI Next-Access Delay Setting	b2 b0 0 0 0: 1 RSPCK + 2 PCLK 0 0 1: 2 RSPCK + 2 PCLK 0 1 0: 3 RSPCK + 2 PCLK 0 1 1: 4 RSPCK + 2 PCLK 1 0 0: 5 RSPCK + 2 PCLK 1 0 1: 6 RSPCK + 2 PCLK 1 1 0: 7 RSPCK + 2 PCLK 1 1 1: 8 RSPCK + 2 PCLK	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SPND sets a non-active period (next-access delay) of the SSLAi signal after termination of a serial transfer when the SPCMDm.SPNDEN bit is 1. If the contents of SPND are changed while both the SPCR.MSTR and SPCR.SPE bits are 1, subsequent operations should not be performed.

SPNDL[2:0] Bits (RSPI Next-Access Delay Setting)

The SPNDL[2:0] bits set a next-access delay when the SPCMDm.SPNDEN bit is 1.
When using the RSPI in slave mode, set the SPNDL[2:0] bits to 000b.

44.2.13 RSPI Control Register 2 (SPCR2)

Address(es): RSPI0.SPCR2 000D 010Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	SCKASE	PTE	SPIIE	SPOE	SPPE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SPPE	Parity Enable	0: Does not add the parity bit to transmit data and does not check the parity bit of receive data 1: Adds the parity bit to transmit data and checks the parity bit of receive data (when SPCR.TXMD = 0) Adds the parity bit to transmit data but does not check the parity bit of receive data (when SPCR.TXMD = 1)	R/W
b1	SPOE	Parity Mode	0: Selects even parity for use in transmission and reception 1: Selects odd parity for use in transmission and reception	R/W
b2	SPIIE	RSPI Idle Interrupt Enable	0: Disables the generation of idle interrupt requests 1: Enables the generation of idle interrupt requests	R/W
b3	PTE	Parity Self-Diagnosis	0: Disables the self-diagnosis function of the parity circuit 1: Enables the self-diagnosis function of the parity circuit	R/W
b4	SCKASE	RSPCK Auto-Stop Function Enable	0: Disables the RSPCK auto-stop function 1: Enables the RSPCK auto-stop function	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

If the SPPE, SPOE, or SCKASE bit in SPCR2 is changed while the SPCR.SPE bit is 1, subsequent operations should not be performed.

SPPE Bit (Parity Enable)

The SPPE bit enables or disables the parity function.

The parity bit is added to transmit data and parity checking is performed for receive data when the SPCR.TXMD bit is 0 and the SPCR2.SPPE bit is 1.

The parity bit is added to transmit data but parity checking is not performed for receive data when the SPCR.TXMD bit is 1 and the SPCR2.SPPE bit is 1.

SPOE Bit (Parity Mode)

The SPOE bit specifies odd or even parity.

When even parity is set, parity bit addition is performed so that the total number of 1-bits in the transmit/receive character plus the parity bit is even. Similarly, when odd parity is set, parity bit addition is performed so that the total number of 1-bits in the transmit/receive character plus the parity bit is odd.

The SPOE bit is valid only when the SPPE bit is 1.

SPIIE Bit (RSPI Idle Interrupt Enable)

The SPIIE bit enables or disables the generation of RSPI idle interrupt requests when the RSPI being in the idle state is detected and the SPSR.IDLNF flag is set to 0.

PTE Bit (Parity Self-Diagnosis)

The PTE bit enables the self-diagnosis function of the parity circuit in order to check whether the parity function is operating correctly.

SCKASE Bit (RSPCK Auto-Stop Function Enable)

The SCKASE bit enables or disables the RSPCK auto-stop function. When this function is enabled, the RSPCK clock is stopped before an overrun error occurs when data is received in master mode. For details, refer to section 44.3.8.1, Overrun Error.

44.2.14 RSPI Command Registers 0 to 7 (SPCMD0 to SPCMD7)

Address(es): RSPI0.SPCMD0 000D 0110h, RSPI0.SPCMD1 000D 0112h, RSPI0.SPCMD2 000D 0114h, RSPI0.SPCMD3 000D 0116h, RSPI0.SPCMD4 000D 0118h, RSPI0.SPCMD5 000D 011Ah, RSPI0.SPCMD6 000D 011Ch, RSPI0.SPCMD7 000D 011Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SCKDEN	SLNDEN	SPNDEN	LSBF	SPB[3:0]				SSLKP	SSLA[2:0]			BRDV[1:0]		CPOL	CPHA
Value after reset:	0	0	0	0	0	1	1	1	0	0	0	0	1	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	CPHA	RSPCK Phase Setting	0: Data sampling on odd edge, data variation on even edge 1: Data variation on odd edge, data sampling on even edge	R/W
b1	CPOL	RSPCK Polarity Setting	0: RSPCK is low when idle 1: RSPCK is high when idle	R/W
b3, b2	BRDV[1:0]	Bit Rate Division Setting	b3 b2 0 0: These bits select the base bit rate 0 1: These bits select the base bit rate divided by 2 1 0: These bits select the base bit rate divided by 4 1 1: These bits select the base bit rate divided by 8	R/W
b6 to b4	SSLA[2:0]	SSL Signal Assertion Setting	b6 b4 0 0 0: SSL0 0 0 1: SSL1 0 1 0: SSL2 0 1 1: SSL3 1 x x: Setting prohibited x: Don't care	R/W
b7	SSLKP	SSL Signal Level Keeping	0: Negates all SSL signals upon completion of transfer 1: Keeps the SSL signal level from the end of transfer until the beginning of the next access	R/W
b11 to b8	SPB[3:0]	RSPI Data Length Setting	b11 b8 0100 to 0111: 8 bits 1 0 0 0: 9 bits 1 0 0 1: 10 bits 1 0 1 0: 11 bits 1 0 1 1: 12 bits 1 1 0 0: 13 bits 1 1 0 1: 14 bits 1 1 1 0: 15 bits 1 1 1 1: 16 bits 0 0 0 0: 20 bits 0 0 0 1: 24 bits 0010, 0011: 32 bits	R/W
b12	LSBF	RSPI LSB First	0: MSB first 1: LSB first	R/W
b13	SPNDEN	RSPI Next-Access Delay Enable	0: A next-access delay of 1 RSPCK + 2 PCLK 1: A next-access delay is equal to the setting of the RSPI next-access delay register (SPND)	R/W
b14	SLNDEN	SSL Negation Delay Setting Enable	0: An SSL negation delay of 1 RSPCK 1: An SSL negation delay is equal to the setting of the RSPI slave select negation delay register (SSLND)	R/W
b15	SCKDEN	RSPCK Delay Setting Enable	0: An RSPCK delay of 1 RSPCK 1: An RSPCK delay is equal to the setting of the RSPI clock delay register (SPCKD)	R/W

SPCMDm register is used to set a transfer format for the RSPI in master mode. Each channel has eight RSPI command registers (SPCMD0 to SPCMD7). Some of the bits in SPCMD0 register is used to set a transfer mode for the RSPI in slave mode. The RSPI in master mode sequentially references SPCMDm register according to the settings in the SPSCR.SPSLN[2:0] bits, and executes the serial transfer that is set in the referenced SPCMDm register.
SPCMDm register should be set while the transmit buffer is empty (data for the next transfer is not set) and before setting of the data that is to be transmitted when that SPCMDm register is referenced.
SPCMDm that is referenced by the RSPI in master mode can be checked by means of the SPSSR.SPCP[2:0] bits. If the contents of SPCMDm are changed while the SPCR.MSTR bit is 0 and the SPCR.SPE bit is 1, subsequent operations should not be performed.

CPHA Bit (RSPCK Phase Setting)

The CPHA bit sets an RSPCK phase of the RSPI in master mode or slave mode. Data communications between RSPI modules require the same RSPCK phase setting between the modules.

CPOL Bit (RSPCK Polarity Setting)

The CPOL bit sets an RSPCK polarity of the RSPI in master mode or slave mode. Data communications between RSPI modules require the same RSPCK polarity setting between the modules.

BRDV[1:0] Bits (Bit Rate Division Setting)

The BRDV[1:0] bits are used to determine the bit rate. A bit rate is determined by combinations of the settings in the BRDV[1:0] bits and SPBR (refer to section 44.2.8, RSPI Bit Rate Register (SPBR)). The settings in SPBR determine the base bit rate. The settings in the BRDV[1:0] bits are used to select a bit rate which is obtained by dividing the base bit rate by 1, 2, 4, or 8. In SPCMDm register, different BRDV[1:0] bit settings can be specified. This enables execution of serial transfers at a different bit rate for each command.

SSLA[2:0] Bits (SSL Signal Assertion Setting)

The SSLA[2:0] bits control the SSLAi signal assertion when the RSPI performs serial transfers in master mode.
Setting the SSLA[2:0] bits controls the assertion for the SSLAi signal. When an SSLAi signal is asserted, its polarity is determined by the set value in the corresponding SSLP. When the SSLA[2:0] bits are set to 000b in multi-master mode, serial transfers are performed with all the SSL signals in the negated state (as the SSLA0 pin acts as input).
When using the RSPI in slave mode, set the SSLA[2:0] bits to 000b.

SSLKP Bit (SSL Signal Level Keeping)

When the RSPI in master mode performs a serial transfer, the SSLKP bit specifies whether the SSLAi signal level for the current command is to be kept or negated between the SSL negation timing associated with the current command and the SSL assertion timing associated with the next command.
Setting the SSLKP bit to 1 enables a burst transfer. For details, refer to section 44.3.10.1, Master Mode Operation (4) Burst Transfer.
When using the RSPI in slave mode, the SSLKP bit should be set to 0.

SPB[3:0] Bits (RSPI Data Length Setting)

The SPB[3:0] bits set a transfer data length for the RSPI in master mode or slave mode. When the SPDCR.SPLW bit is 0, set the SPB[3:0] bits to “0100b” (8 bits) to “1111b” (16 bits).

LSBF Bit (RSPI LSB First)

The LSBF bit sets the data format of the RSPI in master mode or slave mode to MSB first or LSB first.

SPNDEN Bit (RSPI Next-Access Delay Enable)

The SPNDEN bit sets the period from the time the RSPI in master mode terminates a serial transfer and sets the SSLAi signal inactive until the RSPI enables the SSLAi signal assertion for the next access (next-access delay). If the SPNDEN bit is 0, the RSPI sets the next-access delay to 1 RSPCK + 2 PCLK. If the SPNDEN bit is 1, the RSPI inserts a next-access delay in compliance with the SPND setting.

When using the RSPI in slave mode, the SPNDEN bit should be set to 0.

SLNDEN Bit (SSL Negation Delay Setting Enable)

The SLNDEN bit sets the period from the time the RSPI in master mode stops RSPCK oscillation until the RSPI sets the SSLAi signal inactive (SSL negation delay). If the SLNDEN bit is 0, the RSPI sets the SSL negation delay to 1 RSPCK. If the SLNDEN bit is 1, the RSPI negates the SSL signal at an SSL negation delay in compliance with the SSLND setting.

When using the RSPI in slave mode, the SLNDEN bit should be set to 0.

SCKDEN Bit (RSPCK Delay Setting Enable)

The SCKDEN bit sets the period from the point when the RSPI in master mode activates the SSLAi signal until the RSPCK starts oscillation (RSPI clock delay). If the SCKDEN bit is 0, the RSPI sets the RSPCK delay to 1 RSPCK. If the SCKDEN bit is 1, the RSPI starts the oscillation of RSPCK at an RSPCK delay in compliance with the SPCKD setting.

When using the RSPI in slave mode, the SCKDEN bit should be set to 0.

44.3 Operation

In this section, the serial transfer period means a period from the beginning of driving valid data to the fetching of the final valid data.

44.3.1 Overview of RSPI Operations

The RSPI is capable of synchronous serial transfers in slave mode (SPI operation), single-master mode (SPI operation), multi-master mode (SPI operation), slave mode (clock synchronous operation), and master mode (clock synchronous operation). A particular mode of the RSPI can be selected by using the MSTR, MODFEN, and SPMS bits in SPCR. Table 44.5 lists the relationship between RSPI modes and SPCR settings, and a description of each mode.

Table 44.5 Relationship between RSPI Modes and SPCR Settings and Description of Each Mode

Mode	Slave (SPI Operation)	Single-Master (SPI Operation)	Multi-Master (SPI Operation)	Slave (Clock Synchronous Operation)	Master (Clock Synchronous Operation)
MSTR bit setting	0	1	1	0	1
MODFEN bit setting	0 or 1	0	1	0	0
SPMS bit setting	0	0	0	1	1
RSPCKA signal	Input	Output	Output/Hi-Z	Input	Output
MOSIA signal	Input	Output	Output/Hi-Z	Input	Output
MISOA signal	Output/Hi-Z	Input	Input	Output	Input
SSLA0 signal	Input	Output	Input	Hi-Z*1	Hi-Z*1
SSLA1 to SSLA3 signals	Hi-Z*1	Output	Output/Hi-Z	Hi-Z*1	Hi-Z*1
SSL polarity change function	Supported	Supported	Supported	—	—
Transfer rate	Up to PCLK/8	Up to PCLK/2	Up to PCLK/2	Up to PCLK/8	Up to PCLK/2
Clock source	RSPCK input	On-chip baud rate generator	On-chip baud rate generator	RSPCK input	On-chip baud rate generator
Clock polarity	Two				
Clock phase	Two	Two	Two	One (CPHA = 1)	Two
First transfer bit	MSB/LSB				
Transfer data length	8 to 16, 20, 24, 32 bits				
Burst transfer	Possible (CPHA = 1)	Possible (CPHA = 0,1)	Possible (CPHA = 0,1)	—	—
RSPCK delay control	Not supported	Supported	Supported	Not supported	Supported
SSL negation delay control	Not supported	Supported	Supported	Not supported	Supported
Next-access delay control	Not supported	Supported	Supported	Not supported	Supported
Transfer activation method	SSL input active or RSPCK oscillation	Transmit buffer is written to at generation of a transmit buffer empty interrupt request or when the SPTEF flag is 1	Transmit buffer is written to at generation of a transmit buffer empty interrupt request or when the SPTEF flag is 1	RSPCK oscillation	Transmit buffer is written to at generation of a transmit buffer empty interrupt request or when the SPTEF flag is 1
Sequence control	Not supported	Supported	Supported	Not supported	Supported
Transmit buffer empty detection	Supported				
Receive buffer full detection	Supported*2				
Overrun error detection	Supported*2	Supported*2, *4	Supported*2, *4	Supported*2	Supported*2
Parity error detection	Supported*2,*3				
Mode fault error detection	Supported (MODFEN = 1)	Not supported	Supported	Not supported	Not supported

Note 1. This function is not supported in this mode.
Note 2. When the SPCR.TXMD bit is 1, receiver buffer full detection, overrun error detection, and parity error detection are not performed.
Note 3. When the SPCR2.SPPE bit is 0, parity error detection is not performed.
Note 4. When the SPCR2.SCKASE bit is 1, overrun error detection does not proceed.

44.3.2 Controlling RSPI Pins

According to the MSTR, MODFEN, and SPMS bits in SPCR and the ODRn.Bi bit for I/O ports, the RSPI can switch pin states. Table 44.6 lists the relationship between pin states and bit settings. Setting the ODRn.Bi bit for an I/O port to 0 selects CMOS output; setting it to 1 selects open-drain output. The I/O port settings should follow this relationship.

Table 44.6 Relationship between Pin States and Bit Settings

Mode	Pin	Pin State*2	
		ODRn.Bi Bit for I/O Ports = 0	ODRn.Bi Bit for I/O Ports = 1
Single-master mode (SPI operation) (MSTR = 1, MODFEN = 0, SPMS = 0)	RSPCKA	CMOS output	Open-drain output
	SSLA0 to SSLA3	CMOS output	Open-drain output
	MOSIA	CMOS output	Open-drain output
	MISOA	Input	Input
Multi-master mode (SPI operation) (MSTR = 1, MODFEN = 1, SPMS = 0)	RSPCKA*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	SSLA0	Input	Input
	SSLA1 to SSLA3*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MOSIA*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MISOA	Input	Input
Slave mode (SPI operation) (MSTR = 0, SPMS = 0)	RSPCKA	Input	Input
	SSLA0	Input	Input
	SSLA1 to SSLA3*5	Hi-Z*1	Hi-Z*1
	MOSIA	Input	Input
	MISOA*4	CMOS output/Hi-Z	Open-drain output/Hi-Z
Master mode (Clock synchronous operation) (MSTR = 1, MODFEN = 0, SPMS = 1)	RSPCKA	CMOS output	Open-drain output
	SSLA0 to SSLA3*5	Hi-Z*1	Hi-Z*1
	MOSIA	CMOS output	Open-drain output
	MISOA	Input	Input
Slave mode (Clock synchronous operation) (MSTR = 0, SPMS = 1)	RSPCKA	Input	Input
	SSLA0 to SSLA3*5	Hi-Z*1	Hi-Z*1
	MOSIA	Input	Input
	MISOA	CMOS output	Open-drain output

Note 1. This function is not supported in this mode.
Note 2. RSPI settings are not reflected in the multiplex pins for which the RSPI function is not selected.
Note 3. When SSLA0 is at the active level, the pin state is Hi-Z.
Note 4. When SSLA0 is at the non-active level or the SPCR.SPE bit is 0, the pin state is Hi-Z.
Note 5. These pins are available for use as I/O port pins.

The RSPI in single-master mode (SPI operation) or multi-master mode (SPI operation) determines MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) according to MOIFE and MOIFV bit settings in SPPCR, as listed in Table 44.7.

Table 44.7 MOSI Signal Value Determination during SSL Negation Period

MOIFE Bit	MOIFV Bit	MOSIA Signal Value during SSL Negation Period
0	0, 1	Final data from previous transfer
1	0	Low
1	1	High

44.3.3 RSPI System Configuration Examples

44.3.3.1 Single Master/Single Slave (with This MCU Acting as Master)

Figure 44.5 shows a single-master/single-slave RSPI system configuration example when this MCU is used as a master. In the single-master/single-slave configuration, the SSLA0 to SSLA3 output of this MCU (master) are not used. The SSL input of the SPI slave is fixed to the low level, and the SPI slave is maintained in a select state.*1
This MCU (master) drives the RSPCKA and MOSIA. The SPI slave drives the MISO.

Note 1. In the transfer format corresponding to the case where the SPCMDm.CPHA bit is 0, there are slave devices for which the SSL signal cannot be fixed to the active level. In situations where the SSL signal cannot be fixed, the SSLAi output of this MCU should be connected to the SSL input of the slave device.

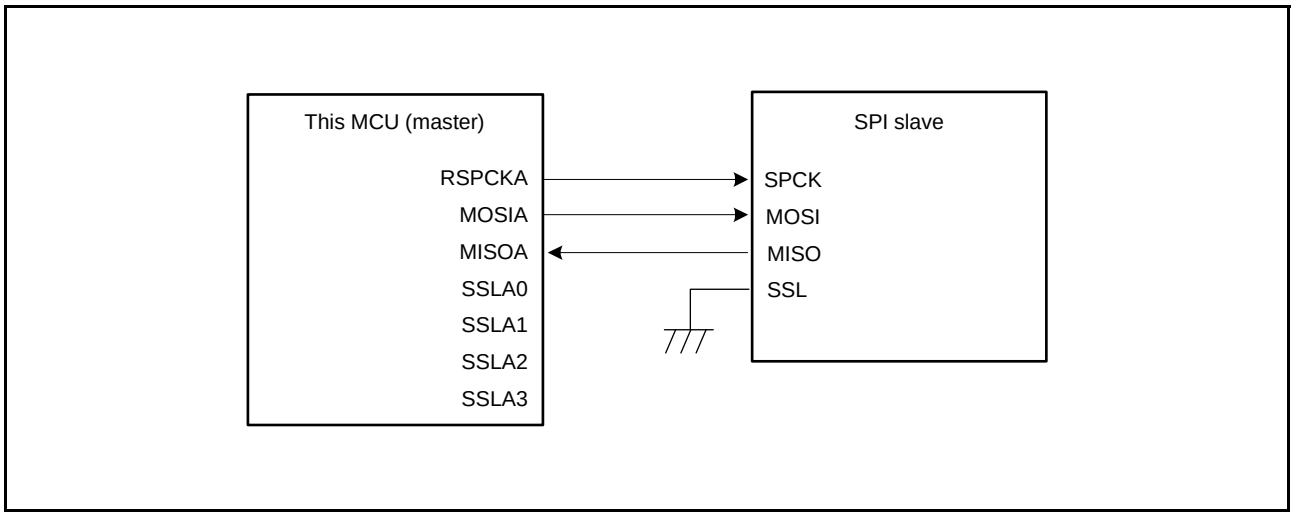


Figure 44.5 Single-Master/Single-Slave Configuration Example (This MCU = Master)

44.3.3.2 Single Master/Single Slave (with This MCU Acting as Slave)

Figure 44.6 shows a single-master/single-slave RSPI system configuration example when this MCU is used as a slave. When this MCU is to operate as a slave, the SSLA0 pin is used as SSL input. The SPI master drives the RSPCK and MOSI. This MCU (slave) drives the MISOA.*1

In the single-slave configuration in which the SPCMDm.CPHA bit is set to 1, the SSLA0 input of this MCU (slave) is fixed to the low level, this MCU (slave) is maintained in a select state, and in this manner it is possible to execute serial transfer (Figure 44.7).

Note 1. When SSLA0 is at the non-active level, the pin state is Hi-Z.

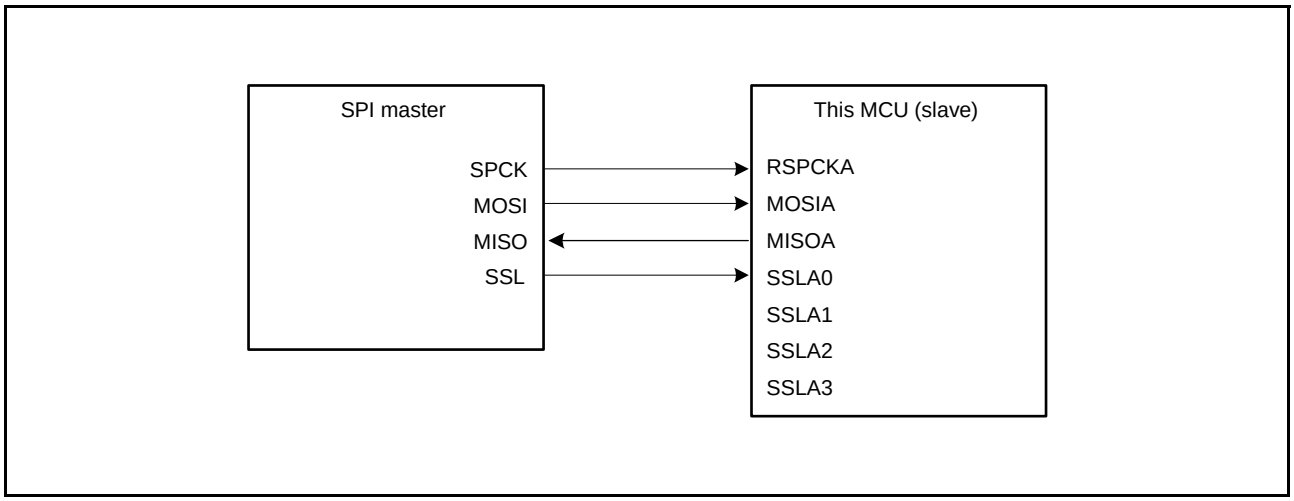

Figure 44.6 Single-Master/Single-Slave Configuration Example (This MCU = Slave, CPHA = 0)

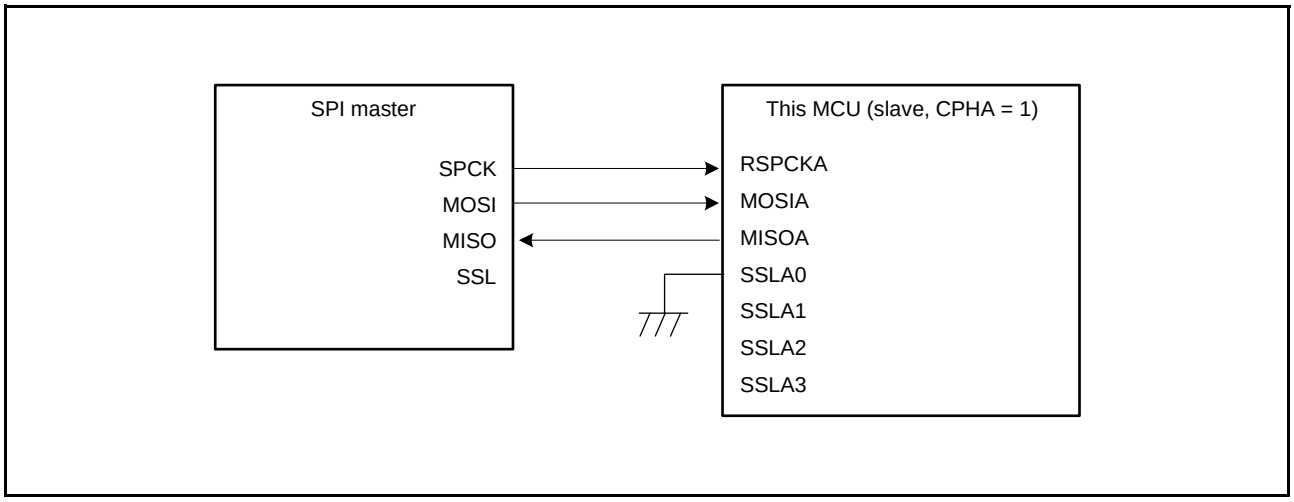

Figure 44.7 Single-Master/Single-Slave Configuration Example (This MCU = Slave, CPHA = 1)

44.3.3.3 Single Master/Multi-Slave (with This MCU Acting as Master)

Figure 44.8 shows a single-master/multi-slave RSPI system configuration example when this MCU is used as a master. In the example of Figure 44.8, the RSPI system is comprised of this MCU (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCKA and MOSIA outputs of this MCU (master) are connected to the RSPCK and MOSI inputs of SPI slave 0 to SPI slave 3. The MISO outputs of SPI slave 0 to SPI slave 3 are all connected to the MISOA input of this MCU (master). SSLA0 to SSLA3 outputs of this MCU (master) are connected to the SSL inputs of SPI slave 0 to SPI slave 3, respectively.

This MCU (master) drives RSPCKA, MOSIA, and SSLA0 to SSLA3. Of the SPI slave 0 to SPI slave 3, the slave that receives low-level input into the SSL input drives MISO.

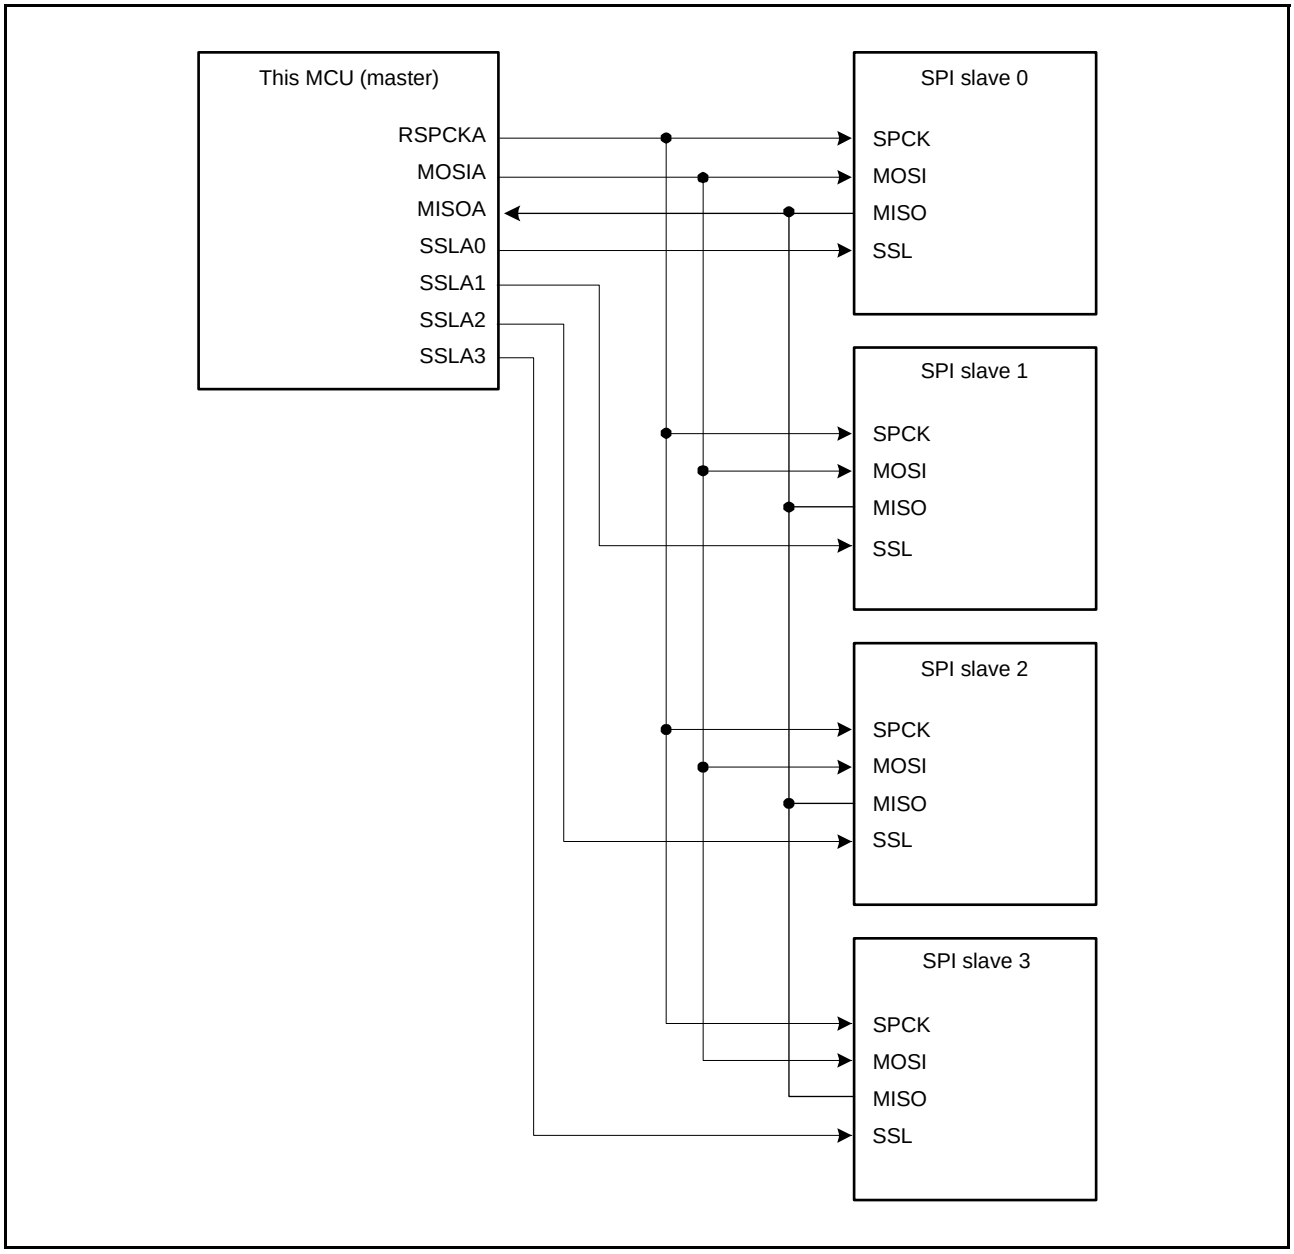

Figure 44.8 Single-Master/Multi-Slave Configuration Example (This MCU = Master)

44.3.3.4 Single Master/Multi-Slave (with This MCU Acting as Slave)

Figure 44.9 shows a single-master/multi-slave RSPI system configuration example when this MCU is used as a slave. In the example of Figure 44.9, the RSPI system is comprised of an SPI master and two MCUs (slave X and slave Y). The SPCK and MOSI outputs of the SPI master are connected to the RSPCKA and MOSIA inputs of the MCUs (slave X and slave Y). The MISOA outputs of the MCUs (slave X and slave Y) are all connected to the MISO input of the SPI master. SSLX and SSLY outputs of the SPI master are connected to the SSLA0 inputs of the MCUs (slave X and slave Y), respectively.
The SPI master drives SPCK, MOSI, SSLX, and SSLY. Of the MCUs (slave X and slave Y), the slave that receives low-level input into the SSLA0 input drives MISOA.

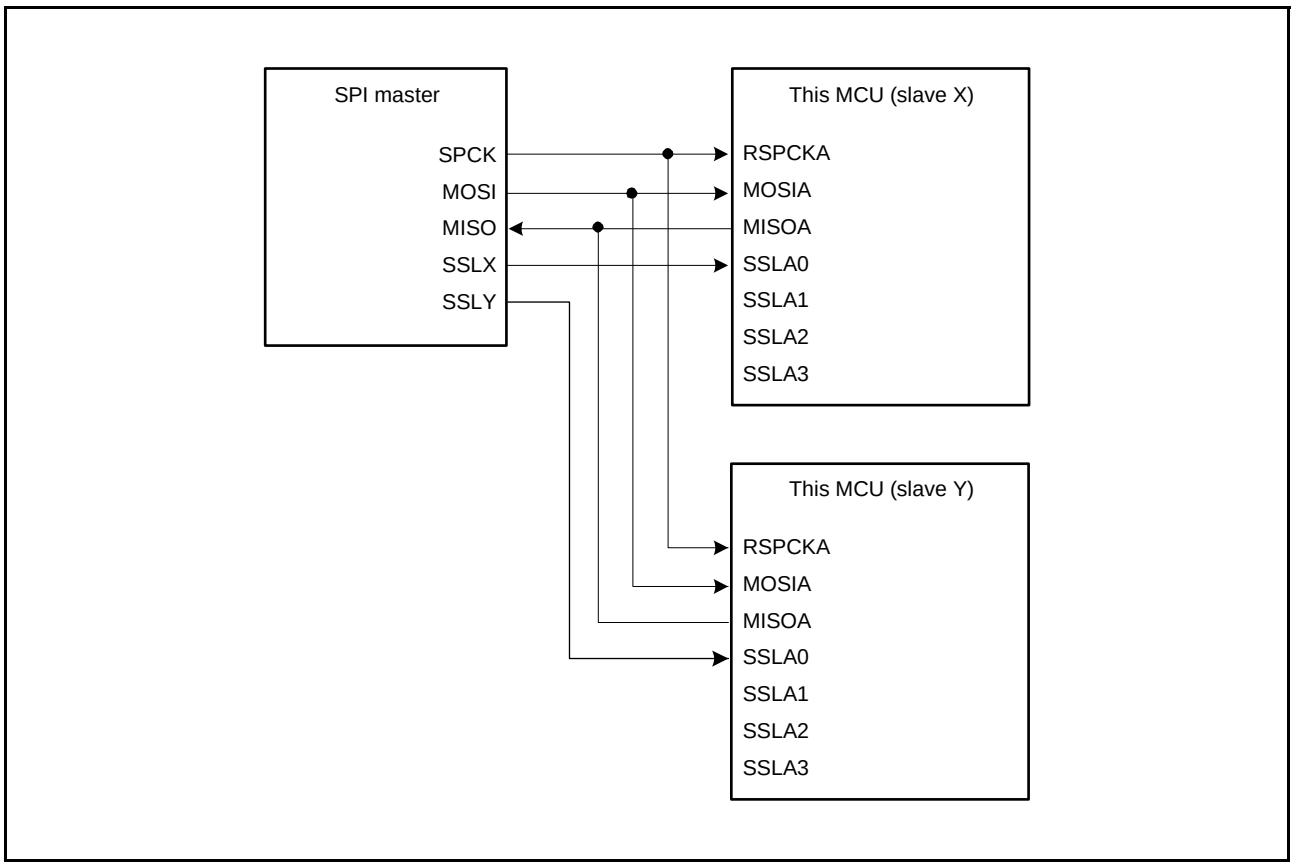

Figure 44.9 Single-Master/Multi-Slave Configuration Example (This MCU = Slave)

44.3.3.5 Multi-Master/Multi-Slave (with This MCU Acting as Master)

Figure 44.10 shows a multi-master/multi-slave RSPI system configuration example when this MCU is used as a master. In the example of Figure 44.10, the RSPI system is comprised of two MCUs (master X and master Y) and two SPI slaves (SPI slave 1 and SPI slave 2).

The RSPCKA and MOSIA outputs of the MCUs (master X and master Y) are connected to the RSPCK and MOSI inputs of SPI slaves 1 and 2. The MISO outputs of SPI slaves 1 and 2 are connected to the MISOA inputs of the MCUs (master X and master Y). Any generic port Y output from this MCU (master X) is connected to the SSLA0 input of this MCU (master Y). Any generic port X output of this MCU (master Y) is connected to the SSLA0 input of this MCU (master X). The SSLA1 and SSLA2 outputs of the MCUs (master X and master Y) are connected to the SSL inputs of the SPI slaves 1 and 2. In this configuration example, since the system can be comprised solely of SSLA0 input, and SSLA1 and SSLA2 outputs for slave connections, the SSLA3 output of this MCU is not required.

This MCU drives RSPCKA, MOSIA, SSLA1, and SSLA2 when the SSLA0 input level is high. When the SSLA0 input level is low, this MCU detects a mode fault error, sets RSPCKA, MOSIA, SSLA1, and SSLA2 to Hi-Z, and releases the RSPI bus right to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives MISO.

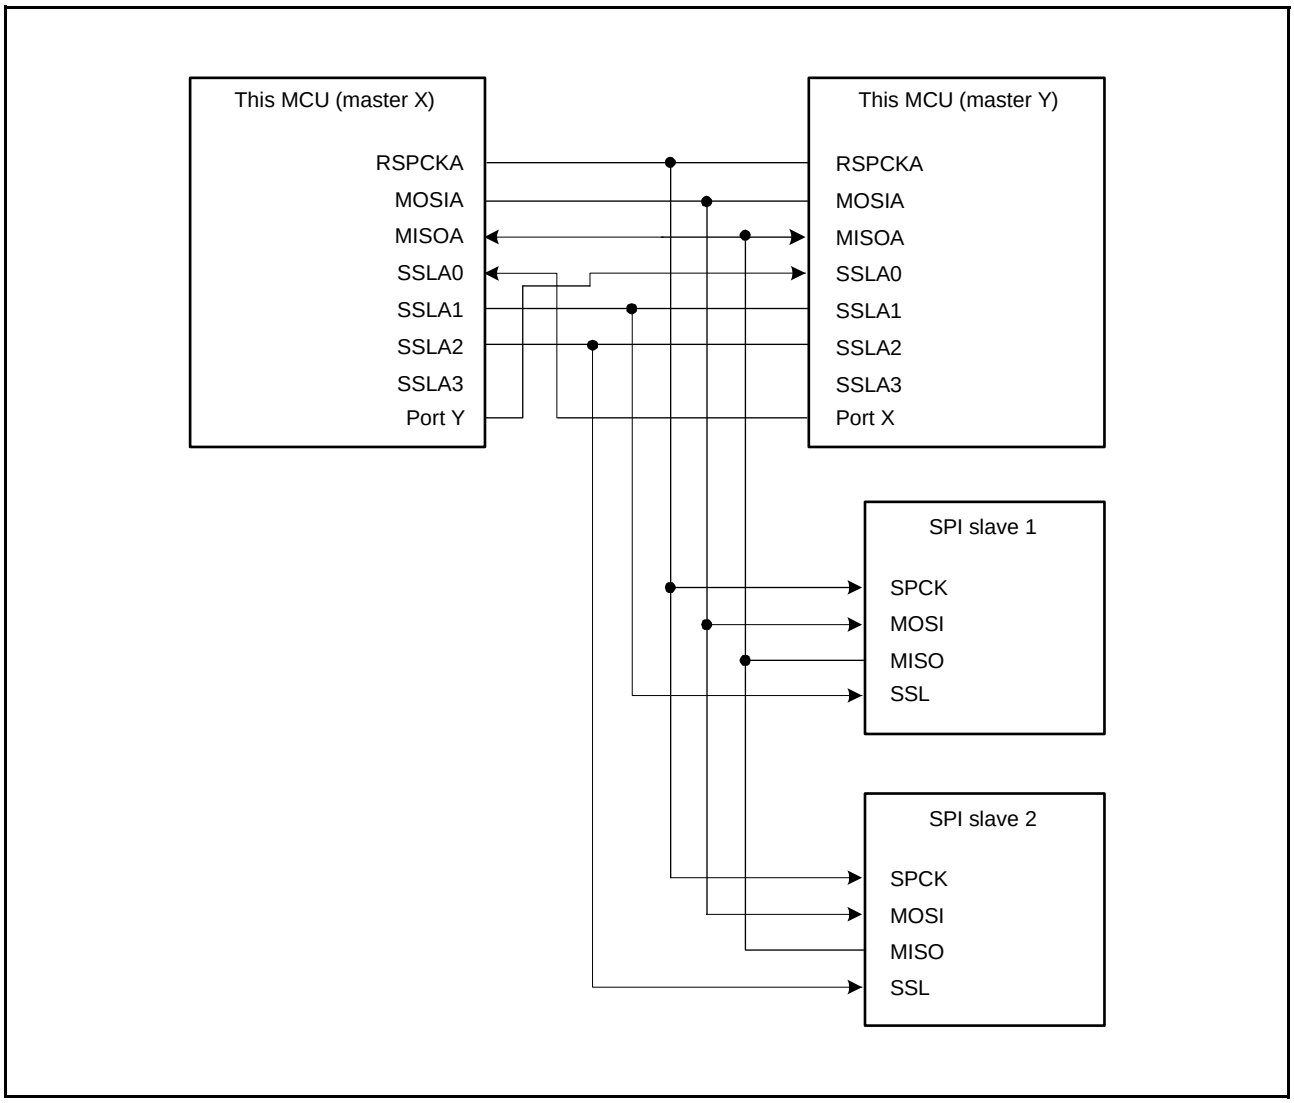

Figure 44.10 Multi-Master/Multi-Slave Configuration Example (This MCU = Master)

44.3.3.6 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (with This MCU Acting as Master)

Figure 44.11 shows a master (clock synchronous operation)/slave (clock synchronous operation) RSPI system configuration example when this MCU is used as a master. In the master (clock synchronous operation)/slave (clock synchronous operation) configuration, SSLA0 to SSLA3 of this MCU (master) are not used.
This MCU (master) drives the RSPCKA and MOSIA. The SPI slave drives the MISO.

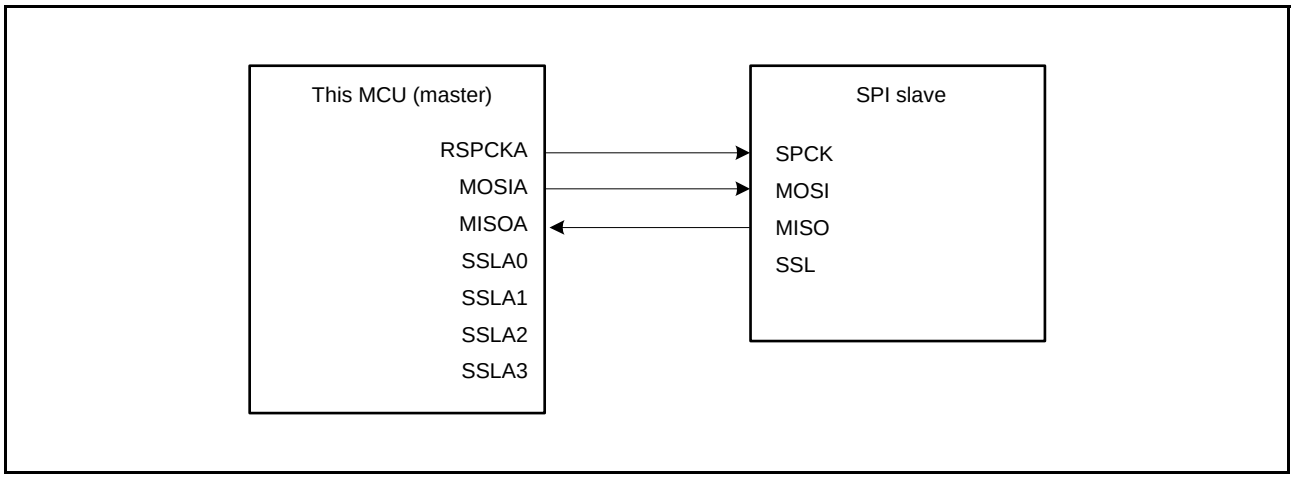

Figure 44.11 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This MCU = Master)

44.3.3.7 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (with This MCU Acting as Slave)

Figure 44.12 shows a master (clock synchronous operation)/slave (clock synchronous operation) RSPI system configuration example when this MCU is used as a slave. When this MCU is to operate as a slave (clock synchronous operation), this MCU (slave) drives the MISOA and the SPI master drives the SPCK and MOSI. In addition, SSLA0 to SSLA3 of this MCU (slave) are not used.
Only in the single-slave configuration in which the SPCMDm.CPHA bit is set to 1, this MCU (slave) can execute serial transfer.

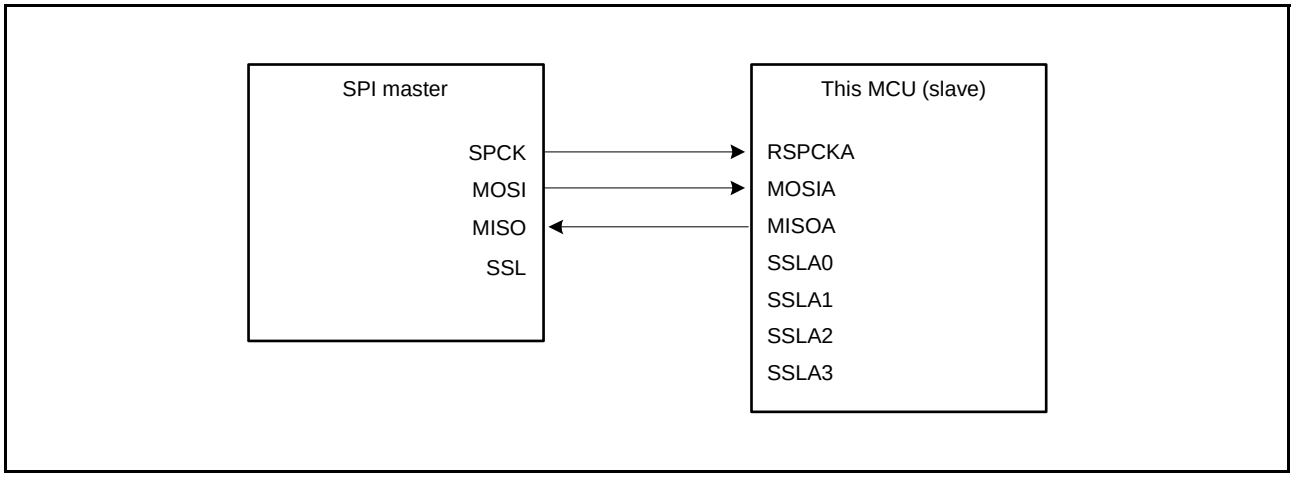

Figure 44.12 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This MCU = Slave, CPHA = 1)

44.3.4 Data Format

The RSPI's data format depends on the settings in RSPI command register m (SPCMDm) (m = 0 to 7) and the parity enable bit in RSPI control register 2 (SPCR2.SPPE). Regardless of whether the MSB or LSB is first, the RSPI treats the range from the LSB bit in the RSPI data register (SPDR) to the selected data length as transfer data.
The format of one frame of data before or after transfer is shown below.

(a) With Parity Disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the RSPI data length setting bits in RSPI command register m (SPCMDm.SPB[3:0]).

(b) With Parity Enabled

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the RSPI data length setting bits in RSPI command register m (SPCMDm.SPB[3:0]). In this case, however, the last bit is a parity bit.

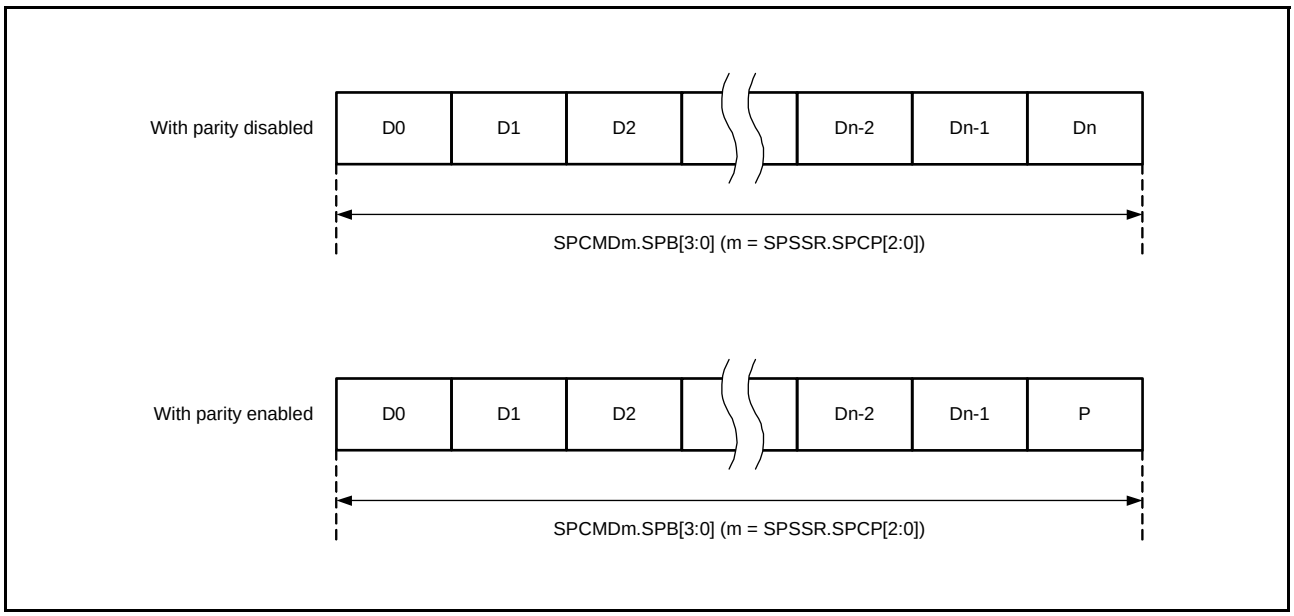

Figure 44.13 Outline of the Data Format (with Parity Disabled/Enabled)

44.3.4.1 When Parity is Disabled (SPCR2.SPPE = 0)

When parity is disabled, data for transmission are copied to the shift register with no prior processing. A description of the connection between the RSPI data register (SPDR) and the shift register in terms of the combination of MSB or LSB first and data length is given below.

(1) MSB First Transfer (32-Bit Data)

Figure 44.14 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, an RSPI data length of 32 bits, and MSB first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are copied to the shift register. Data for transmission are shifted out from the shift register in order from T31, through T30, and so on to T00.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R31 to R00 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer.

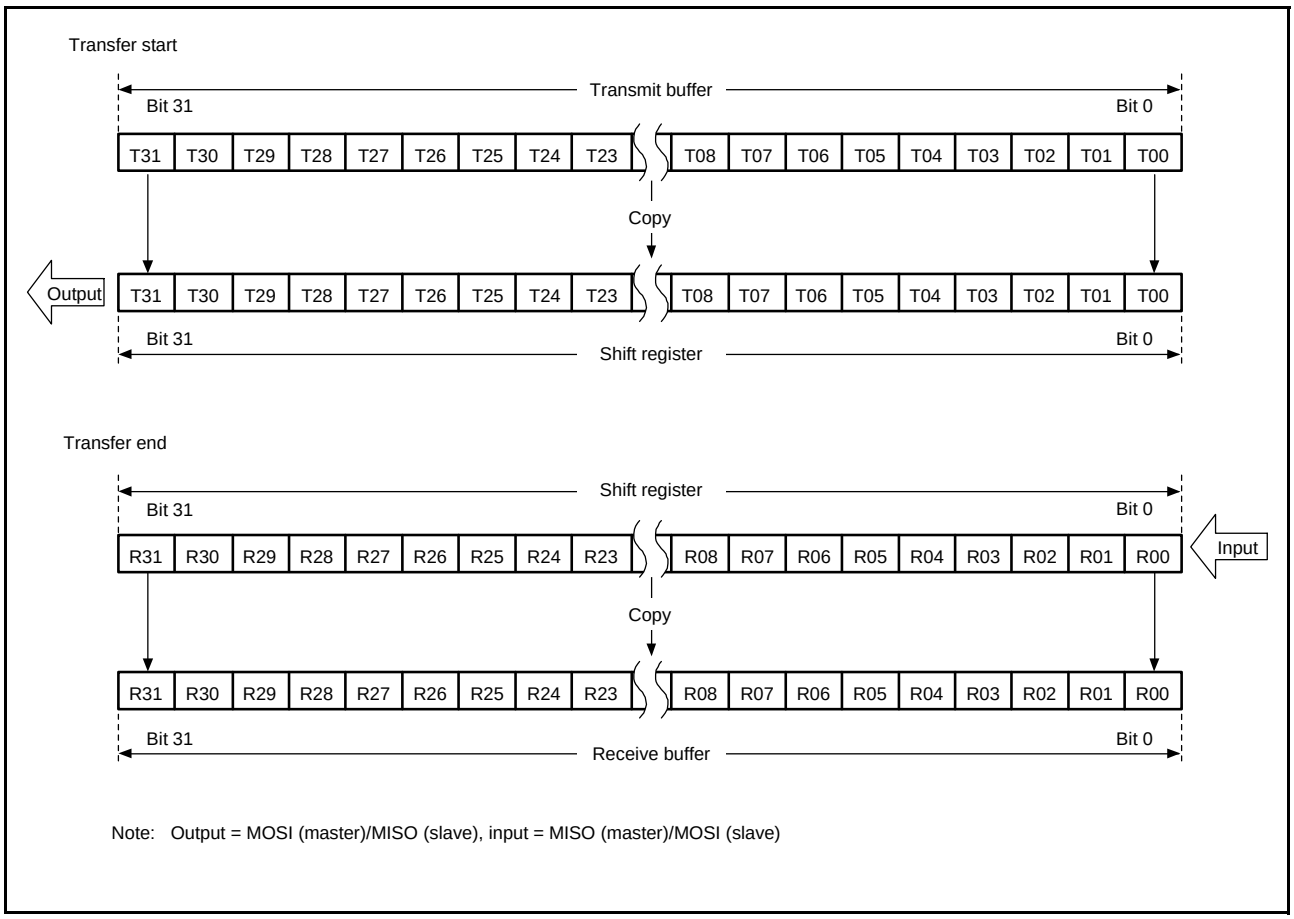

Figure 44.14 MSB First Transfer (32-Bit Data, Parity Disabled)

(2) MSB First Transfer (24-Bit Data)

Figure 44.15 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, 24 bits as the RSPI data length for an example that is not 32 bits, and MSB first selected.

In transmission, the lower-order 24 bits (T23 to T00) from the current stage of the transmit buffer are copied to the shift register. Data for transmission are shifted out from the shift register in order from T23, through T22, and so on to T00.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R23 to R00 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. At this time, the higher-order 8 bits of the transmit buffer are stored in the higher-order 8 bits of the receive buffer.

Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being inserted in the higher-order 8 bits of the receive buffer.

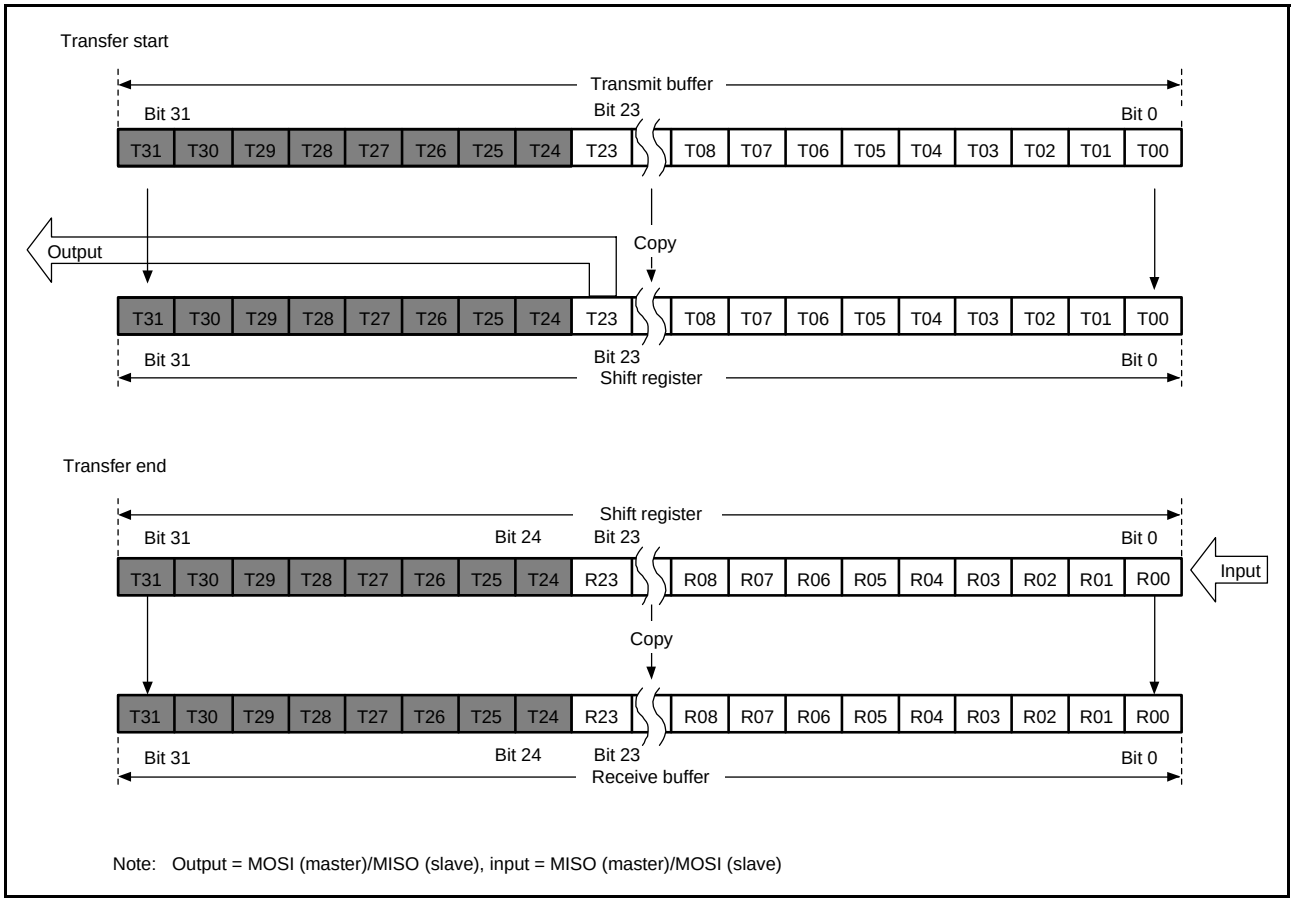

Figure 44.15 MSB First Transfer (24-Bit Data, Parity Disabled)

(3) LSB First Transfer (32-Bit Data)

Figure 44.16 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, an RSPI data length of 32 bits, and LSB first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are reordered bit by bit to obtain the order T00 to T31 for copying to the shift register. Data for transmission are shifted out from the shift register in order from T00, through T01, and so on to T31.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R00 to R31 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer.

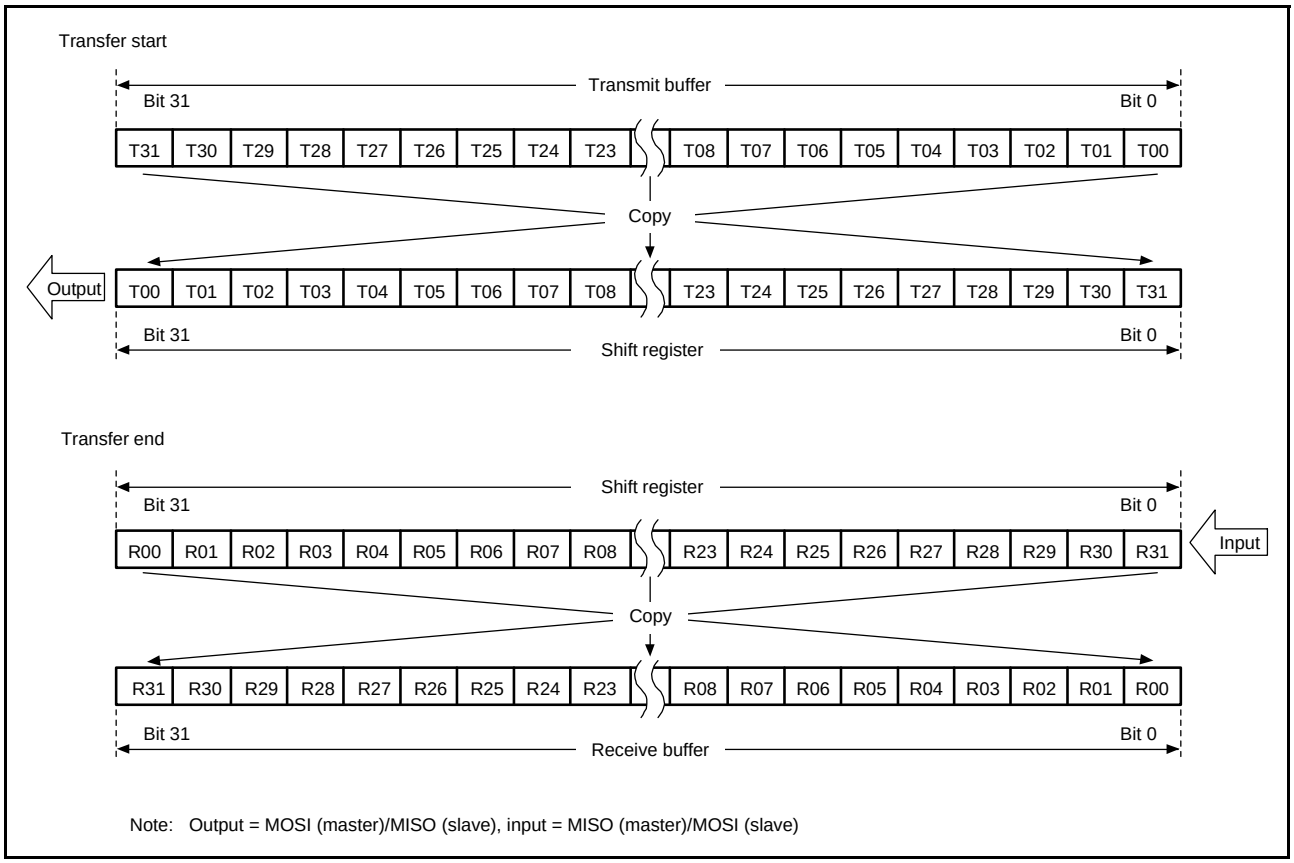

Figure 44.16 LSB First Transfer (32-Bit Data, Parity Disabled)

(4) LSB First Transfer (24-Bit Data)

Figure 44.17 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, 24 bits as the RSPI data length for an example that is not 32 bits, and LSB first selected.

In transmission, the lower-order 24 bits (T23 to T00) from the current stage of the transmit buffer are reordered bit by bit to obtain the order T00 to T23 for copying to the shift register. Data for transmission are shifted out from the shift register in order from T00, through T01, and so on to T23.

In reception, received data are shifted in bit by bit through bit 8 of the shift register. When bits R00 to R23 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer.

At this time, the higher-order 8 bits of the transmit buffer are stored in the higher-order 8 bits of the receive buffer.

Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being inserted in the higher-order 8 bits of the receive buffer.

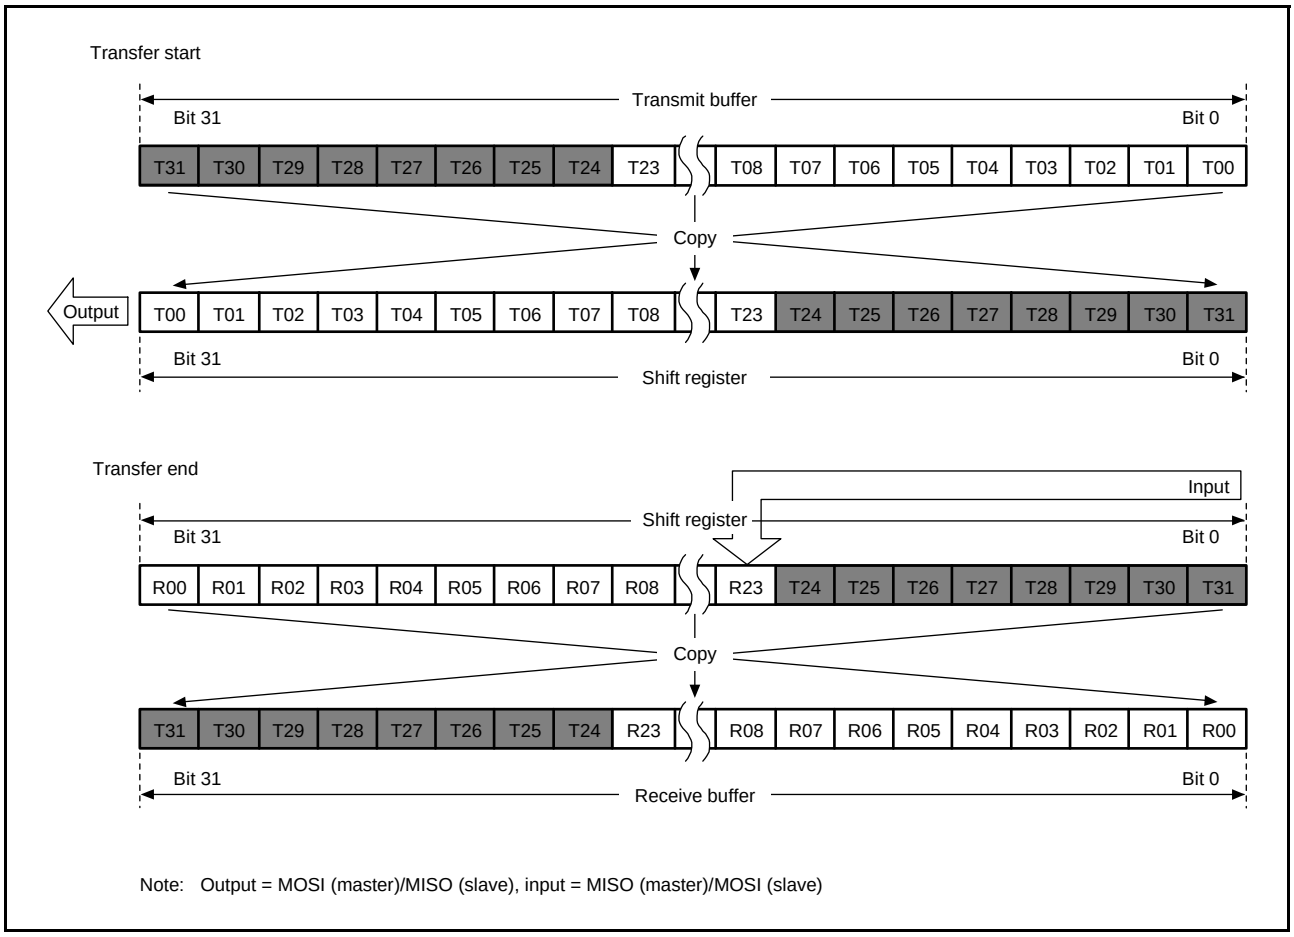

Figure 44.17 LSB First Transfer (24-Bit Data, Parity Disabled)

44.3.4.2 When Parity is Enabled (SPCR2.SPPE = 1)

When parity is enabled, the lowest-order bit of the data for transmission becomes a parity bit. Hardware calculates the value of the parity bit.

(1) MSB First Transfer (32-Bit Data)

Figure 44.18 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, an RSPI data length of 32 bits, and MSB first selected.

In transmission, the value of the parity bit (P) is calculated from bits T31 to T01. This replaces the final bit, T00, and the whole is copied to the shift register. Data are transmitted in the order T31, T30, …, T01, and P.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R31 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R31 to P are checked by judging the parity.

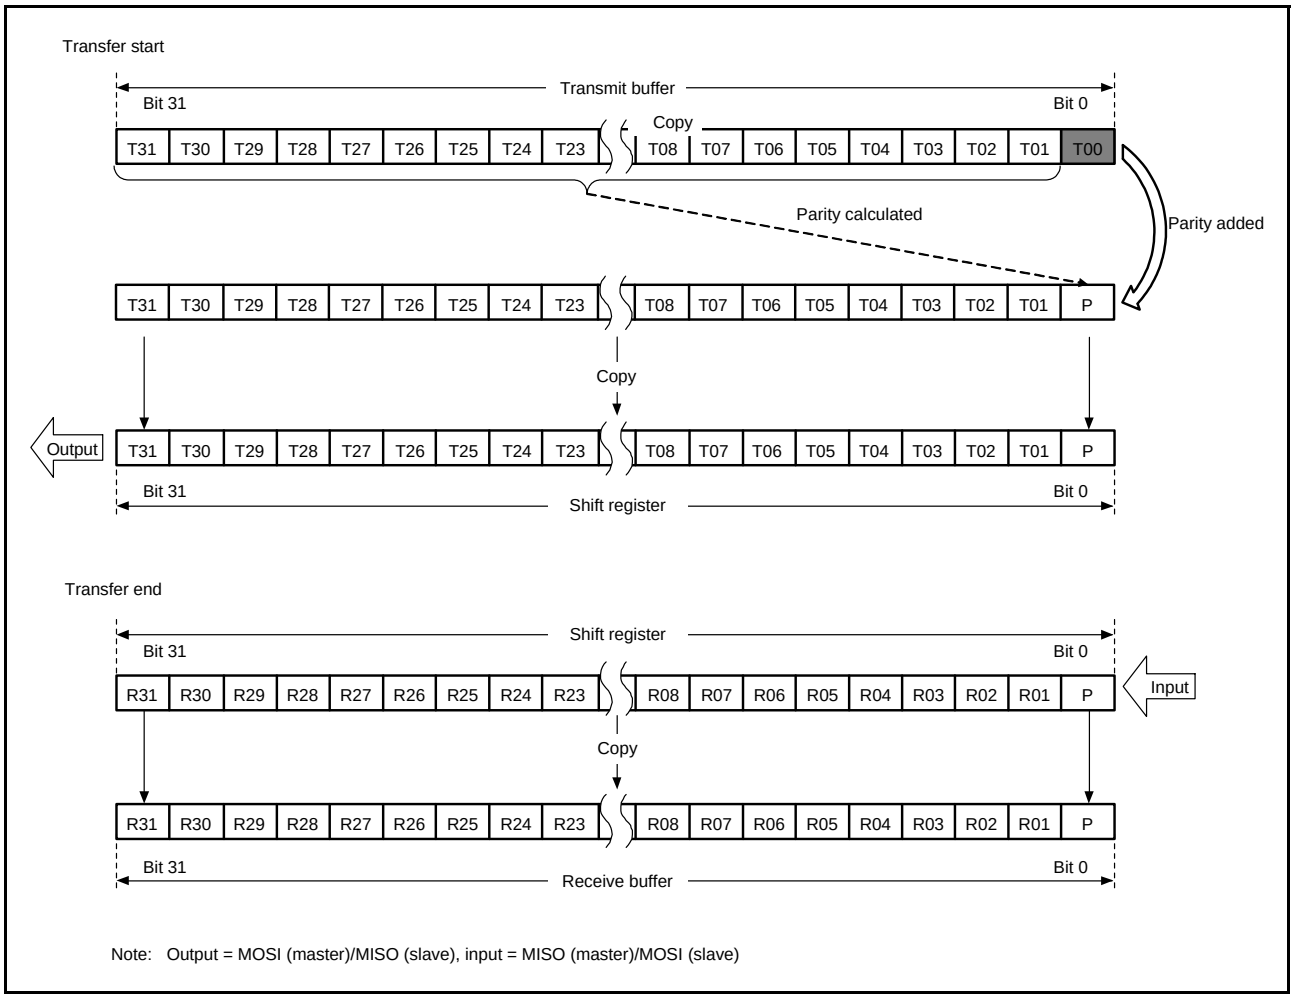

Figure 44.18 MSB First Transfer (32-Bit Data, Parity Enabled)

(2) MSB First Transfer (24-Bit Data)

Figure 44.19 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, 24 bits as the RSPI data length for an example that is not 32 bits, and MSB first selected.
In transmission, the value of the parity bit (P) is calculated from bits T23 to T01. This replaces the final bit, T00, and the whole is copied to the shift register. Data are transmitted in the order T23, T22, …, T01, and P.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R23 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R23 to P are checked by judging the parity. At this time, the higher-order 8 bits of the transmit buffer are stored in the higher-order 8 bits of the receive buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being inserted in the higher-order 8 bits of the receive buffer.

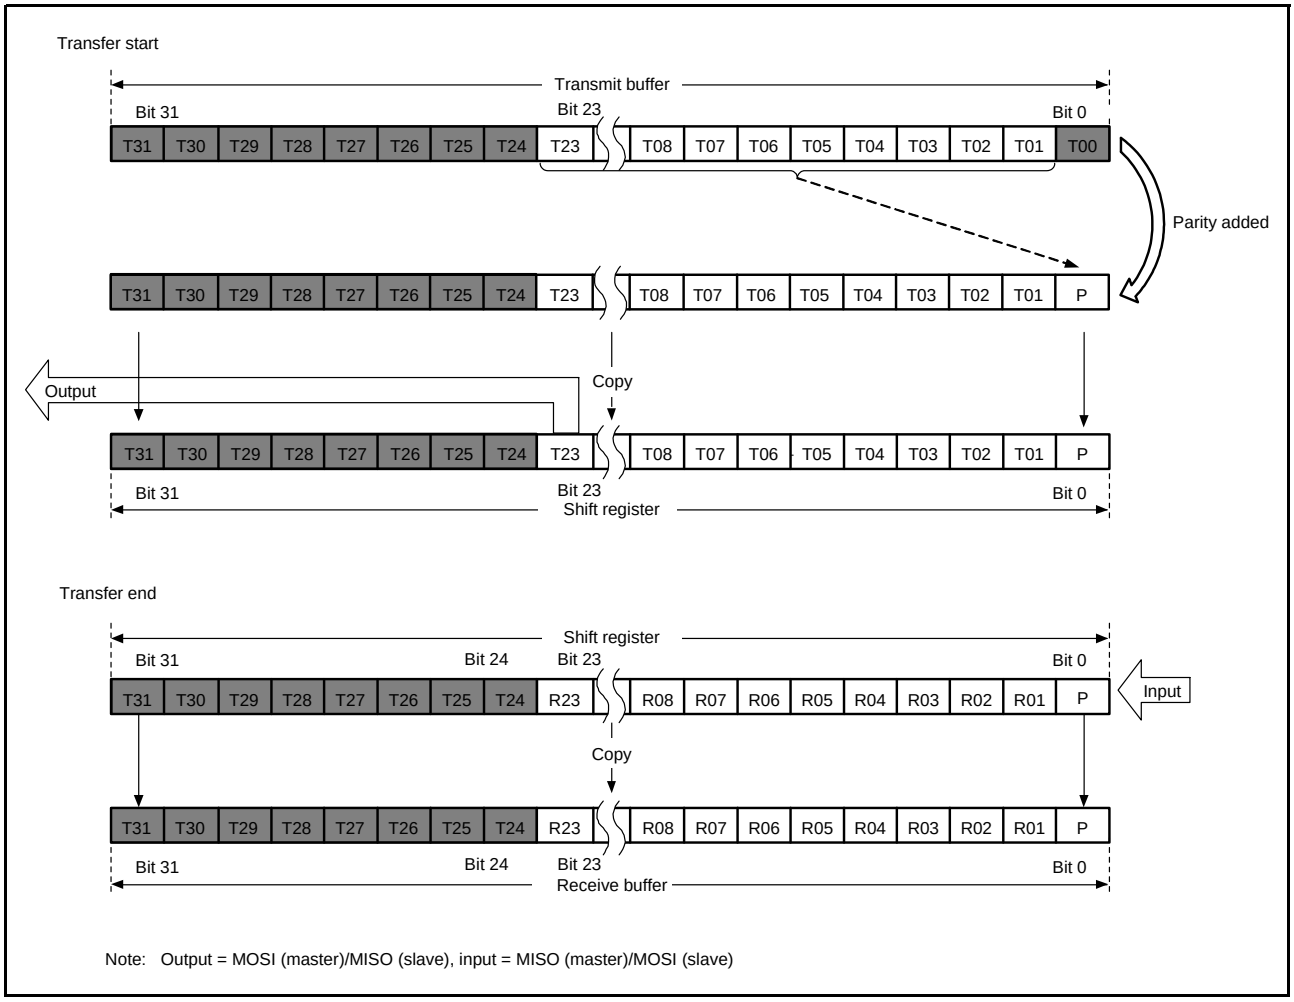

Figure 44.19 MSB First Transfer (24-Bit Data, Parity Enabled)

(3) LSB First Transfer (32-Bit Data)

Figure 44.20 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, an RSPI data length of 32 bits, and LSB first selected.

In transmission, the value of the parity bit (P) is calculated from bits T30 to T00. This replaces the final bit, T31, and the whole is copied to the shift register. Data are transmitted in the order T00, T01, …, T30, and P.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R00 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P are checked by judging the parity.

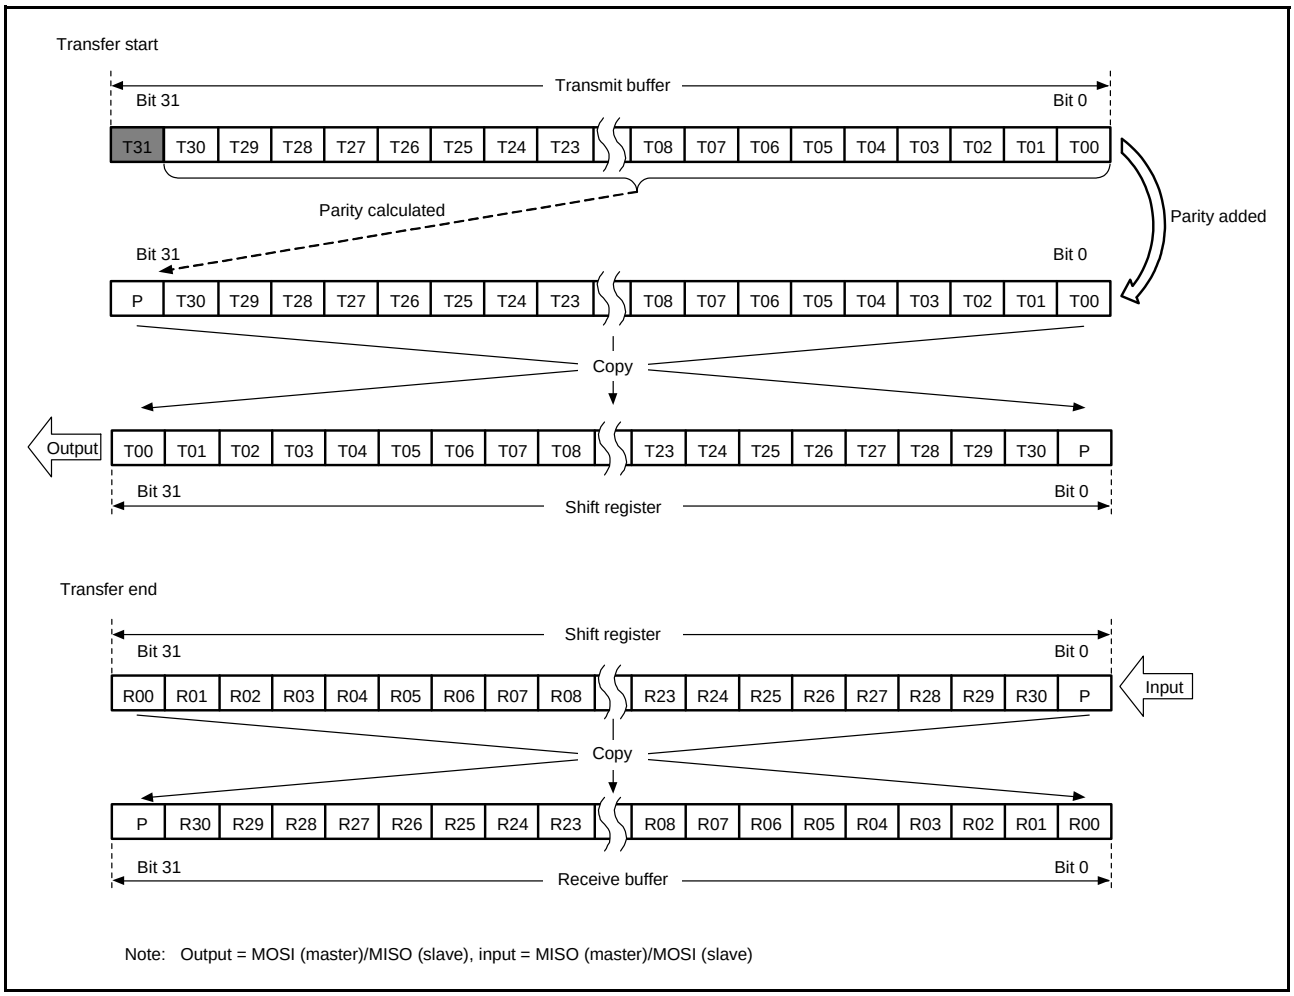

Figure 44.20 LSB First Transfer (32-Bit Data, Parity Enabled)

(4) LSB First Transfer (24-Bit Data)

Figure 44.21 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, 24 bits as the RSPI data length for an example that is not 32 bits, and LSB first selected.
In transmission, the value of the parity bit (P) is calculated from bits T22 to T00. This replaces the final bit, T23, and the whole is copied to the shift register. Data are transmitted in the order T00, T01, …, T22, and P.
In reception, received data are shifted in bit by bit through bit 8 of the shift register. When bits R00 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P are checked by judging the parity. At this time, the higher-order 8 bits of the transmit buffer are stored in the higher-order 8 bits of the receive buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being inserted in the higher-order 8 bits of the receive buffer.

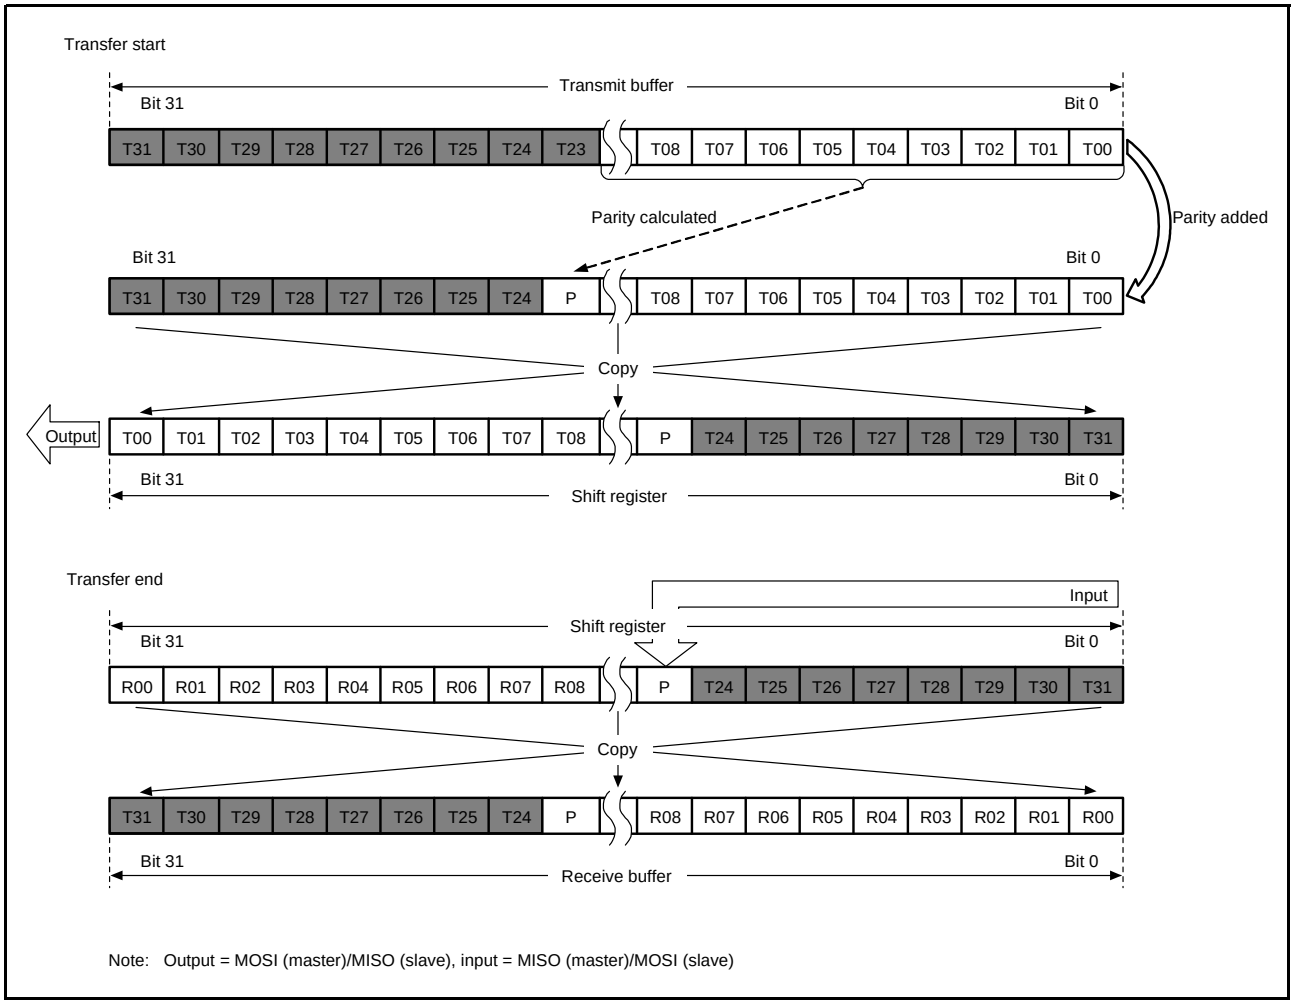

Figure 44.21 LSB First Transfer (24-Bit Data, Parity Enabled)

44.3.5 Transfer Format

44.3.5.1 CPHA = 0

Figure 44.22 shows a sample transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Note that clock synchronous operation (the SPCR.SPMS bit is 1) should not performed when the RSPI operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In Figure 44.22, RSPCKA (CPOL = 0) indicates the RSPCKA signal waveform when the SPCMDm.CPOL bit is 0; RSPCKA (CPOL = 1) indicates the RSPCKA signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the RSPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the RSPI settings. For details, refer to section 44.3.2, Controlling RSPI Pins.

When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSIA and MISOA signals commences at an SSLAi signal assertion timing. The first RSPCKA signal change timing that occurs after the SSLAi signal assertion becomes the first transfer data fetch timing. After this timing, data is sampled at every 1 RSPCK cycle. The change timing for MOSIA and MISOA signals is 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCKA signal operation timing; it only affects the signal polarity.

t1 denotes a period from an SSLAi signal assertion to RSPCKA oscillation (RSPCK delay). t2 denotes a period from the termination of RSPCKA oscillation to an SSLAi signal negation (SSL negation delay). t3 denotes a period in which SSLAi signal assertion is suppressed for the next transfer after the end of serial transfer (next-access delay). t1, t2, and t3 are controlled by a master device running on the RSPI system. For a description of t1, t2, and t3 when the RSPI of this MCU is in master mode, refer to section 44.3.10.1, Master Mode Operation.

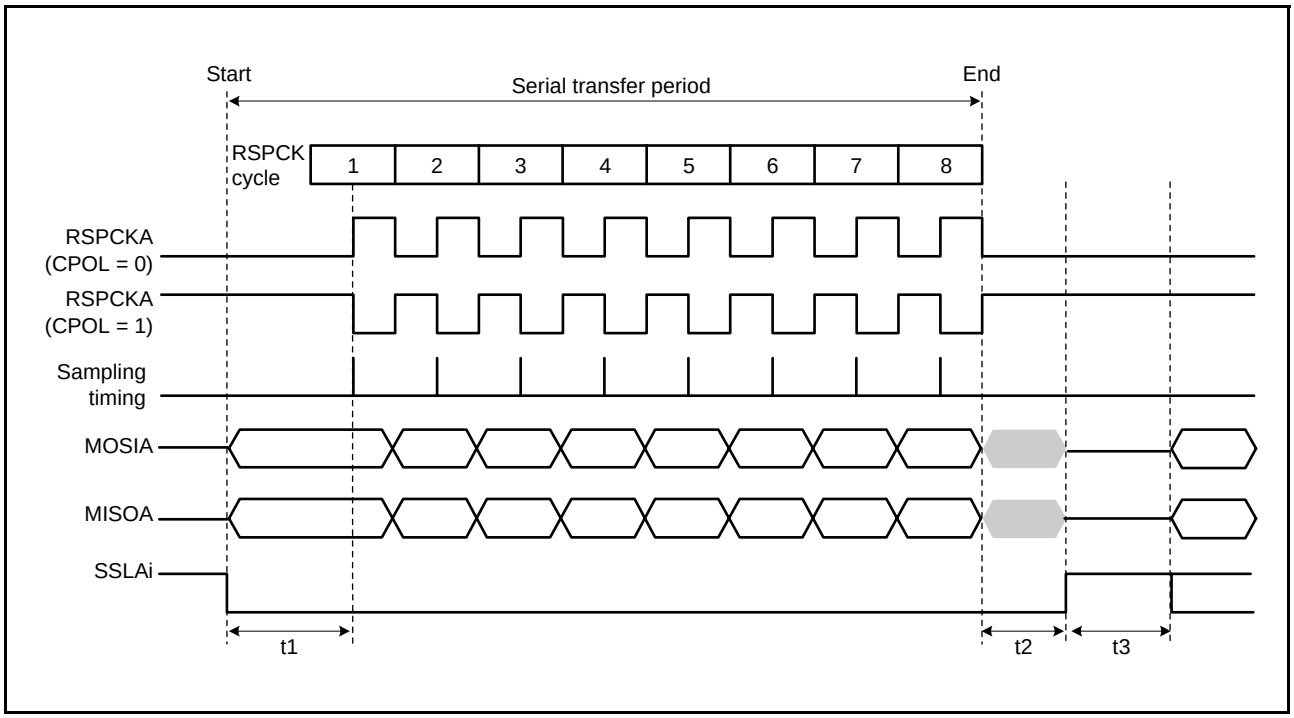

Figure 44.22 RSPI Transfer Format (CPHA = 0)

44.3.5.2 CPHA = 1

Figure 44.23 shows a sample transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSLAi signals are not used, and only the three signals RSPCKA, MOSIA, and MISOA handle communications. In Figure 44.23, RSPCK (CPOL = 0) indicates the RSPCKA signal waveform when the SPCMDm.CPOL bit is 0; RSPCKA (CPOL = 1) indicates the RSPCKA signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the RSPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the RSPI mode (master or slave). For details, refer to section 44.3.2, Controlling RSPI Pins.

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISOA signal commences at an SSLAi signal assertion timing. The output of valid data to the MOSIA and MISOA signals commences at the first RSPCKA signal change timing that occurs after the SSLAi signal assertion. After this timing, data is updated at every 1 RSPCK cycle. The transfer data fetch timing is 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCKA signal operation timing; it only affects the signal polarity.

t1, t2, and t3 are the same as those in the case of CPHA = 0. For a description of t1, t2, and t3 when the RSPI of this MCU is in master mode, refer to section 44.3.10.1, Master Mode Operation.

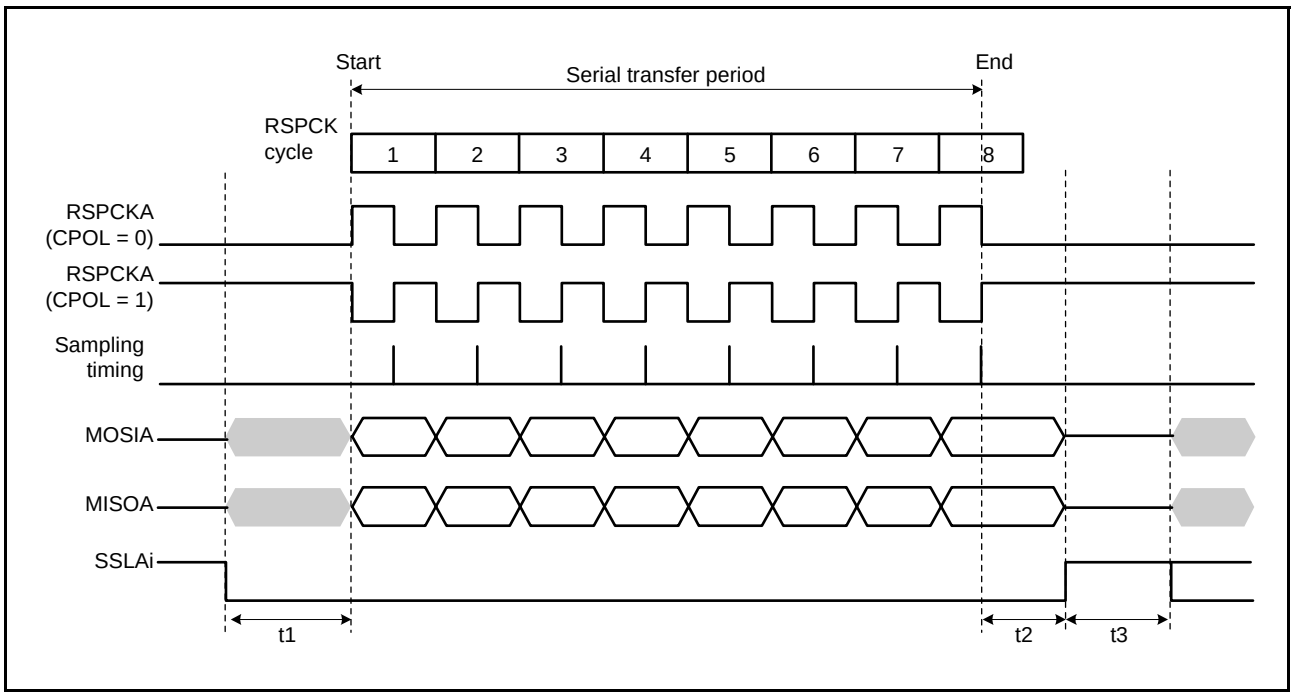

Figure 44.23 RSPI Transfer Format (CPHA = 1)

44.3.6 Communications Operating Mode

Full-duplex synchronous serial communications or transmit operations only can be selected by the communications operating mode select bit (SPCR.TXMD). The SPDR access shown in Figure 44.24 and Figure 44.25 indicate the condition of access to the SPDR register, where W denotes a write cycle.

44.3.6.1 Full-Duplex Synchronous Serial Communications (SPCR.TXMD = 0)

Figure 44.24 shows an example of operation when the communications operating mode select bit (SPCR.TXMD) is set to 0. In the example in Figure 44.24, the RSPI performs an 8-bit serial transfer in which the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKA waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

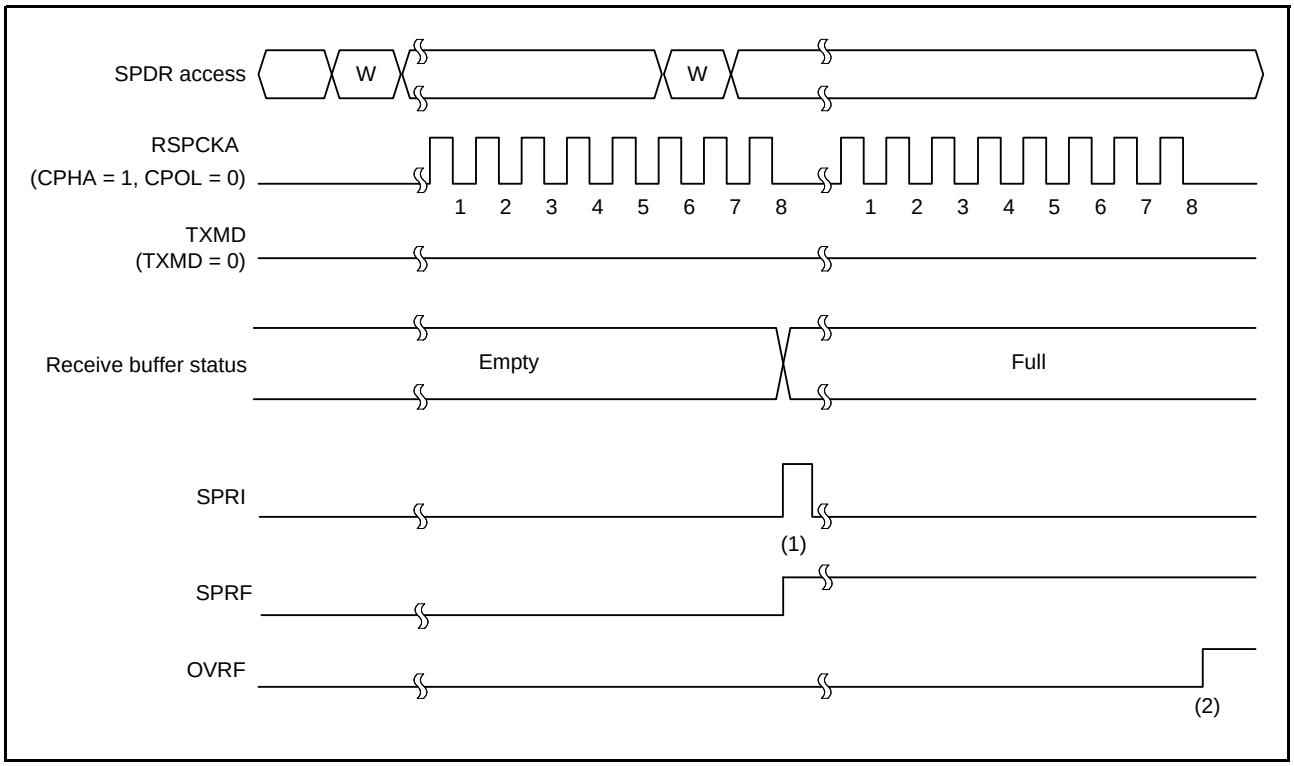

Figure 44.24 Operation Example of SPCR.TXMD = 0

The operation of the flags at timings shown in steps (1) and (2) in the figure is described below.

(1) When a serial transfer ends with the receive buffer of SPDR empty, the RSPI generates a receive buffer full interrupt request (SPRI) (sets the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer.

(2) When a serial transfer ends with the receive buffer of SPDR holding data that was received in the previous serial transfer, the RSPI sets the SPSR.OVRF flag to 1 and discards the received data in the shift register.

When full-duplex synchronous serial communications (SPCR.TXMD = 0) is selected, reception occurs simultaneously with transmit operations. As such, the SPRF and OVRF flags in the SPSR register become 1 at the timing described in (1) and (2), respectively, according to the state of the receive buffer.

44.3.6.2 Transmit Operations Only (SPCR.TXMD = 1)

Figure 44.25 shows an example of operation when the communications operating mode select bit (SPCR.TXMD) is set to 1. In the example in Figure 44.25, the RSPI performs an 8-bit serial transfer in which the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKA waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

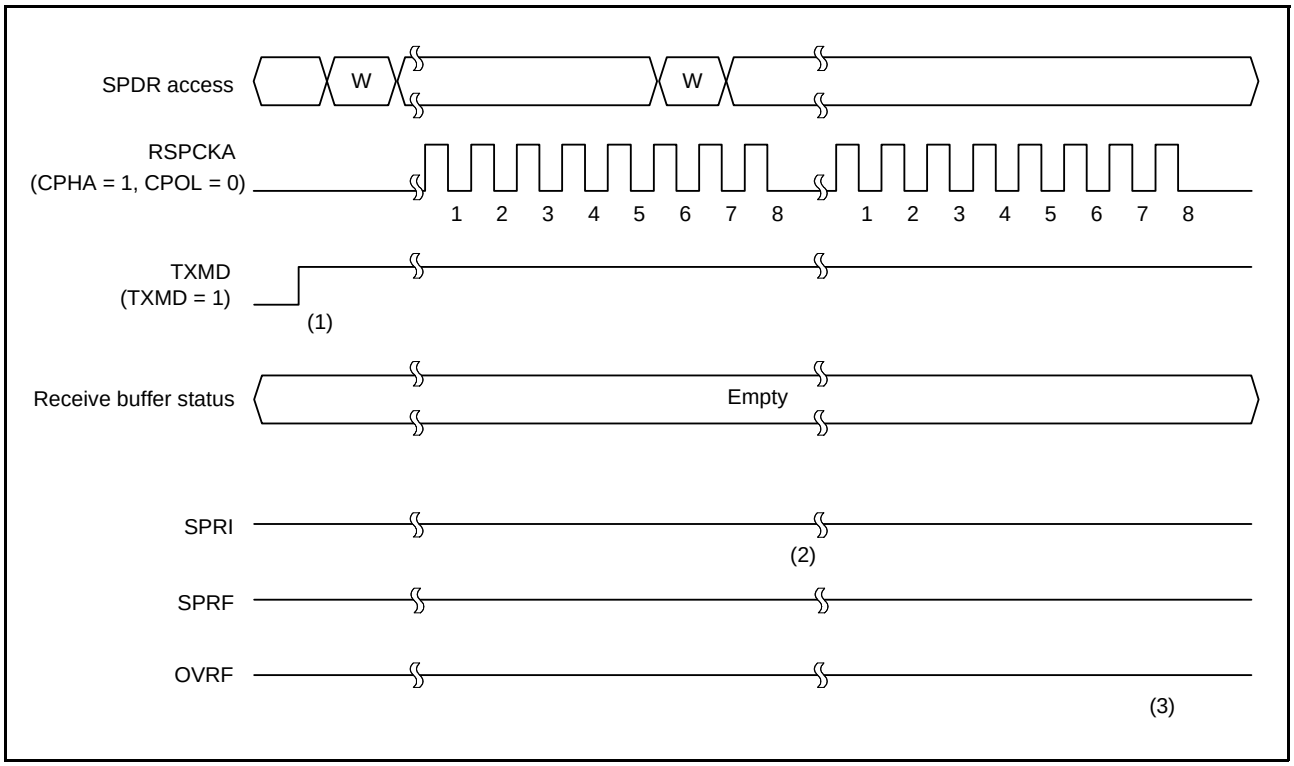

Figure 44.25 Operation Example of SPCR.TXMD = 1

The operation of the flags at timings shown in steps (1) to (3) in the figure is described below.

(1) Make sure there is no data left in the receive buffer and the SPSR.SPRF, OVRF flags are 0 before entering the mode of transmit operations only (SPCR.TXMD = 1).

(2) When a serial transfer ends with the receive buffer of SPDR empty, if the mode of transmit operations only is selected (SPCR.TXMD = 1), the SPRF flag remains 0 and the RSPI does not copy the data from the shift register to the receive buffer.

(3) Since the receive buffer of SPDR does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the receive buffer.

When performing transmit operations only (SPCR.TXMD = 1), the RSPI transmits data but does not receive data. Therefore, the SPSR.SPRF, OVRF flags remain 0 at the timings of (1) to (3).

44.3.7 Transmit Buffer Empty/Receive Buffer Full Interrupts

Figure 44.26 shows an example of operation of the transmit buffer empty interrupt (SPTI) and the receive buffer full interrupt (SPRI). The SPDR register access shown in Figure 44.26 indicates the condition of access to the SPDR register, where W denotes a write cycle, and R a read cycle. In the example in Figure 44.26, the RSPI performs an 8-bit serial transfer in which the SPCR.TXMD bit is 0, the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKA waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

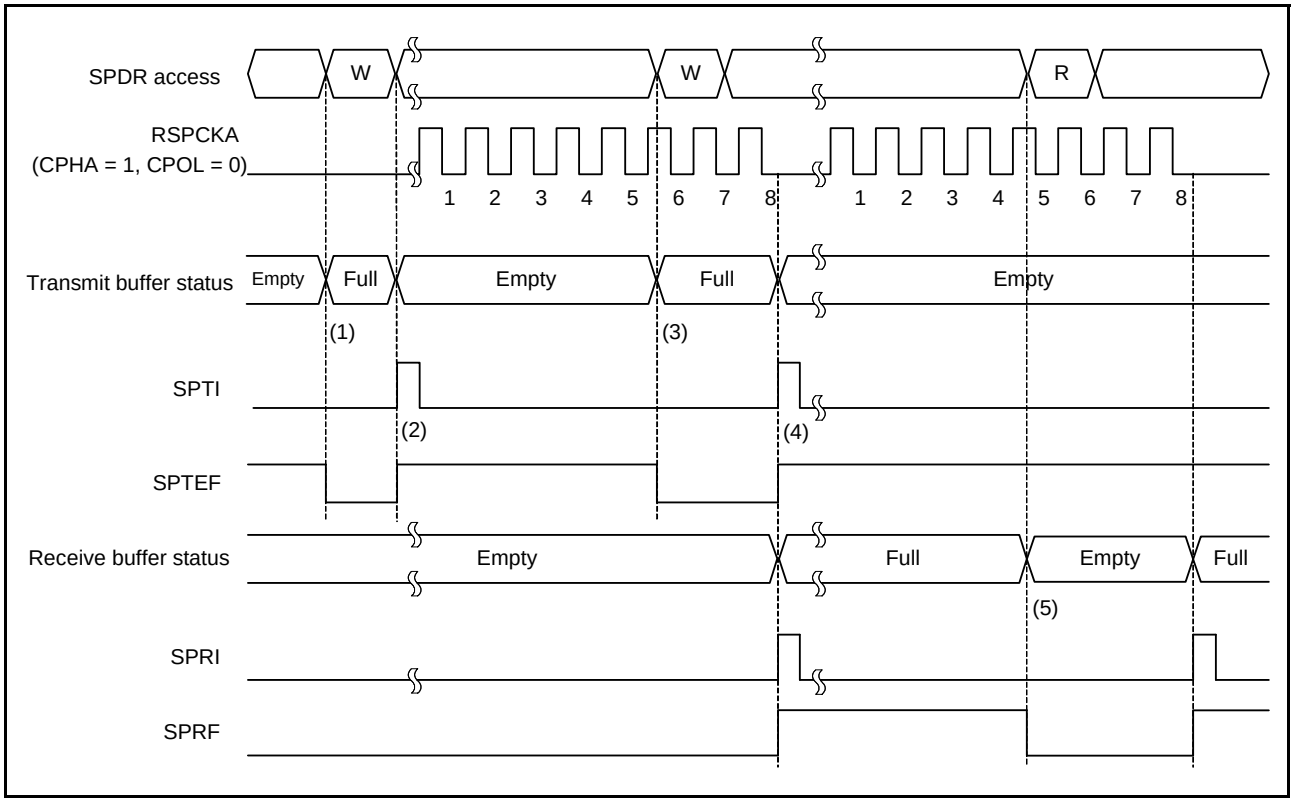

Figure 44.26 Operation Example of SPTI and SPRI Interrupts

The operation of the interrupts at timings shown in steps (1) to (5) in the figure is described below.

(1) When transmit data is written to SPDR when the transmit buffer of SPDR is empty (data for the next transfer is not set), the RSPI writes data to the transmit buffer and sets the SPSR.SPTEF flag to 0.

(2) If the shift register is empty, the RSPI copies the data from the transmit buffer to the shift register and generates a transmit buffer empty interrupt request (SPTI) and sets the SPSR.SPTEF flag to 1. How a serial transfer is started depends on the mode of the RSPI. For details, refer to section 44.3.10, SPI Operation, and section 44.3.11, Clock Synchronous Operation.

(3) When transmit data is written to SPDR in the transmit buffer empty interrupt routine or in the transmit buffer empty detecting process by polling the SPTEF flag, the data is transferred to the transmit buffer and the SPSR.SPTEF flag becomes 0. Because the data being transmitted is stored in the shift register, the RSPI does not copy the data from the transmit buffer to the shift register.

(4) When the serial transfer ends with the receive buffer of SPDR being empty, the RSPI copies the receive data from the shift register to the receive buffer, generates a receive buffer full interrupt request (SPRI), and sets the SPSR.SPRF flag to 1. Since the shift register becomes empty upon completion of serial transfer, when the transmit buffer had been full before the serial transfer ended, the RSPI sets the SPSR.SPTEF flag to 1 and copies the data from the transmit buffer to the shift register. Even when received data is not copied from the shift register to the receive buffer in an overrun error status, upon completion of the serial transfer, the RSPI determines that the shift register is empty, thus data transfer from the transmit buffer to the shift register is enabled.

(5) When SPDR is read in the receive buffer full interrupt routine or in the receive buffer full detecting process by polling the SPRF flag, the receive data can be read. When the receive data is read, the SPRF flag becomes 0.

If transmit data is written to SPDR while the transmit buffer holds data that has not yet been transmitted (the SPTEF flag is 0), the RSPI does not update the data in the transmit buffer. Transmit data should be written to SPDR in the transmit buffer empty interrupt request routine or in the transmit buffer empty detecting process by polling the SPTEF flag. To use a transmit buffer empty interrupt, set the SPTIE bit in SPCR to 1.
When setting the SPCR.SPE bit to 0 (RSPI disabled), the SPCR.SPTIE bit should also be set to 0. Otherwise (if the SPCR.SPE bit is 0 and the SPCR.SPTIE is 1), a transmit buffer empty interrupt request will occur.
When serial transfer ends with the receive buffer being full (the SPRF flag is 1), the RSPI does not copy data from the shift register to the receive buffer, and detects an overrun error (refer to section 44.3.8, Error Detection). To prevent a receive data overrun error, read the received data using a receive buffer full interrupt request before the next serial transfer ends. To use an RSPI receive buffer full interrupt, set the SPCR.SPRIE bit to 1.
Transmit and receive interrupts or the corresponding IRn.IR flags (where n is the interrupt vector number) in the ICU can be used to confirm the states of the transmit and receive buffers. Refer to section 15, Interrupt Controller (ICUA), for the interrupt vector numbers. The status of the transmit and receive buffers can be also confirmed by the SPTEF and SPRF flags.

44.3.8 Error Detection

In the normal RSPI serial transfer, the data written to the transmit buffer of SPDR is transmitted, and the received data can be read from the receive buffer of SPDR. If access is made to SPDR, depending on the status of the transmit/receive buffer or the status of the RSPI at the beginning or end of serial transfer, in some cases non-normal transfers can be executed.

If a non-normal transfer operation occurs, the RSPI detects the event as an overrun error, parity error, or mode fault error. Table 44.8 lists the relationship between non-normal transfer operations and the RSPI's error detection function.

Table 44.8 Relationship between Non-Normal Transfer Operations and RSPI Error Detection Function

	Occurrence Condition	RSPI Operation	Error Detection
1	SPDR is written when the transmit buffer is full.	• The contents of the transmit buffer are kept. • Missing write data.	None
2	SPDR is read when the receive buffer is empty.	Data received previously is output to the bus.	None
3	Serial transfer is started in slave mode when transmit data is still not loaded on the shift register.	Data received in previous serial transfer is transmitted.	None
4	Serial transfer terminates when the receive buffer is full.	• The contents of the receive buffer are kept. • Missing receive data.	Overrun error
5	An incorrect parity bit is received when performing full-duplex synchronous serial communications with the parity function enabled.	The parity error flag is asserted.	Parity error
6	The SSLA0 input signal is asserted when the serial transfer is idle in multi-master mode.	• Driving of the RSPCKA, MOSIA, SSLA1 to SSLA3 output signals is stopped. • RSPI function is disabled.	Mode fault error
7	The SSLA0 input signal is asserted during serial transfer in multi-master mode.	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the RSPCKA, MOSIA, SSLA1 to SSLA3 output signals is stopped. • RSPI function is disabled.	Mode fault error
8	The SSLA0 input signal is negated during serial transfer in slave mode.	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the MISOA output signal is stopped. • RSPI function is disabled.	Mode fault error

On operation 1 described in Table 44.8, the RSPI does not detect an error. To prevent data omission during the writing to SPDR, the SPDR register should be written when a transmit buffer empty interrupt request occurs or while the SPSR.SPTEF flag is 1.

Likewise, the RSPI does not detect an error on operation 2. To prevent extraneous data from being read, the SPDR register should be read when an RSPI receive buffer full interrupt request occurs or while the SPSR.SPRF flag is 1.

Similarly, the RSPI does not detect an error on operation 3. In a serial transfer that was started before the shift register was updated, the RSPI sends the data that was received in the previous serial transfer, and does not treat the operation indicated in 3 as an error. Note that the received data from the previous serial transfer is retained in the receive buffer of SPDR, thus it can be correctly read (if SPDR is not read before the end of the serial transfer, an overrun error may occur).

An overrun error shown in 4 is described in section 44.3.8.1, Overrun Error. A parity error shown in 5 is described in section 44.3.8.2, Parity Error. A mode fault error shown in 6 to 8 is described in section 44.3.8.3, Mode Fault Error. For the transmit and receive interrupts, refer to section 44.3.7, Transmit Buffer Empty/Receive Buffer Full Interrupts.

44.3.8.1 Overrun Error

If a serial transfer ends when the receive buffer of SPDR is full, the RSPI detects an overrun error, and sets the SPSR.OVRF flag to 1. When the OVRF flag is 1, the RSPI does not copy data from the shift register to the receive buffer so that the data prior to the occurrence of the error is retained in the receive buffer. To set the OVRF flag to 0, write 0 to the OVRF flag after the CPU has read SPSR with the OVRF flag set to 1.
Figure 44.27 shows an example of operations of the SPRF and OVRF flags. The SPSR and SPDR accesses shown in Figure 44.27 indicate the condition of accesses to SPSR and SPDR, respectively, where W denotes a write cycle, and R a read cycle. In the example in Figure 44.27, the RSPI performs an 8-bit serial transfer in which the SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKA waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

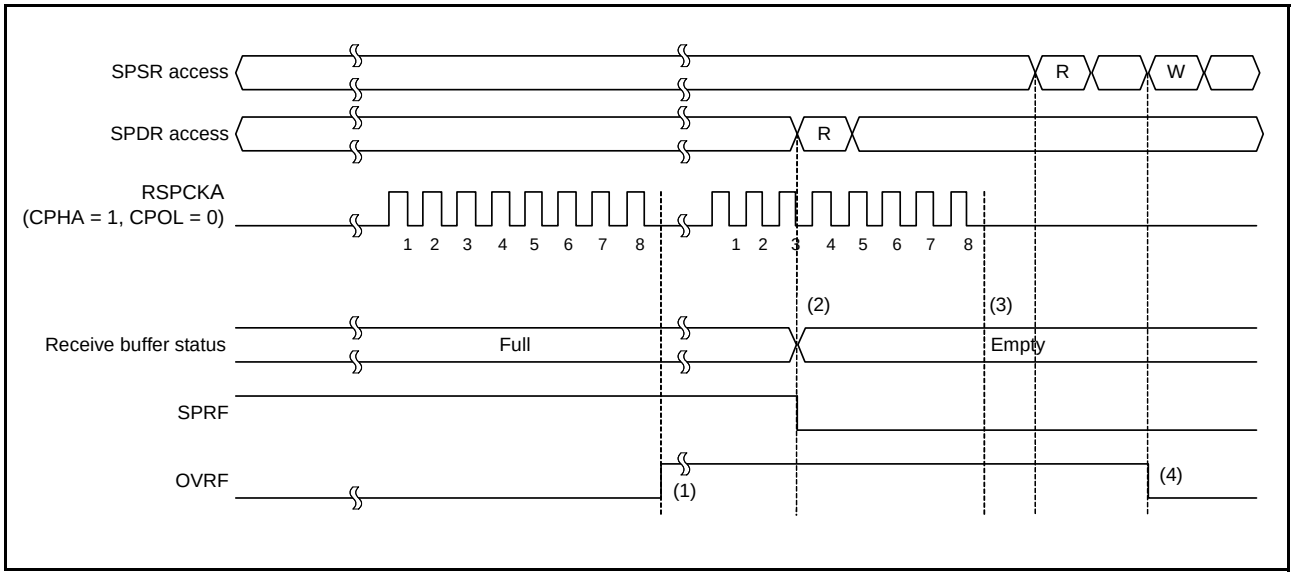

Figure 44.27 Operation Example of SPRF and OVRF Flags

The operation of the flags at the timing shown in steps (1) to (4) in the figure is described below.

(1) If a serial transfer terminates with the receive buffer full (the SPRF flag is 1), the RSPI detects an overrun error, and sets the OVRF flag to 1. The RSPI does not copy the data in the shift register to the receive buffer. Even if the SPPE bit is 1, parity errors are not detected. In master mode, the RSPI copies the pointer value to SPCMDm register to the SPSSR.SPECM[2:0] bits.

(2) When SPDR is read, the RSPI outputs the data in the receive buffer. At this time the SPRF flag becomes 0. Even if the receive buffer becomes empty, the OVRF flag does not become 0.

(3) If the serial transfer ends with the OVRF flag being 1 (an overrun error occurs), the RSPI does not copy the data in the shift register to the receive buffer (the SPRF flag remains 0). A receive buffer full interrupt is not generated. Even if the SPPE bit is 1, parity errors are not detected. When in master mode, the RSPI does not update the SPSSR.SPECM[2:0] bits. When in an overrun error state and the RSPI does not copy the received data from the shift register to the receive buffer, upon termination of the serial transfer, the RSPI determines that the shift register is empty; in this manner, data transfer from the transmit buffer to the shift register is enabled.

(4) If 0 is written to the OVRF flag after SPSR is read when the OVRF flag is 1, the OVRF flag is set to 0.

The occurrence of an overrun can be checked either by reading SPSR or by using an RSPI error interrupt and reading SPSR. When executing a serial transfer, measures should be taken to ensure the early detection of overrun errors, such as reading SPSR immediately after SPDR is read. When the RSPI is used in master mode, the pointer value to SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.
If an overrun error occurs and the OVRF flag is set to 1, normal reception operations cannot be performed until the OVRF flag is set to 0.

When the RSPCK auto-stop function is enabled in master mode, an overrun error does not occur. Figure 44.28 and Figure 44.29 show the clock stop waveform when a serial transfer continues while the receive buffer is full in master mode.

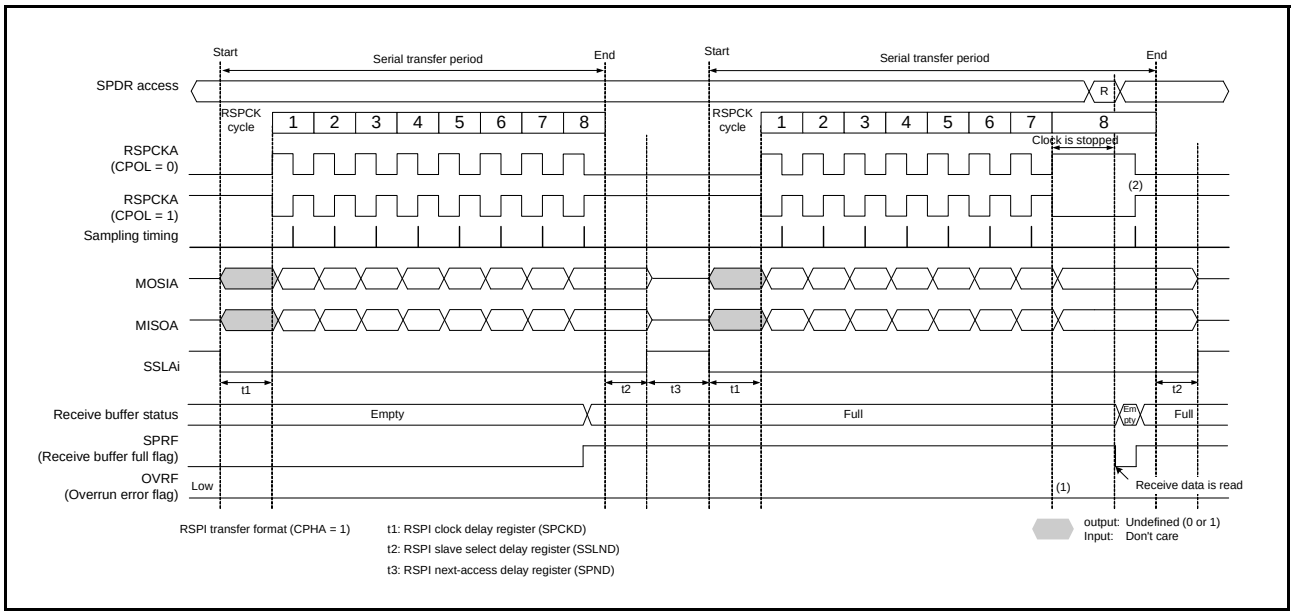

Figure 44.28 Clock Stop Waveform When a Serial Transfer Continues While the Receive Buffer is Full in Master Mode (CPHA = 1)

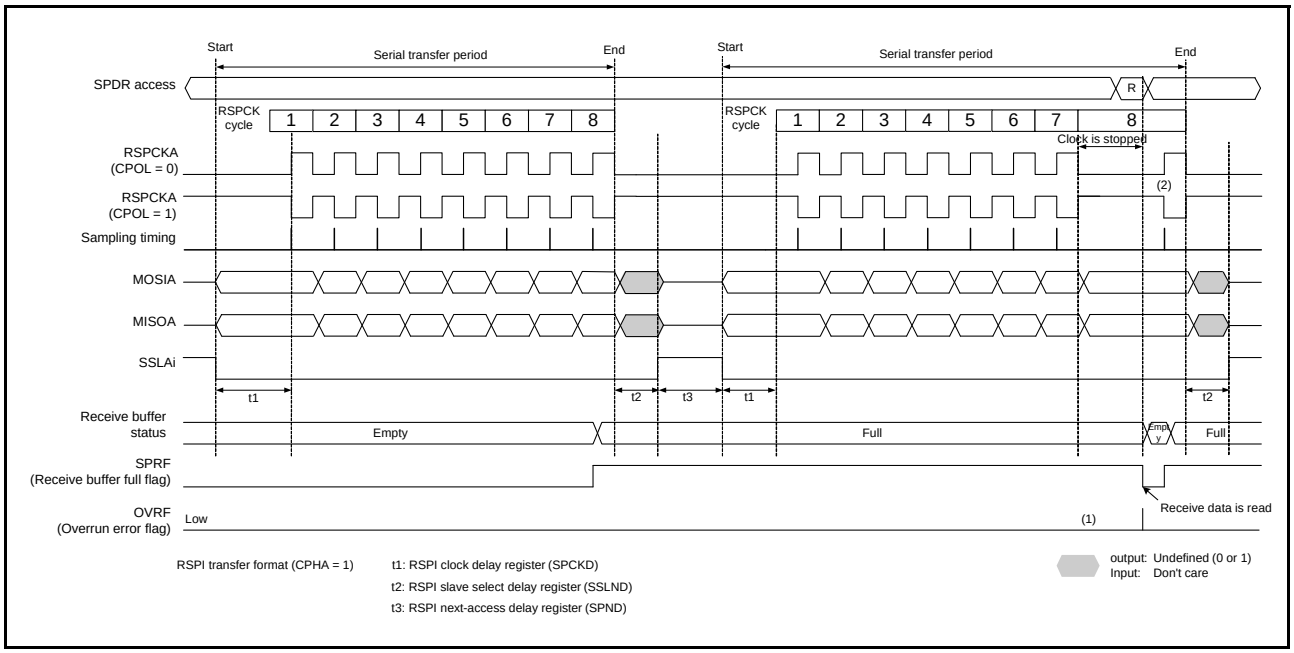

Figure 44.29 Clock Stop Waveform When a Serial Transfer Continues While the Receive Buffer is Full in Master Mode (CPHA = 0)

The operation of the flags at the timings shown in steps (1) and (2) in the figure is described below.

(1) When the receive buffer is full, an overrun error does not occur because the RSPCK clock is stopped.

(2) If SPDR is read while the clock is stopped, data in the receive buffer can be read. The RSPCK clock restarts after reading the receive buffer (after the SPRF flag becomes 0).

44.3.8.2 Parity Error

If full-duplex synchronous serial communications is performed with the SPCR.TXMD bit set to 0 and the SPCR2.SPPE bit set to 1, when serial transfer ends, the RSPI checks whether there are parity errors. Upon detecting a parity error in the received data, the RSPI sets the SPSR.PERF flag to 1. Since the RSPI does not copy the data in the shift register to the receive buffer when the SPSR.OVRF flag is set to 1, parity error detection is not performed for the received data. To set the PERF flag to 0, write 0 to the PERF flag after SPSR register is read with the PERF flag set to 1.
Figure 44.30 shows an example of operation of the OVRF and PERF flags. The SPSR access shown in Figure 44.30 indicates the condition of access to SPSR register, where W denotes a write cycle, and R a read cycle. In the example of Figure 44.30, full-duplex synchronous serial communications is performed while the SPCR.TXMD bit is 0 and the SPCR2.SPPE bit is 1. The RSPI performs an 8-bit serial transfer in which the SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKA waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

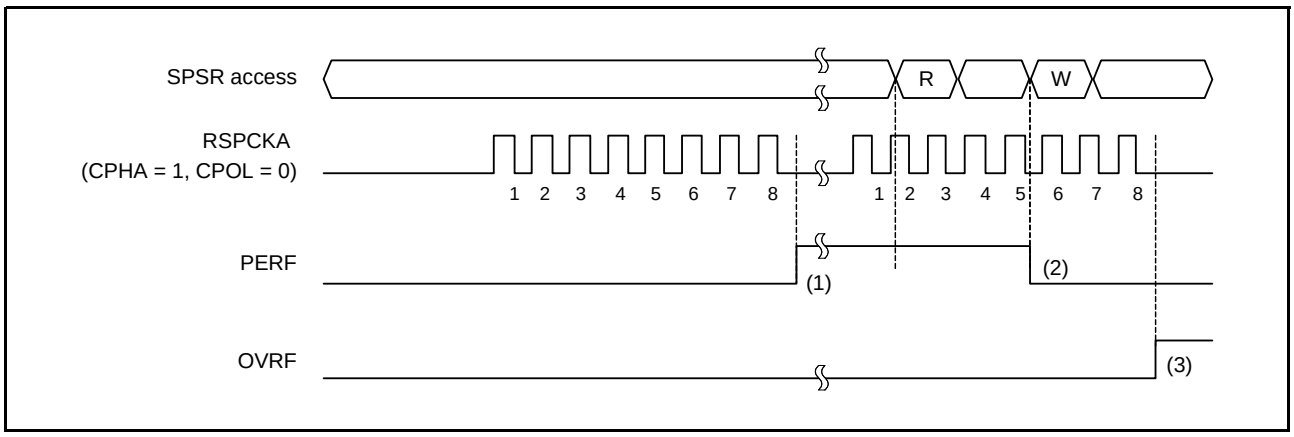

Figure 44.30 Operation Example of PERF Flag

The operation of the flags at the timing shown in steps (1) to (3) in the figure is described below.

(1) If a serial transfer terminates with the RSPI not detecting an overrun error, the RSPI copies the data in the shift register to the receive buffer. The RSPI judges the received data at this timing, and sets the PERF flag to 1 if a parity error is detected. In master mode, the RSPI copies the pointer value to SPCMDm register to the SPSSR.SPECM[2:0] bits.

(2) If 0 is written to the PERF flag after SPSR register is read when the PERF flag is 1, the PERF flag is set to 0.

(3) When the RSPI detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the receive buffer. The RSPI does not perform parity error detection at this timing.

The occurrence of a parity error can be checked either by reading the SPSR register or by using an RSPI error interrupt and reading the SPSR register. When executing a serial transfer, measures should be taken to ensure the early detection of parity errors, such as reading SPSR. When the RSPI is used in master mode, the pointer value to SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

44.3.8.3 Mode Fault Error

The RSPI operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1. If the active level is input with respect to the SSLA0 input signal of the RSPI in multi-master mode, the RSPI detects a mode fault error irrespective of the status of the serial transfer, and sets the SPSR.MODF flag to 1. Upon detecting the mode fault error, the RSPI copies the value of the pointer to SPCMDm to the SPSSR.SPECM[2:0] bits. The active level of the SSLA0 signal is determined by the SSLP.SSL0P bit.

When the MSTR bit is 0, the RSPI operates in slave mode. The RSPI detects a mode fault error if the MODFEN bit of the RSPI in slave mode is 1, and the SPMS bit is 0, and if the SSLA0 input signal is negated during the serial transfer period (from the time the driving of valid data is started to the time the final valid data is fetched).

Upon detecting a mode fault error, the RSPI stops driving of the output signals and clears the SPCR.SPE bit to 0 (refer to section 44.3.9, Initializing RSPI). In the case of multi-master configuration, detection of a mode fault error is used to stop driving of the output signals and the RSPI function, which allows the master right to be released.

The occurrence of a mode fault error can be checked either by reading SPSR or by using an RSPI error interrupt and reading SPSR. Detecting mode fault errors without utilizing the RSPI error interrupt requires polling of SPSR. When using the RSPI in master mode, the pointer value to SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

When the MODF flag is 1, writing of the value 1 to the SPE bit is ignored by the RSPI. To enable the RSPI function after the detection of a mode fault error, set the MODF flag to 0.

44.3.9 Initializing RSPI

If 0 is written to the SPCR.SPE bit or the RSPI sets the SPE bit to 0 because of the detection of a mode fault error, the RSPI disables the RSPI function, and initializes some of the module functions. When a system reset is generated, the RSPI initializes all of the module functions. The following describes initialization by the clearing of the SPCR.SPE bit and initialization by a system reset.

44.3.9.1 Initialization by Clearing the SPE Bit

When the SPCR.SPE bit is set to 0, the RSPI performs the following initialization:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state of the RSPI
- Initializing the transmit buffer of the RSPI (Set the SPTEF flag to 1)

Initialization by the clearing of the SPE bit does not initialize the control bits of the RSPI. For this reason, the RSPI can be started in the same transfer mode as prior to the initialization if the SPE bit is set to 1 again.
The SPSR.SPRF, SPSR.OVRF, SPSR.MODF, and SPSR.PERF flags are not initialized, nor is the value of the RSPI sequence status register (SPSSR) initialized. For this reason, even after the RSPI is initialized, data from the receive buffer can be read in order to check the status of error occurrence during an RSPI transfer.
The transmit buffer is initialized to an empty state (the SPTEF flag is 1). Therefore, if the SPCR.SPTIE bit is set to 1 after RSPI initialization, a transmit buffer empty interrupt is generated. When the RSPI is initialized, in order to disable any transmit buffer empty interrupt, 0 should be written to the SPTIE bit simultaneously with the writing of 0 to the SPE bit.

44.3.9.2 System Reset

The initialization by a system reset completely initializes the RSPI through the initialization of all bits for controlling the RSPI, initialization of the status bits, and initialization of data registers, in addition to the requirements described in section 44.3.9.1, Initialization by Clearing the SPE Bit.

44.3.10 SPI Operation

44.3.10.1 Master Mode Operation

The only difference between single-master mode operation and multi-master mode operation lies in mode fault error detection (refer to section 44.3.8, Error Detection). When operating in single-master mode, the RSPI does not detect mode fault errors whereas the RSPI running in multi-master mode does detect mode fault errors. This section explains operations that are common to single-master mode and multi-master mode.

(1) Starting a Serial Transfer

The RSPI updates the data in the transmit buffer (SPTX) when data is written to the RSPI data register (SPDR) with the RSPI transmit buffer being empty (the SPTEF flag is 1 and data for the next transfer is not set). When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR, the RSPI copies data from the transmit buffer to the shift register and starts serial transfer. Upon copying transmit data to the shift register, the RSPI changes the status of the shift register to “full”, and upon termination of serial transfer, it changes the status of the shift register to “empty”. The status of the shift register cannot be referenced.
For details on the RSPI transfer format, refer to section 44.3.5, Transfer Format. The polarity of the SSLAi output pins depends on the SSLP register settings.

(2) Terminating a Serial Transfer

Irrespective of the SPCMDm.CPHA bit, the RSPI terminates the serial transfer after transmitting an RSPCKA edge corresponding to the final sampling timing. If free space is available in the receive buffer (SPRX) (the SPRF flag is 0), upon termination of serial transfer, the RSPI copies data from the shift register to the receive buffer of the SPDR register. It should be noted that the final sampling timing varies depending on the bit length of transfer data. In master mode, the RSPI data length depends on the SPCMDm.SPB[3:0] bit setting. The polarity of the SSLAi output pin depends on the SSLP register settings.
For details on the RSPI transfer format, refer to section 44.3.5, Transfer Format.

(3) Sequence Control

The transfer format that is employed in master mode is determined by SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers.

SPSCR is a register used to determine the sequence configuration for serial transfers that are executed by the RSPI in master mode. The following items are set in SPCMDm register: SSLAi pin output signal value, MSB/LSB first, data length, some of the bit rate settings, RSPCK polarity/phase, whether SPCKD is to be referenced, whether SSLND is to be referenced, and whether SPND is to be referenced. SPBR holds some of the bit rate settings; SPCKD, an RSPI clock delay value; SSLND, an SSL negation delay; and SPND, a next-access delay value.

According to the sequence length that is assigned to SPSCR, the RSPI makes up a sequence comprised of a part or all of SPCMDm register. The RSPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the RSPI function is enabled, the RSPI loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The RSPI increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, the RSPI sets the pointer in SPCMD0, and in this manner the sequence is executed repeatedly.

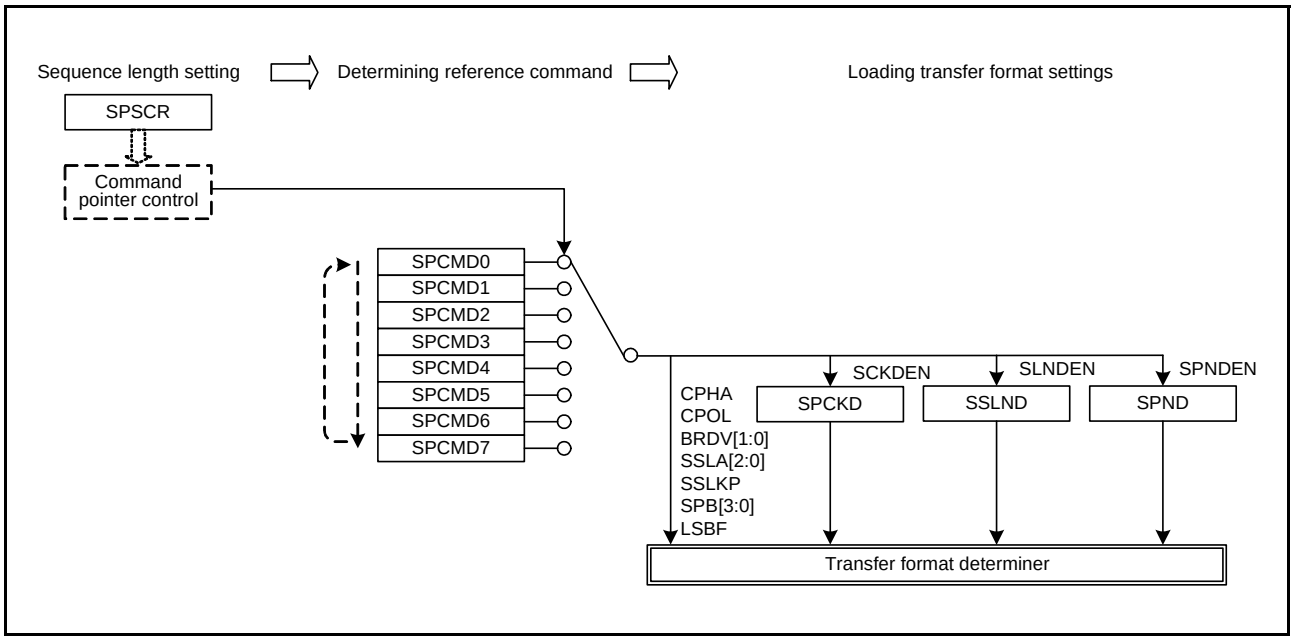

Figure 44.31 Procedure for Determining the Form of Serial Transfer in Master Mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

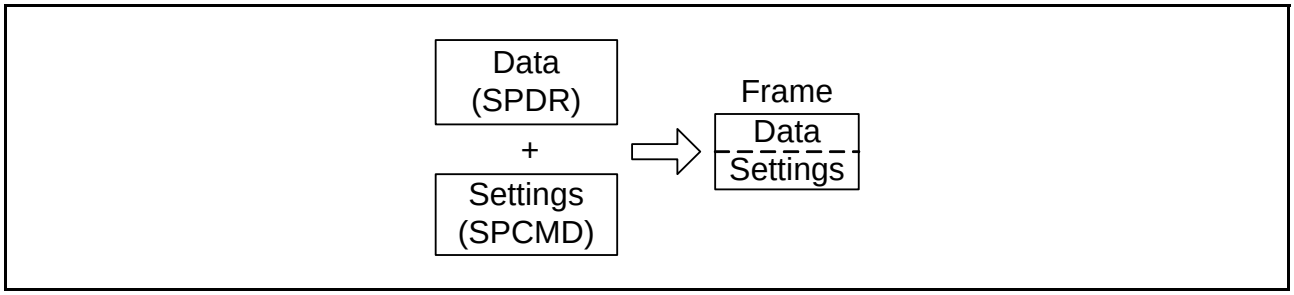

Figure 44.32 Concept of a Frame

Figure 44.33 shows the relationship between the command and the transmit and receive buffers in the sequence of operations specified by the settings in Table 44.4.

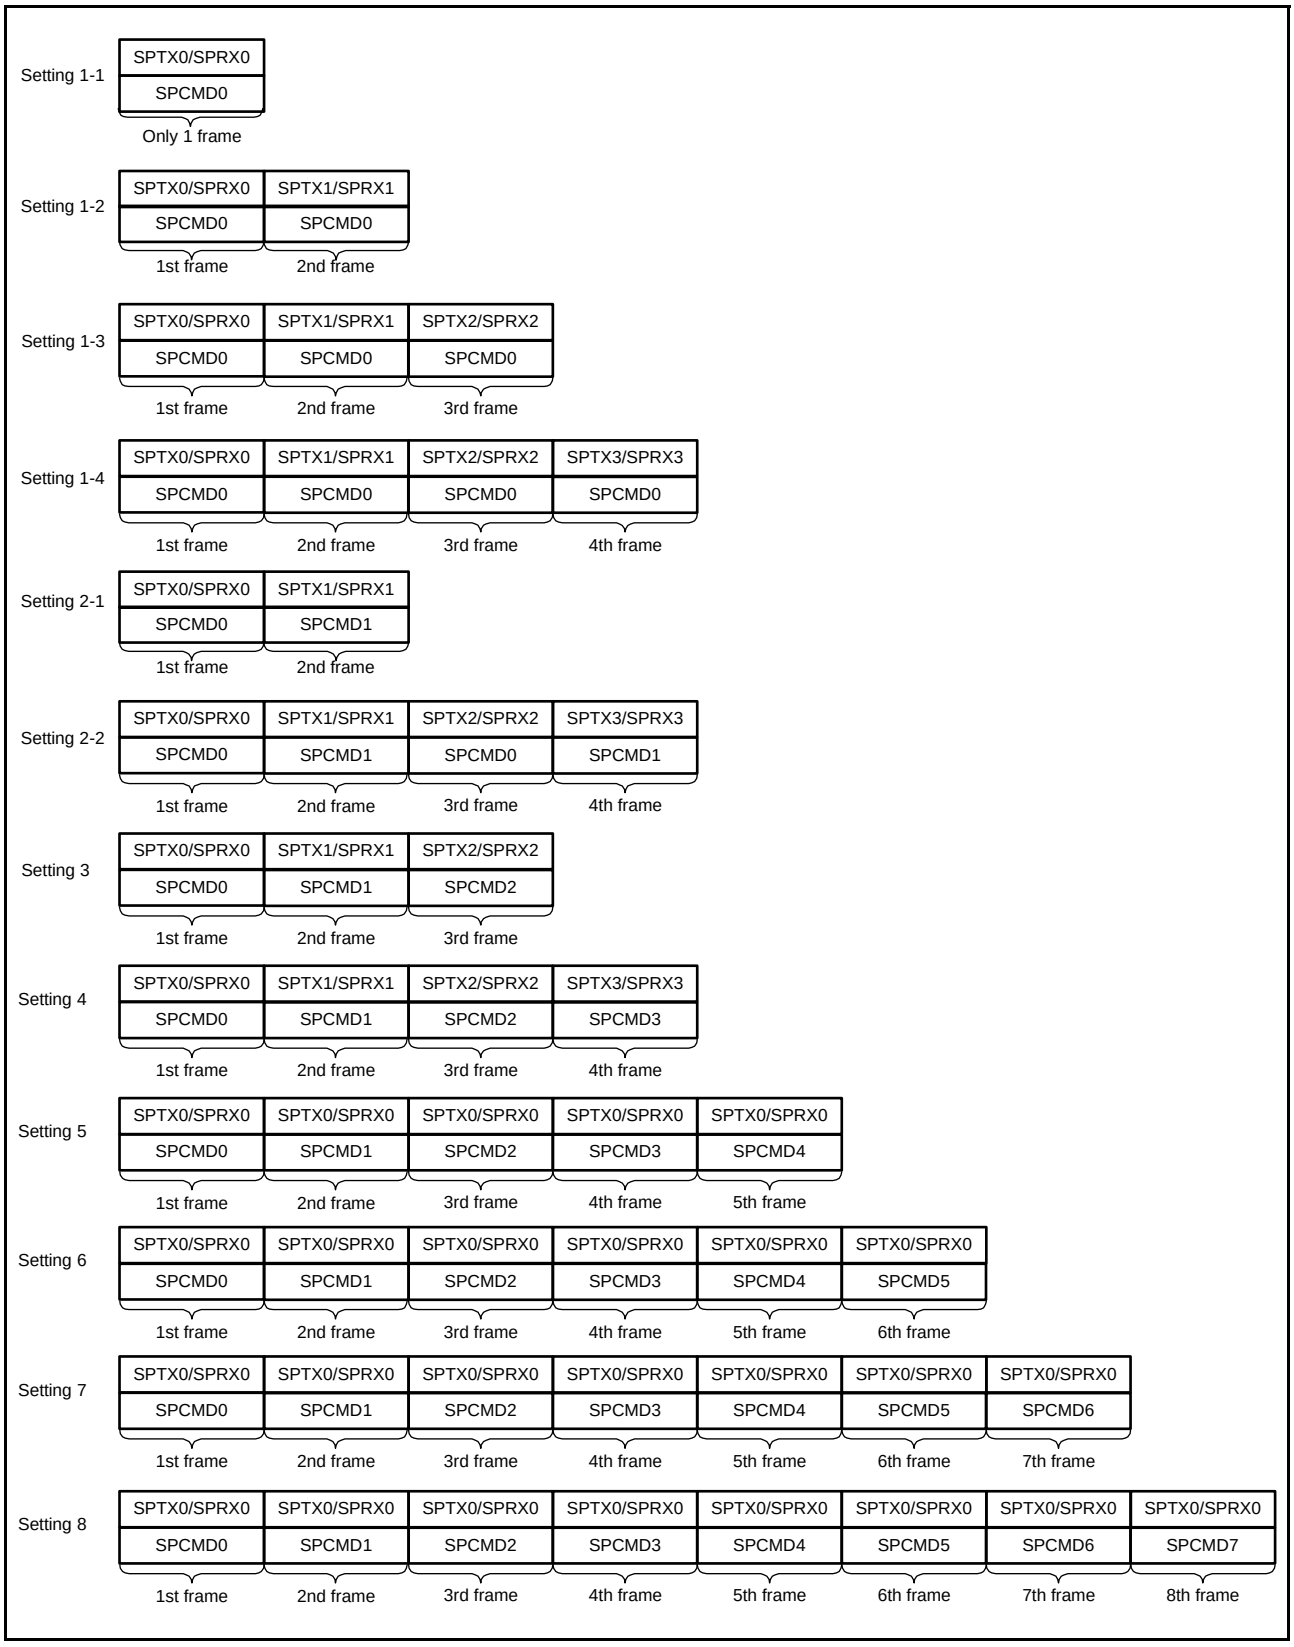

Figure 44.33 Correspondence between the RSPI Command Register and Transmit/Receive Buffers in Sequence Operations

(4) Burst Transfer

If the SPCMDm.SSLKP bit that the RSPI references during the current serial transfer is 1, the RSPI keeps the SSLAi signal level during the serial transfer until the beginning of the SSLAi signal assertion for the next serial transfer. If the SSLAi signal level for the next serial transfer is the same as the SSLAi signal level for the current serial transfer, the RSPI can execute continuous serial transfers while keeping the SSLAi signal assertion status (burst transfer).
Figure 44.34 shows an example of an SSLAi signal operation for the case where a burst transfer is implemented using SPCMD0 and SPCMD1 register settings. The text below explains the RSPI operations (1) to (7) as shown in Figure 44.34. It should be noted that the polarity of the SSLAi output signal depends on the SSLP register settings.

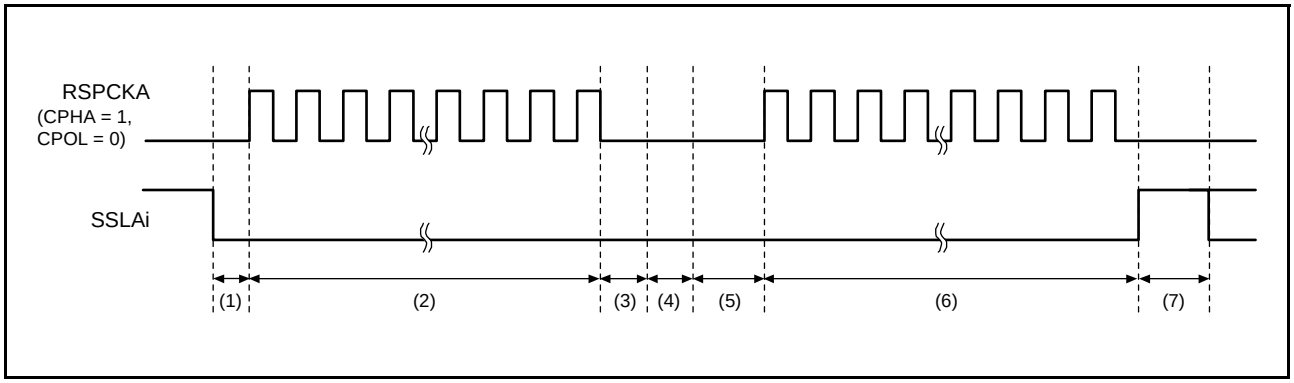

Figure 44.34 Example of Burst Transfer Operation Using SSLKP Bit

(1) Based on SPCMD0, the RSPI asserts the SSLAi signal and inserts RSPCK delays.
(2) The RSPI executes serial transfers according to SPCMD0.
(3) The RSPI inserts SSL negation delays.
(4) Since the SPCMD0.SSLKP bit is 1, the RSPI keeps the SSLAi signal value on SPCMD0. This period is sustained, at the shortest, for a period equal to the next-access delay of SPCMD0. If the shift register is empty after the passage of a minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
(5) Based on SPCMD1, the RSPI asserts the SSLAi signal and inserts RSPCK delays.
(6) The RSPI executes serial transfers according to SPCMD1.
(7) Because the SPCMD1.SSLKP bit is 0, the RSPI negates the SSLAi signal. In addition, a next-access delay is inserted according to SPCMD1.

If the SSLAi signal output settings in the SPCMDm register in which 1 is assigned to the SSLKP bit are different from the SSLAi signal output settings in the SPCMDm register to be used in the next transfer, the RSPI switches the SSLAi signal status to SSLAi signal assertion ((5) in Figure 44.34) corresponding to the command for the next transfer. Note that if such an SSLAi signal switching occurs, the slaves that drive the MISOA signal compete, and collision of signal levels may occur.
The RSPI in master mode references the SSLAi signal operation within the module for the case where the SSLKP bit is not used. Even when the SPCMDm.CPHA bit is 0, the RSPI can accurately start serial transfers by using the SSLAi signal assertion for the next transfer that is detected internally.

(5) RSPCK Delay (t1)

The RSPCK delay value of the RSPI in master mode depends on the SPCMDm.SCKDEN bit setting and the SPCKD register setting. The RSPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines an RSPCK delay value during serial transfer by using the SPCMDm.SCKDEN bit and SPCKD, as listed in Table 44.9. For a definition of RSPCK delay, refer to section 44.3.5, Transfer Format.

Table 44.9 Relationship among SCKDEN Bit, SPCKD, and RSPCK Delay Value

SPCMDm.SCKDEN Bit	SPCKD.SCKDL[2:0] Bits	RSPCK Delay Value
0	000b to 111b	1 RSPCK
1	000b	1 RSPCK
	001b	2 RSPCK
	010b	3 RSPCK
	011b	4 RSPCK
	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(6) SSL Negation Delay (t2)

The SSL negation delay value of the RSPI in master mode depends on the SPCMDm.SLNDEN bit setting and the SSLND register setting. The RSPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines an SSL negation delay value during serial transfer by using the SPCMDm.SLNDEN bit and SSLND, as listed in Table 44.10. For a definition of SSL negation delay, refer to section 44.3.5, Transfer Format.

Table 44.10 Relationship among SLNDEN Bit, SSLND, and SSL Negation Delay Value

SPCMDm.SLNDEN Bit	SSLND.SLNDL[2:0] Bits	SSL Negation Delay Value
0	000b to 111b	1 RSPCK
1	000b	1 RSPCK
	001b	2 RSPCK
	010b	3 RSPCK
	011b	4 RSPCK
	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(7) Next-Access Delay (t3)

The next-access delay value of the RSPI in master mode depends on the SPCMDm.SPNDEN bit setting and the SPND setting. The RSPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines a next-access delay value during serial transfer by using the SPCMDm.SPNDEN bit and SPND, as listed in Table 44.11. For a definition of next-access delay, refer to section 44.3.5, Transfer Format.

Table 44.11 Relationship among SPNDEN Bit, SPND, and Next-Access Delay Value

SPCMDm.SPNDEN Bit	SPND.SPNDL[2:0] Bits	Next-Access Delay Value
0	000b to 111b	1 RSPCK + 2 PCLK
1	000b	1 RSPCK + 2 PCLK
	001b	2 RSPCK + 2 PCLK
	010b	3 RSPCK + 2 PCLK
	011b	4 RSPCK + 2 PCLK
	100b	5 RSPCK + 2 PCLK
	101b	6 RSPCK + 2 PCLK
	110b	7 RSPCK + 2 PCLK
	111b	8 RSPCK + 2 PCLK

(8) Initialization Flowchart

Figure 44.35 is a flowchart illustrating an example of initialization in SPI operation when the RSPI is used in master mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

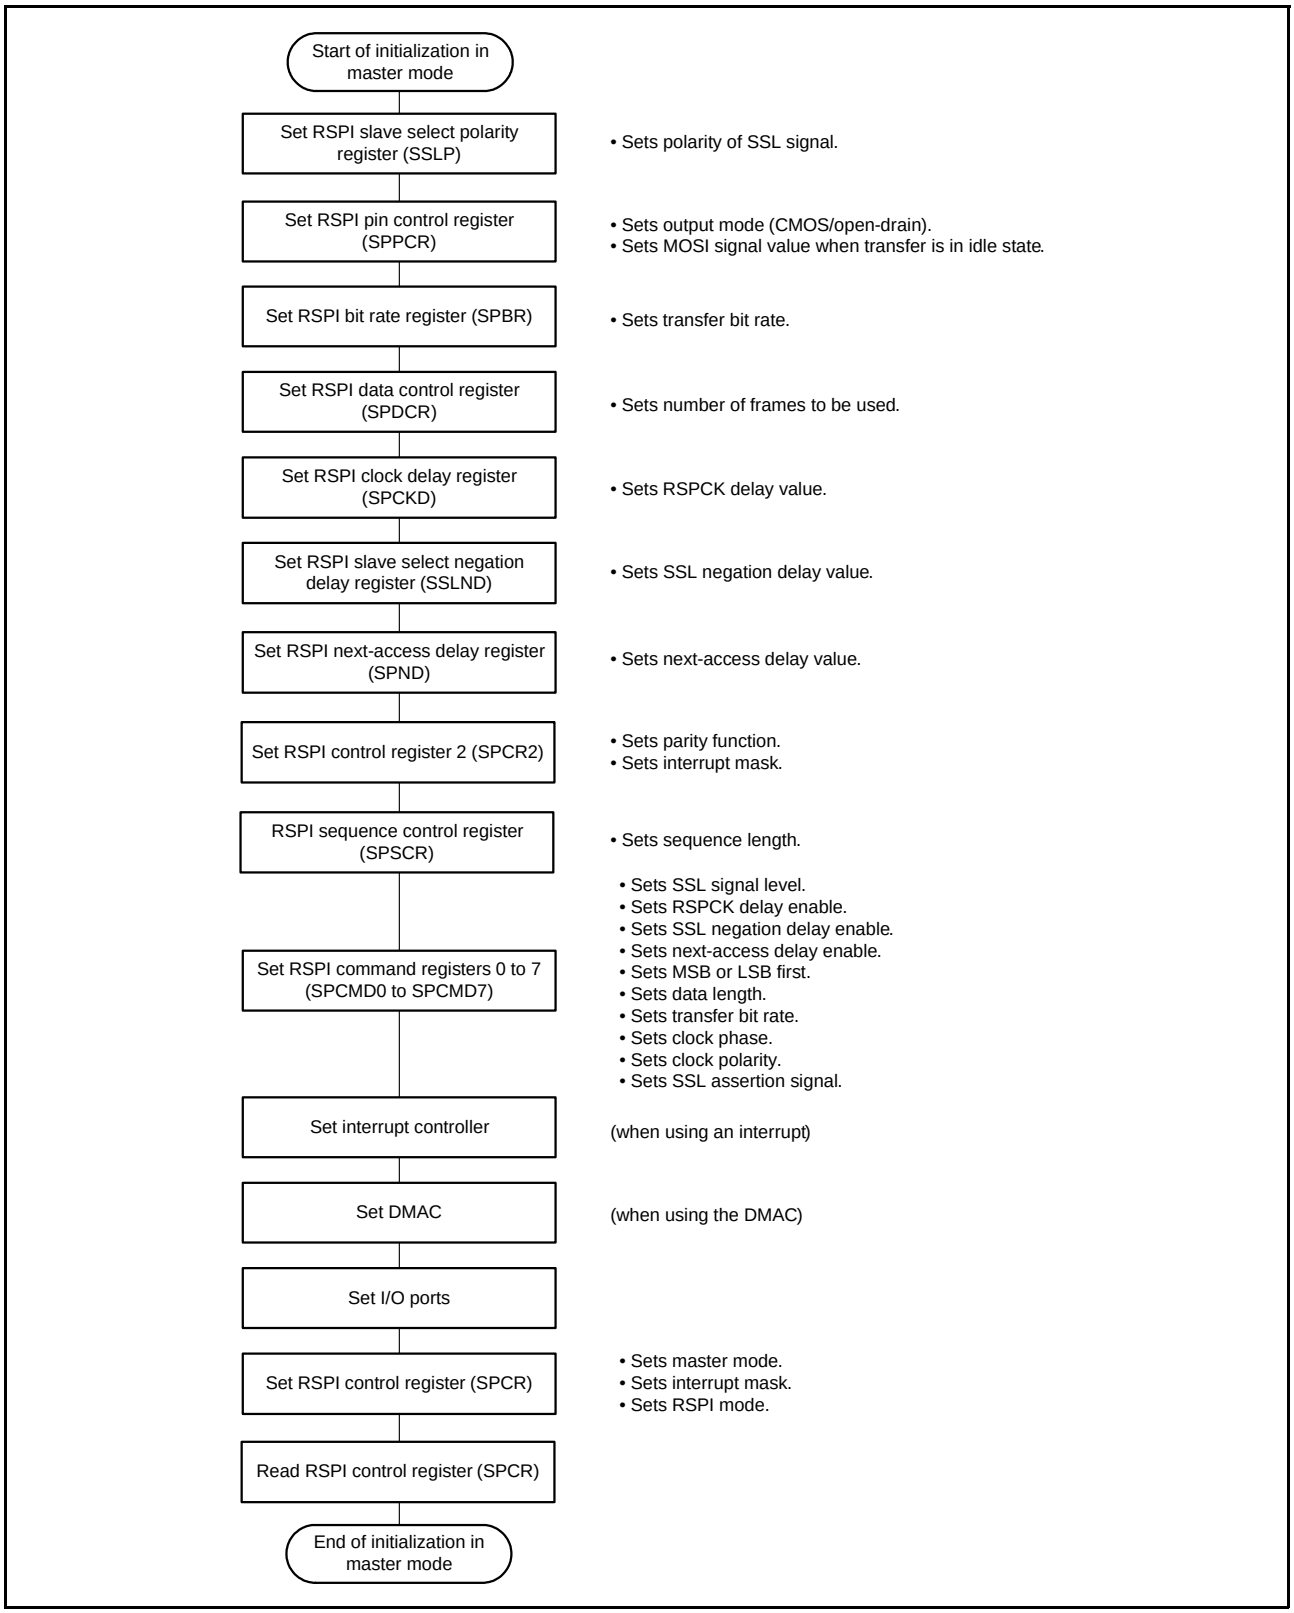

Figure 44.35 Example of Initialization Flowchart in Master Mode (SPI Operation)

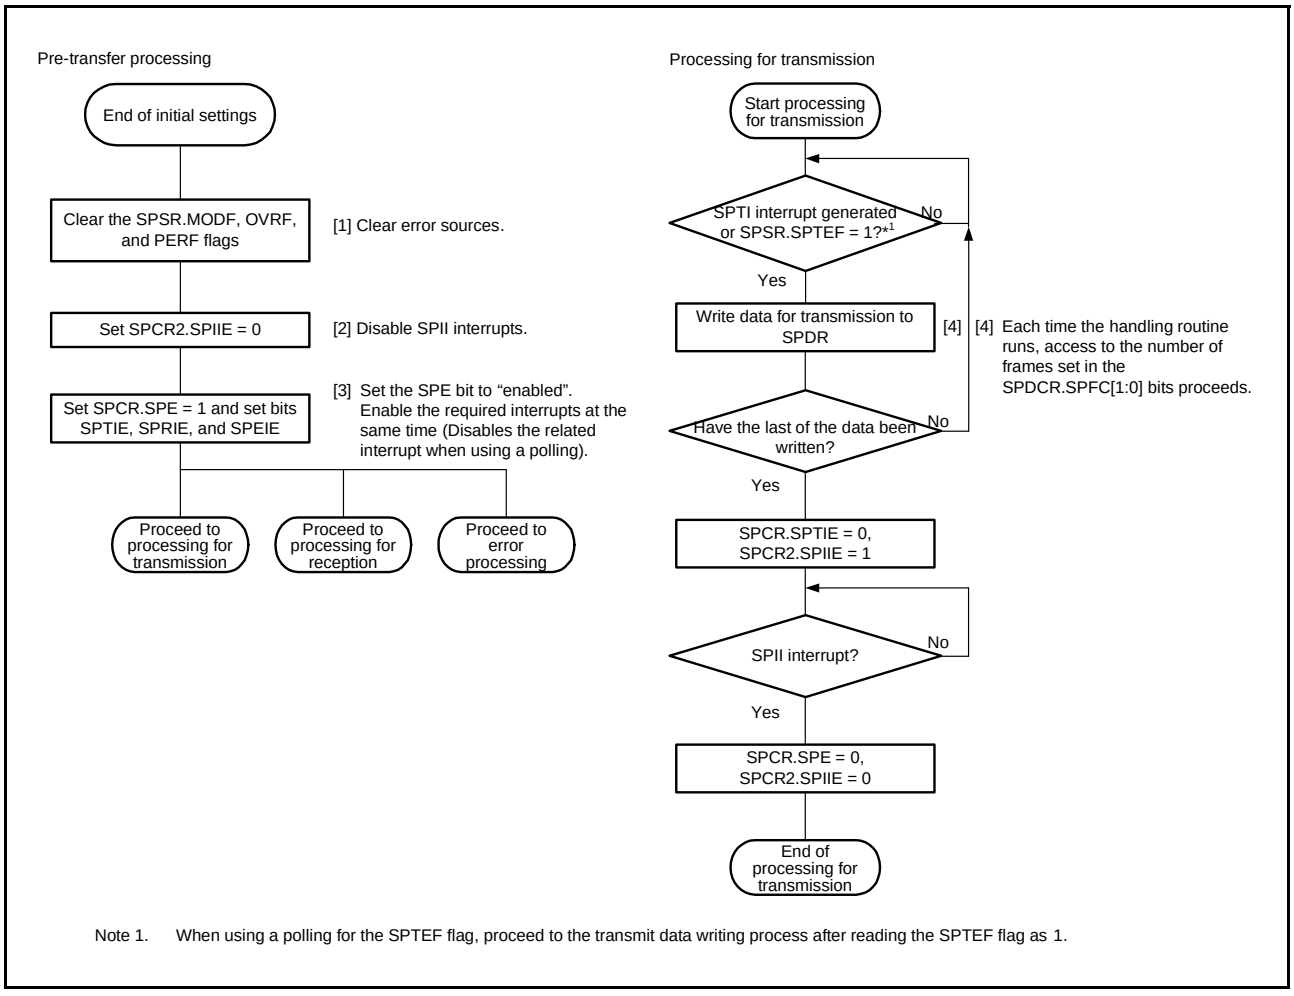
(9) Software Processing Flow

Figure 44.36 to Figure 44.38 show examples of the flow of software processing.

(a) Transmit Processing Flow

When transmitting data, the CPU will be notified of the completion of data transmission by enabling the SPI interrupt after the last writing of data for transmission.
The completion of data transmission can also be checked by polling to see if the SPSR.IDLNF flag has become 0, instead of using the SPII interrupt. However, one cycle of PCLK is required for the time from when data for transmission is written in the SPDR register to when the IDLNF flag becomes 1. After the last data is written in the SPDR register, discard the value of the SPSR register once not to judge the condition with the IDLNF flag which has not yet become 1, and read and use the value of the SPSR.IDLNF flag to confirm the completion of data transmission.



Note 1. When using a polling for the SPTEF flag, proceed to the transmit data writing process after reading the SPTEF flag as 1.

Figure 44.36 Flowchart in Master Mode (Transmission)

(b) Receive Processing Flow

The RSPI does not handle receive-only operation, so processing for transmission is required.

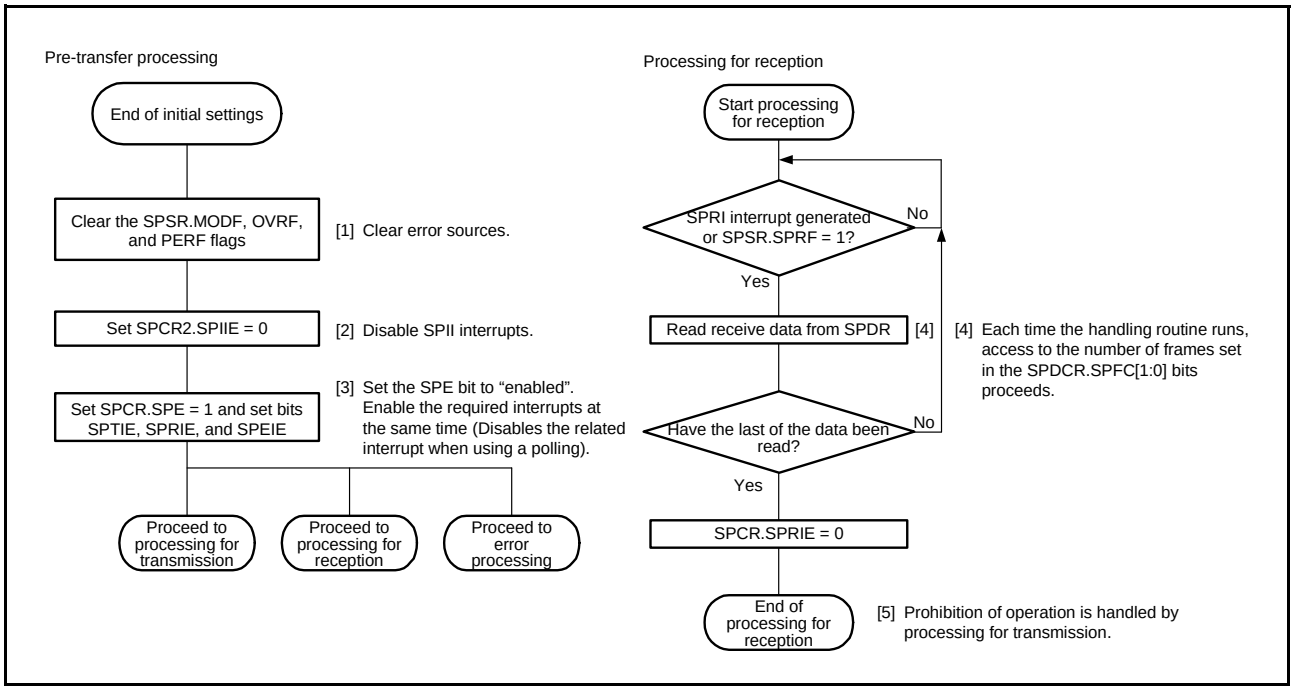


Figure 44.37 Flowchart in Master Mode (Reception)

(c) Flow of Error Processing

The RSPI has three types of error. When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, however, the SPCR.SPE bit is not cleared and operations for transmission and reception continue; accordingly, we recommend clearing of the SPCR.SPE bit to stop operations in the case of errors other than mode fault errors. Not doing so will lead to updating of the SPSSR.SPECM[2:0] bits.

When interrupts are used and an error occurs, if the ICU.IRn.IR flag for the SPTI or SPRI interrupt request is set to 1, clear the ICU.IRn.IR flag in the error processing routine. If the SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the RSPI.

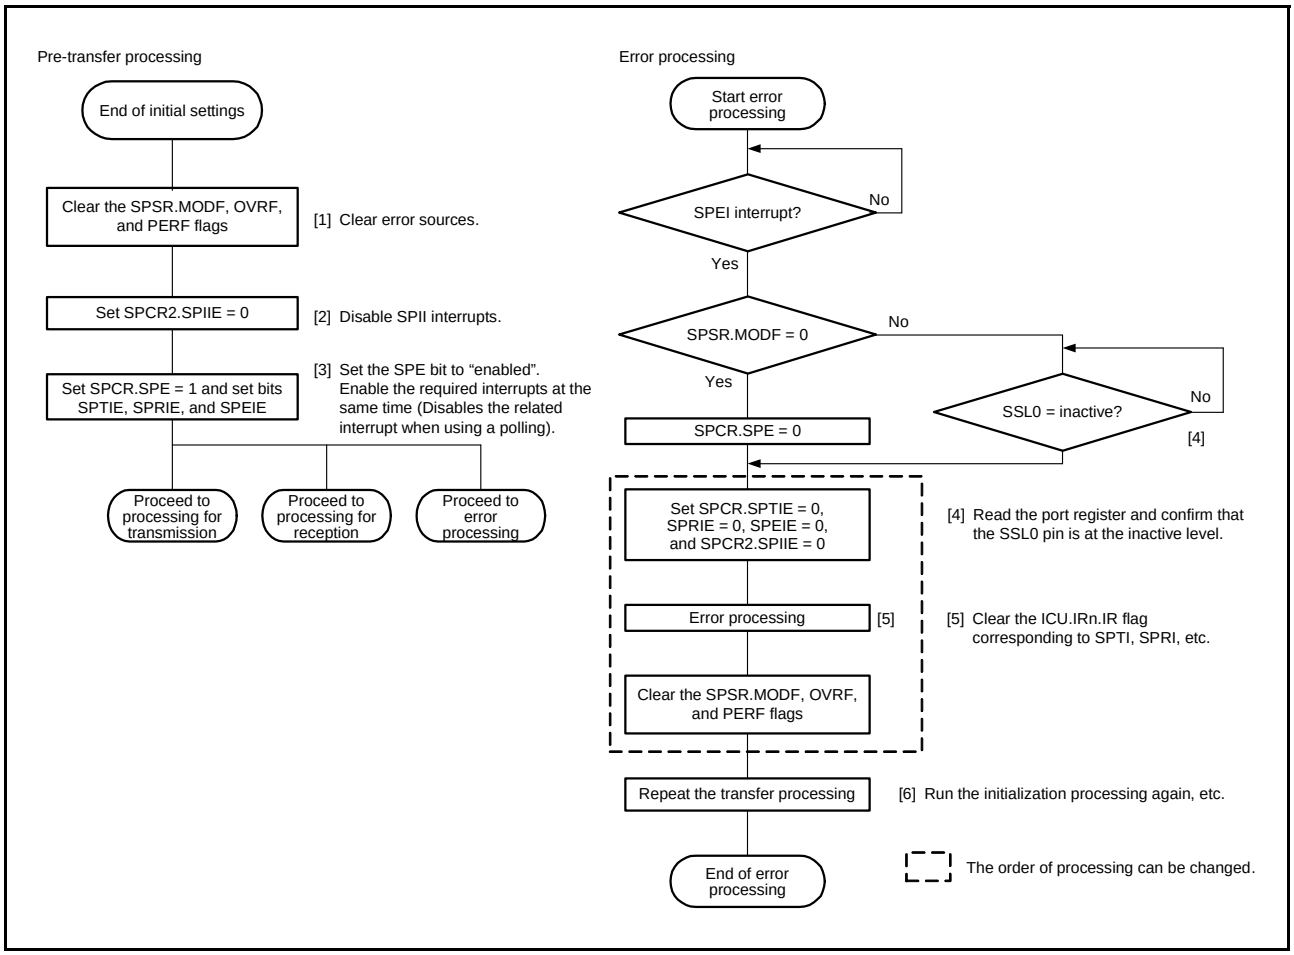

Figure 44.38 Flowchart for Master Mode (Error Processing)

44.3.10.2 Slave Mode Operation

(1) Starting a Serial Transfer

If the SPCMD0.CPHA bit is 0, when detecting an SSLA0 input signal assertion, the RSPI needs to start driving valid data to the MISOA output signal. For this reason, when the CPHA bit is 0, the assertion of the SSLA0 input signal triggers the start of a serial transfer.

If the CPHA bit is 1, when detecting the first RSPCKA edge in an SSLA0 signal asserted condition, the RSPI needs to start driving valid data to the MISOA output signal. For this reason, when the CPHA bit is 1, the first RSPCKA edge in an SSLA0 signal asserted condition triggers the start of a serial transfer.

When detecting the start of a serial transfer in a condition in which the shift register is empty, the RSPI changes the status of the shift register to “full”, so that data cannot be copied from the transmit buffer to the shift register when serial transfer is in progress. If the shift register was full before the serial transfer started, the RSPI leaves the status of the shift register unchanged, in the full state.

Irrespective of the CPHA bit setting, the timing at which the RSPI starts driving of the MISOA output signal is the SSLA0 signal assertion timing. The data which is output by the RSPI is either valid or invalid, depending on the CPHA bit setting.

For details on the RSPI transfer format, refer to section 44.3.5, Transfer Format. The polarity of the SSLA0 input signal depends on the setting of the SSLP.SSL0P bit.

(2) Terminating a Serial Transfer

Irrespective of the SPCMD0.CPHA bit, the RSPI terminates the serial transfer after detecting an RSPCKA edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPRF flag is 0), upon termination of serial transfer the RSPI copies received data from the shift register to the receive buffer of the SPDR register. Upon termination of a serial transfer the RSPI changes the status of the shift register to “empty”, regardless of the receive buffer state. A mode fault error occurs if the RSPI detects an SSLA0 input signal negation from the beginning of serial transfer to the end of serial transfer (refer to section 44.3.8, Error Detection).

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the RSPI data length depends on the SPCMD0.SPB[3:0] bit setting. The polarity of the SSLA0 input signal depends on the SSLP.SSL0P bit setting.

For details on the RSPI transfer format, refer to section 44.3.5, Transfer Format.

(3) Notes on Single-Slave Operations

If the SPCMD0.CPHA bit is 0, the RSPI starts serial transfers when it detects the assertion edge for an SSLA0 input signal. In the type of configuration shown in Figure 44.7 as an example, if the RSPI is used in single-slave mode, the SSLA0 signal is fixed at the active state. Therefore, when the CPHA bit is set to 0, the RSPI cannot correctly start a serial transfer. To correctly execute transmit/receive operations by the RSPI in slave mode in a configuration in which the SSLA0 input signal is fixed at the active state, the CPHA bit should be set to 1. If there is a need for setting the CPHA bit to 0, the SSLA0 input signal should not be fixed.

(4) Burst Transfer

If the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSLA0 input signal. If the CPHA bit is 1, the period from the first RSPCKA edge to the sampling timing for the reception of the final bit in an SSLA0 signal active state corresponds to a serial transfer period. Even when the SSLA0 input signal remains at the active level, the RSPI can accommodate burst transfers because it can detect the start of an access.
If the CPHA bit is 0, the second and subsequent serial transfers during burst transfer cannot be executed correctly.

(5) Initialization Flowchart

Figure 44.39 is a flowchart illustrating an example of initialization in SPI operation when the RSPI is used in slave mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

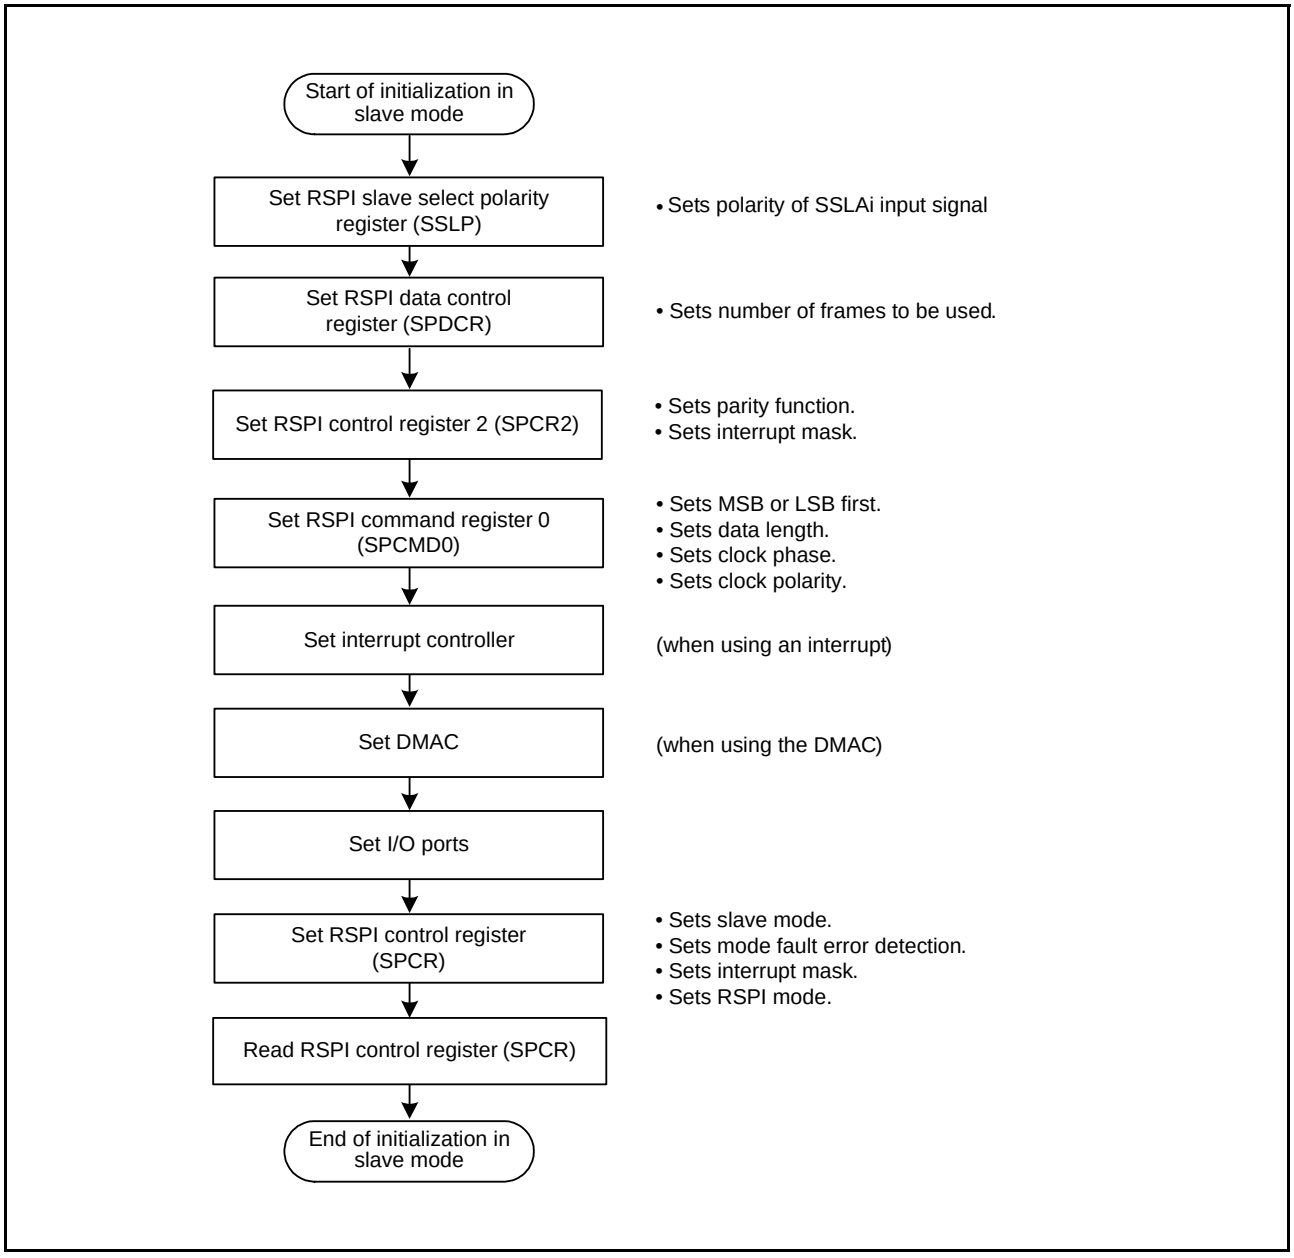

Figure 44.39 Example of Initialization Flowchart in Slave Mode (SPI Operation)

(6) Software Processing Flow

Figure 44.40 to Figure 44.42 show examples of the flow of software processing.

(a) Transmit Processing Flow

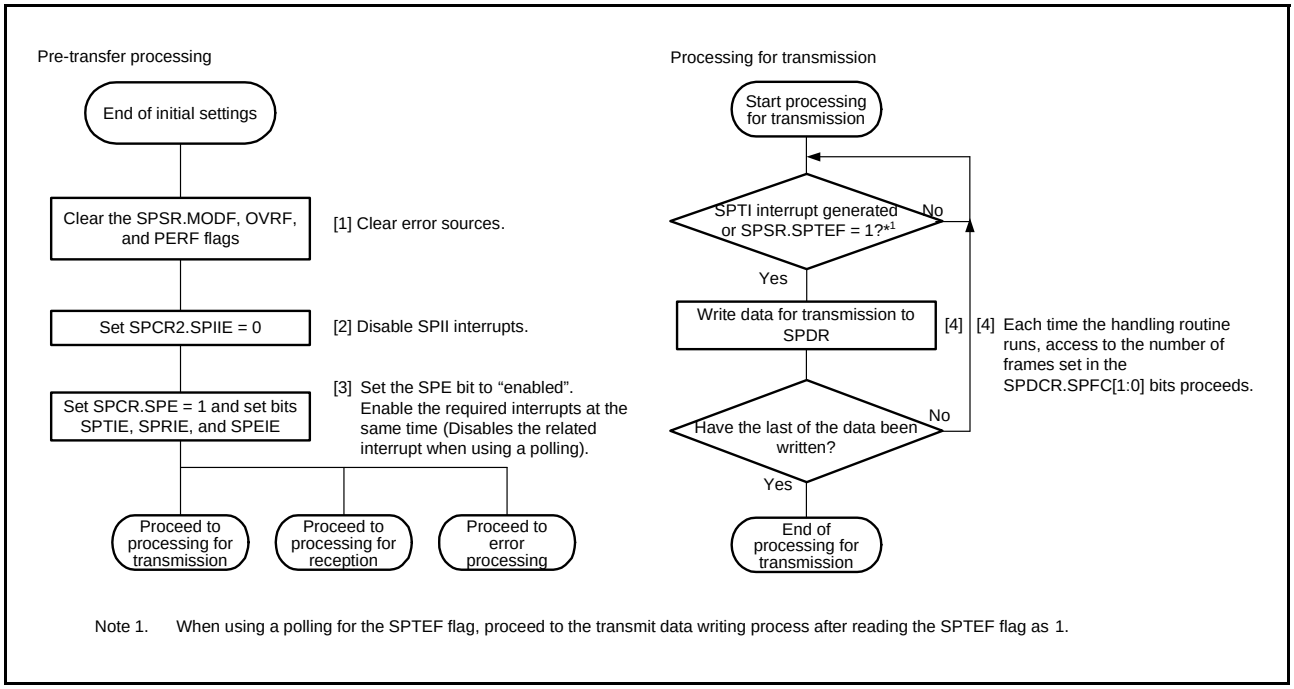

Figure 44.40 Flowchart in Slave Mode (Transmission)

(b) Receive Processing Flow

The RSPI does not handle receive-only operation, so processing for transmission is required.

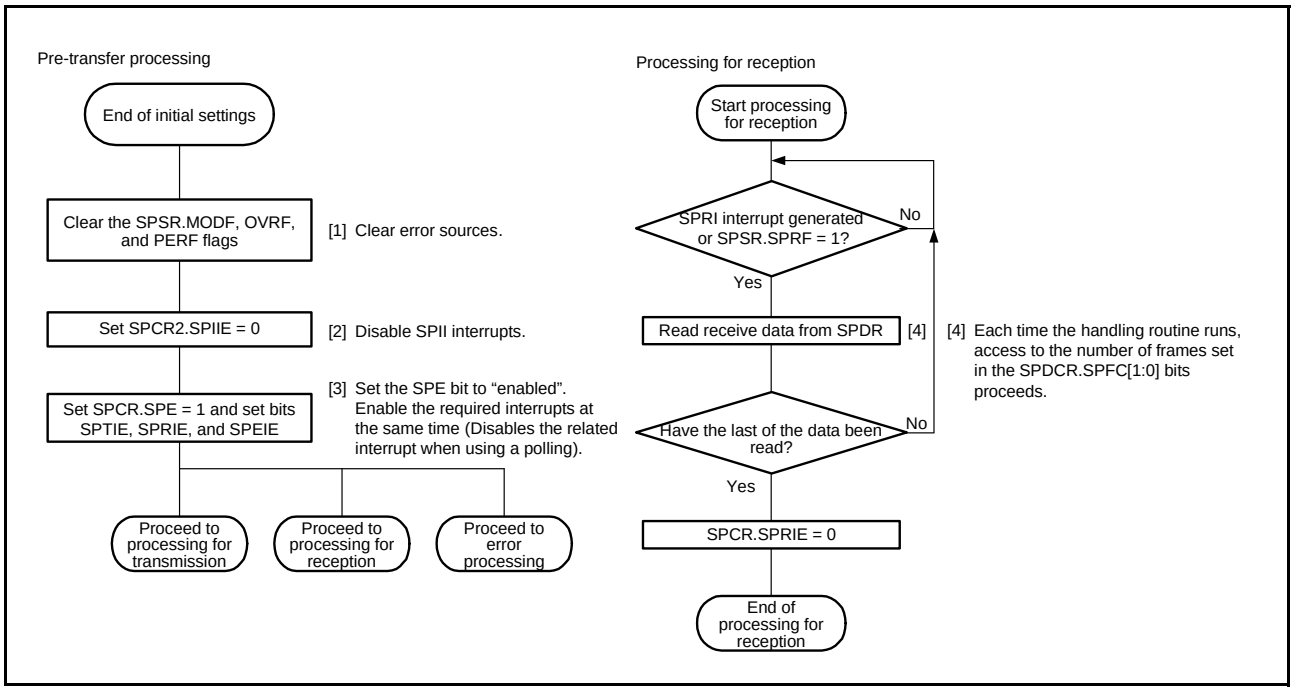

Figure 44.41 Flowchart in Slave Mode (Reception)

(c) Flow of Error Processing

In slave operation, even when a mode fault error is generated, the SPSR.MODF flag can be cleared regardless of the status of the SSLA0 pin.

When interrupts are used and an error occurs, if the ICU.IRn.IR flag for the SPTI or SPRI interrupt request is set to 1, clear the ICU.IRn.IR flag in the error processing routine. If the SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the RSPI.

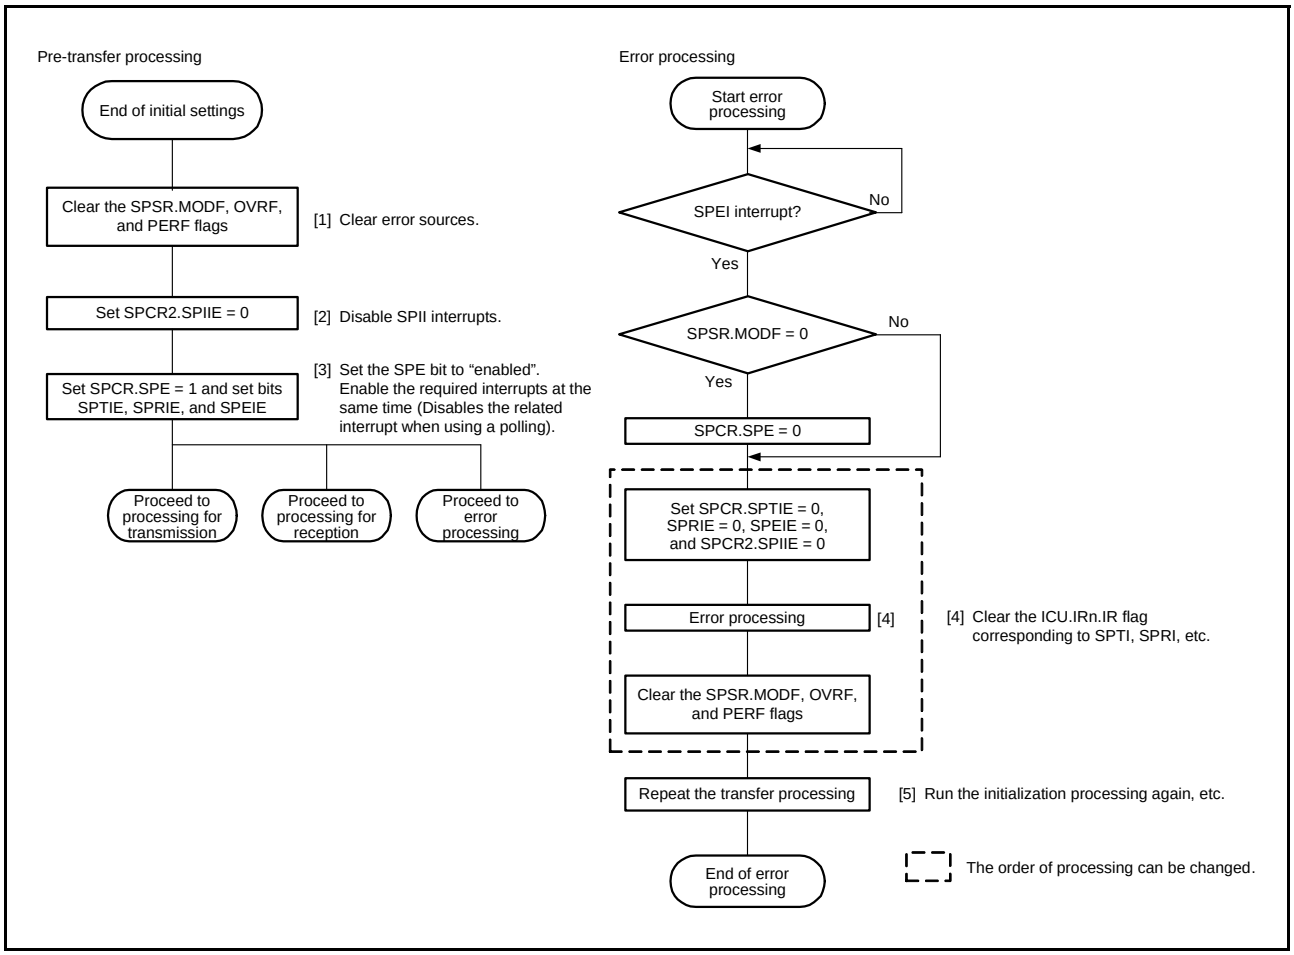

Figure 44.42 Flowchart for Slave Mode (Error Processing)

44.3.11 Clock Synchronous Operation

Setting the SPCR.SPMS bit to 1 selects clock synchronous operation of the RSPI. In clock synchronous operation, the SSLAi pin is not used, and the three pins of RSPCKA, MOSIA, and MISOA handle communications. The SSLAi pin is available as I/O port pins.
Although clock synchronous operation does not require use of the SSLAi pin, operation of the module is the same as in SPI operation. That is, in both master and slave operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected because the SSLAi pin is not used.
Furthermore, operation should not be performed if clock synchronous operation proceeds when the SPCMDm.CPHA bit is set to 0 in slave mode (SPCR.MSTR = 0).

44.3.11.1 Master Mode Operation

(1) Starting a Serial Transfer

The RSPI updates the data in the transmit buffer (SPTX) of SPDR when data is written to the SPDR register with the transmit buffer being empty (the SPTEF flag is 1 and data for the next transfer is not set). When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR, the RSPI copies data from the transmit buffer to the shift register and starts serial transmission. Upon copying transmit data to the shift register, the RSPI changes the status of the shift register to “full”, and upon termination of serial transfer, it changes the status of the shift register to “empty”. The status of the shift register cannot be referenced.
For details on the RSPI transfer format, refer to section 44.3.5, Transfer Format.
However, transfer in clock synchronous operation is conducted without the SSLA0 output signal.

(2) Terminating a Serial Transfer

The RSPI terminates the serial transfer after transmitting an RSPCKA edge corresponding to the sampling timing. If free space is available in the receive buffer (SPRX) (the SPRF flag is 0), upon termination of serial transfer, the RSPI copies data from the shift register to the receive buffer of the RSPI data register (SPDR).
It should be noted that the final sampling timing varies depending on the bit length of transfer data. In master mode, the RSPI data length depends on the SPCMDm.SPB[3:0] bit setting.
For details on the RSPI transfer format, refer to section 44.3.5, Transfer Format.
However, transfer in clock synchronous operation is conducted without the SSLA0 output signal.

(3) Sequence Control

The transfer format employed in master mode is determined by SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers. Although the SSLAi signals are not output in clock synchronous operation, these settings are valid.
SPSCR is a register used to determine the sequence configuration for serial transfers that are executed by the RSPI in master mode. The following items are set in SPCMDm register: SSLAi output signal value, MSB/LSB first, data length, some of the bit rate settings, RSPCKA polarity/phase, whether SPCKD is to be referenced, whether SSLND is to be referenced, and whether SPND is to be referenced. SPBR holds some of the bit rate settings; SPCKD, an RSPI clock delay value; SSLND, an SSL negation delay; and SPND, a next-access delay value.
According to the sequence length that is assigned to SPSCR, the RSPI makes up a sequence comprised of a part or all of SPCMDm register. The RSPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the RSPI function is enabled, the RSPI loads the pointer to the commands in SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The RSPI increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, the RSPI sets the pointer in SPCMD0 register, and in this manner the sequence is executed repeatedly.

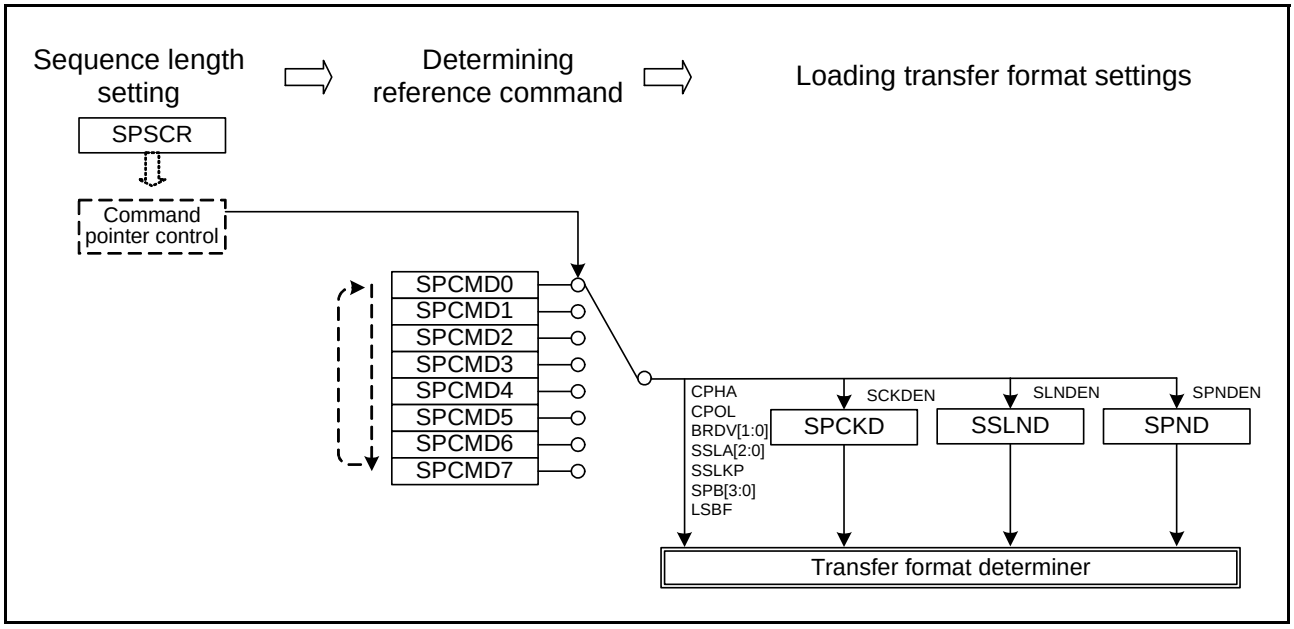

Figure 44.43 Procedure for Determining the Form of Serial Transmission in Master Mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

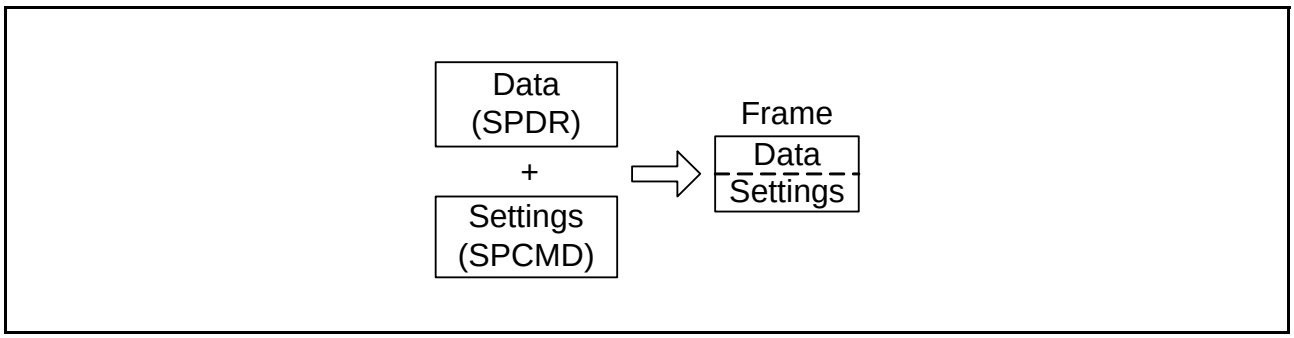

Figure 44.44 Concept of a Frame

Figure 44.45 shows the relationship between the command and the transmit and receive buffers in the sequence of operations specified by the settings in Table 44.4.

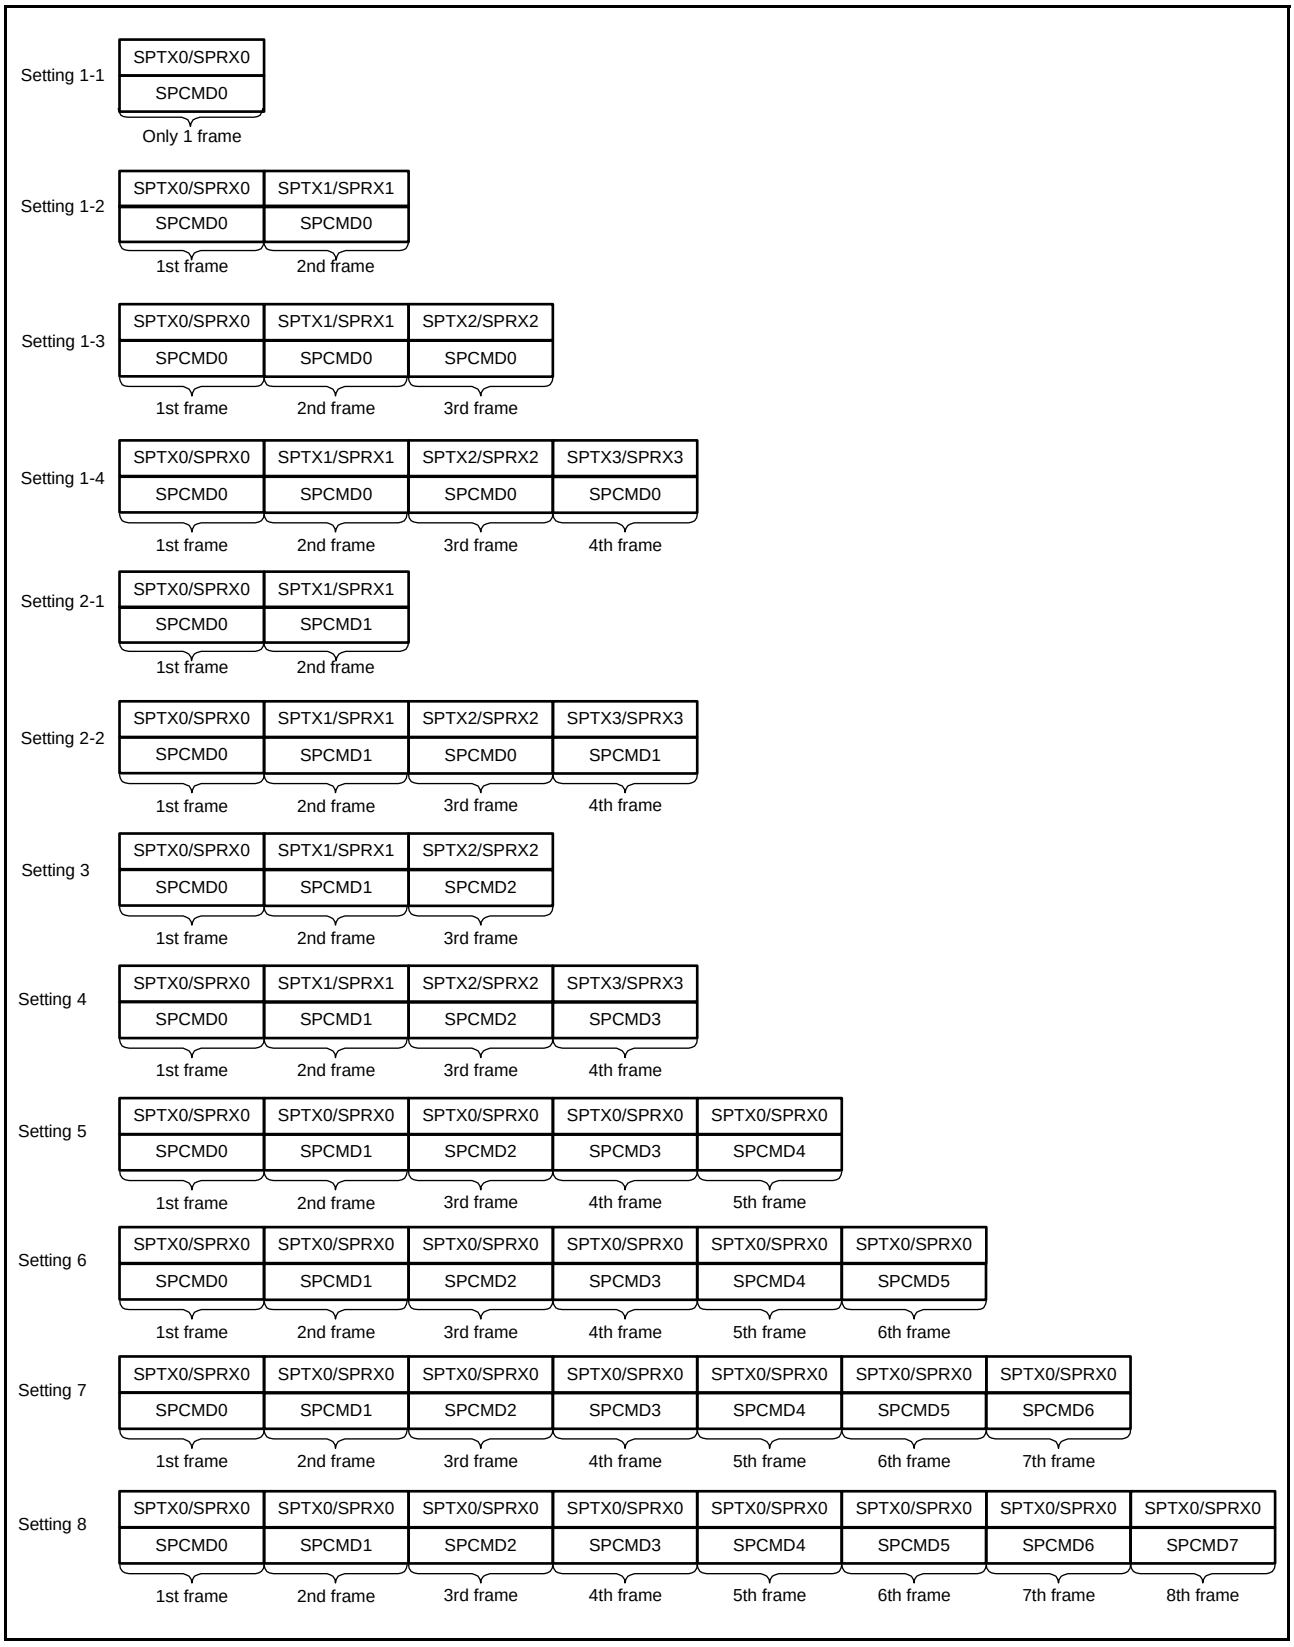

Figure 44.45 Correspondence between the RSPI Command Register and Transmit/Receive Buffers in Sequence Operations

(4) Initialization Flowchart

Figure 44.46 is a flowchart illustrating an example of initialization in clock synchronous operation when the RSPI is used in master mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

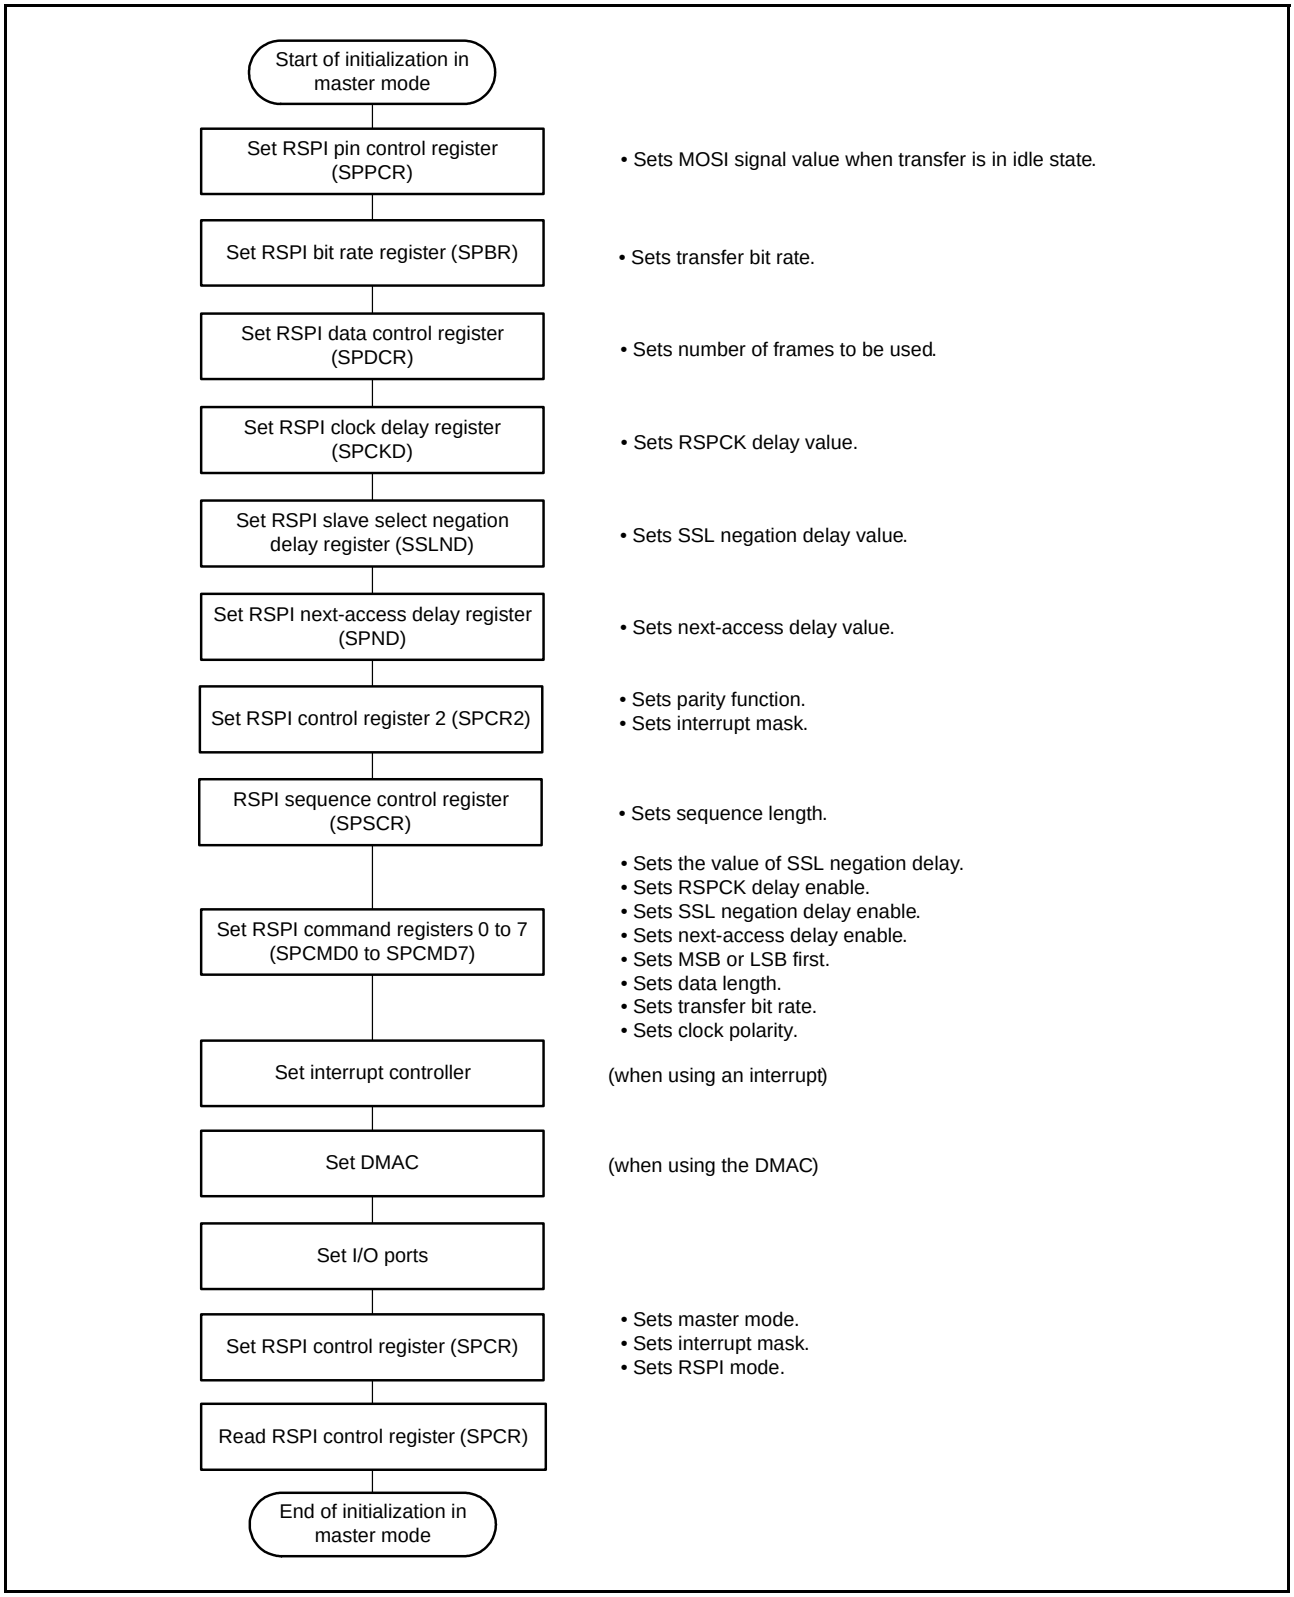

Figure 44.46 Example of Initialization Flowchart in Master Mode (Clock Synchronous Operation)

(5) Flow of Software Processing

Software processing during clock-synchronous master operation is the same as that for SPI master operation. For details, refer to section 44.3.10.1, (9) Software Processing Flow. Note that mode fault errors will not occur.

44.3.11.2 Slave Mode Operation

(1) Starting a Serial Transfer

When the SPCR.SPMS bit is 1, the first RSPCKA edge triggers the start of a serial transfer in the RSPI.
When detecting the start of a serial transfer in a condition in which the shift register is empty, the RSPI changes the status of the shift register to “full”, so that data cannot be copied from the transmit buffer to the shift register when serial transfer is in progress. If the shift register was full before the serial transfer started, the RSPI keeps the status of the shift register unchanged, in the full state.
When the SPMS bit is 1, the RSPI drives the MISOA output signal.
For details on the RSPI transfer format, refer to section 44.3.5, Transfer Format.
It should be noted that the SSLA0 input signal is not used in clock synchronous operation.

(2) Terminating a Serial Transfer

The RSPI terminates the serial transfer after detecting an RSPCKA edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPRF flag is 0), upon termination of serial transfer the RSPI copies received data from the shift register to the receive buffer of the SPDR register. Upon termination of a serial transfer the RSPI changes the status of the shift register to “empty” regardless of the receive buffer status. The final sampling timing changes depending on the bit length of transfer data. In slave mode, the RSPI data length depends on the SPCMD0.SPB[3:0] bit setting.
For details on the RSPI transfer format, refer to section 44.3.5, Transfer Format.

(3) Initialization Flowchart

Figure 44.47 is a flowchart illustrating an example of initialization in clock synchronous operation when the RSPI is used in slave mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

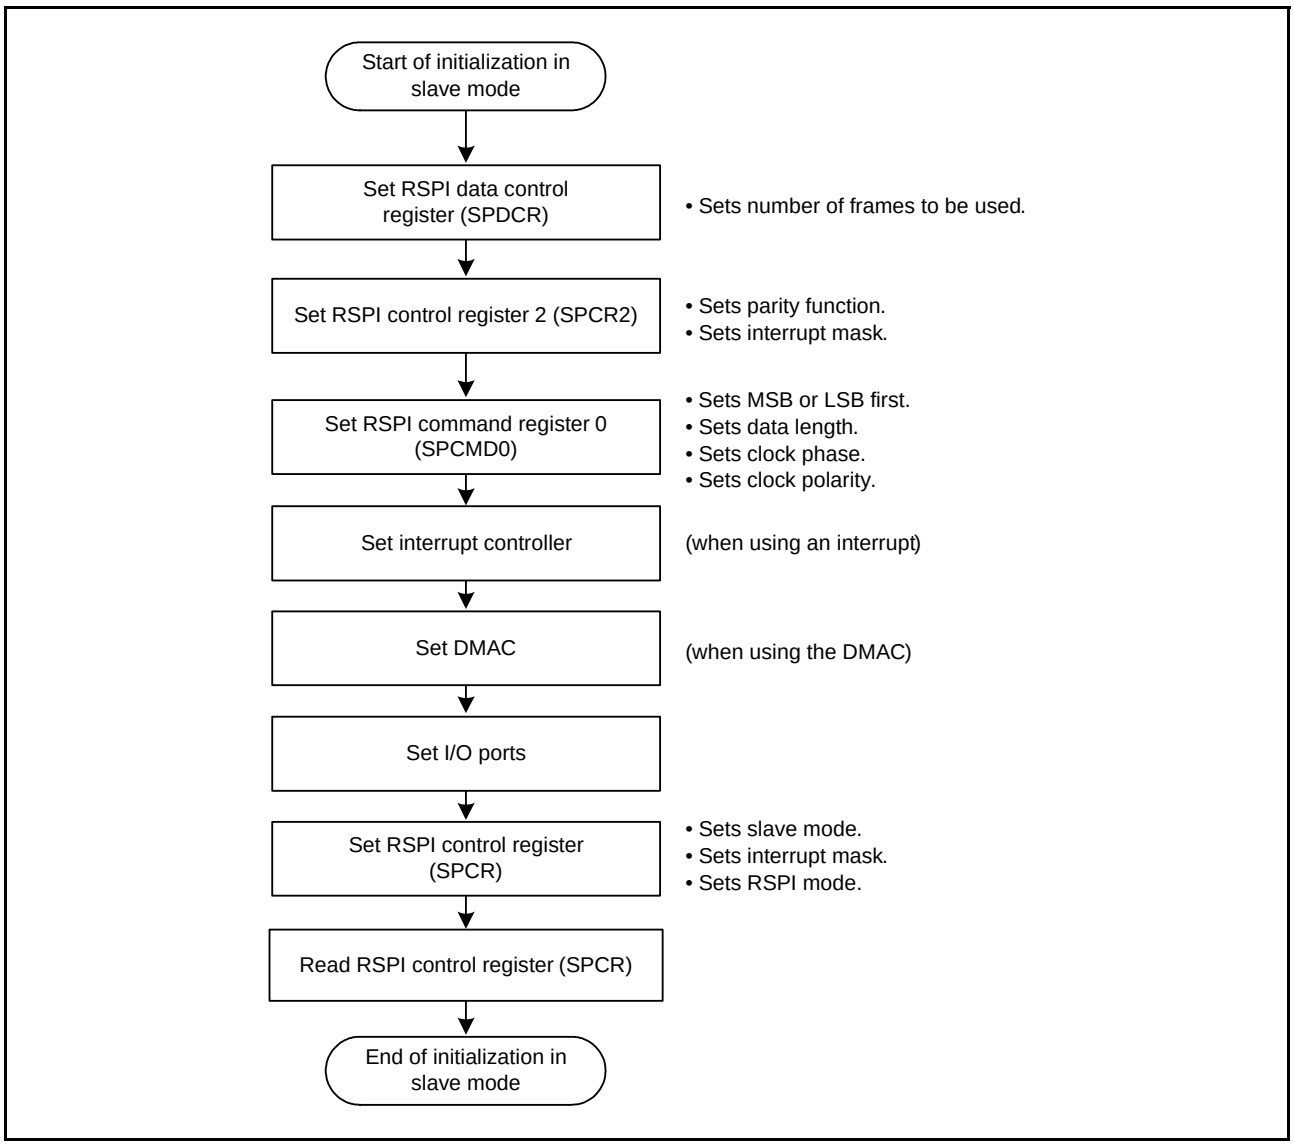

Figure 44.47 Example of Initialization Flowchart in Slave Mode (Clock Synchronous Operation)

(4) Flow of Software Processing

Software processing during clock-synchronous slave operation is the same as that for SPI slave operation. For details, refer to section 44.3.10.2, (6) Software Processing Flow. Note that mode fault errors will not occur.

44.3.12 Loopback Mode

When 1 is written to the SPPCR.SPLP2 bit or SPPCR.SPLP bit, the RSPI shuts off the path between the MISOA pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIA pin and the shift register if the SPCR.MSTR bit is 0, and connects the input path and output path of the shift register. The RSPI does not shut off the path between the MOSIA pin and the shift register if the SPCR.MSTR bit is 1, and between the MISOA pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data for the RSPI or the reversed transmit data becomes the received data for the RSPI.
Table 44.12 lists the relationship among the SPLP2 and SPLP bits and the received data. Figure 44.48 shows the configuration of the shift register I/O paths for the case where the RSPI in master mode is set in loopback mode (SPPCR.SPLP2 = 0, SPPCR.SPLP = 1).

Table 44.12 SPLP2 and SPLP Bit Settings and Received Data

SPPCR.SPLP2 Bit	SPPCR.SPLP Bit	Received Data
0	0	Input data from the MOSIA pin or MISOA pin
0	1	Inverted transmit data
1	0	Transmit data
1	1	Transmit data

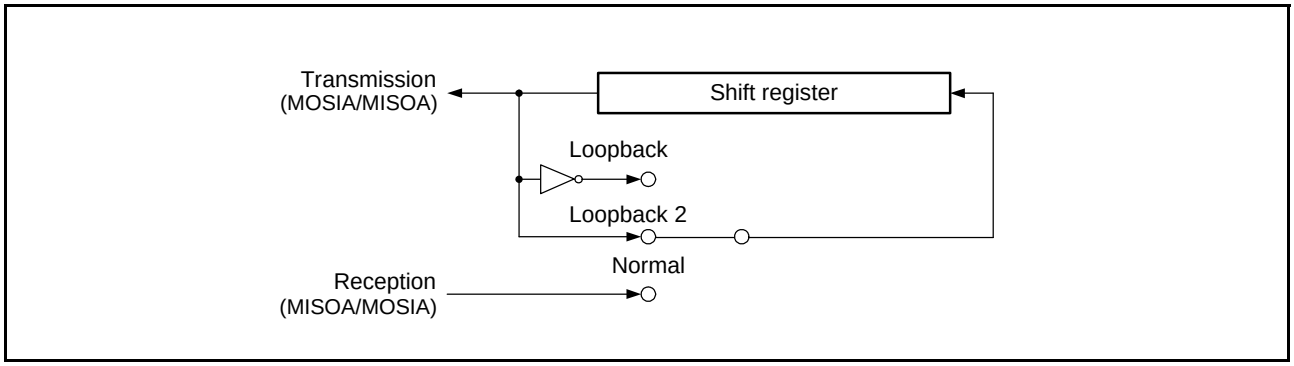

Figure 44.48 Configuration of Shift Register I/O Paths in Loopback Mode (Master Mode)

44.3.13 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. In order to detect defects in the parity bit adding unit and error detecting unit of the parity circuit, self-diagnosis is executed for the parity circuit following the flowchart shown in Figure 44.49.

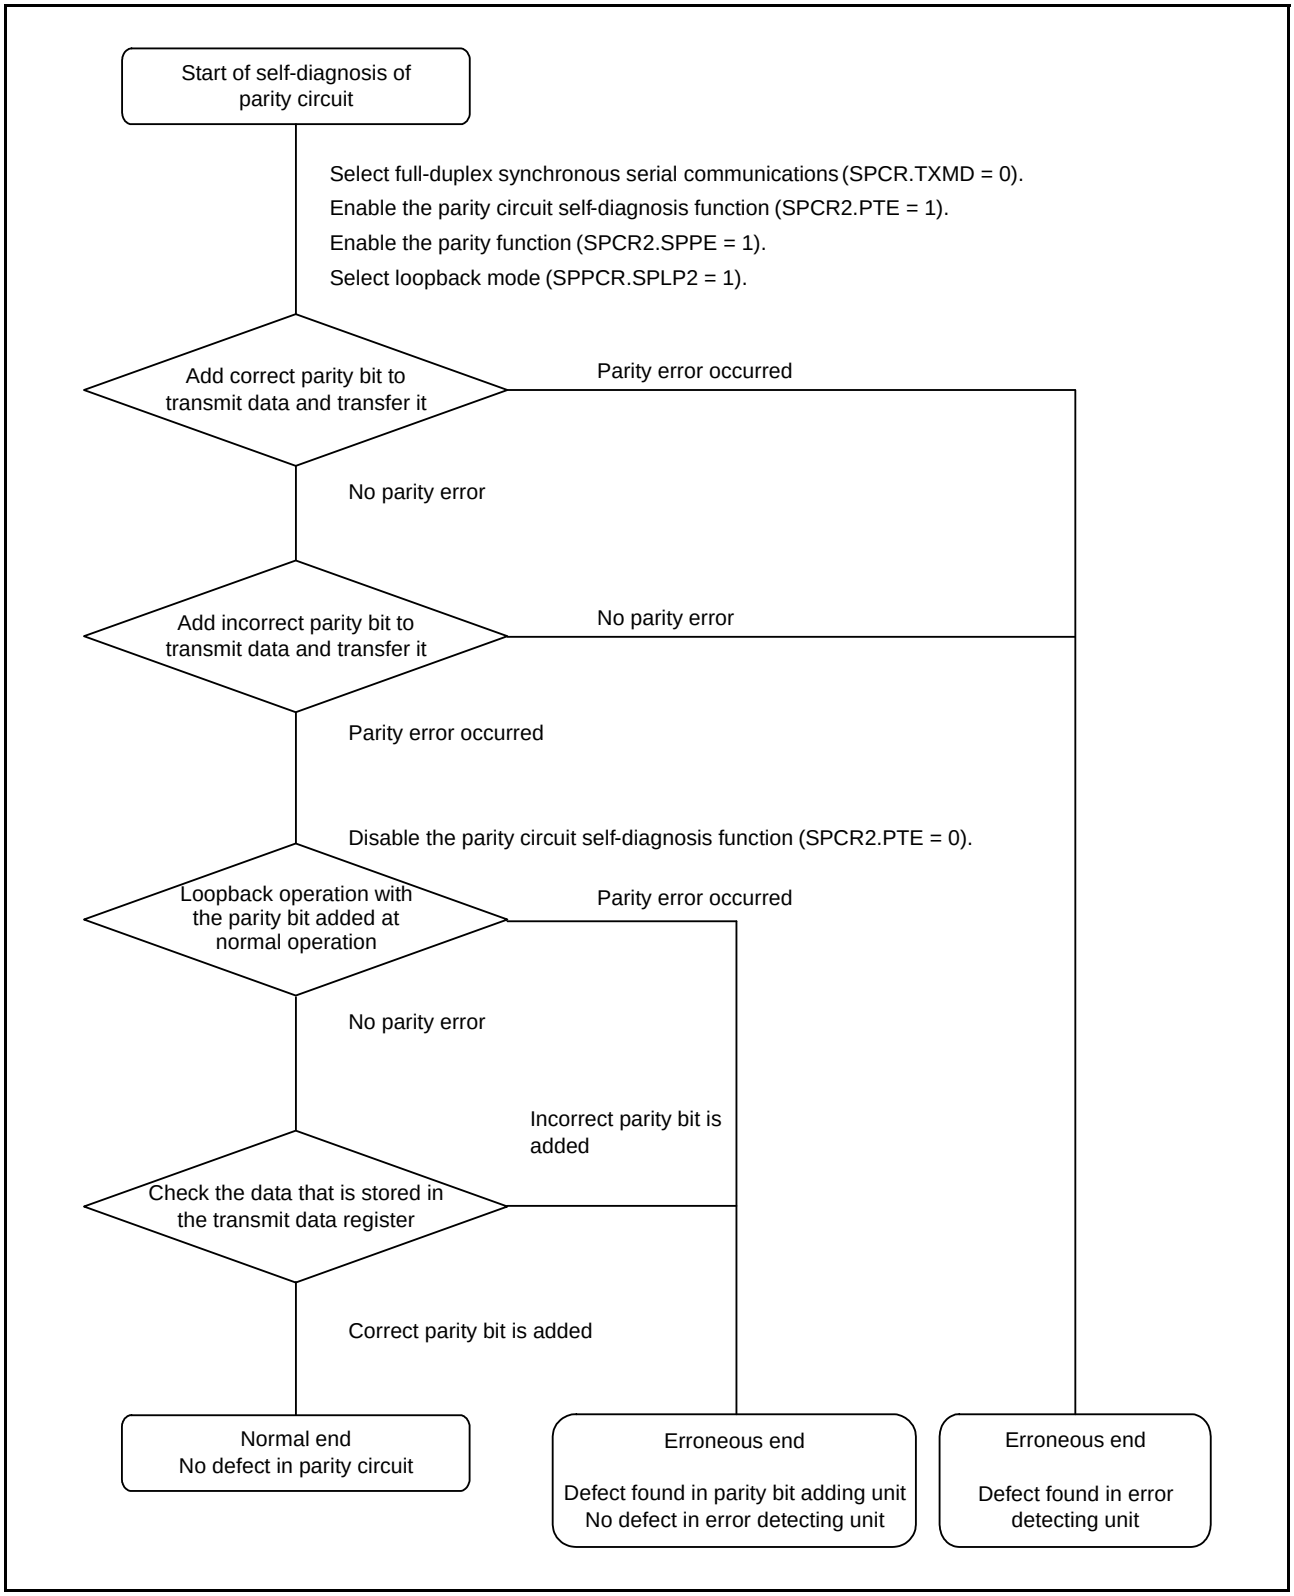

Figure 44.49 Flowchart for Self-Diagnosis of Parity Circuit

44.3.14 Interrupt Sources

The RSPI has interrupt sources of receive buffer full, transmit buffer empty, mode fault, overrun, parity error, and RSPI idle. In addition, the DTC or DMAC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Since the vector address for SPEI is allocated to interrupt requests due to mode fault, overrun, and parity errors, the actual interrupt source must be determined from the flags. Interrupt sources for the RSPI are listed in Table 44.13. An interrupt is generated on satisfaction of an interrupt condition in Table 44.13. Clear the receive buffer full and transmit buffer empty sources through data transfer.

When using the DTC or DMAC to perform data transmission/reception, the DTC or DMAC must be set up first to be in a status in which transfer is enabled before making the RSPI settings. For the method for setting the DTC or DMAC, refer to section 18, DMA Controller (DMACAa), or section 20, Data Transfer Controller (DTCa).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt are generated while the ICU.IRn.IR flag is 1, the interrupt is not output as a request for ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IRn.IR flag becomes 0. A retained interrupt request is automatically discarded once it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be cleared to 0.

Table 44.13 Interrupt Sources of RSPI

Interrupt Source	Symbol	Interrupt Condition	DMAC/DTC Activation
Receive buffer full	SPRI	The receive buffer becomes full (the SPRF flag becomes 1) while the SPCR.SPRIE bit is 1.	Possible
Transmit buffer empty	SPTI	The transmit buffer becomes empty (the SPTEF flag becomes 1) while the SPCR.SPTIE bit is 1.	Possible
RSPI errors (mode fault, overrun and parity error)	SPEI	The SPSR.MODF, OVRF, or PERF flag is set to 1 while the SPCR.SPEIE bit is 1.	Impossible
RSPI idle	SPII	The SPSR.IDLNF flag is set to 0 while the SPCR2.SPIIE bit is 1.	Impossible

44.4 Link Operation by Event Linking

The RSPI0 supports the following event output for the event link controller (ELC). The event link output signal is output regardless of the interrupt enable bit setting.

44.4.1 Receive Buffer Full Event Output

This event signal is output when received data have been transferred from the shift register to the SPDR on completion of serial transfer.

44.4.2 Transmit Buffer Empty Event Output

This event signal is output when data for transmission have been transferred from the transmit buffer to the shift register and when the value of the SPE bit has changed from 0 to 1.

44.4.3 Mode Fault, Overrun, or Parity Error Event Output

(1) Mode Fault

Table 44.14 lists the occurrence conditions of a mode fault event.

Table 44.14 Occurrence Conditions of Mode Fault Event

	SPCR.MODFEN Bit	SSLA0 Pin	Remarks
Master (SPCR.MSTR bit = 1)	1	Active	Under the condition (the SPCR.MSTR bit is 1 and the MODFEN bit is 1), if the SPCR.SPMS bit is 0, mode fault error, overrun error, and parity error event output cannot be used. Do not set the ELSRn register to 52h.
Slave (SPCR.MSTR bit = 0)	1	Not active	Event is output only when the pin is deactivated during transmission.

(2) Overrun

The condition for this event signal being output in response to an overrun is completion of serial transfer while the receive buffer contains data that have not been read and the value of the SPCR.TXMD bit is 0, in which case the OVRF flag is set to 1.

(3) Parity Error

The condition for this event signal being output in response to a parity error is detection of a parity error on completion of serial transfer while the value of the TXMD bit in SPCR is 0 and the value of the SPPE bit in SPCR2 is 1.

44.4.4 RSPI Idle Event Output

(1) In Master Mode

In master mode, an event is output when the condition for setting the IDLNF flag (RSPI idle flag) to 0 is satisfied.

(2) In Slave Mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (RSPI is initialized).

44.4.5 Transmission-Completed Event Output

During both SPI operation and clock synchronous operation in master mode, an event is output under the condition for setting the IDLNF flag (RSPI idle flag) from 1 to 0.

Table 44.15 Conditions for Generation of a Transmission-Completed Event (Slave)

	Transmit Buffer State	Shift Register State	Others
SPI operation (SPMS = 0)	Empty	Empty	Negation of SSLA0 input
Clock synchronous operation (SPMS = 1)	Empty	Empty	Edge detection of the last RSPCKA

Whether the operation is in master mode or slave mode, an event is not output if 0 is written to the SPCR.SPE bit in transmission or the SPCR.SPE bit is cleared by the mode fault error.

44.5 Usage Notes

44.5.1 Setting Module Stop Function

Module stop control register B (MSTPCRB) can be used to enable or disable the RSPI. Immediately after a reset, operation of the RSPI is disabled. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

44.5.2 Note on Low Power Consumption Functions

When using the module stop function and entering a low power consumption mode other than sleep mode, set the SPCR.SPE bit to 0 before completing communication.

44.5.3 Notes on Starting Transfer

If the ICU.IRn.IR flag is 1 at the time transfer is to be started, an interrupt request is internally retained after transfer starts, and this can lead to unanticipated behavior of the ICU.IRn.IR flag.
When the ICU.IRn.IR flag is 1 at the time transfer is to start, follow the procedure below to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1).

1. Confirm that transfer has stopped (i.e. that the SPCR.SPE bit is 0).
2. Set the relevant interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) to 0.
3. Read the relevant interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the ICU.IRn.IR flag to 0.

44.5.4 Notes on the SPRF and SPTEF flags

When polling the SPSR.SPRF flag and/or SPSR.SPTEF flag, set the SPCR.SPRIE bit and/or SPCR.SPTIE bit to 0.

45. Quad Serial Peripheral Interface (QSPI)

This MCU includes a one-channel quad serial peripheral interface.
In this section, “PCLK” is used to refer to PCLKB.

45.1 Overview

Table 45.1 lists the specifications of the QSPI, Figure 45.1 shows a block diagram of the QSPI, and Table 45.2 lists the I/O pins of the QSPI.

Table 45.1 QSPI Specifications

Item	Description
Number of channels	1 channel
QSPI transfer function	Capable of communications to the serial flash memory through single-/dual-/quad-SPI operation • Single-SPI operation (full-duplex communications) Use of QMO (master out), QMI (master in), QSSL (slave select), and QSPCLK (SPI clock) signals allow for communications to the serial flash memory through SPI operation (four-wire method). QMO output pin and QMI input pin QSSL and QSPCLK serve as output pins. • Dual-SPI operation (half-duplex communications) Use of QIO1, QIO0, QSSL, and QSPCLK signals allow for communications to the serial flash memory through SPI operation (four-wire method). QSSL and QSPCLK serve as output pins. Bidirectional QIO1 and QIO0 pins • Quad-SPI operation (half-duplex communications) Use of QIO3 to QIO0, QSSL, and QSPCLK signals allow for communications to the serial flash memory through SPI operation (six-wire method). QSSL and QSPCLK serve as output pins. Bidirectional QIO3 to QIO0 pins
Data format	• Transfer data length is selectable from 8 bits to 128 Gbits. Data is continuously transferred 1 through 4,294,967,296 times in 8-, 16-, or 32-bit units.
Bit rate	• QSPCLK can be divided by 2 to 4080 (max.). • QSPCLK can be generated by dividing PCLK by the on-chip baud rate generator.
Buffer configuration	• 32 bytes for transmission • 32 bytes for reception
Shift registers	• 32 bits each for transmission and reception
QSSL pin control	• Controllable delay from QSSL signal assertion to QSPCLK operation (clock delay) Range: 0 and 1.5 to 8.5 QSPCLK cycles (set in QSPCLK-cycle units) • Controllable delay from QSPCLK stoppage to QSSL output negation (QSSL negation delay) Range: 0 to 8 QSPCLK cycles (set in QSPCLK-cycle units) • Controllable wait for next-access QSSL output assertion (next-access delay) Range: 0 to 8 QSPCLK cycles (set in QSPCLK-cycle units) • Capable of holding QSSL output value from transfer end to next access • QSSL polarity can be changed.
Transfer control	• A transfer of up to four commands can be executed sequentially in looped execution. • Single-SPI transfer start condition: The specified length of data is in the transmit buffer and there is a space for the specified length of data in the receive buffer. However, when the SPDCR.TXDMY bit is set, receive operation can be started even when the specified length of data is not in the transmit buffer. • Dual-/quad-SPI write start condition: The specified length of data is in the transmit buffer. • Dual-/quad-SPI read start condition: There is a space for the specified length of data in the receive buffer. • QIO3 to QIO0 and QMO output values during the QSSL negation period can be specified. • QIO3 and QIO2 can be specified to output fixed values in single-/dual-SPI modes.
Interrupt sources	• Receive buffer full interrupt • Transmit buffer empty interrupt • QSSL negation interrupt
Others	• QSPI initialization function • Loop back mode
Low power consumption function	Module stop state can be set.

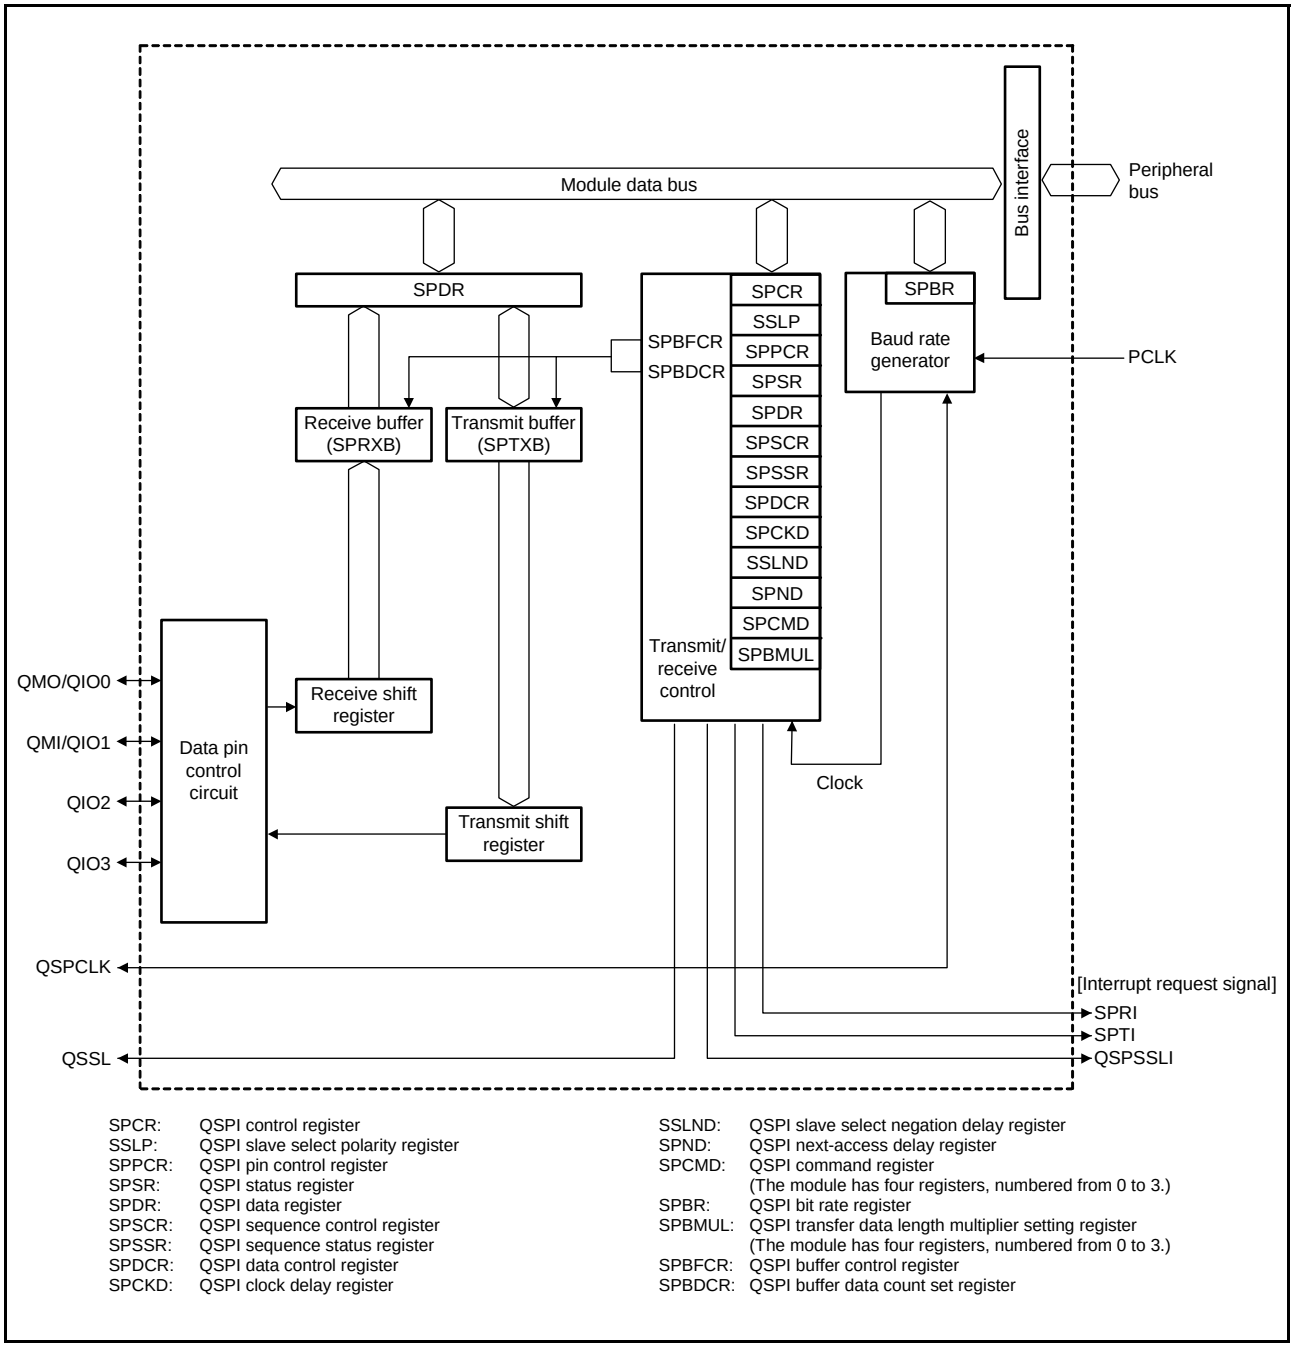

Figure 45.1 QSPI Block Diagram

Table 45.2 QSPI I/O Pins

Pin Name	I/O	Function
QSPCLK	Output	Clock output
QMO/QIO0*1	I/O	Master output data/data 0
QMI/QIO1*1	I/O	Master input data/data 1
QIO2*2	I/O	Data 2
QIO3*2	I/O	Data 3
QSSL	Output	Slave selection

Note 1. In single-SPI mode, QMO and QMI are enabled; QIO0 and QIO1 in dual-/quad-SPI modes.
Note 2. In single-/dual-SPI modes, fixed value according to register setting is output; QIO2 and QIO3 in quad-SPI mode.

45.2 Register Descriptions

45.2.1 QSPI Control Register (SPCR)

Address(es): QSPI.SPCR 0008 9E00h

	b7	b6	b5	b4	b3	b2	b1	b0
	SPRIE	SPE	SPTIE	—	MSTR	—	SPSSLIE	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	SPSSLIE	QSSL Negation Interrupt Enable	0: Disables interrupt requests. 1: Enables interrupt requests.	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	MSTR	QSPI Master/Slave Mode Select *1	0: Slave mode 1: Master mode (output from QSPCLK and QSSL pins enabled)	R/W
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	SPTIE	Transmit Interrupt Enable	0: Disables interrupt requests. 1: Enables interrupt requests.	R/W
b6	SPE	SPI Function Enable	0: Disables the function. 1: Enables the function.	R/W
b7	SPRIE	Receive Interrupt Enable	0: Disables interrupt requests. 1: Enables interrupt requests.	R/W

Note 1. This MCU does not support slave mode. When using this bit, set it to 1.

The SPCR register sets the operating mode for the QSPI. If the set value of the MSTR bit is changed while the SPE bit is 1, subsequent operation cannot be guaranteed.

SPSSLIE Bit (QSSL Negation Interrupt Enable)

This bit enables or disables generation of QSSL negation interrupt requests when the SPSR.SPSSLF flag is set to 1.

MSTR Bit (QSPI Master/Slave Mode Select)

This bit selects master or slave mode. Setting this bit to 1 allows the QSPCLK and QSSL pins to be used as output pins. When setting the MSTR bit, specify the following while the SPE bit is 0, and then set the MSTR bit to 1.

- SSLP.SSLP bit setting (QSSL pin level setting)
- SPCMDn.CPOL bit (n = 0 to 3) setting (QSPCLK pin level setting)

Note that this MCU does not support slave mode.

SPTIE Bit (Transmit Interrupt Enable)

This bit enables or disables generation of transmit interrupt requests when the number of transmit data units in the transmit buffer is equal to or less than the specified transmit buffer data triggering number leading the corresponding flag in the SPSR register being set to 1.

SPE Bit (SPI Function Enable)

Setting this bit to 1 enables the module function.
Setting this bit to 0 disables and partially initializes the module function.

SPRIE Bit (Receive Interrupt Enable)

This bit enables or disables generation of receive interrupt requests when the number of receive data units in the receive buffer is equal to or greater than the specified receive buffer data triggering number leading the corresponding flag in the status register being set to 1.

45.2.2 QSPI Slave Select Polarity Register (SSLP)

Address(es): QSPI.SSLP 0008 9E01h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SSLP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SSLP	QSSL Signal Polarity Setting	0: QSSL signal is active-low. 1: QSSL signal is active-high.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SSLP register sets the polarity of the QSSL signal. If this register is modified while the SPCR.SPE bit is 1, subsequent operation cannot be guaranteed.

SSLP Bit (QSSL Signal Polarity Setting)

This bit sets the polarity of the QSSL signal. The polarity should be same as that of the device to be communicated with.

45.2.3 QSPI Pin Control Register (SPPCR)

Address(es): QSPI.SPPCR 0008 9E02h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	MOIFE	MOIFV	—	IO3FV	IO2FV	SPLP
Value after reset:	0	0	0	0	0	1	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	SPLP	Loopback mode*1	0: Normal mode 1: Loopback mode	R/W
b1	IO2FV	Single-/Dual-SPI Mode QIO2 Output Fixed Value	0: QIO2 output fixed value equals 0. 1: QIO2 output fixed value equals 1.	R/W
b2	IO3FV	Single-/Dual-SPI Mode QIO3 Output Fixed Value	0: QIO3 output fixed value equals 0. 1: QIO3 output fixed value equals 1.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	MOIFV	Idle State Output Data Fixed Value	0: Data output value in the idle state (during the QSSL negation period) is 0. 1: Data output value in the idle state (during the QSSL negation period) is 1.	R/W
b5	MOIFE	Idle State Output Data Fixing Enable*2	0: Output value equals final data from previous transfer. 1: Output value equals the value set in the MOIFV bit.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. When the loopback mode is specified in dual-/quad-SPI modes, the SPCMDn.SPRW bit (n = 0 to 3) should be set to 0 (write operation).

Note 2. In dual-/quad-SPI modes, QIO1 and QIO0/QIO3 to QIO0 are driven to the Hi-Z state after read transfer regardless of this bit setting (see section 45.3.2, Pin Control).

The SPPCR register sets the modes of the pins. If this register is modified while the SPCR.SPE bit is 1, subsequent operation cannot be guaranteed.

SPLP Bit (Loopback mode)

When the SPLP bit is set to 1, this module shuts off the path between the data I/O pin and the transmit/receive shift register, and connects the input path and the output path for the transmit/receive shift register.

IO2FV Bit (Single-/Dual-SPI Mode QIO2 Output Fixed Value)

This bit sets the output value of the QIO2 pin in single-/dual-SPI modes. This bit is valid only in single-/dual-SPI modes, and is not affected by the MOIFE or MOIFV bit values.

IO3FV Bit (Single-/Dual-SPI Mode QIO3 Output Fixed Value)

This bit sets the output value of the QIO3 pin in single-/dual-SPI modes. This bit is valid only in single-/dual-SPI modes, and is not affected by the MOIFE or MOIFV bit values.

MOIFV Bit (Idle State Output Data Fixed Value)

If the MOIFE bit is 1, the pin output value during the QSSL negation period is determined according to this bit setting.

MOIFE Bit (Idle State Output Data Fixing Enable)

This bit fixes the pin output value in a QSSL negation period or the QSSL keeping period during a burst transfer. In single-SPI mode, this bit setting applies to QMO. In dual-SPI mode, this bit setting applies to QIO1 and QIO0. In quad-SPI mode, this bit setting applies to QIO3 through QIO0.

45.2.4 QSPI Status Register (SPSR)

Address(es): QSPI.SPSR 0008 9E03h

	b7	b6	b5	b4	b3	b2	b1	b0
	SPRFF	TREND	SPTEF	SPSSLF	—	—	—	—
Value after reset:	0	1	1	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	SPSSLF	QSSL Negation Flag	0: QSSL negation is not detected. 1: QSSL negation is detected.	R/(W) *1
b5	SPTEF	Transmit Buffer Empty Flag	0: The number of transmit data units in the transmit buffer is greater than the transmit buffer data triggering number. 1: The number of transmit data units in the transmit buffer is equal to or less than the specified transmit buffer data triggering number.	R/(W) *1
b6	TREND	Transmit End Flag	0: Transmission is not completed. 1: Transmission is completed.	R
b7	SPRFF	Receive Buffer Full Flag	0: The number of receive data units in the receive buffer is less than the receive buffer data triggering number. 1: The number of receive data units in the receive buffer is equal to or greater than the receive buffer data triggering number.	R/(W) *1

Note 1. Only 0 can be written to clear the flag after reading 1.

The SPSR register holds flags indicating the operating state of this module.

SPSSLF Flag (QSSL Negation Flag)

This flag indicates the state of QSSL. This flag should be read after the receive buffer (SPRXB) is read.
[Setting conditions]

- QSSL output is changed from 0 to 1 when the SSLP.SSLP bi is 0.
- QSSL output is changed from 1 to 0 when the SSLP.SSLP bi is 1.

[Clearing conditions]

- After reading the SPSSLF flag = 1, 0 is written to it.
- Reset

SPTEF Flag (Transmit Buffer Empty Flag)

This flag indicates that the number of transmit data units in the transmit buffer is equal to or less than the transmit buffer data triggering number specified in the buffer control register. A flag-clearing operation takes precedence over a flag-setting operation.
[Setting conditions]

- When the number of transmit data units in the transmit buffer is equal to or less than the specified transmit buffer data triggering number.
- When transmit buffer reset is enabled.
- Reset

[Clearing conditions]

- When 0 is written to the SPTEF flag after reading SPTEF = 1.
- When data is written to the transmit buffer (SPTXB) using DTC or DMAC transfer (transfer of the last block in block transfer).

Note: Do not clear the SPTEF flag to 0 during DTC or DMAC transfer.

TREND Flag (Transmit End Flag)

This flag is set to 1 when transmission is completed, and this flag is 0 when transmission is not completed. When the value of the SPCR.SPE bit is changed from 1 to 0, read this flag after waiting for the division ratio setting cycles plus four PCLK cycles.

For division ratio settings, see Table 45.3, SPBR Register and SPCMDn.BRDV[1:0] Bit Settings and Bit Rates.

[Setting condition]

- When the number of data units stored in the transmit buffer is zero when a serial transmission is completed except when the SPDCR.TXDMY bit is set to 1.

[Clearing condition]

- When transmit data is transferred from the transmit buffer to the transmit shift register.

SPRFF Flag (Receive Buffer Full Flag)

This flag indicates that the number of receive data units in the receive buffer is equal to or greater than the receive buffer data triggering number specified in the buffer control register. A flag-clearing operation takes precedence over a flag-setting operation.

[Setting condition]

- The number of data units in the receive buffer is equal to or greater than the specified receive buffer data triggering number.

[Clearing conditions]

- When 0 is written to the SPRFF flag after reading SPRFF = 1.
- When data is read from the receive buffer (SPRXB) using DTC or DMAC transfer (transfer of the last block in block transfer). Do not clear the SPRFF flag to 0 during DTC or DMAC transfer.

45.2.5 QSPI Data Register (SPDR)

- When accessing in longword size

Address(es): QSPI.SPDR 0008 9E04h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

- When accessing in word size

Address(es): QSPI.SPDR.H 0008 9E04h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	H															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

- When accessing in byte size

Address(es): QSPI.SPDR.HH 0008 9E04h

	b7	b6	b5	b4	b3	b2	b1	b0
	HH							
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

The SPDR register accesses transmit/receive data buffer.
The transmit buffer (SPTXB) and receive buffer (SPRXB) are independent and are mapped to the SPDR register.
When data is written to this register, the data will be written to the transmit buffer.
When data is read from this register, the data will be read from the receive buffer.
This register should be read or written to in byte, word, or longword units.
This register should be accessed in longword, word, or byte size.

45.2.6 QSPI Sequence Control Register (SPSCR)

Address(es): QSPI.SPSCR 0008 9E08h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	SPSC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	SPSC[1:0]	Sequence Control Specification	Number of SPCMDn register (n = 0 to 3) to be referenced b1 b0 0 0: 0 → 0 → ... 0 1: 0 → 1 → 0 → ... 1 0: 0 → 1 → 2 → 0 → ... 1 1: 0 → 1 → 2 → 3 → 0 → ...	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SPSCR register sets the sequence controlled method. If this register is modified while the SPCR.SPE bit is 1, subsequent operation cannot be guaranteed.

SPSC[1:0] Bits (Sequence Control Specification)

These bits specify sequential operations.

This module references the SPCMDn register (n = 0 to 3) in the order according to these bit settings.

45.2.7 QSPI Sequence Status Register (SPSSR)

Address(es): QSPI.SPSSR 0008 9E09h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	SPSS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	SPSS[1:0]	Sequence Status	b1 b0 0 0: SPCMD0 register 0 1: SPCMD1 register 1 0: SPCMD2 register 1 1: SPCMD3 register	R
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SPSSR register indicates the sequence control status.

SPSS[1:0] Bits (Sequence Status)

During sequence control, these bits indicate the SPCMDn register (n = 0 to 3) that is currently referenced.

45.2.8 QSPI Bit Rate Register (SPBR)

Address(es): QSPI.SPBR 0008 9E0Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	SPBR7	SPBR6	SPBR5	SPBR4	SPBR3	SPBR2	SPBR1	SPBR0
Value after reset:	1	1	1	1	1	1	1	1

The SPBR register sets the bit rate that is used as the base. If this register is modified while the SPCR.SPE bit is 1, subsequent operation cannot be guaranteed.
The bit rate is determined by combinations of SPBR register settings and the bit settings in the SPCMDn.BRDV[1:0] bits (n = 0 to 3).
Setting this register to 0 is prohibited.
The equation for calculating the bit rate when SPBR is not 0 is given below. In the equation, m denotes an SPBR register setting (1 to 255), and N denotes bit settings (0 to 3) in the SPCMDn.BRDV[1:0] bits, and 2 × m × 2N denotes a division ratio.

$$\text{Bit rate} = \frac{f(PCLK)}{2 \times m \times 2^{N}}$$

Table 45.3 shows the relationship between SPBR register and SPCMDn.BRDV[1:0] bit settings and bit rates.

Table 45.3 SPBR Register and SPCMDn.BRDV[1:0] Bit Settings and Bit Rates

SPBR Register (m)	SPCMDn.BRDV[1:0] Bits (N)	Division Ratio	Bit Rate PCLK = 60 MHz
1	0	2	30.00 Mbps
2	0	4	15.00 Mbps
3	0	6	10.00 Mbps
4	0	8	7.50 Mbps
5	0	10	6.00 Mbps
6	0	12	5.00 Mbps
6	1	24	2.50 Mbps
6	2	48	1.25 Mbps
6	3	96	625 kbps
255	3	4080	14.70 kbps

Note: Set the SPBR register and the SPCMDn.BRDV[1:0] bits so that the division ratio of QSPCLK is 2 or more.

45.2.9 QSPI Data Control Register (SPDCR)

Address(es): QSPI.SPDCR 0008 9E0Bh

	b7	b6	b5	b4	b3	b2	b1	b0
	TXDMY	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	TXDMY	Dummy Data Transmission Enable	0: Disables dummy data transmission. 1: Enables dummy data transmission.	R/W

The SPDCR register enables or disables dummy data transmission.

TXDMY Bit (Dummy Data Transmission Enable)

This bit enables or disables dummy data transmission from the QMO pin in single-SPI mode when the transmit buffer is empty.

If the TXDMY bit is set to 1 when the transmit buffer is empty, setting the SPCR.SPE bit = 1 allows 0 to be output from the QMO pin as a dummy data. This enables starting of receive operation without writing transmit data to the transmit buffer.

If this bit is modified while the SPCR.SPE bit is 1, subsequent operation cannot be guaranteed.

This bit is invalid in dual-/quad-SPI operations.

45.2.10 QSPI Clock Delay Register (SPCKD)

Address(es): QSPI.SPCKD 0008 9E0Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SCKDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SCKDL[2:0]	Clock Delay Setting	b2 b1 b0 0 0 0: 1.5 QSPCLK 0 0 1: 2.5 QSPCLK 0 1 0: 3.5 QSPCLK 0 1 1: 4.5 QSPCLK 1 0 0: 5.5 QSPCLK 1 0 1: 6.5 QSPCLK 1 1 0: 7.5 QSPCLK 1 1 1: 8.5 QSPCLK	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SPCKD register sets a period (clock delay) from the beginning of QSSL signal assertion to QSPCLK oscillation when the SPCMDn.SCKDEN bit (n = 0 to 3) is 1.
If this register is modified while the SPCR.SPE bit is 1, subsequent operation cannot be guaranteed.

SCKDL[2:0] Bits (Clock Delay Setting)

These bits set a period (clock delay) from the beginning of QSSL signal assertion to QSPCLK oscillation when the SPCMDn.SCKDEN bit is 1.

45.2.11 QSPI Slave Select Negation Delay Register (SSLND)

Address(es): QSPI.SSLND 0008 9E0Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SLNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SLNDL[2:0]	QSSL Negation Delay Setting	b2 b1 b0 0 0 0: 1 QSPCLK 0 0 1: 2 QSPCLK 0 1 0: 3 QSPCLK 0 1 1: 4 QSPCLK 1 0 0: 5 QSPCLK 1 0 1: 6 QSPCLK 1 1 0: 7 QSPCLK 1 1 1: 8 QSPCLK	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SSLND register sets a period (QSSL negation delay) from a final QSPCLK edge to the negation of the QSSL signal during a serial transfer. when the SPCMDn.SLNDEN bit (n = 0 to 3) is 1. If this register is modified while the SPCR.SPE bit is 1, subsequent operation cannot be guaranteed.

SLNDL[2:0] Bits (QSSL Negation Delay Setting)

These bits set a period (QSSL negation delay) from a final QSPCLK edge to the negation of the QSSL signal during a serial transfer when the SPCMDn.SLNDEN bit (n = 0 to 3) is 1.

45.2.12 QSPI Next-Access Delay Register (SPND)

Address(es): QSPI.SPND 0008 9E0Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SPNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SPNDL[2:0]	Next-Access Delay Setting	b2 b1 b0 0 0 0: 1 QSPCLK 0 0 1: 2 QSPCLK 0 1 0: 3 QSPCLK 0 1 1: 4 QSPCLK 1 0 0: 5 QSPCLK 1 0 1: 6 QSPCLK 1 1 0: 7 QSPCLK 1 1 1: 8 QSPCLK	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SPND register sets a period (next-access delay) from termination of a serial transfer to the beginning of the next serial transfer when the SPCMDn.SPNDEN bit (n = 0 to 3) is 1. If this register is modified while the SPCR.SPE bit is 1, subsequent operation cannot be guaranteed.

SPNDL[2:0] Bits (Next-Access Delay Setting)

These bits set a period (next-access delay) from termination of a serial transfer to the beginning of the next serial transfer when the SPCMDn.SPNDEN bit is 1.

45.2.13 QSPI Command Register n (SPCMDn) (n = 0 to 3)

Address(es): QSPI.SPCMD0 0008 9E10h, QSPI.SPCMD1 0008 9E12h, QSPI.SPCMD2 0008 9E14h, QSPI.SPCMD3 0008 9E16h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SCKDEN	SLNDEN	SPNDEN	LSBF	SPB[3:0]				SSLKP	SPIMOD[1:0]		SPRW	BRDV[1:0]		CPOL	CPHA
Value after reset:	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	CPHA	QSPCLK Phase Setting*1	0: Data latch on odd edge, data shift on even edge 1: Data shift on odd edge, data latch on even edge	R/W
b1	CPOL	QSPCLK Polarity Setting	0: Positive (QSPCLK = 0 when idle) 1: Negative (QSPCLK = 1 when idle)	R/W
b3, b2	BRDV[1:0]	Bit Rate Frequency Division Setting *2	b3 b2 0 0: Base bit rate 0 1: Base bit rate divided by 2 1 0: Base bit rate divided by 4 1 1: Base bit rate divided by 8	R/W
b4	SPRW	SPI Read/Write Access	0: Write operation (QIO1 and QIO0/QIO3 to QIO0: Output) 1: Read operation (QIO1 and QIO0/QIO3 to QIO0: Input)	R/W
b6, b5	SPIMOD[1:0]	SPI Operating Mode	b6 b5 0 0: Single-SPI 0 1: Dual-SPI 1 0: Quad-SPI 1 1: Setting prohibited	R/W
b7	SSLKP	QSSL Signal Level Keeping	0: Negates all QSSL signals upon completion of transfer. 1: Keeps the QSSL signal level from the end of the transfer to the beginning of the next access.	R/W
b11 to b8	SPB[3:0]	Transfer Data Length Setting	b11 b8 0 0 0 0: 8 bits (1 byte) 0 0 0 1: 16 bits (2 bytes) 0 0 1 0: 32 bits (4 bytes) Settings other than above are prohibited.	R/W
b12	LSBF	LSB First	0: MSB first 1: LSB first	R/W
b13	SPNDEN	Next-Access Delay Enable	0: A next-access delay of 0 QSPCLK cycle 1: A next-access delay equal to SPND register settings.	R/W
b14	SLNDEN	QSSL Negation Delay Setting Enable	0: A QSSL negation delay of 0 QSPCLK cycle 1: A QSSL negation delay equal to SSLND register settings.	R/W
b15	SCKDEN	Clock Delay Setting Enable	0: A clock delay of 0 QSPCLK cycle 1: A clock delay equal to SPCKD register settings.	R/W

Note: When setting any or all of the clock delay period, QSSL negation delay period, and next-access delay period to 0, set the SSLKP bit to 1 to select the continuous access in which QSSL is not negated. Otherwise, operation cannot be guaranteed. For the method of setting the various delay periods for the continuous access in which QSSL is not negated, see below.

Note: For the continuous access in which QSSL is not negated, QSPCLK clock stopping is followed by the QSSL negation delay period, next-access delay period, and next command clock delay period, in this order. There are restrictions on setting the SCKDEN, SLNDEN, and SPNDEN bits at this time. For details, see the SCKDEN bit description.

Note 1. The first QSPCLK edge is treated as the first edge.

Note 2. Set the SPBR register and the SPCMDn.BRDV[1:0] bits (n = 0 to 3) so that the division ratio of QSPCLK is 2 or more.

The SPCMDn register (n = 0 to 3) is used to set a transfer format. This module sequentially references the SPCMDn register according to the settings in the SPSCR register, and executes the serial transfer that is set in the referenced the SPCMDn register.

If the SPCMDn register (n = 0 to 3) currently being referred to is modified while the SPE bit is 1, subsequent operation cannot be guaranteed. The SPCMDn register currently being referred to can be checked by reading the SPSSR register.

CPHA Bit (QSPCLK Phase Setting)

This bit sets a QSPCLK edge for latching and shifting data to be transferred. The phase should be the same as that of the device to be communicated with.
This MCU supports four SPI modes listed in the Table 45.4 in combination of the CPHA bit with the CPOL bit.

CPOL Bit (QSPCLK Polarity Setting)

This bit sets a QSPCLK polarity. The polarity should be same as that of the device to be communicated with.
This MCU supports four SPI modes listed in the Table 45.4 in combination of the CPOL bit with the CPHA bit.

Table 45.4 SPI Modes Definitions

SPI Mode	CPOL	CPHA
Mode 0	0	0
Mode 1	0	1
Mode 2	1	0
Mode 3	1	1

BRDV[1:0] Bits (Bit Rate Frequency Division Setting)

The settings of these bits and of the SPBR register together determine the bit rate. The base bit rate depends on the setting of the SPBR register . The setting of these bits selects division of the base bit rate by 1, 2, 4 or 8.

Note: In transmission, set the SPBR register and these bits so that the division ratio of QSPCLK is 2 or more.
Note: In communication and burst transfer using sequence control, the set value of the BRDV[1:0] bits cannot be changed for each of the commands that configure the sequence.

SPRW Bit (SPI Read/Write Access)

This bit sets an access direction in dual-/quad-SPI modes.
This bit is invalid in single-SPI mode.

SPIMOD[1:0] Bits (SPI Operating Mode)

These bits select the operating mode from single-, dual-, or quad-SPI.

SSLKP Bit (QSSL Signal Level Keeping)

This bit specifies whether the QSSL signal level for the current command is to be kept or not from the end of the transfer for the current command to the beginning of the transfer for the next command. Setting this bit to 1 enables a transition to the next access while the QSSL signal is kept asserted.

SPB[3:0] Bits (Transfer Data Length Setting)

These bits set the basic transfer data length for serial transfer. For LSB first transfer, the transfer data is reversed within the data width specified with these bits. The actual amount of data to be transferred is determined by multiplying the value set with these bits by the value set with the SPBMULn register (n = 0 to 3).

LSBF Bit (LSB First)

This bit sets the data format to MSB first or LSB first.

SPNDEN Bit (Next-Access Delay Enable)

This bit sets the period (next-access delay) from termination of a serial transfer to the beginning of the next serial transfer. If this bit is 0, this module sets the next-access delay to 0 QSPCLK cycle. If this bit is 1, this module starts next

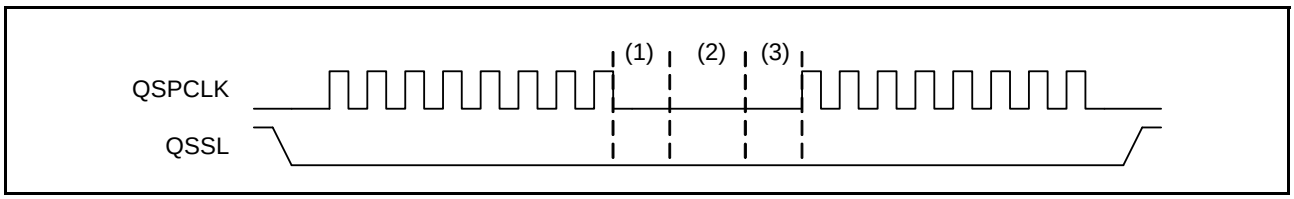
serial transfer in compliance with the SPND register settings. For the continuous access in which QSSL is kept asserted over the multiple commands, this bit can be set to 0 only when the pertinent command is not the last one. Otherwise, this bit should be set to 1.

SLNDEN Bit (QSSL Negation Delay Setting Enable)

This bit sets a period (QSSL negation delay) from QSPCLK oscillation stoppage to QSSL signal negation. If this bit is 0, this module sets the QSSL negation delay to 0 QSPCLK cycle. If this bit is 1, this module negates the QSSL signal in compliance with the SSLND register settings. For the continuous access in which QSSL is kept asserted over the multiplier commands, this bit can be set to 0 only when the pertinent command is not the last one. Otherwise, this bit should be set to 1.

SCKDEN Bit (Clock Delay Setting Enable)

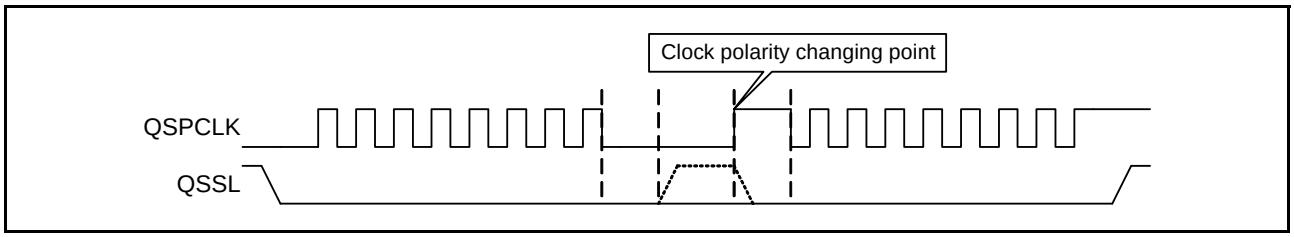
This bit sets a period (clock delay) from the beginning of QSSL signal assertion to QSPCLK oscillation. If this bit is 0, this module sets the clock delay to 0 QSPCLK cycle. If this bit is 1, this module starts QSPCLK oscillation in compliance with the SPCKD register settings. For the continuous access in which QSSL is kept asserted over the multiple commands, this bit can be set to 0 only when the pertinent command is the second or subsequent one. Otherwise, this bit should be set to 1.



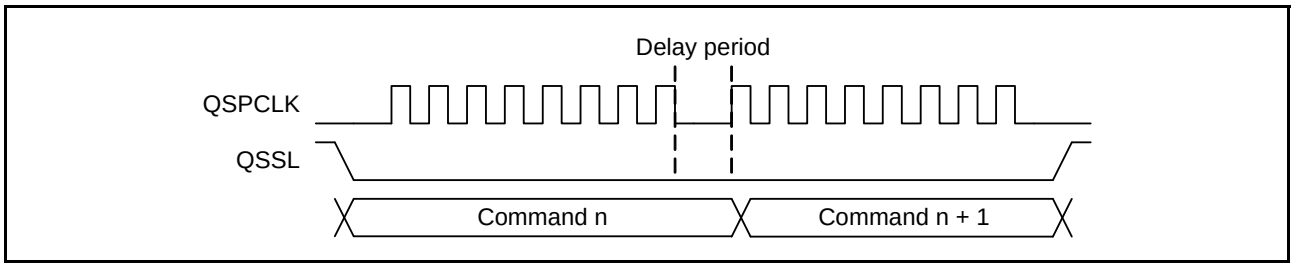
In the above figure, (1), (2), and (3) refer to the QSSL negation delay period, next-access delay period, and next command clock delay period, respectively.
Allowed setting is {(1), (2), (3)} = {1, 1, 1}, {1, 1, 0}, {1, 0, 0}, {0, 0, 0}. If a combination other than these is set, operation cannot be guaranteed.

Note: When changing the BRDV[1:0] bits or CPOL bit for each command for the continuous access in which the QSSL level is held, insert the QSSL negation delay period, next-access delay period, and clock delay period between commands. Otherwise, operation cannot be guaranteed.

Note: A clock polarity changing point may be detected as a clock edge if the CPOL bit is changed with the QSSL level held.



Note: When changing the SPIMOD[1:0] bits or CPHA bit for each command for the continuous access in which the QSSL level is held, insert one cycle or more between commands. Otherwise, operation cannot be guaranteed. (This also applies to write-to-read or read-to-write switching in dual-/quad-SPI modes.)
In the figure below, the data line is driven during the command n period if command n is for dual-/quad-SPI write access.



45.2.14 QSPI Buffer Control Register (SPBFCR)

Address(es): QSPI.SPBFCR 0008 9E18h

	b7	b6	b5	b4	b3	b2	b1	b0
	TXRST	RXRST	TXTRG[1:0]		TXTRGEX	RXTRG[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	RXTRG[2:0]	Receive Buffer Data Triggering Number	b2 b0 0 0 0: 1 byte (31 bytes available) 0 0 1: 2 bytes (30 bytes available) 0 1 0: 4 bytes (28 bytes available) 0 1 1: 5 bytes (27 bytes available) 1 0 0: 8 bytes (24 bytes available) 1 0 1: 16 bytes (16 bytes available) 1 1 0: 24 bytes (8 bytes available) 1 1 1: 32 bytes (0 byte available)	R/W
b3	TXTRGEX	Transmit Buffer Data Triggering Number	b5 b3 0 0 0: 31 bytes (1 byte available) 0 1 0: 30 bytes (2 bytes available) 1 0 0: 28 bytes (4 bytes available) 1 1 0: 0 byte (32 bytes available)	R/W
b5, b4	TXTRG[1:0]		0 0 1: 24 bytes (8 bytes available) 0 1 1: 16 bytes (16 bytes available) 1 0 1: 8 bytes (24 bytes available) 1 1 1: 4 bytes (28 bytes available)	
b6	RXRST	Receive Buffer Data Reset	0: Allows the receive buffer normal operation. 1: Resets the receive buffer.	R/W
b7	TXRST	Transmit Buffer Data Reset	0: Allows the transmit buffer normal operation. 1: Resets the transmit buffer.	R/W

The SPBFCR register resets the number of data units in the transmit buffer (SPTXB) or receive buffer (SPRXB) and sets the number of triggering data units. If this register is modified, perform a dummy read after data is written, and then execute the subsequent instruction. In addition, if this register is modified while the SPCR.SPE bit is 1, subsequent operation cannot be guaranteed.

RXTRG[2:0] Bits (Receive Buffer Data Triggering Number)

These bits specify the timing at which the receive buffer full state is determined, that is when the SPSR.SPRFF flag in the status register is set. When the number of bytes of data in the receive buffer (SPRXB) is equal to or greater than the specified triggering number, the SPSR.SPRFF flag is set to 1. If these bits are modified, perform a dummy read after data is written, and then execute the subsequent instruction. These bits should be modified when the SPCR.SPE bit is 0.

TXTRG[1:0] Bits and TXTRGEX Bit (Transmit Buffer Data Triggering Number)

These bits specify the timing at which the transmit buffer empty state is determined, that is when the SPSR.SPRFF flag in the status register is set. When the number of bytes of data in the transmit buffer (SPTXB) is equal to or less than the specified triggering number, the SPSR.SPTEF flag is set to 1. If these bits are modified, perform a dummy read after data is written, and then execute the subsequent instruction. These bits should be modified when the SPCR.SPE bit is 0.

RXRST Bit (Receive Buffer Data Reset)

This bit invalidates receive data in the receive buffer and resets the receive buffer to an empty state. If this bit is modified, perform a dummy read after data is written, and then execute the subsequent instruction. This bit should be modified when the SPCR.SPE bit is 0.

TXRST Bit (Transmit Buffer Data Reset)

This bit invalidates transmit data in the transmit buffer and resets the transmit buffer to an empty state. If this bit is modified, perform a dummy read after data is written, and then execute the subsequent instruction. This bit should be modified when the SPCR.SPE bit is 0.

45.2.15 QSPI Buffer Data Count Set Register (SPBDCR)

Address(es): QSPI.SPBDCR 0008 9E1Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	TXBC[5:0]						—	—	RXBC[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	RXBC[5:0]	Receive Data Byte Counter	000000b indicates that SPRXB is empty. 100000b indicates that SPRXB is full.	R
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13 to b8	TXBC[5:0]	Transmit Data Byte Counter	000000b indicates that SPTXB is empty. 100000b indicates that SPTXB is full.	R
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SPBDCR register indicates the number of data units stored in the transmit buffer (SPTXB) and receive buffer (SPRXB). The upper eight bits indicate the number of transmit data units in the transmit buffer and the lower 8 bits indicate the number of receive data units in the receive buffer.

RXBC[5:0] Bits (Receive Data Byte Counter)

These bits indicate the number of receive data bytes in the receive data buffer (SPRXB).

TXBC[5:0] Bits (Transmit Data Byte Counter)

These bits indicate the number of transmit data bytes in the transmit data buffer (SPTXB).

45.2.16 QSPI Transfer Data Length Multiplier Setting Register n (SPBMULn) (n = 0 to 3)

Address(es): QSPI.SPBMUL0 0008 9E1Ch, QSPI.SPBMUL1 0008 9E20h, QSPI.SPBMUL2 0008 9E24h, QSPI.SPBMUL3 0008 9E28h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SPBMUL[31:24]								SPBMUL[23:16]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SPBMUL[15:8]								SPBMUL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	SPBMUL[31:0]	Transfer Data Length Multiplier Setting	These bits set the multiplier for the transfer data length.	R/W

The SPBMULn register (n = 0 to 3) sets the number of times to transfer the specific length of data defined by the SPCMDn.SPB[3:0] bits (n = 0 to 3). The SPBMUL0 to SPBMUL3 registers correspond to the SPCMD0 to SPCMD3 registers, respectively.

If the SPBMULn register corresponding to the SPCMDn register currently being referred to is modified while the SPCR.SPE bit is 1, subsequent operation cannot be guaranteed. The SPCMDn register currently being referred to can be checked by reading the SPSSR register.

SPBMUL[31:0] Bits (Transfer Data Length Multiplier Setting)

These bits set the multiplier for transfer data; that is, the number of times to transfer the specific length of data defined by the SPCMDn.SPB[3:0] bits (n = 0 to 3).

The actual amount of data to be transferred is determined by the SPCMDn.SPB[3:0] bits × the SPBMUL[31:0] bits.

Setting these bits to 0000 0000h allows the defined size of data to be transferred 4,294,967,296 times.

45.3 Operation

In this section, the serial transfer period means a period from the beginning of driving valid data to the fetching of the final valid data, and the idle period means the QSSL negation period.

45.3.1 Overview of Operations

This module is capable of serial transfers in single-/dual-/quad-SPI modes. Table 45.5 shows the features of each SPI mode.

Table 45.5 Features of Each SPI Mode

	Single-SPI	Dual-SPI	Quad-SPI
Number of data lines	One input line and one output line	Two I/O lines	Four I/O lines
Data line direction	Single-directional	Bidirectional	Bidirectional
Simultaneous transmission/ reception	Supported	Not supported	Not supported

Table 45.6 shows the overview of operation.

Table 45.6 Overview of Operation

Items	Specification
QSPCLK signal	Output
QMO signal (single-SPI)	Output
QMI signal (single-SPI)	Input
QIO1 and QIO0 (dual-SPI)/QIO3 to QIO0 (quad-SPI)	Input/output
QSSL signal	Output
Switching QSSL polarity	Supported
Transfer bit rate	Up to PCLK
Clock source	On-chip baud rate generator
Clock polarity	Positive/negative
Clock phase	Data latch at odd edge, data shift at even edge/ data shift at odd edge, data latch at even edge
Transfer bit order	MSB first/LSB first
Transfer data length	(8/16/32) × (1 to 4,294,967,296) bits
Burst transfer	Supported
QSPCLK delay control	Supported
QSSL negation delay control	Supported
Next-access delay control	Supported
Transfer start method	The specified length of data is in the transmit buffer when the SPCR.SPE bit = 1 There is a space for the length of data in the receive buffer when the SPCR.SPE bit = 1*1
Sequence control	Supported
Transmit buffer empty detection	Supported
Receive buffer full detection	Supported
QSSL negation detection	Supported

Note 1. In single-SPI operation, a transfer is started when the specified length of data is in the transmit buffer and there is a space for the specified length of data in the receive buffer. In dual-/quad-SPI operation, a transfer is started when the specified length of data is in the transmit buffer during transmission, and there is a space for the specified length of data in the receive buffer during reception.

45.3.2 Pin Control

This module automatically switches the pin states according to the status after write/read transfer in single-/dual-/quad-SPI mode. The status of the data pins (QMO/QMI/QIO[3:0]) in the idle state depends on the SPPCR.MOIFE, MOIFV, IO3FV, and IO2FV bit settings. Table 45.7 shows the pin states in single-SPI mode. Table 45.8 shows the pin states in dual-/quad-SPI modes.

Table 45.7 Pin States in Single-SPI Mode

Items	Single-SPI
QSSL	Output
QSPCLK	Output
QMO	Output
QMI	Input
QMO in the idle state	SPPCR.MOIFE bit = 0: Final output value SPPCR.MOIFE bit = 1: SPPCR.MOIFV bit setting value
QMI in the idle state	—
QIO2	SPPCR.IO2FV bit setting value output or not used
QIO3	SPPCR.IO3FV bit setting value output or not used

Table 45.8 Pin States in Dual-/Quad-SPI Mode

Items	Dual-SPI	Quad-SPI
QSSL	Output	Output
QSPCLK	Output	Output
QIO0	Input/output	Input/output
QIO1	Input/output	Input/output
QIO2	SPPCR.IO2FV bit setting value output or not used	Input/output
QIO3	SPPCR.IO3FV bit setting value output or not used	Input/output
QIO0 in the idle state	After writing: SPPCR.MOIFE bit = 0: Final output value SPPCR.MOIFE bit = 1: SPPCR.MOIFV bit setting value After reading: Hi-Z	After writing: SPPCR.MOIFE bit = 0: Final output value SPPCR.MOIFE bit = 1: SPPCR.MOIFV bit setting value After reading: Hi-Z
QIO1 in the idle state	After writing: SPPCR.MOIFE bit = 0: Final output value SPPCR.MOIFE bit = 1: SPPCR.MOIFV bit setting value After reading: Hi-Z	After writing: SPPCR.MOIFE bit = 0: Final output value SPPCR.MOIFE bit = 1: SPPCR.MOIFV bit setting value After reading: Hi-Z
QIO2 in the idle state	SPPCR.IO2FV bit setting value output or not used	After writing: SPPCR.MOIFE bit = 0: Final output value SPPCR.MOIFE bit = 1: SPPCR.MOIFV bit setting value After reading: Hi-Z
QIO3 in the idle state	SPPCR.IO3FV bit setting value output or not used	After writing: SPPCR.MOIFE bit = 0: Final output value SPPCR.MOIFE bit = 1: SPPCR.MOIFV bit setting value After reading: Hi-Z

45.3.3 Transfer Format

The SPI has four modes determined by setting the SPCMDn.CPOL and SPCMDn.CPHA bits (n = 0 to 3). Figure 45.2 shows the data latch/shift timing based on each mode in an 8-bit MSB first transfer. In Figure 45.2, L indicates the latch timing and S indicates the shift timing. DATA corresponds to QMI/QMO in single-SPI mode; QIO1 and QIO0 in dual-SPI mode; or QIO3 to QIO0 in quad-SPI mode. t_{ckd} indicates the clock delay period when the SPCMDn.SCKDEN bit is set to 1. Similarly, t_{slnd} indicates the QSSL negation delay period when the SPCMDn.SLNDEN bit is set to 1, and t_{spnd} indicates the next-access delay period when the SPCMDn.SPNDEN bit is set to 1.

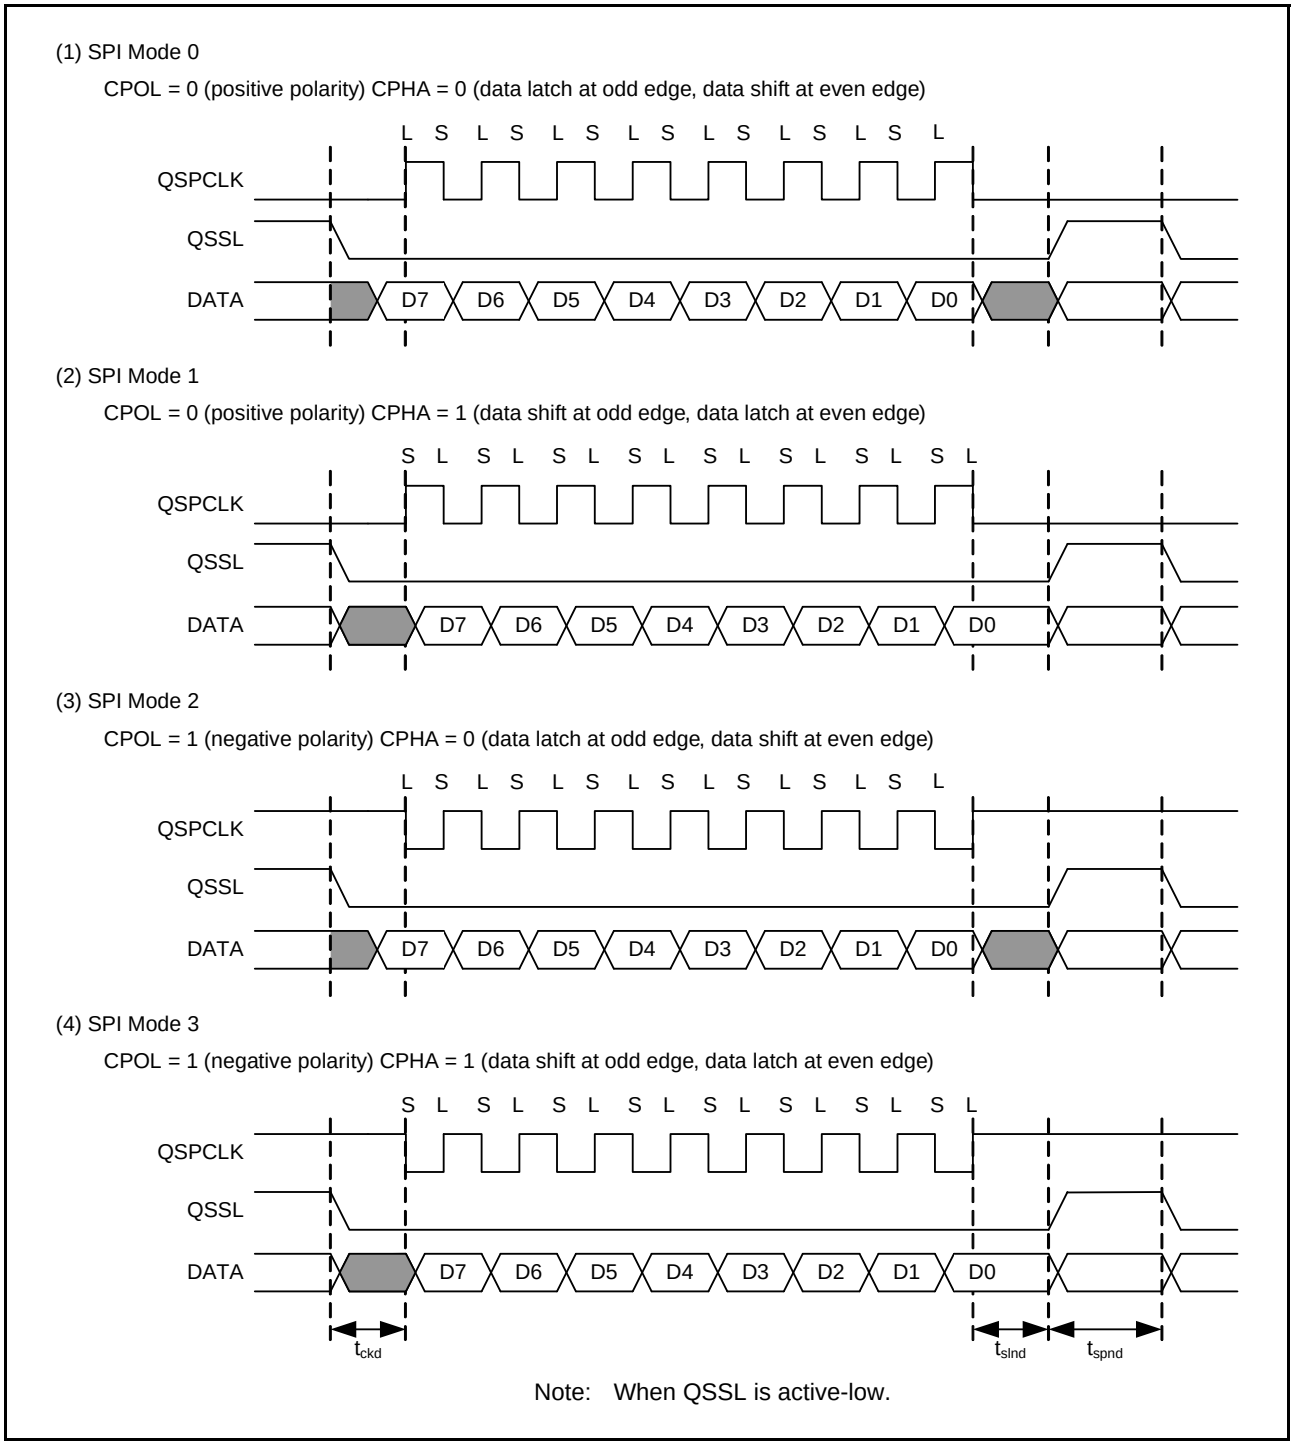


Figure 45.2 Clock Setting and Transfer Timing

Note that when the base bit rate is used, transmission and reception when the SPCMDn.CPHA bit (n = 0 to 3) = 0 is not available.
The following describes 8-bit MSB first transfer in single-/dual-/quad-SPI modes when the SPCMDn.CPOL bit = 0 and the SPCMDn.CPHA bit = 0.

(1) Single-SPI Mode

Figure 45.3 shows the transfer format in single-SPI mode. This mode provides transmission and reception simultaneously. Since one data line is used for serial communication both in transmission and reception, the communication speed is 1 bit per QSPCLK clock cycle. Transfer data is specified using the SPCMDn register (n = 0 to 3). For details of transfer data, see section 45.3.4, Transfer Data.

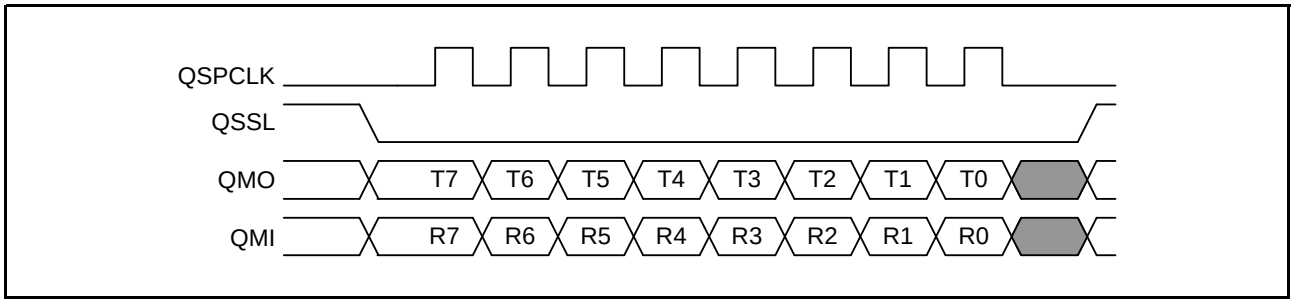

Figure 45.3 Transfer Format in Single-SPI Format

(2) Dual-SPI Mode

Figure 45.4 shows the transfer format in dual-SPI mode. This mode only provides operation of a single direction, that is, either transmission or reception. Transmission or reception can be set using the SPCMDn.SPRW bit (n = 0 to 3). Transmission is carried out by write operation and reception by read operation. The I/O directions of QIO1 and QIO0 are switched accordingly. Since two data lines are used for serial communication both in transmission and reception, the communication speed is 2 bits per QSPCLK clock cycle. The start bit of the transfer data is output from QIO1. Transfer data is specified using the SPCMDn register. For details of transfer data, see section 45.3.4, Transfer Data.

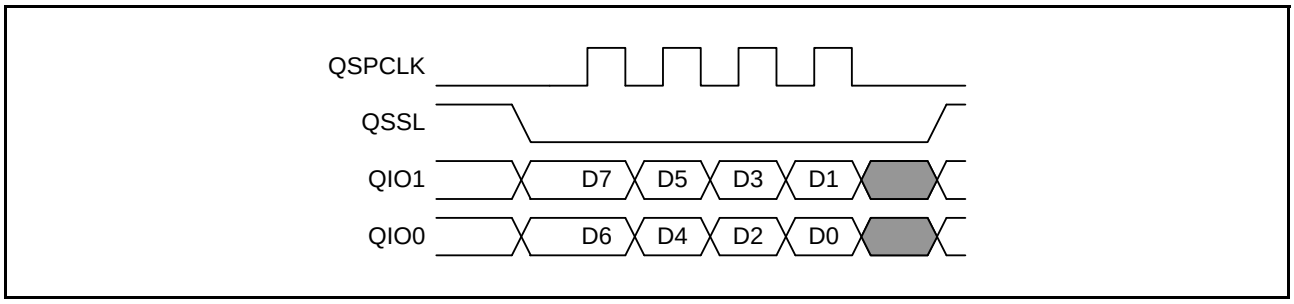

Figure 45.4 Transfer Format in Dual-SPI Format

(3) Quad-SPI Mode

Figure 45.5 shows the transfer format in quad-SPI mode. This mode provides operation of a single direction, that is, either transmission or reception. Transmission or reception can be set using the SPCMDn.SPRW bit (n = 0 to 3). Transmission and reception are carried out by writing and reading, respectively. The I/O directions of QIO3 to QIO0 are switched accordingly. Since four data lines are used for serial communication both in transmission and reception, the communication speed is 4 bits per QSPCLK clock cycle. The start bit of the transfer data is output from QIO3. Transfer data is specified using the SPCMDn register. For details of transfer data, see section 45.3.4, Transfer Data.

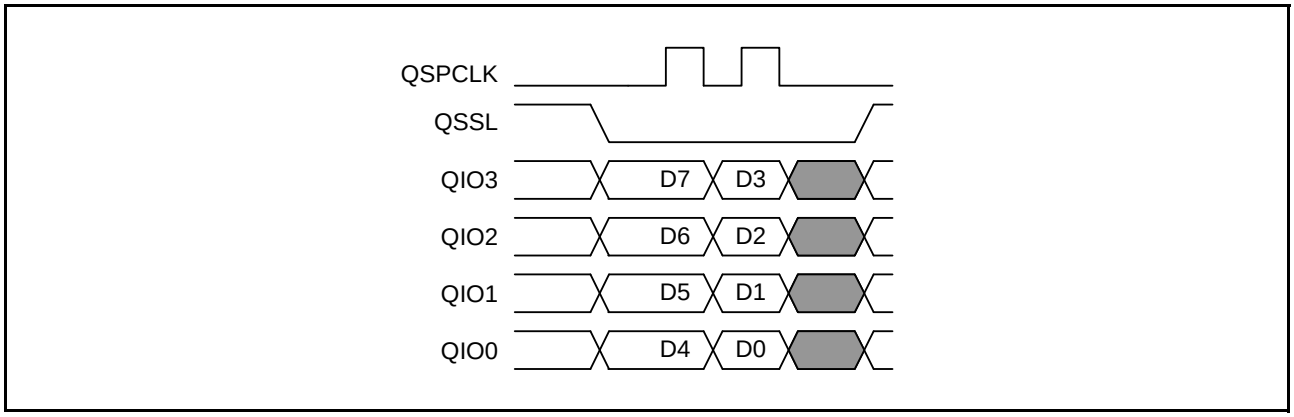

Figure 45.5 Transfer Format in Quad-SPI Format

45.3.4 Transfer Data

The data format is determined by the SPCMDn.SPB[3:0] bits and LSBF bit (n = 0 to 3) and the SPBMULn register (n = 0 to 3). This module treats the specified size of data beginning at the MSB of the transmit shift register as transmit data, and the specified length of data beginning at the LSB of the receive shift register as receive data, regardless of whether the actual arrangement is MSB or LSB first. The following sections describe MSB first and LSB first transfers in 32-bit, 16-bit, and 8-bit data units.

(1) MSB First Transfer (32-Bit Data)

Figure 45.6 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs a 32-bit MSB-first data transfer.

For data transmission, the CPU, DTC, or DMAC writes 32-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module copies the data in the transmit buffer to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the QSPCLK clock cycle required for the serial transfer of 32 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the receive shift register beginning at the LSB (bit 0). When the QSPCLK clock cycle required for the serial transfer of 32 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 32 bits or more, this module copies the 32-bit data beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 32 bits or more, data reception is not carried out. In order to start reception, the specified length of data should be read from the receive buffer to secure the space for 32 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by the SPBMULn register (n = 0 to 3).

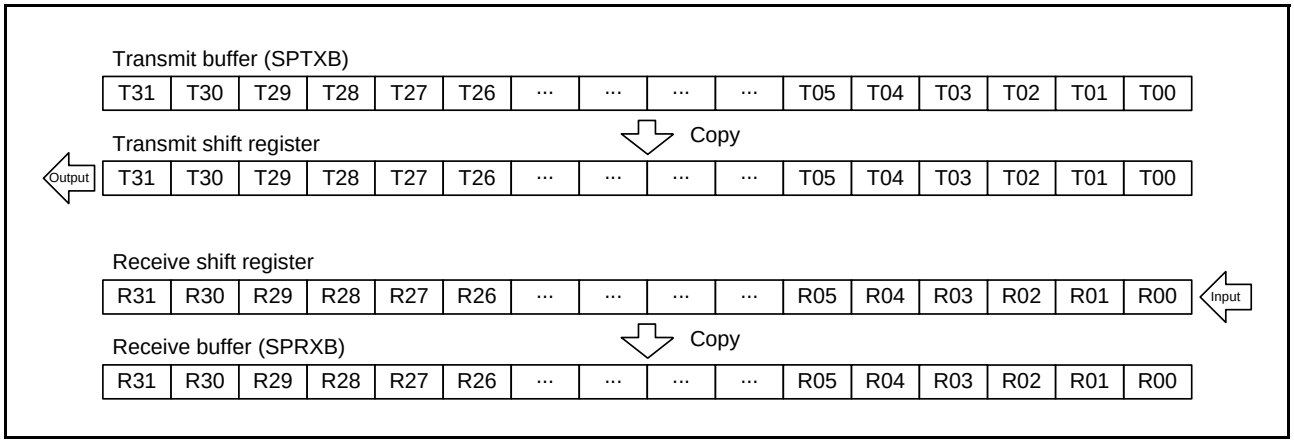

Figure 45.6 MSB First Transfer (32-Bit Data)

(2) MSB First Transfer (16-Bit Data)

Figure 45.7 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs a 16-bit MSB-first data transfer.

For data transmission, the CPU, DTC, or DMAC writes 16-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module copies the data with MSB-aligned in the transmit buffer to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the QSPCLK clock cycle required for the serial transfer of 16 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the receive shift register beginning at the LSB (bit 0). When the QSPCLK clock cycle required for the serial transfer of 16 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 16 bits or more, this module copies the 16-bit data beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 16 bits or more, data reception is not carried out. In order to start reception, the specified length of data should be read from the receive buffer to secure the space for 16 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by the SPBMULn register (n = 0 to 3).

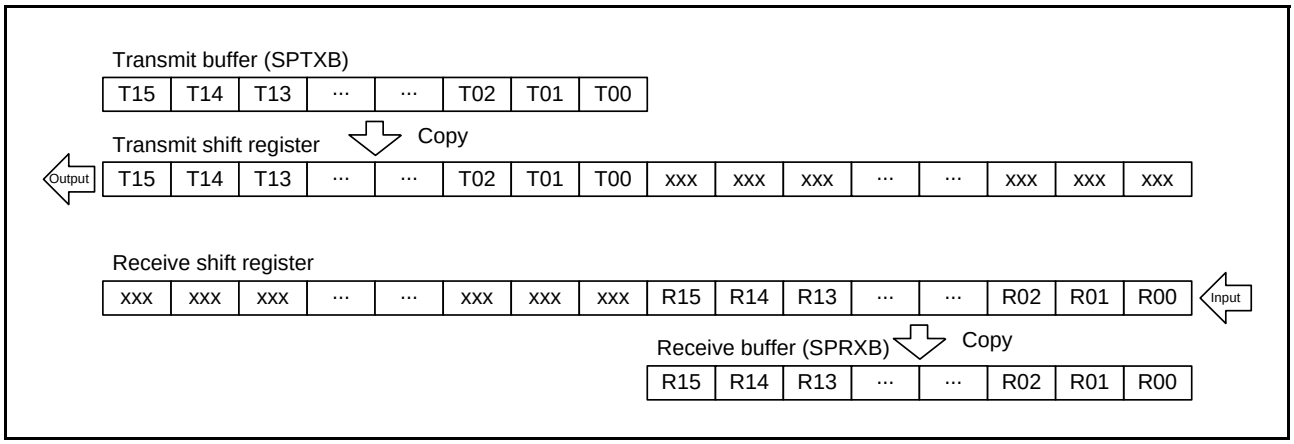

Figure 45.7 MSB First Transfer (16-Bit Data)

(3) MSB First Transfer (8-Bit Data)

Figure 45.8 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs an 8-bit MSB-first data transfer.

For data transmission, the CPU, DTC, or DMAC writes 8-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module copies the data with MSB-aligned in the transmit buffer to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the QSPCLK clock cycle required for the serial transfer of 8 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the receive shift register beginning at the LSB (bit 0). When the QSPCLK clock cycle required for the serial transfer of 8 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 8 bits or more, this module copies the 8-bit data beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 8 bits or more, data reception is not carried out. In order to start reception, data for the specified length of data should be read from the receive buffer to secure the space for 8 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by the SPBMULn register (n = 0 to 3).

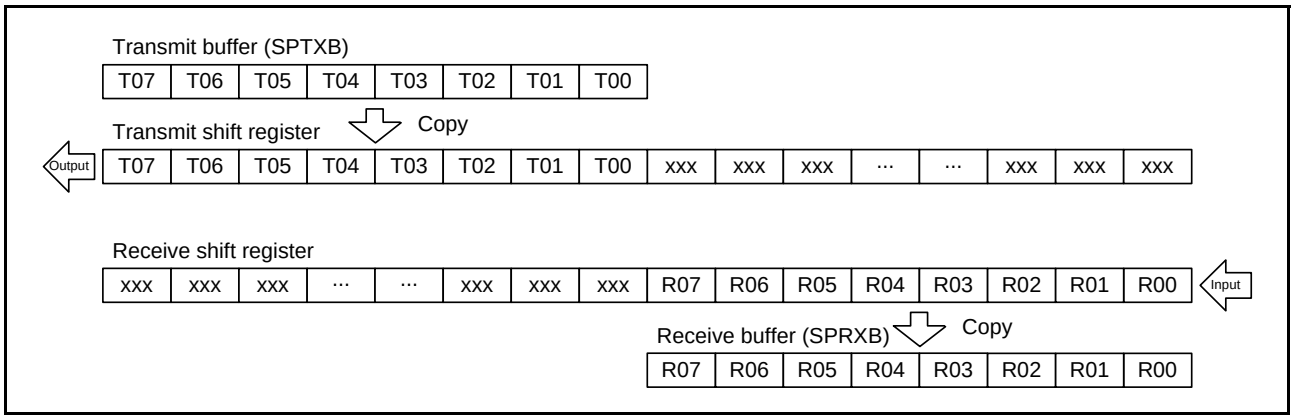

Figure 45.8 MSB First Transfer (8-Bit Data)

(4) LSB First Transfer (32-Bit Data)

Figure 45.9 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs a 32-bit LSB-first data transfer.

For data transmission, the CPU, DTC, or DMAC writes 32-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module reverses the bit order in the 32-bit transmit data, copies it to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the QSPCLK clock cycle required for the serial transfer of 32 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the receive shift register beginning at the LSB (bit 0). When the QSPCLK clock cycle required for the serial transfer of 32 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 32 bits or more, this module reverses the order of the bits of the 32-bit data, copies it beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 32 bits or more, data reception is not carried out. In order to start reception, the specified length of data should be read from the receive buffer to secure the space for 32 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by the SPBMULn register (n = 0 to 3).

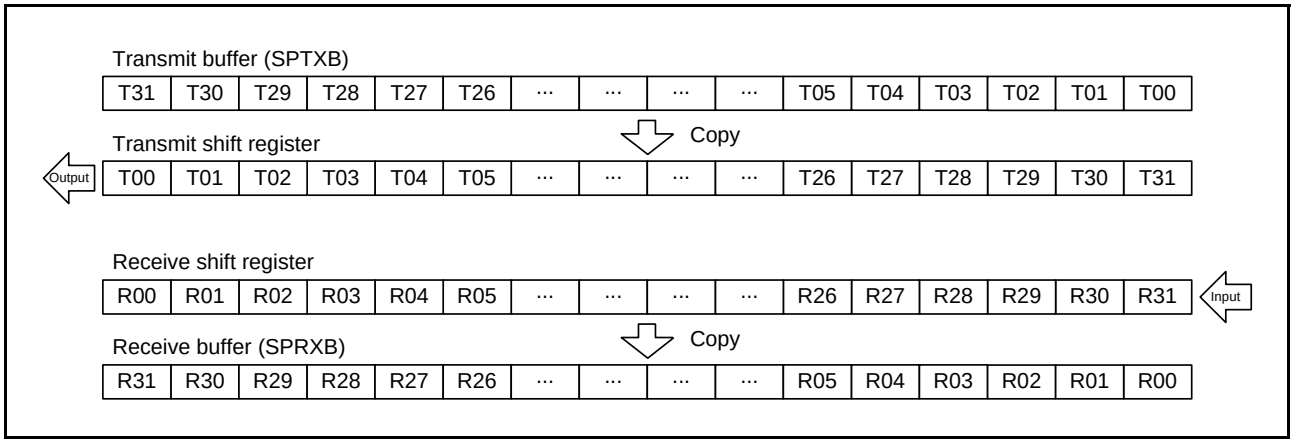

Figure 45.9 LSB First Transfer (32-Bit Data)

(5) LSB First Transfer (16-Bit Data)

Figure 45.10 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs a 16-bit LSB-first data transfer.

For data transmission, the CPU, DTC, or DMAC writes 16-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module reverses the bit order in the 16-bit transmit data, copies it with MSB-aligned to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the QSPCLK clock cycle required for the serial transfer of 16 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the receive shift register beginning at the LSB (bit 0). When the QSPCLK clock cycle required for the serial transfer of 16 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 16 bits or more, this module reverses the bit order in the 16-bit data, copies it beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 16 bits or more, data reception is not carried out. In order to start reception, the specified length of data should be read from the receive buffer to secure the space for 16 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by the SPBMULn register (n = 0 to 3).

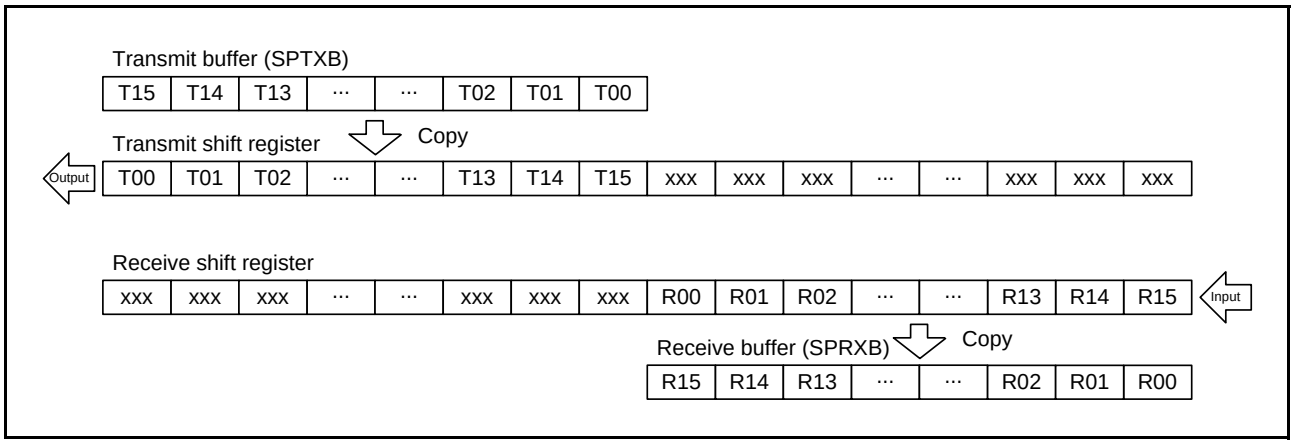

Figure 45.10 LSB First Transfer (16-Bit Data)

(6) LSB First Transfer (8-Bit Data)

Figure 45.11 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs an 8-bit LSB-first data transfer.
For data transmission, the CPU, DTC, or DMAC writes 8-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module reverses the bit order in the 8-bit transmit data, copies it with MSB-aligned to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the QSPCLK clock cycle required for the serial transfer of 8 bits has passed, the transmit shift register becomes empty.
For data reception, data received from the data pin is stored in the receive shift register beginning at the LSB (bit 0). When the QSPCLK clock cycle required for the serial transfer of 8 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 8 bits or more, this module reverses the bit order in the 8-bit data, copies it beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 8 bits or more, data reception is not carried out. In order to start reception, the specified length of data should be read from the receive buffer to secure the space for 8 bits or more in the receive buffer. In actual transfer, this operation is repeated for the number of times defined by the SPBMULn register (n = 0 to 3).

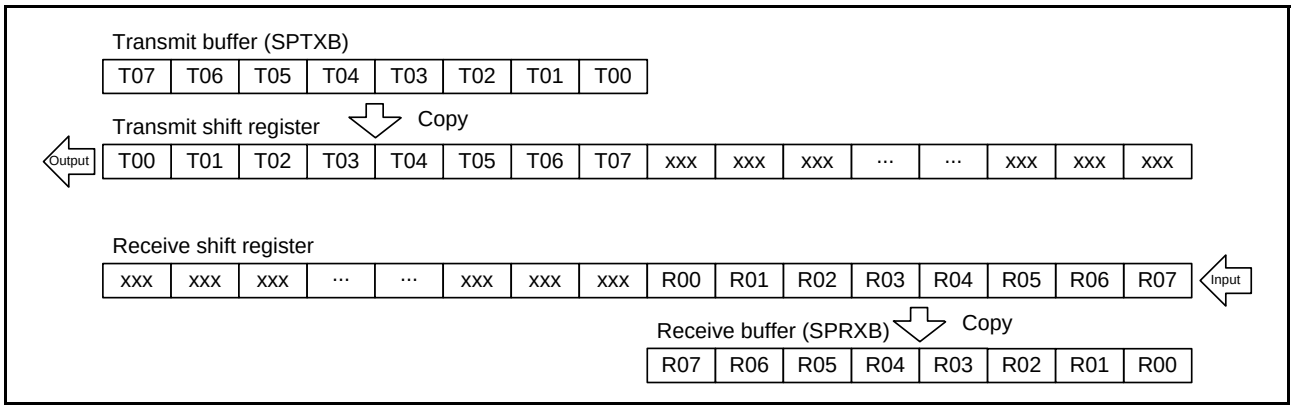

Figure 45.11 LSB First Transfer (8-Bit Data)

45.3.5 Non-Normal Transfer Operations

In the normal serial transfer, the data written from the SPDR register to the transmit buffer is serially transmitted, and the serially received data can be read from the receive buffer of the SPDR register. If access is made to the SPDR register, depending on the status of the transmit buffer/receive buffer, in some cases non-normal transfers can be executed. Table 45.9 shows the relationship between non-normal transfer operations.

Table 45.9 Relationship between Non-Normal Transfer Operations

	Occurrence Condition	Operation
A	The SPDR register is written when the transmit buffer is full.	Missing write data.
B	The SPDR register is read when the receive buffer is empty.	The output data is undefined.

On operation A shown in Table 45.9, whether the SPDR register can be written to or not can be checked using the SPBDCR.TXBC[5:0] bits.
Similarly, on operation B shown in Table 45.9, whether the valid data is stored in the receive buffer or not can be checked by reading the SPBDCR.RXBC[5:0] bits.

45.3.6 Initialization

If 0 is written to the SPCR.SPE bit, this module disables the module function, and initializes a part of the module function. When a power-on reset is generated, this module initializes all of the module function.
When the SPCR.SPE bit is cleared to 0, this module performs the following initialization:

- Suspending any serial transfer that is being executed
- Initializing the transmit shift register and the receive shift register
- Initializing the internal state machine
- Initializing the sequence
- Initializing the SPSR.TREND flag

Initialization by the clearing of the SPCR.SPE bit to 0 does not initialize the control bits of this module and the transmit/receive buffer. For this reason, this module can be started in the same transfer state as prior to the initialization if the SPCR.SPE bit is re-set to 1. However, clearing the SPCR.SPE bit to 0 initializes the transmit shift register and the receive shift register, thus the data that is being transferred will be discarded.

45.3.7 SPI Operation

The operating modes of this module are listed below.

- Single-SPI mode
- Dual-SPI mode/quad-SPI mode

The operation in each mode is described below.

(1) Single-SPI Mode

(a) Starting Serial Transfer

The serial transfer start conditions are: there is the specified length of data in the transmit buffer; and there is space for the specified length of data in the receive buffer.

(b) Terminating Serial Transfer

Irrespective of the clock setting, this module terminates the serial transfer after transmitting an QSPCLK edge corresponding to the final sampling timing. After the serial transfer is completed, receive data is copied from the receive shift register to the receive buffer. If there is not enough space for the specified length of data in the receive buffer after receive data is copied from the receive shift register to the receive buffer, another serial transfer will not be performed.

(c) Sequence Control

In single-SPI mode, according to the sequence length that is assigned to the SPSCR register, this module makes up a sequence comprised of a part or all of the SPCMDn register (n = 0 to 3) and the SPBMULn register (n = 0 to 3). This module contains a pointer to the SPCMDn register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR register.

When the SPCR.SPE bit is set to 1 and the function of this module is enabled, this module loads the pointer to the commands in the SPCMD0 register, and incorporates the SPCMD0 and SPBMUL0 register settings into the transfer format at the beginning of serial transfer. This module increments the pointer each time the next-access delay period for a data transfer that corresponds to the referenced the SPCMDn register ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, this module sets the pointer in the SPCMD0 register, and in this manner the sequence is executed repeatedly.

The following items are set in the SPCMDn register: basic transfer data length, MSB or LSB first, clock settings, some of the bit rate settings, SPI transfer mode and transfer direction (only in dual-/quad-SPI modes), whether QSSL level is held, a clock delay period, an QSSL negation delay period, and a next-access delay period. The total amount of data to be transferred is determined by multiplying the basic length of data to be transferred by the value set with the SPBMULn register.

Figure 45.12 shows an operation example when the SPSCR register is set to 02h, and the sequence is configured based on SPCMD0 to SPCMD2 register settings. In Figure 45.12, shaded areas of QMO/QMI indicate invalid data. Periods (1) to (3) in the figure indicate the followings.

(1) Clock delay period (SPCKD) setting value = 000b (1.5 QSPCLK cycles)
(2) QSSL negation delay period (SSLND) setting value = 000b (1 QSPCLK cycle)
(3) Next-access delay period (SPND) setting value = 000b (1 QSPCLK cycle)

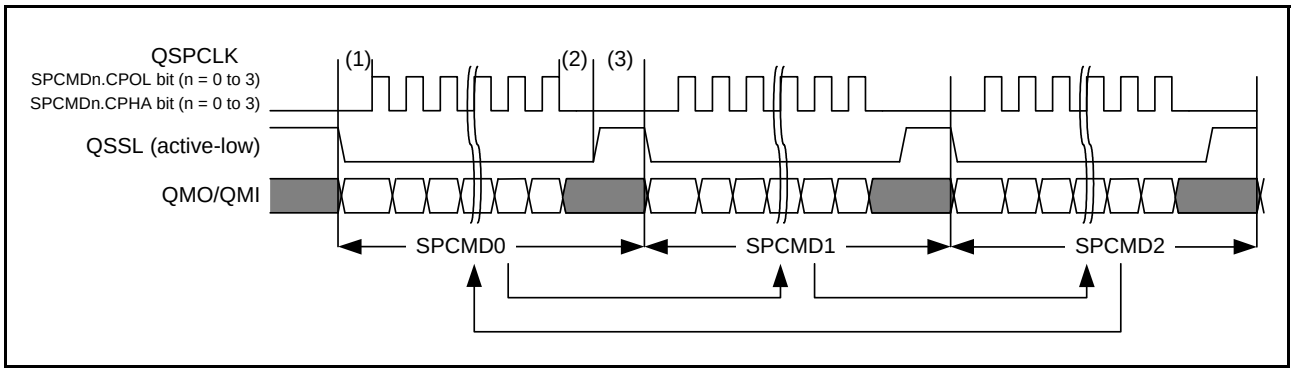

Figure 45.12 Sequence Control Operation

(d) Burst Transfer

This module can execute burst transfer with the following two methods in single-SPI mode.
One method uses the SPCMDn.SPB[3:0] bits (n = 0 to 3) and the SPBMULn register (n = 0 to 3). Setting SPCMDn.SPB[3:0] bits to select 8, 16, or 32 bits and setting the SPBMULn register to select 1 through 4,294,967,296 allows the specified length of data to be continuously transferred for the specified times, where the length is specified by SPCMDn.SPB[3:0] bits and the number of times is specified by the SPBMULn register. However, if the transmit buffer (SPTXB) becomes empty during transfer, or the receive buffer (SPRXB) has no longer a space enough to receive the specified length of data defined by SPCMDn.SPB[3:0] bits, the clock is stopped until transfer is resumed. Figure 45.13 shows a burst transfer example in which SPCMDn.SPB[3:0] bits are set to select 32 bits and the SPBMULn register to select four times thus specifying 128 bits as a total transfer data amount. The following describes operations (1) to (4) in the figure.

(1) First 32-bit data transfer
(2) Second 32-bit data transfer
(3) When the transmit buffer becomes empty or the receive buffer has no longer a space for 32 or more bits, the clock is stopped. Here, the QMO continues outputting the previous value. When data is written to the transmit buffer or an enough space is created in the receive buffer, the clock output is resumed to restart transfer.
(4) Third and fourth 32-bit data transfer

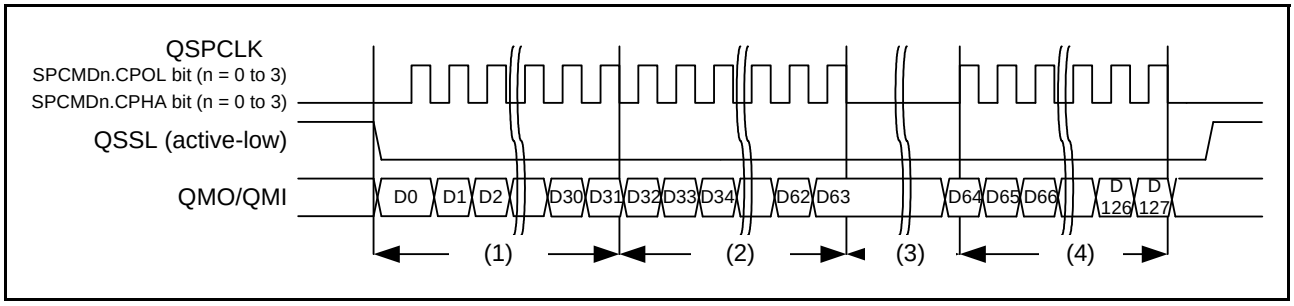

Figure 45.13 Burst Transfer Example in which Total Transfer Data Amount is 128 Bits (Single-SPI Mode)

In the other method, QSSL is kept asserted after a serial transfer is completed until the next serial transfer. Setting the SPCMDn.SSLKP bit (n = 0 to 3) allows the QSSL signal to be kept asserted after the transfer corresponding to the SPCMDn register is completed until the next transfer. Figure 45.14 shows a burst transfer example in which the QSSL signal level keeping function is used. The following describes operations (1) to (6) in the figure.

(1) Clock delay period according to the SPCMD0 register setting. The setting should be made so that the delay period should be at least 1.5 QSPCLK cycles for the first transfer in the burst transfer.
(2) QSSL negation delay period according to the SPCMD0 register setting. Since the SPCMD0.SSLKP bit is set to 1, QSSL is not negated even after QSSL negation delay period is over. The QSSL negation delay period depends on the SPCMD0.SLNDEN bit setting. When the SPCMD0.SLNDEN bit is 1, the QSSL negation delay period is determined by the SSLND register setting, and the delay period is 0 QSPCLK cycle when the SPCMD0.SLNDEN bit is 0.
(3) Next-access delay period according to the SPCMD0 register setting. Since the SPCMD0.SSLKP bit is set to 1, QSSL is not negated even during next-access delay period. The next-access delay period depends on the SPCMD0.SPNDEN bit setting. When the SPCMD0.SPNDEN bit is 1, the next-access delay period is determined by the SPND register setting, and the delay period is 0 QSPCLK cycle when the SPCMD0.SPNDEN bit is 0.
(4) Clock delay period according to the SPCMD1 register setting. The clock delay period depends on the SPCMD1.SCKDEN bit setting. When the SPCMD1.SCKDEN bit is 1, the clock delay period is determined by the SPCKD register setting, and the delay period is 0 QSPCLK cycle when the SPCMD1.SCKDEN bit is 0.
(5) QSSL negation delay period according to the SPCMD1 register setting. The setting should be made so that the delay period should be at least one QSPCLK cycle for the last transfer in the burst transfer. Since the SPCMD1.SSLKP bit is set to 0, QSSL is negated after QSSL negation delay period is over.
(6) Next-access delay period according to the SPCMD1 register setting. The setting should be made so that the delay period should be at least one QSPCLK cycle for the last transfer in the burst transfer. Set the SPCMD1.SSLKP bit to 0 to negate QSSL.

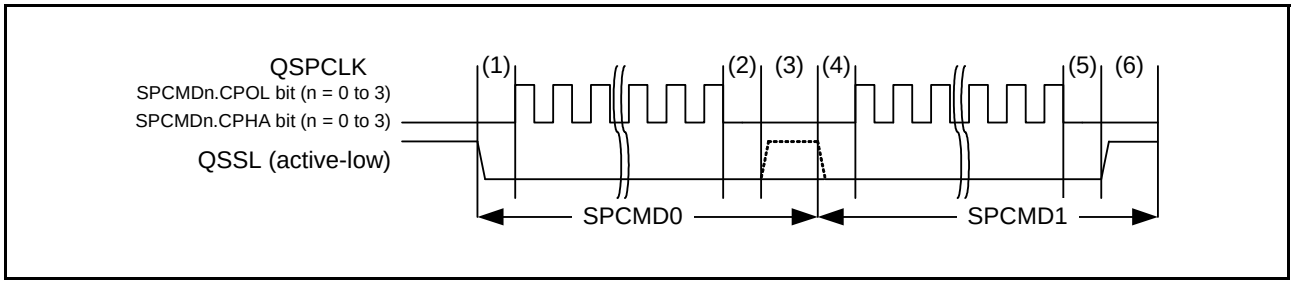

Figure 45.14 Burst Transfer Example in which QSSL Signal Level Keeping Function is Used (Single-SPI Mode)

Note the following when specifying a burst transfer using this method.
Periods (2) to (4) should be inserted without fail when changing the clock polarity through command update.

(e) Initialization Flowchart

Figure 45.15 is a flowchart illustrating an example of initialization in SPI operation when this module is used in single-SPI mode. For a description of how to set up the interrupt controller, DTC, or DMAC, see the descriptions given in the corresponding sections.

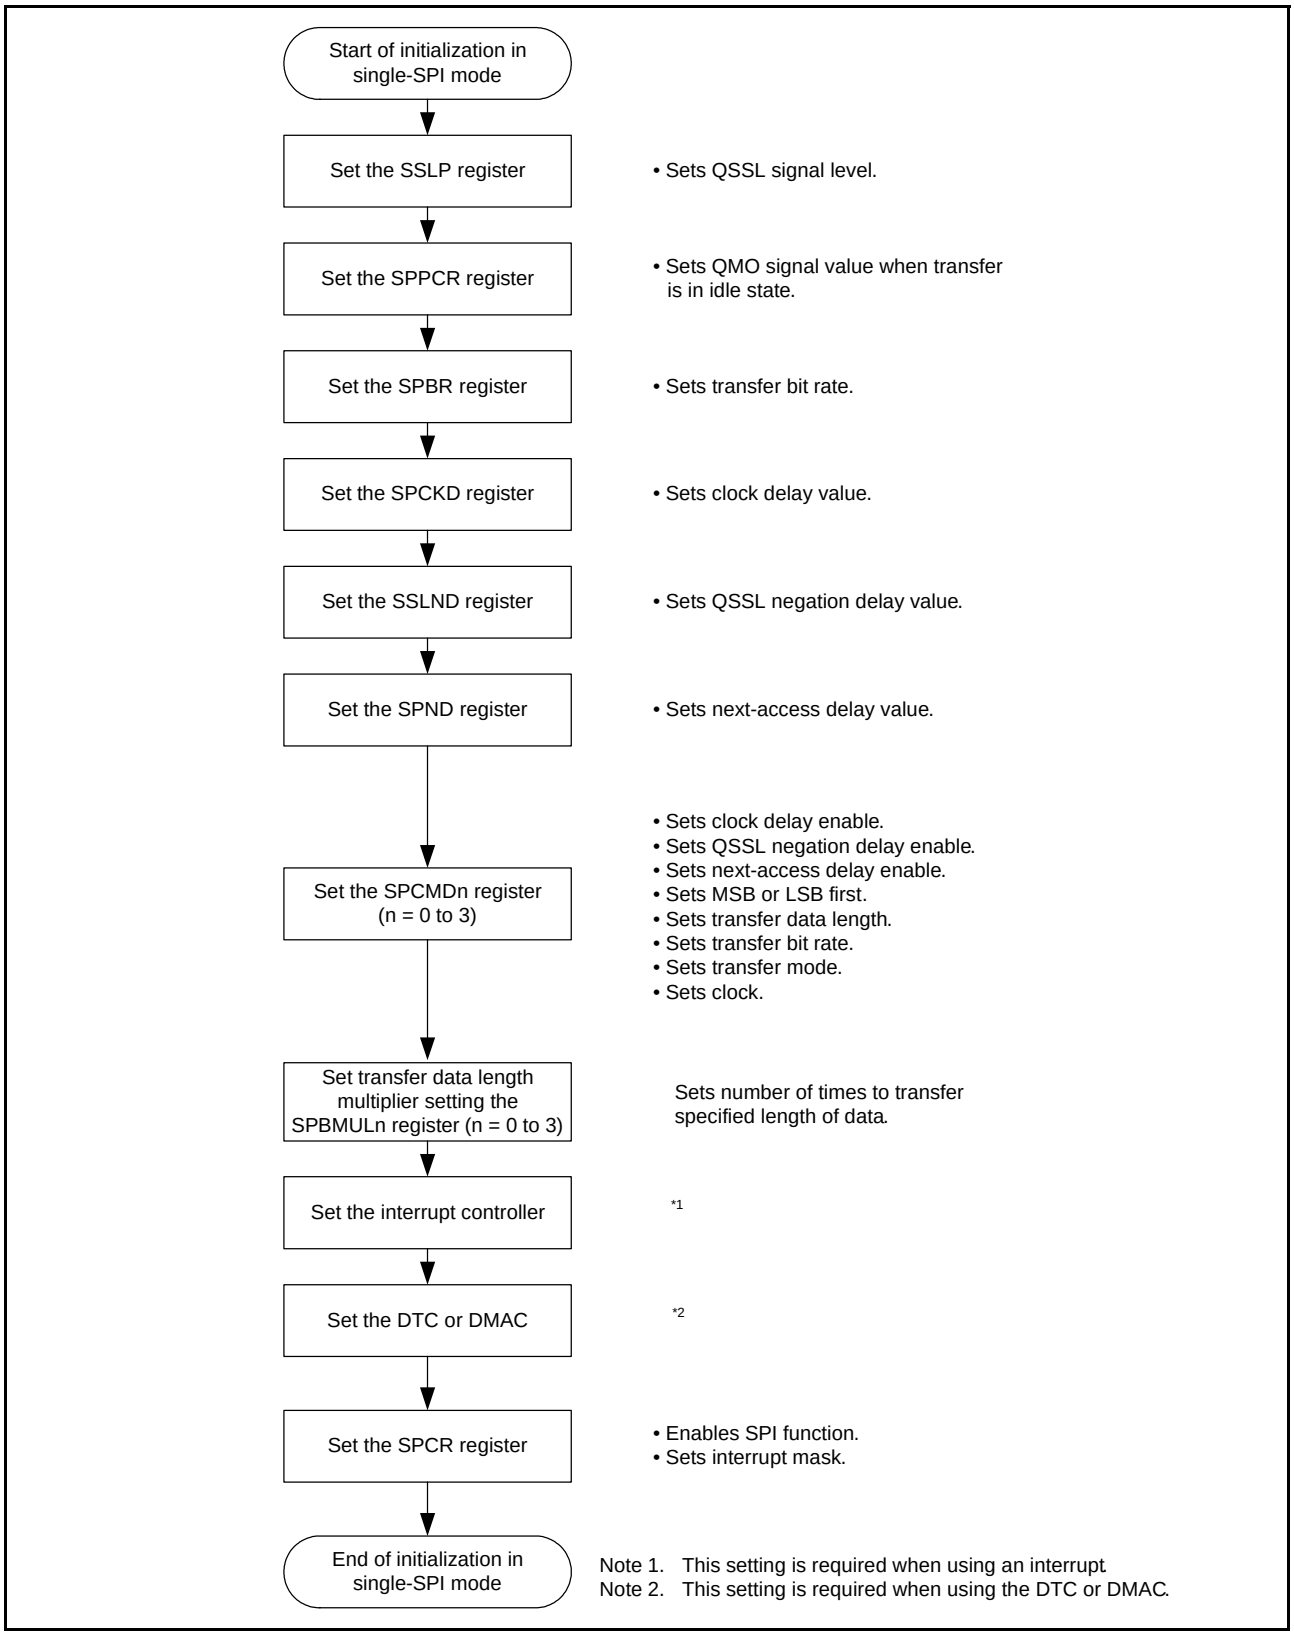

Figure 45.15 Example of Initialization Flowchart in Single-SPI Mode

(f) Transfer Operation Flowchart

Figure 45.16 is a flowchart illustrating a transfer in SPI operation when this module is used in single-SPI mode. Burst transfer by setting the transfer data length is also executed based on this flowchart.

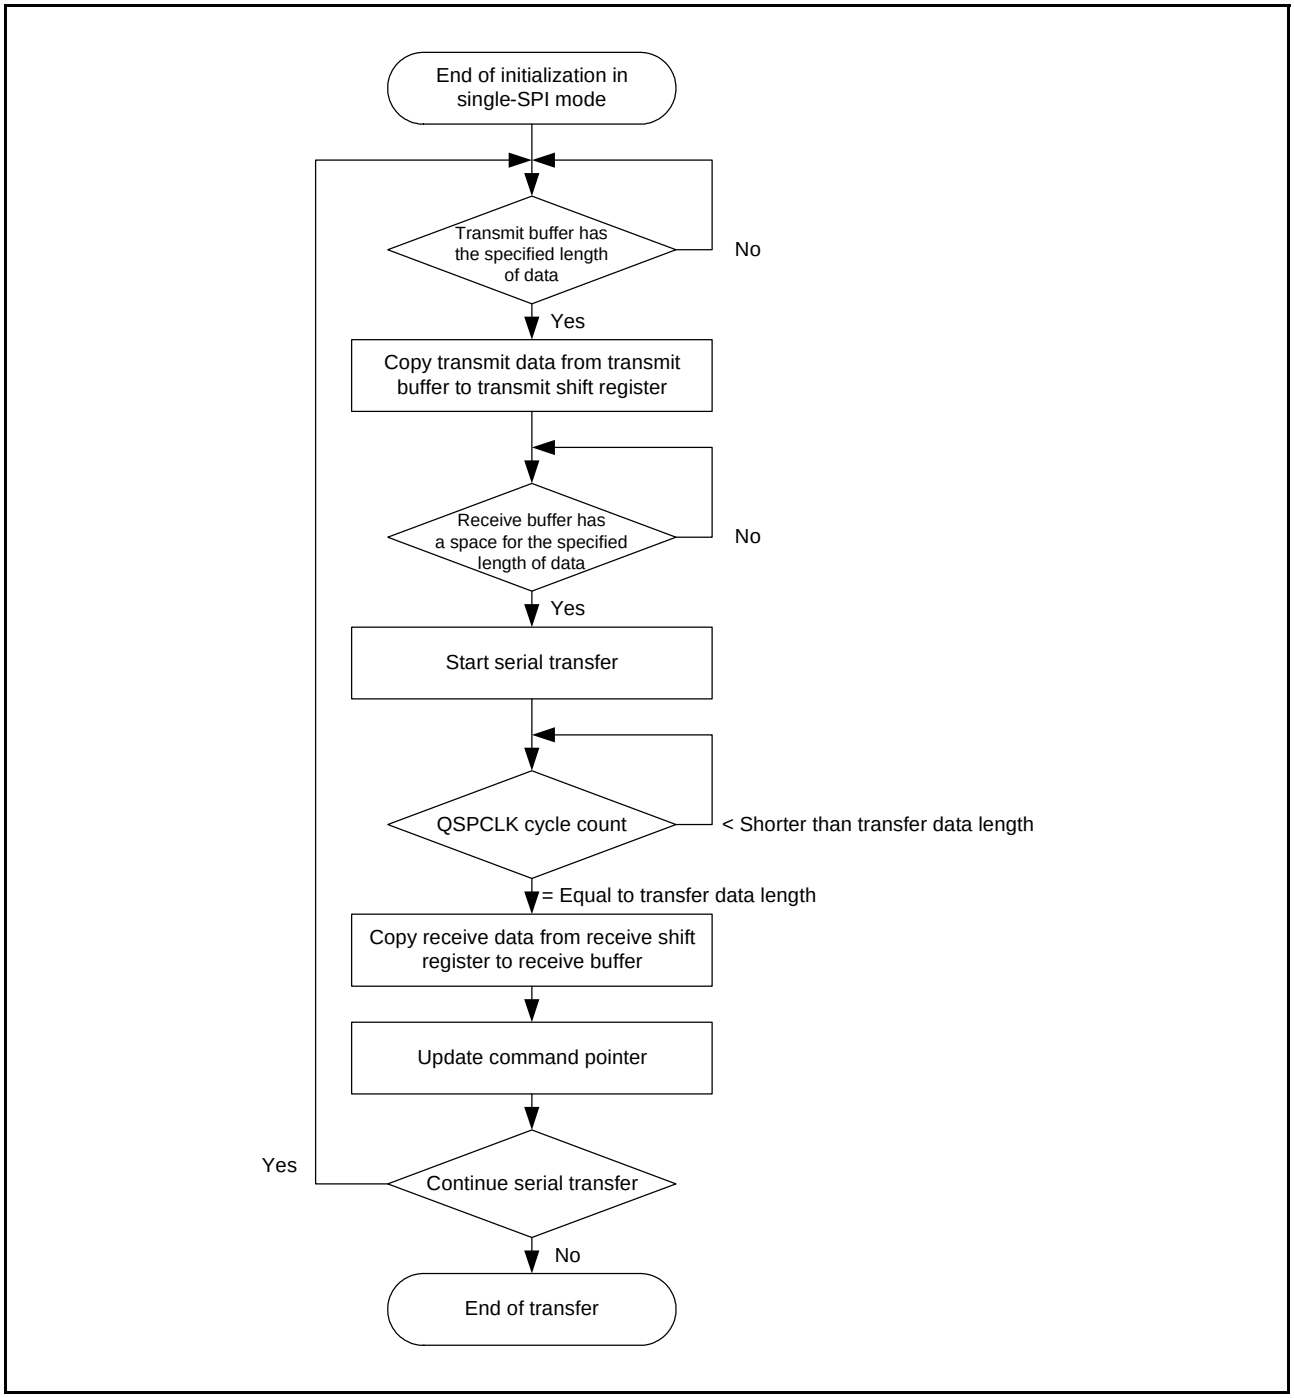

Figure 45.16 Transfer Operation Flowchart in Single-SPI Mode

(2) Dual-SPI/Quad-SPI Mode

(a) Starting Serial Transfer

In dual-/quad-SPI modes, the serial transfer start condition is different depending on the data transfer direction (transmission or reception).
In data transmission, the serial transfer start condition is that there is the specified length of data in the transmit buffer.
In data reception, the serial transfer start condition is that there is a space for the specified length of data in the receive buffer.

(b) Terminating Serial Transfer

Irrespective of data transmission or reception, this module terminates the serial transfer after transmitting an QSPCLK edge corresponding to the final sampling timing.
During idle cycles in dual-/quad-SPI modes, the I/O pins are controlled differently depending on whether it is after write or read operation. The I/O pins output either the last output data or the fixed level depending on the register setting after write operation, whereas the I/O pins are driven to the Hi-Z state after read operation. Figure 45.17 shows an example of the pin states after quad-SPI mode access is completed. The following describes operations (1) and (2) in the figure.

(1) During write operation, QIO0 to QIO3 serve as output pins. Thus, when QSSL is negated upon completion of write operation, QIO0 to QIO3 output different values depending on the value of SPPCR.MOIFE bit. The I/O pins output the level specified by the SPPCR.MOIFV bit when the SPPCR.MOIFE bit is 1, whereas the I/O pins output the last output data when SPPCR.MOIFE bit is 0.
(2) During read operation, QIO0 to QIO3 serve as input pins. Thus, when QSSL is negated upon completion of read operation, QIO0 to QIO3 are driven to Hi-Z state irrespective of the values of SPPCR.MOIFE and SPPCR.MOIFV bits. In dual-/quad-SPI read operations, receive operation is continued as long as the receive buffer has an enough space for the receive data. To terminate read operation, clear the SPCR.SPE bit to 0 after receiving the required length of data, or execute write operation for the last sequence to empty the transmit buffer.

For details on the pin control in dual-/quad-SPI modes, see section 45.3.2, Pin Control.

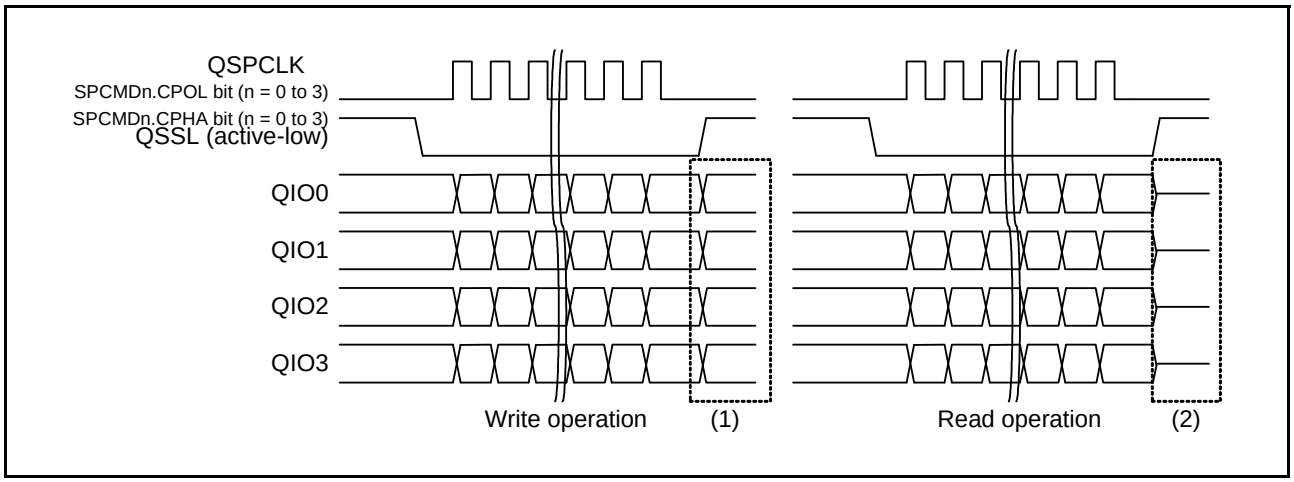

Figure 45.17 Example of Pin States after Quad-SPI Mode Transfer is Completed

(c) Sequence Control

As with the single-SPI mode, in dual-/quad-SPI modes, according to the sequence length that is assigned to the SPSCR register, this module makes up a sequence comprised of the SPCMDn register (n = 0 to 3) and the SPBMULn register (n = 0 to 3). For details on operation, refer to section 45.3.7 (1) (c), Sequence Control.
Dual-/quad-SPI modes only provide operation of a single direction, that is, either transmission or reception for serial transfer. Transmission or reception is set using the the SPCMDn.SPRW bit. One of the three operating modes including dual-SPI mode, quad-SPI mode, and single-SPI mode is set using the SPCMDn.SPIMOD[1:0] bits. Combining these bits allow switching single-SPI mode, dual-SPI mode transmission/reception, and quad-SPI mode transmission/reception to control sequence. Figure 45.18 shows an example of sequence configuration with transfer mode switching.
For sequence control, use either of the following methods.

(1) When a sequence is started by write operation and then read operation is performed, terminate the sequence upon completion of read operation. Do not perform write operation again after read operation.

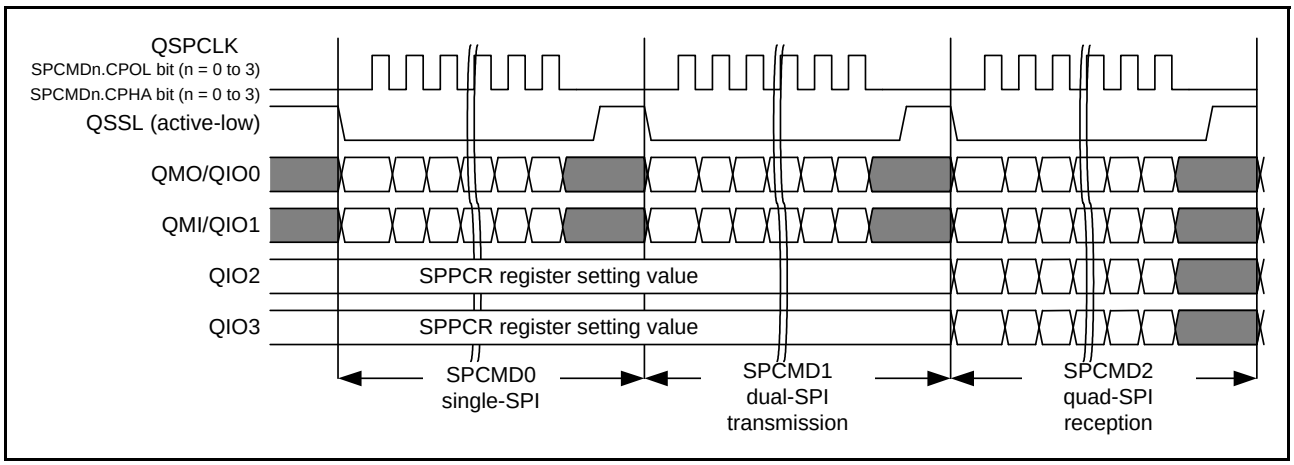

Figure 45.18 Example of Sequence Configuration with Transfer Mode Switching

(2) Note the following when configuring a sequence in dual-/quad-SPI modes. When all the commands configuring a sequence are dual-/quad-SPI read operations, the sequential operation is continued as long as the receive buffer has an enough space for the receive data. Figure 45.19 and Figure 45.20 show examples of sequence configuration with transfer mode switching.

To terminate read operation, there are the following two methods.

[Termination Method 1]

Clear the SPCR.SPE bit to 0 after receiving the required length of data. The receive command is continuously executed, allowing QSPCLK to be output and QSSL to be asserted. However, SPE is forcibly cleared to 0 when the receive buffer is read as the condition for terminating read operation. At that time, QSSL and QSPCLK are stopped asynchronously.

[Termination Method 2]

After receiving the required length of data, execute write operation in quad-SPI mode for the last sequence and ensure the transmit buffer is empty. Since the transmit command is not started unless transmit data is written, unnecessary QSPCLK is not output and QSSL is not asserted.

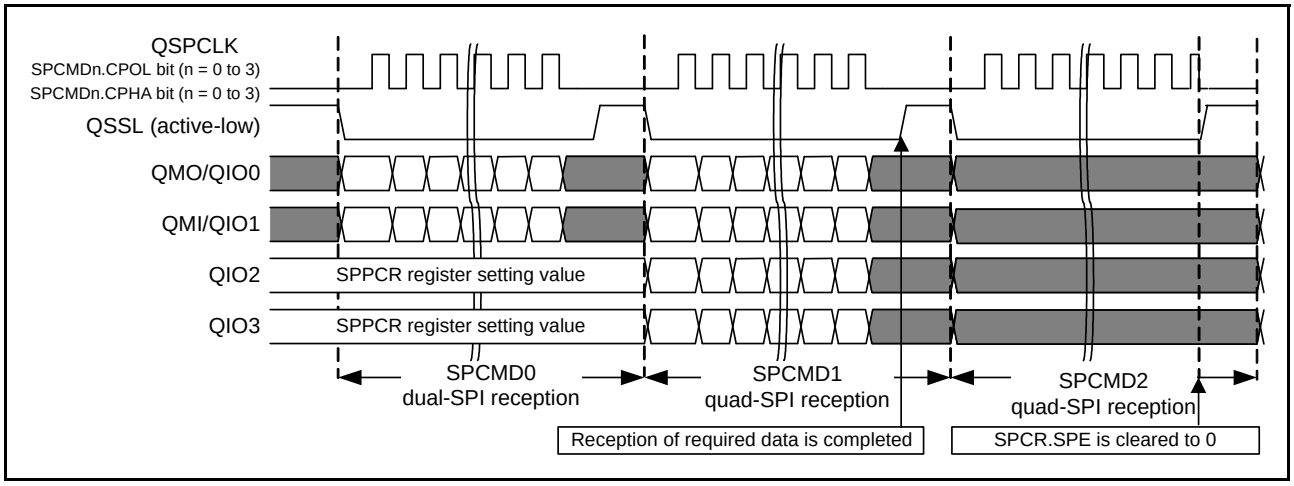

Figure 45.19 Example of Sequence Configuration with Transfer Mode Switching (Termination Method 1 When All the Commands Configuring a Sequence Are Dual-/Quad-SPI Read Operations)

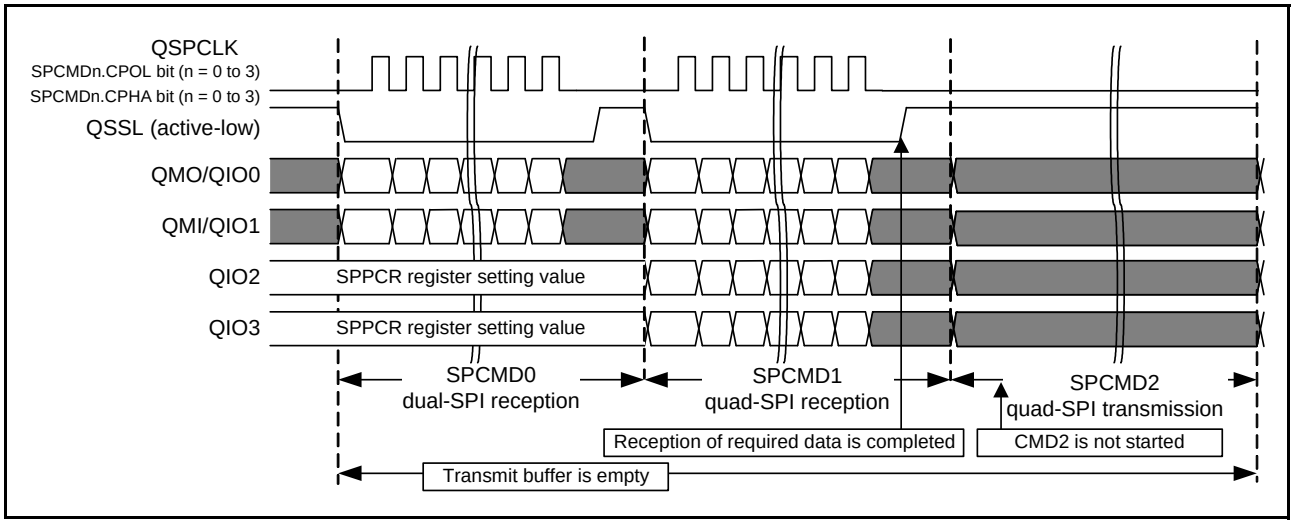

Figure 45.20 Example of Sequence Configuration with Transfer Mode Switching (Termination Method 2 When All the Commands Configuring a Sequence Are Dual-/Quad-SPI Read Operations)

(d) Burst Transfer

This module can execute burst transfer with the following two methods in dual/quad SPI modes.
One method uses the SPCMDn.SPB[3:0] bits (n = 0 to 3) and the SPBMULn register (n = 0 to 3). As with the single-SPI mode, setting the SPCMDn.SPB[3:0] bits to select 8, 16, or 32 bits and setting the SPBMULn register to select 1 through 4,294,967,296 allows the specified length of data to be continuously transferred for the specified times, where the length is specified by the SPCMDn.SPB[3:0] bits and the number of times is specified by the SPBMULn register. However, if the transmit buffer (SPTXB) becomes empty during transfer, or the receive buffer (SPRXB) has no longer a space enough to receive the specified length of data defined by the SPCMDn.SPB[3:0] bits, the clock is stopped until transfer is resumed. This method is effective to transfer a large amount of data in dual-/quad SPI modes. Figure 45.21 shows a burst transfer example in which the SPCMDn.SPB[3:0] bits are set to select 32 bits and the SPBMULn register to select four times thus specifying 128 bits as a total transfer data amount. The following describes operations (1) to (4) in the figure.

(1) First 32-bit data transfer
(2) Second 32-bit data transfer
(3) When the transmit buffer becomes empty or the receive buffer has no longer a space for 32 or more bits, the clock is stopped. Here, when QIO3 to QIO0 serve as output pins, QIO3 to QIO0 continue outputting the previous value. When QIO3 to QIO0 serve as input pins, the inputs to QIO3 to QIO0 depend on the output value of the device to communicate with. When data is written to the transmit buffer or an enough space is created in the receive buffer, the clock output is resumed to restart transfer.
(4) Third and fourth 32-bit data transfer

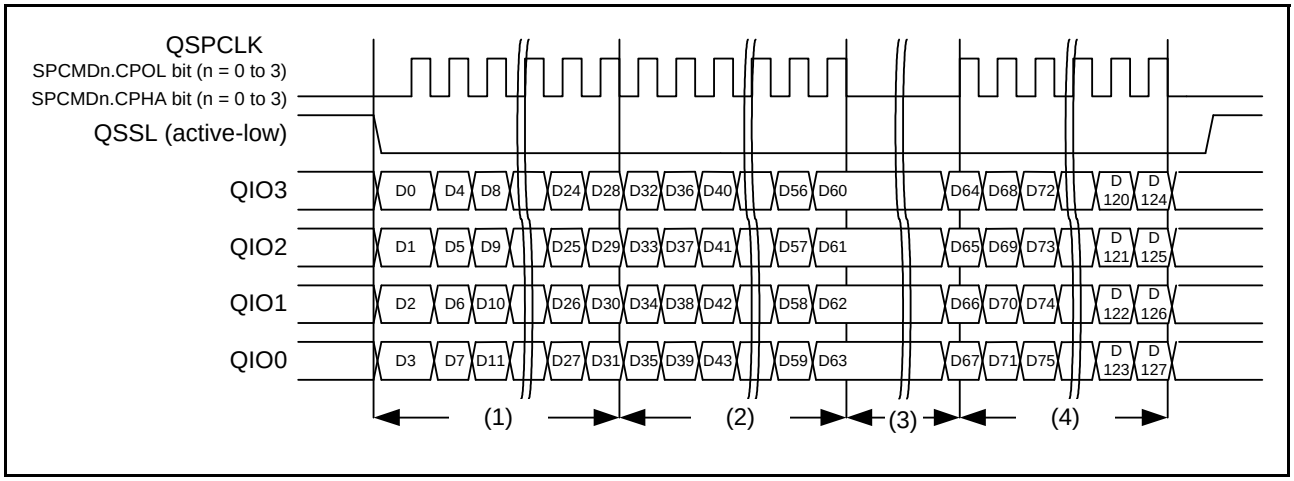

Figure 45.21 Burst Transfer Example in which Total Transfer Data Amount is 128 Bits (Quad-SPI Mode)

The other method uses the QSSL signal level keeping function as in single-SPI mode. Since this method allows switching the SPI transfer modes (single-/dual-/quad-SPI) during a transfer, it is particularly convenient when used with serial flash memory, where command data is written in single-SPI mode and data to be stored in memory is written in quad-SPI mode. Note, however, that at least one delay cycle should be inserted between transfers when switching the SPI transfer modes. Figure 45.22 shows a burst transfer example in which both single-SPI and quad-SPI modes are used. The following describes operations (1) to (6) in the figure.

(1) Clock delay period according to the SPCMD0 register setting. The setting should be made so that the delay period should be at least 1.5 QSPCLK cycles for the first transfer in the burst transfer.
(2) QSSL negation delay period according to the SPCMD0 register setting. Since the SPCMD0.SSLKP bit is set to 1, QSSL is not negated even after QSSL negation delay period is over. The QSSL negation delay period depends on the SPCMD0.SLNDEN bit setting. When the SPCMD0.SLNDEN bit is 1, the QSSL negation delay period is determined by the SSLND register setting, and the delay period is 0 QSPCLK cycle when the SPCMD0.SLNDEN bit is 0.
(3) Next-access delay period according to the SPCMD0 register setting. Since the SPCMD0.SSLKP bit is set to 1, QSSL is not negated even during next-access delay period. The next-access delay period depends on the SPCMD0.SPNDEN bit setting. When the SPCMD0.SPNDEN bit is 1, the next-access delay period is determined by the SPND register setting, and the delay period is 0 QSPCLK cycle when the SPCMD0.SPNDEN bit is 0. Up to this period, the data pin is driven according to the SPCMD0 register setting.
(4) Clock delay period according to the SPCMD1 register setting. The clock delay period depends on the the SPCMD1.SCKDEN bit setting. When the SPCMD1.SCKDEN bit is 1, the clock delay period is determined by the SPCKD register setting, and the delay period is 0 QSPCLK cycle when the SPCMD1.SCKDEN bit is 0.
(5) QSSL negation delay period according to the SPCMD1 register setting. The setting should be made so that the delay period should be at least one QSPCLK cycle for the last transfer in the burst transfer. Since the SPCMD1.SSLKP bit is set to 0, QSSL is negated after QSSL negation delay period is over.
(6) Next-access delay period according to the SPCMD1 register setting. The setting should be made so that the delay period should be at least one QSPCLK cycle for the last transfer in the burst transfer. Set the SPCMD1.SSLKP bit to 0 to negate QSSL.

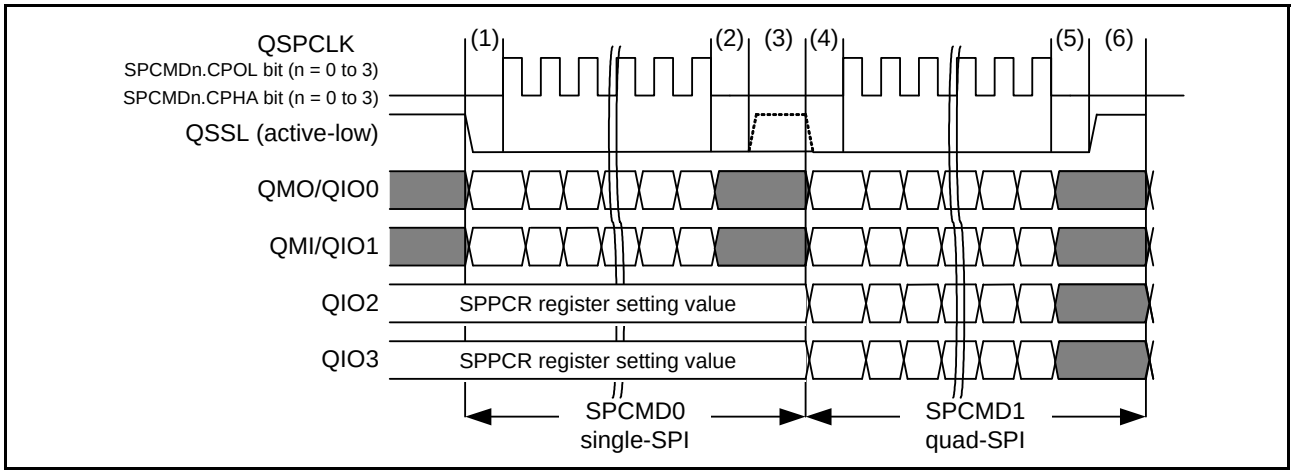

Figure 45.22 Burst Transfer Example in which QSSL Signal Level Keeping Function is Used (Single- and Quad-SPI Modes Used)

Note the following when specifying a burst transfer using this method.
Periods (2) to (4) should be inserted without fail when changing the clock polarity through command update.

(e) Initialization Flowchart

Figure 45.23 is a flowchart illustrating an example of initialization in SPI operation when this module is used in dual-/quad-SPI mode. For a description of how to set up the interrupt controller, DTC, or DMAC, see the descriptions given in the corresponding sections.

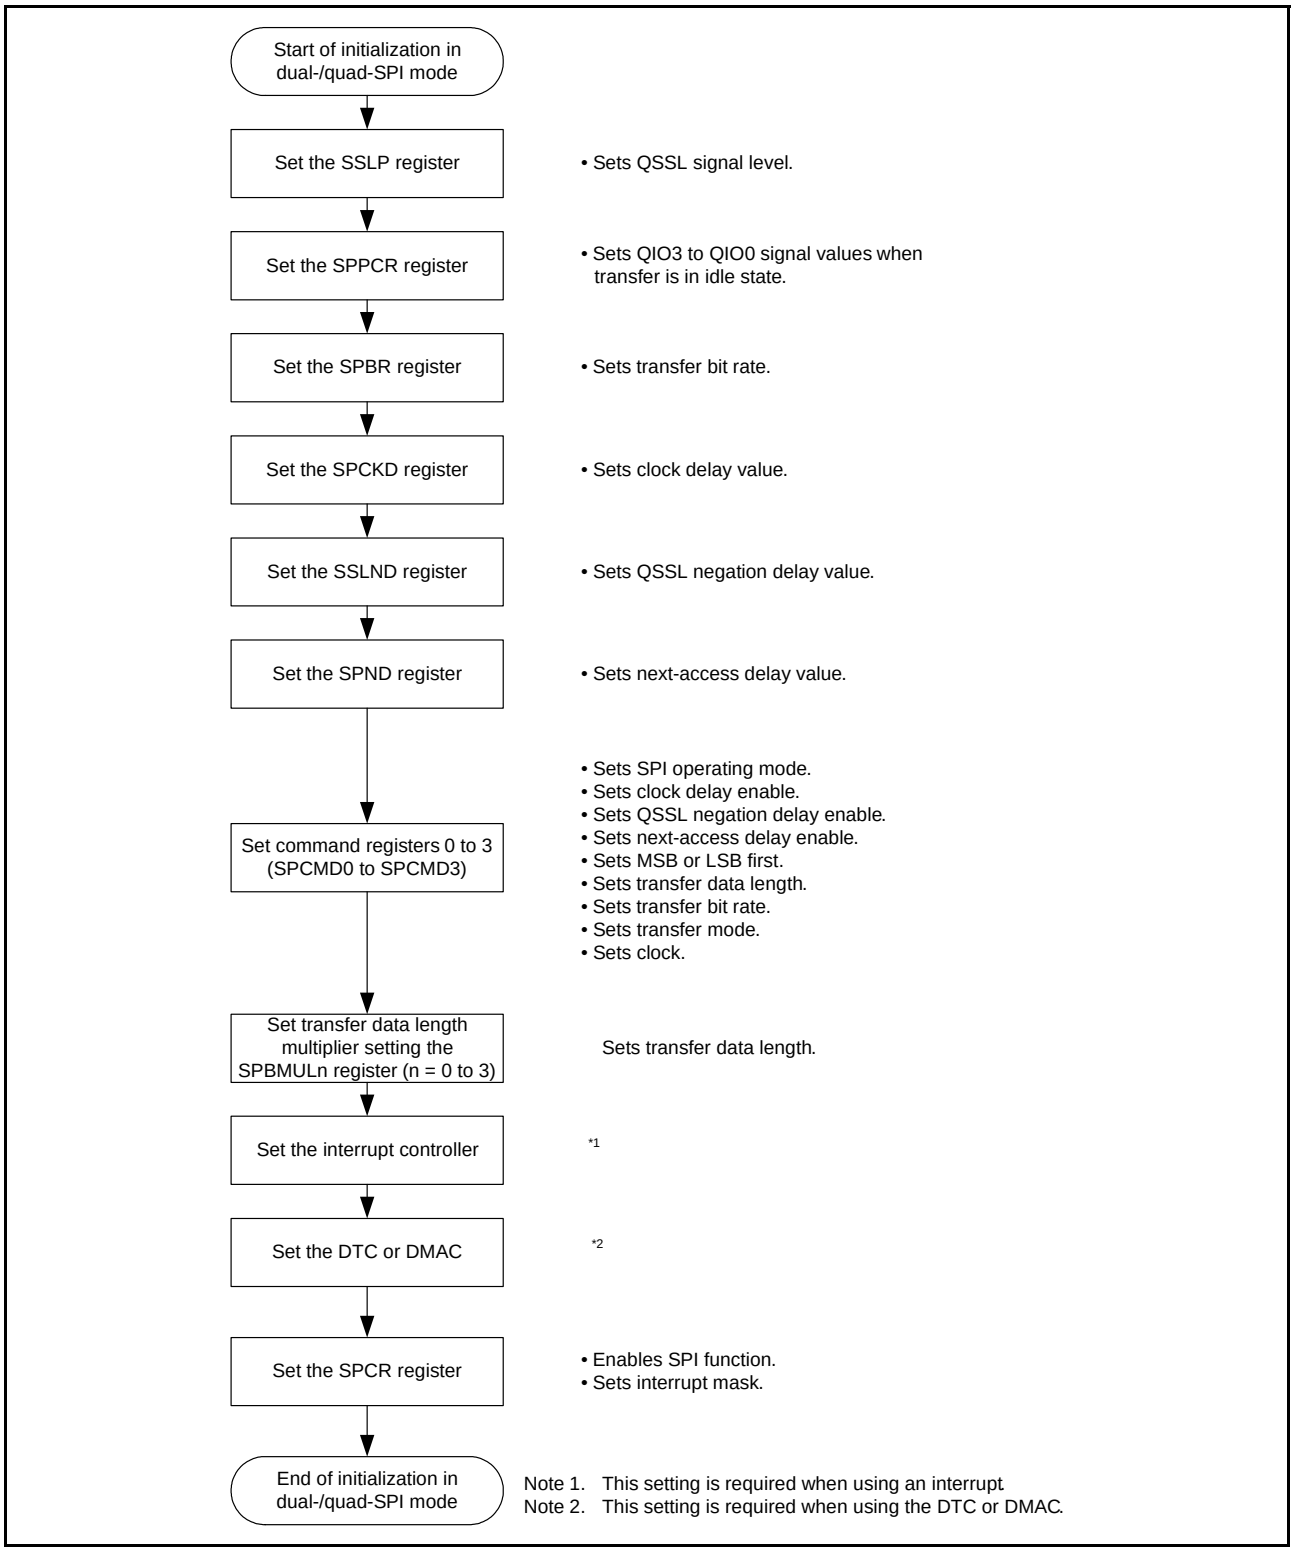

Figure 45.23 Example of Initialization Flowchart in Dual-/Quad-SPI Mode

(f) Transfer Operation Flowchart

Figure 45.24 shows an operation flowchart (the sequence is started by write operation) and Figure 45.25 shows an operation flowchart (the sequence is configured only with dual-/quad-read operation) in dual-/quad-SPI mode.

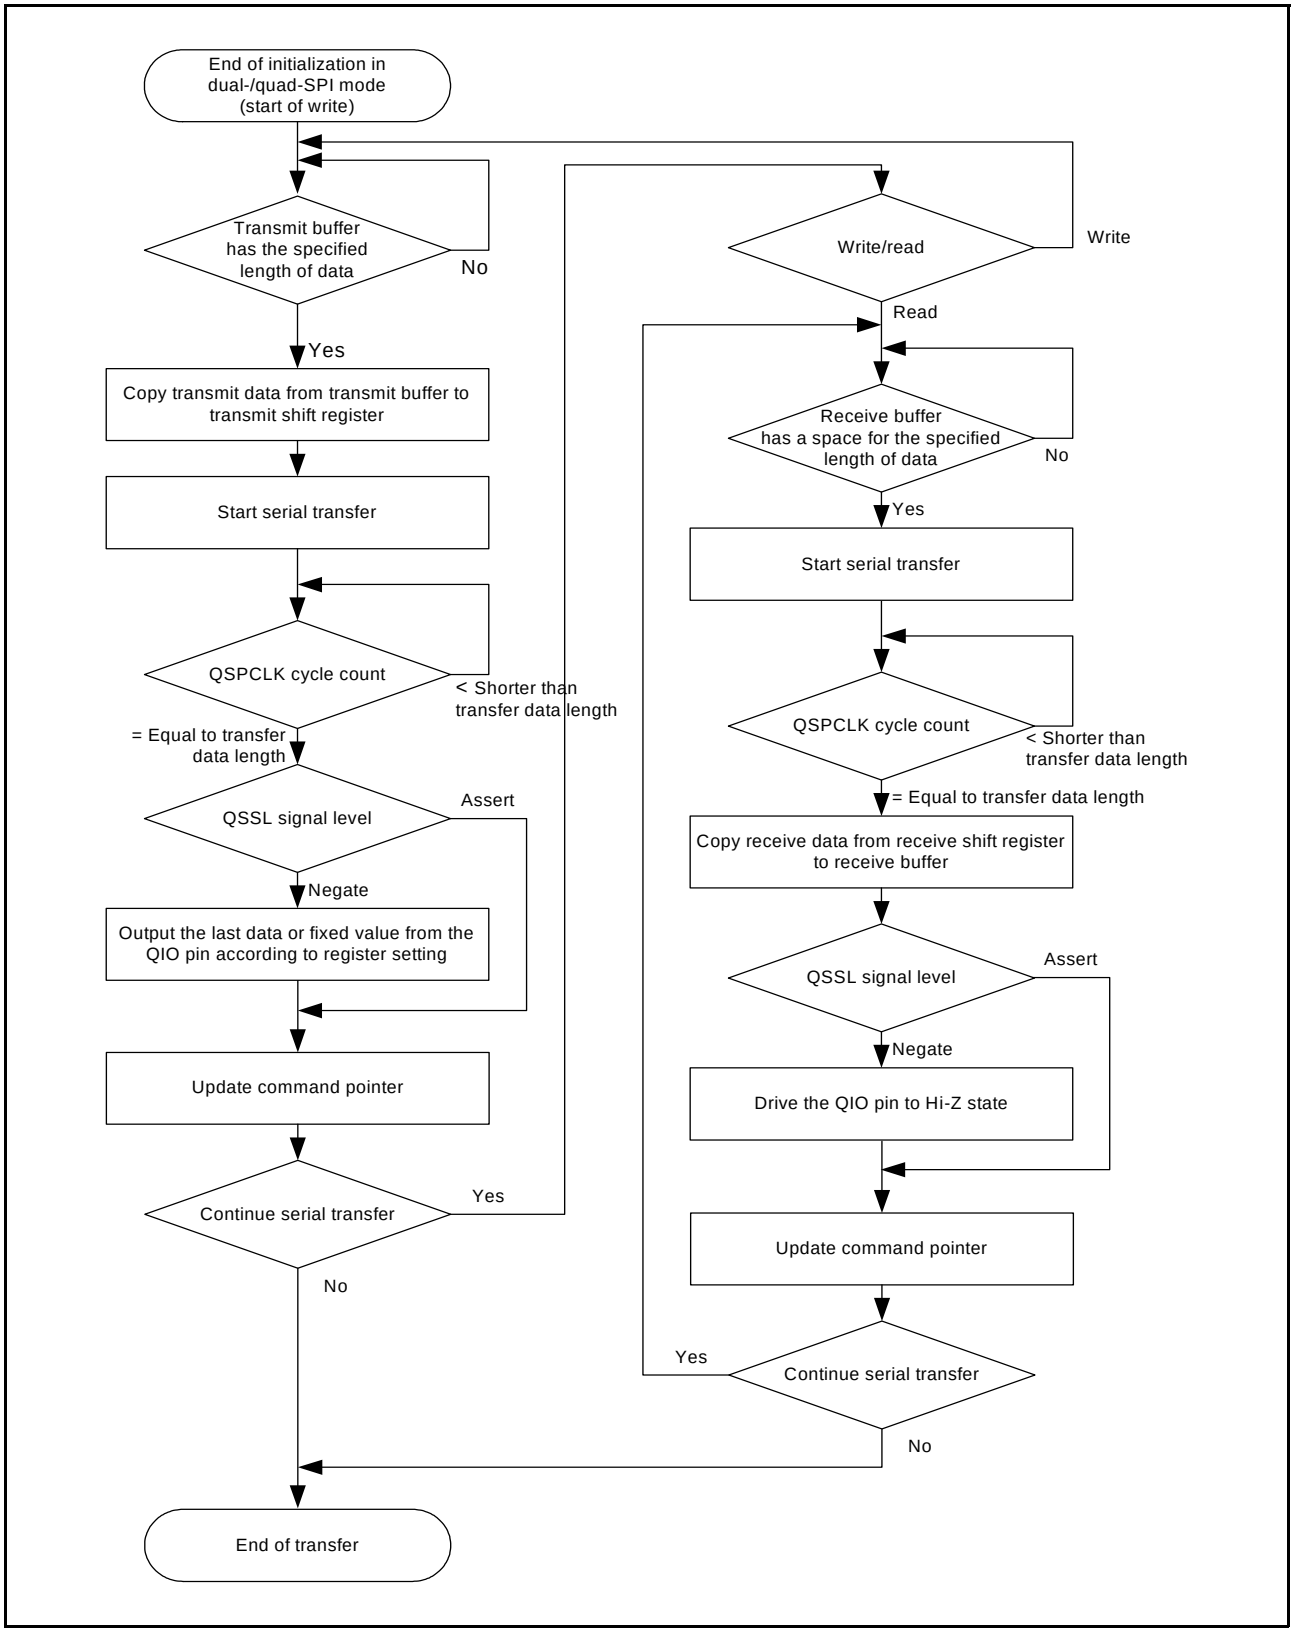

Figure 45.24 Transfer Operation Flowchart in Dual-/Quad-SPI Mode (Sequence is Started by Write Operation)

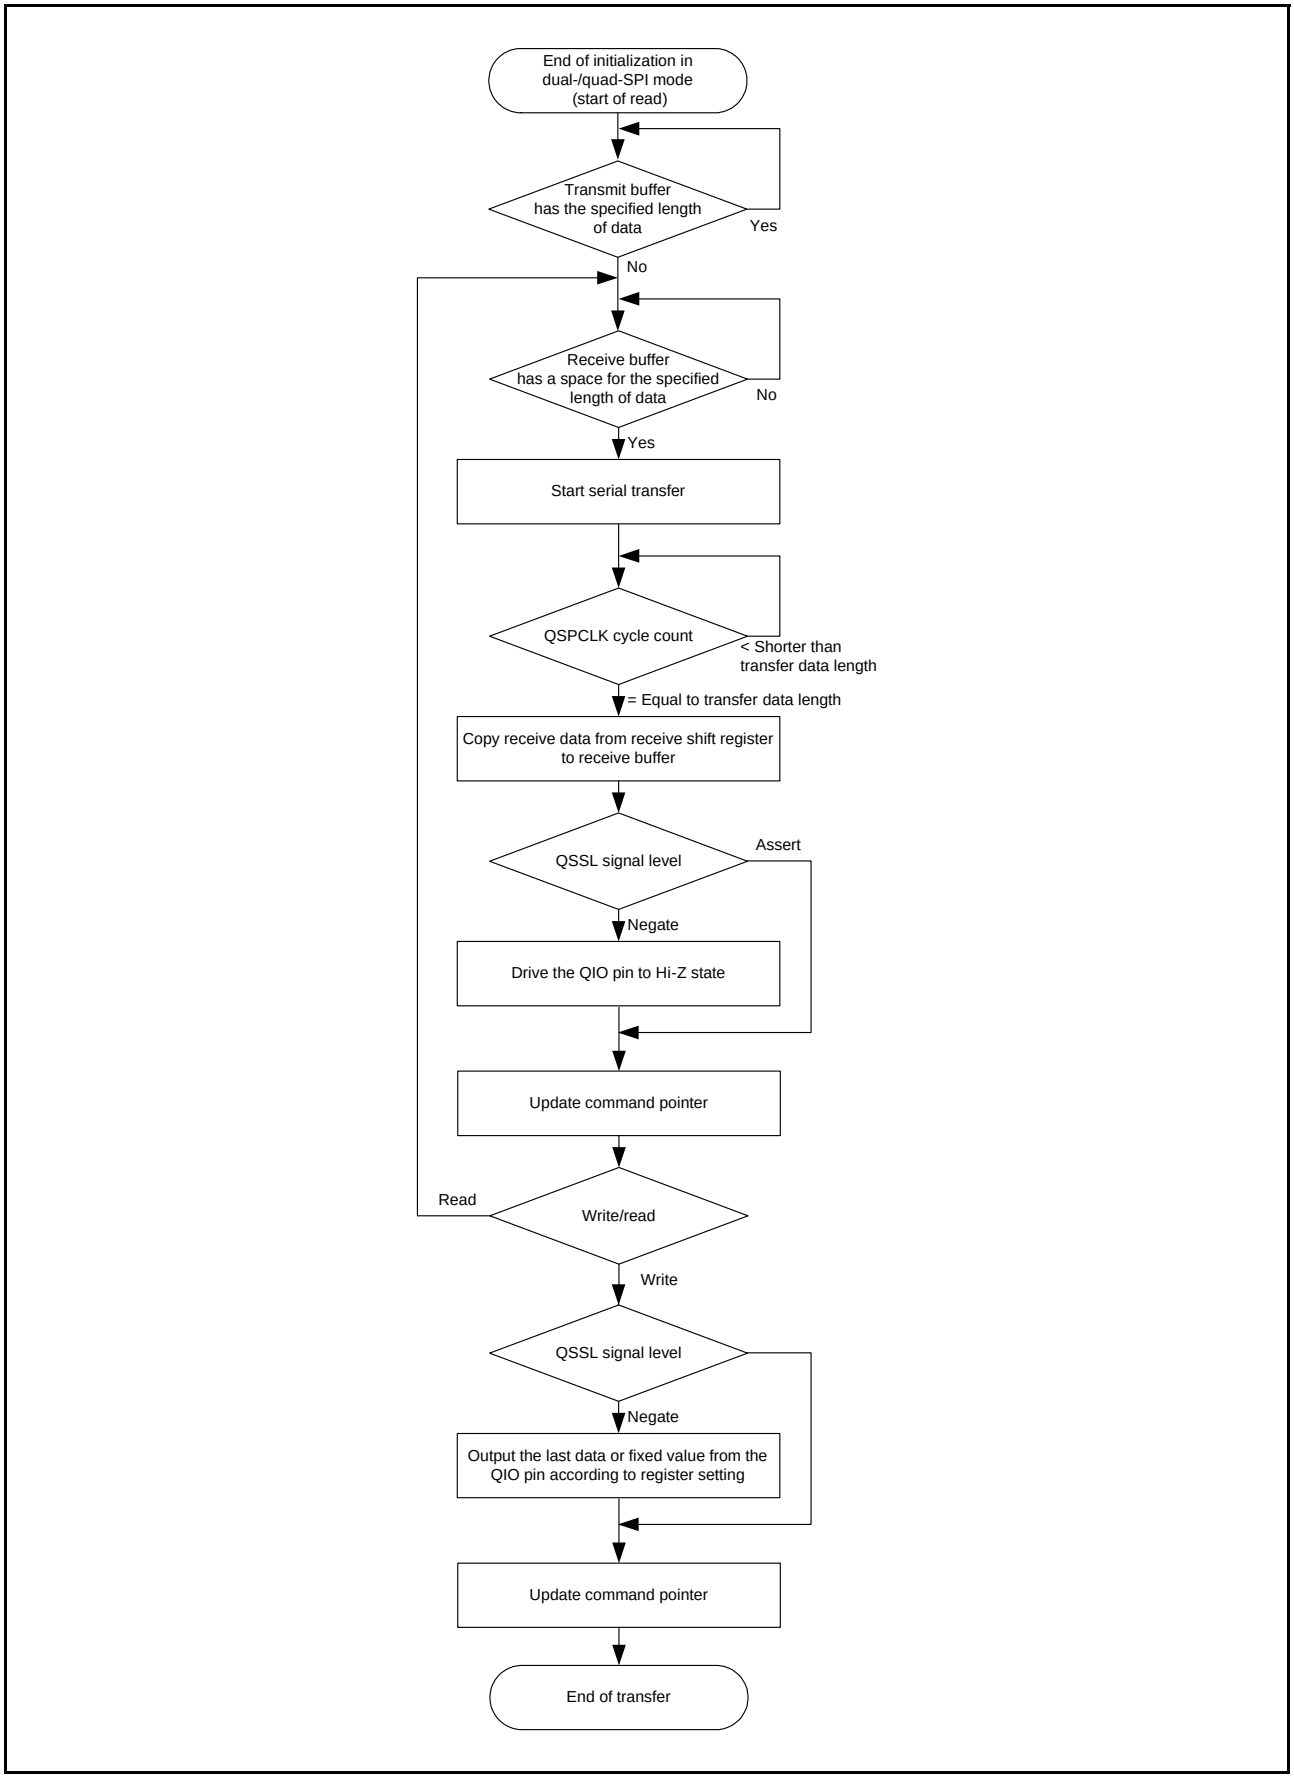

Figure 45.25 Transfer Operation Flowchart in Dual-/Quad-SPI Mode (Sequence is Configured only with Dual-/Quad Read Operations)

45.3.8 Interrupt Sources

This module has interrupt sources of receive buffer full, transmit buffer empty and QSSL negation. In addition, the DTC or DMAC can be activated by the receive buffer full or transmit buffer empty interrupt for data transfer.
Table 45.10 shows the interrupt sources. When any of the interrupt conditions in Table 45.10 is met, an interrupt is generated. The interrupt sources should be cleared with data transfer by the CPU, DTC, or DMAC.

Table 45.10 Interrupt Sources

Name	Interrupt Source	Interrupt Condition
SPRI	Receive buffer full	SPSR.SPRFF flag =1 and SPCR.SPRIE bit = 1
SPTI	Transmit buffer empty	SPSR.SPTEF flag = 1 and SPCR.SPTIE bit = 1
QSPSSLI	QSSL negation	SPSR.SPSSLF flag = 1 and SPCR.SPSSLIE bit = 1

If the conditions for a transmit buffer empty interrupt (SPTI) and receive buffer full interrupt (SPRI) are satisfied while the ICU.IRn.IR flag is 1, the interrupt request is not output to the ICU, but is retained internally. When the ICU.IRn.IR flag is cleared to 0, the retained interrupt request is output to the ICU.
For the ICU.IRn.IR flag, refer to section 15, Interrupt Controller (ICUA).
If the interrupt source (transmit buffer empty or receive buffer full) for the transfer buffer empty interrupt or receive buffer full interrupt is not cleared upon completion of transfer, the interrupt request generation conditions are as follows.

- DTC or DMAC transfer: When the interrupt condition is satisfied after the completion of access with the last DTC or DMAC transfer.
- CPU interrupt: When the interrupt condition is satisfied after the status flag has been cleared by register access.

Note that while the DTC or DMAC is in use, access to the flags by register reading or writing is prohibited.

45.3.9 Loopback Mode

This module provides loopback mode for testing. Writing 1 to the SPPCR.SPLP bit enables loopback mode. In loopback mode, this module connects the outputs from the transmit shift register to the inputs to the receive shift register instead.
Figure 45.26 shows a schematic internal connection in loopback mode.

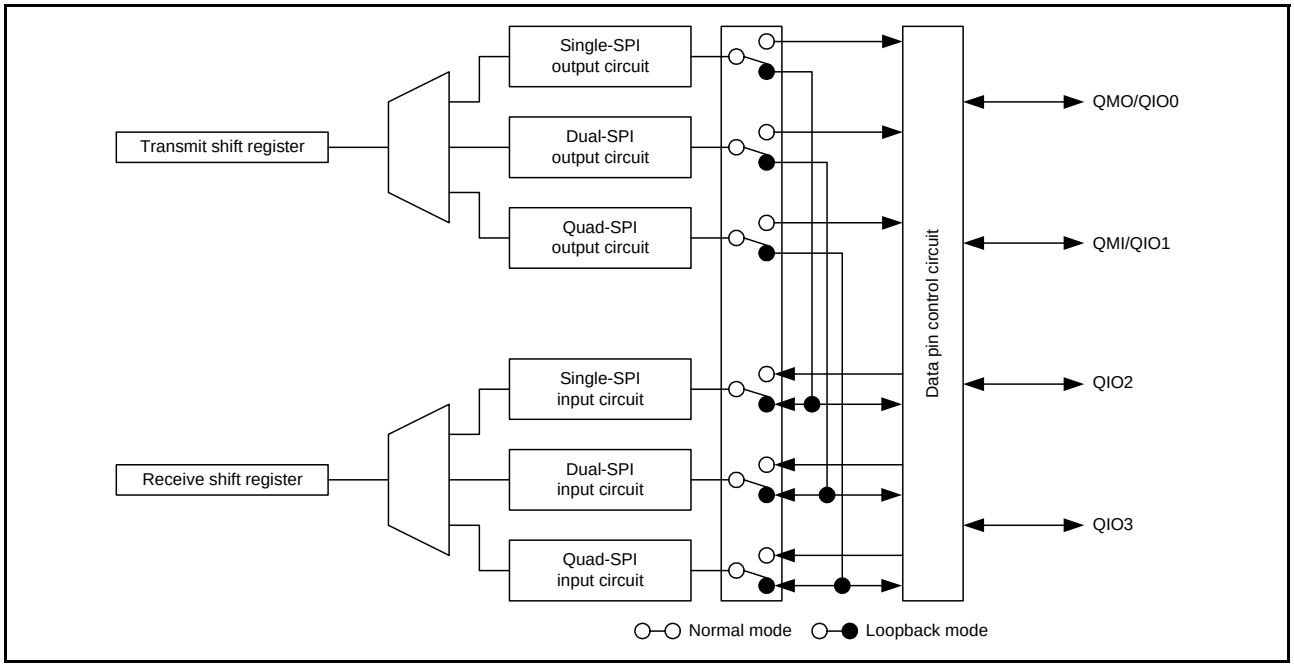

Figure 45.26 Schematic Internal Connection in Loopback Mode

45.4 Usage Notes

45.4.1 Notes on Starting Transfer

When the ICU.IRn.IR flag for the DTC or DMAC is 1 at the time transfer is to start, follow the procedure below to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1).

(1) Confirm that transfer has stopped (i.e. that the SPCR.SPE bit is 0).
(2) Clear the relevant interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) to 0.
(3) Read the relevant interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) and confirm that its value is 0.
(4) Clear the ICU.IRn.IR flag to 0.

45.4.2 Module Stop Function Setting

Operation of the QSPI can be disabled or enabled by module stop control register C (MSTPCRC). The initial setting is for operation of the QSPI to be stopped. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

45.4.3 Notes on Using the Serial Flash Memory

When using the flash memory in dual- or quad-SPI operating mode, set the SPCMDn.CPOL and CPHA bits (n = 0 to 3) to 1 and select SPI mode 3. SPI mode 0 to 2 cannot be used. In addition, set the SPCMDn.SPNDEN, SLNDEN, and SCKDEN bits to 1 to secure delay period.

46. CRC Calculator (CRC)

The CRC (Cyclic Redundancy Check) calculator generates CRC codes.

46.1 Overview

Table 46.1 lists the specifications of the CRC calculator, and Figure 46.1 shows a block diagram of the CRC calculator.

Table 46.1 CRC Specifications

Item	Description
Data for CRC calculation*1	CRC codes are generated for any desired data in 8n-bit units (where n is a whole number)
CRC processor unit	8-bit parallel processing
CRC generating polynomial	One of three generating polynomials is selectable • 8-bit CRC $X^8 + X^2 + X + 1$ • 16-bit CRC $X^{16} + X^{15} + X^2 + 1$ $X^{16} + X^{12} + X^5 + 1$
CRC calculation switching	The bit order of CRC calculation results can be switched for LSB first or MSB first communication
Low power consumption function	Module stop state can be set.

Note 1. The circuit does not have a function to divide data for calculation into CRC calculation units. Write data in 8-bit units.

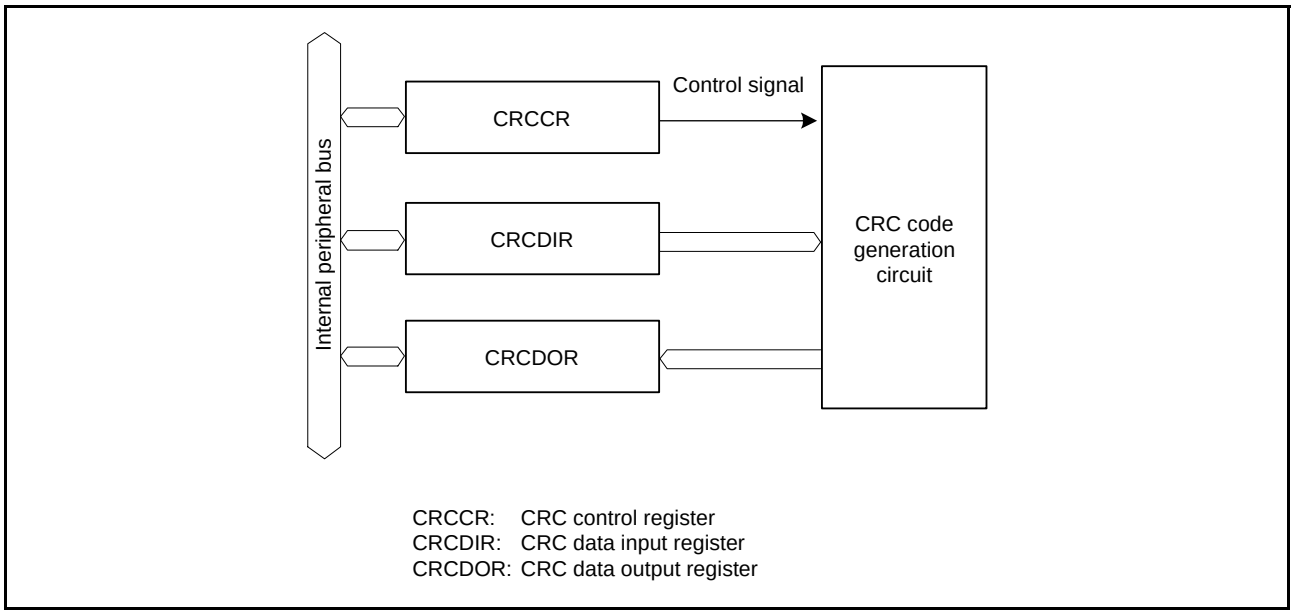

Figure 46.1 CRC Block Diagram

46.2 Register Descriptions

46.2.1 CRC Control Register (CRCCR)

Address(es): 0008 8280h

	b7	b6	b5	b4	b3	b2	b1	b0
	DORCLR	—	—	—	—	LMS	GPS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	GPS[1:0]	CRC Generating Polynomial Switching	b1 b0 0 0: No calculation is executed. 0 1: 8-bit CRC ($X^8 + X^2 + X + 1$) 1 0: 16-bit CRC ($X^{16} + X^{15} + X^2 + 1$) 1 1: 16-bit CRC ($X^{16} + X^{12} + X^5 + 1$)	R/W
b2	LMS	CRC Calculation Switching	0: Generates CRC for LSB first communication. 1: Generates CRC for MSB first communication.	R/W
b6 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	DORCLR	CRCDOR Register Clear	1: Clears the CRCDOR register. This bit is read as 0.	R/W*1

Note 1. Only 1 can be written.

LMS Bit (CRC Calculation Switching)

This bit selects the bit order of generated 16-bit CRC code. Transmit the lower-order byte (b7 to b0) of the CRC code first for LSB first communication and the higher-order byte (b15 to b8) first for MSB first communication. For details on the transmission and reception of CRC codes, refer to section 46.3, Operation.

DORCLR Bit (CRCDOR Register Clear)

Write 1 to this bit so that the CRCDOR register is set to 0000h.
This bit is read as 0. Only 1 can be written.

46.2.2 CRC Data Input Register (CRCDIR)

Address(es): 0008 8281h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

CRCDIR is a readable and writable register. Write data for CRC calculation to this register.

46.2.3 CRC Data Output Register (CRCDOR)

Address(es): 0008 8282h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CRCDOR is a readable and writable register.
Since its initial value is 0000h, rewrite the CRCDOR register to perform calculation using a value other than the initial value.
Data written to the CRCDIR register is CRC calculated and the result is stored in the CRCDOR register. If the CRC code is calculated following the transferred data and the result is 0000h, there is no CRC error.
When an 8-bit CRC ($X^8 + X^2 + X + 1$ polynomial) is in use, the valid CRC code is obtained in the low-order byte (b7 to b0). The high-order byte (b15 to b8) is not updated.

46.3 Operation

The CRC calculator generates CRC codes for use in LSB first or MSB first transfer.
The following shows examples of generating the CRC code for input data (F0h) using the 16-bit CRC generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC data output register (CRCDOR) is cleared before CRC calculation.
When an 8-bit CRC (with the polynomial $X^8 + X^2 + X + 1$) is in use, the valid bits of the CRC code are obtained in the lower-order byte of the CRCDOR register.

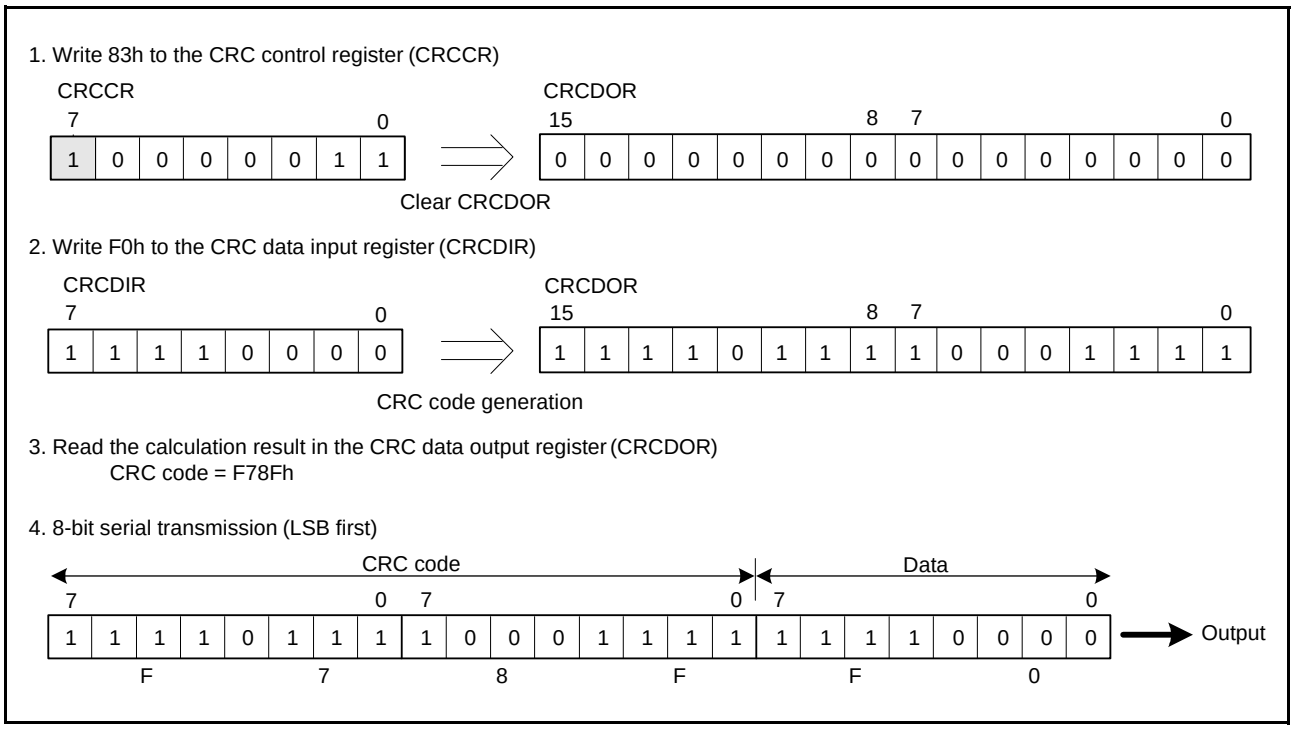

Figure 46.2 LSB First Data Transmission

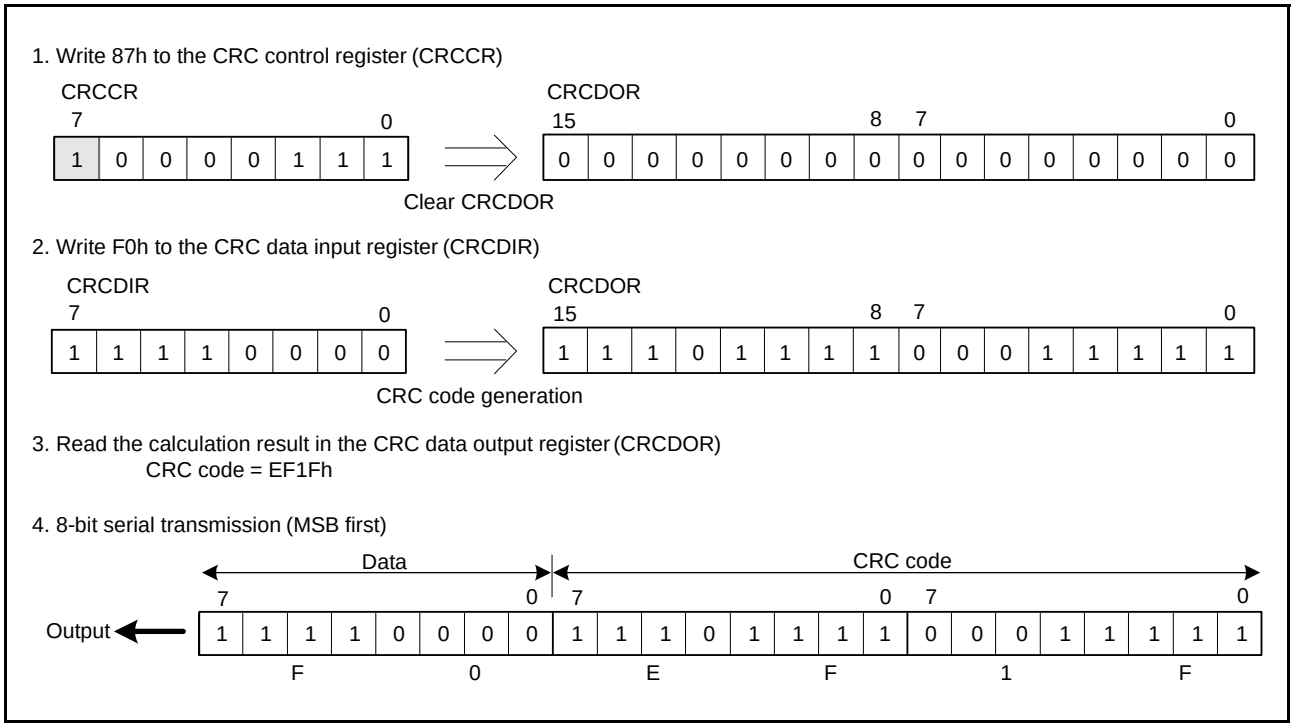

Figure 46.3 MSB First Data Transmission

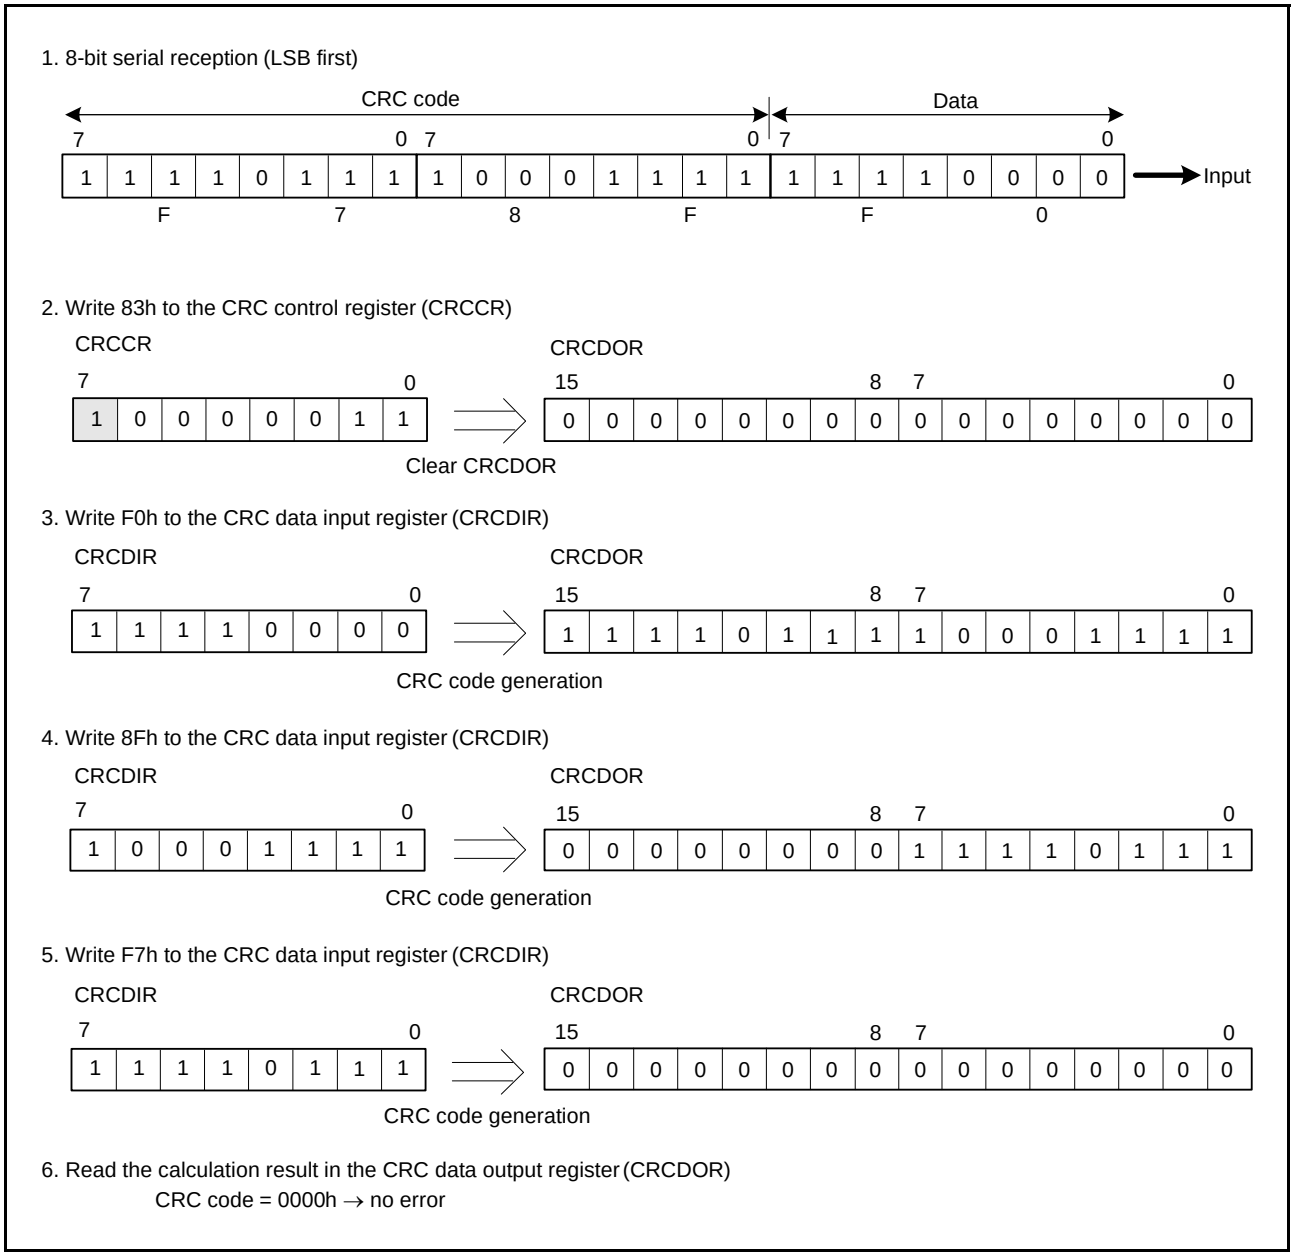

Figure 46.4 LSB First Data Reception

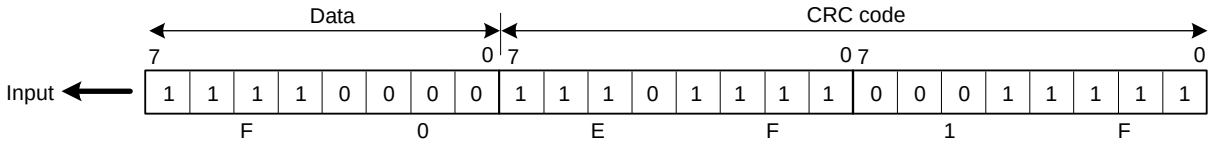
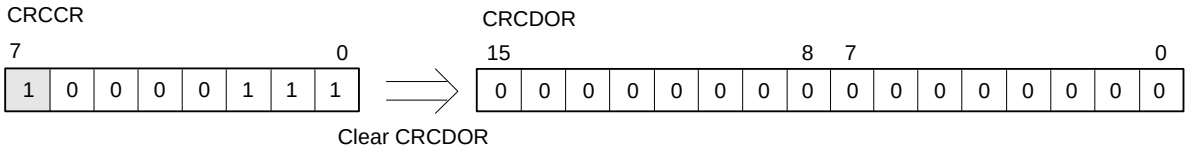
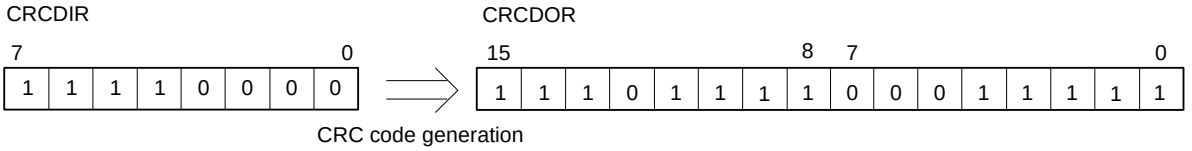
1. 8-bit serial reception (MSB first)



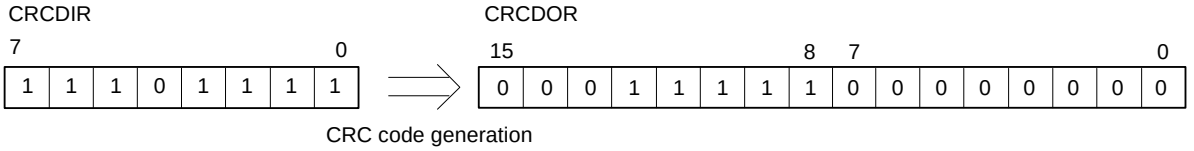
2. Write 87h to the CRC control register (CRCCR)



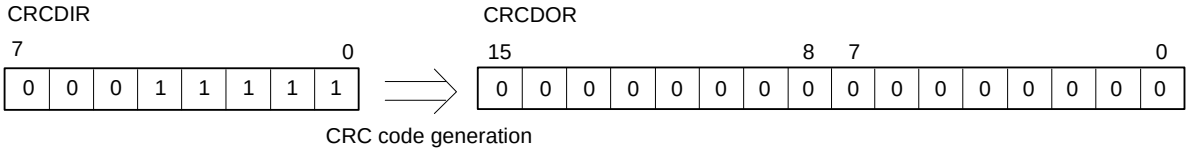
3. Write F0h to the CRC data input register (CRCDIR)



4. Write EFh to the CRC data input register (CRCDIR)



5. Write 1Fh to the CRC data input register (CRCDIR)



6. Read the calculation result in the CRC data output register (CRCDOR)

CRC code = 0000h → no error

Figure 46.5 MSB First Data Reception

46.4 Usage Notes

46.4.1 Module Stop Function Setting

Operation of the CRC calculator can be disabled or enabled using the module stop control register B (MSTPCRB). After a reset, the CRC is in the module stop state. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

46.4.2 Note on Transmission

Note that the sequence of transmission for the CRC code differs according to whether transmission is LSB first or MSB first.

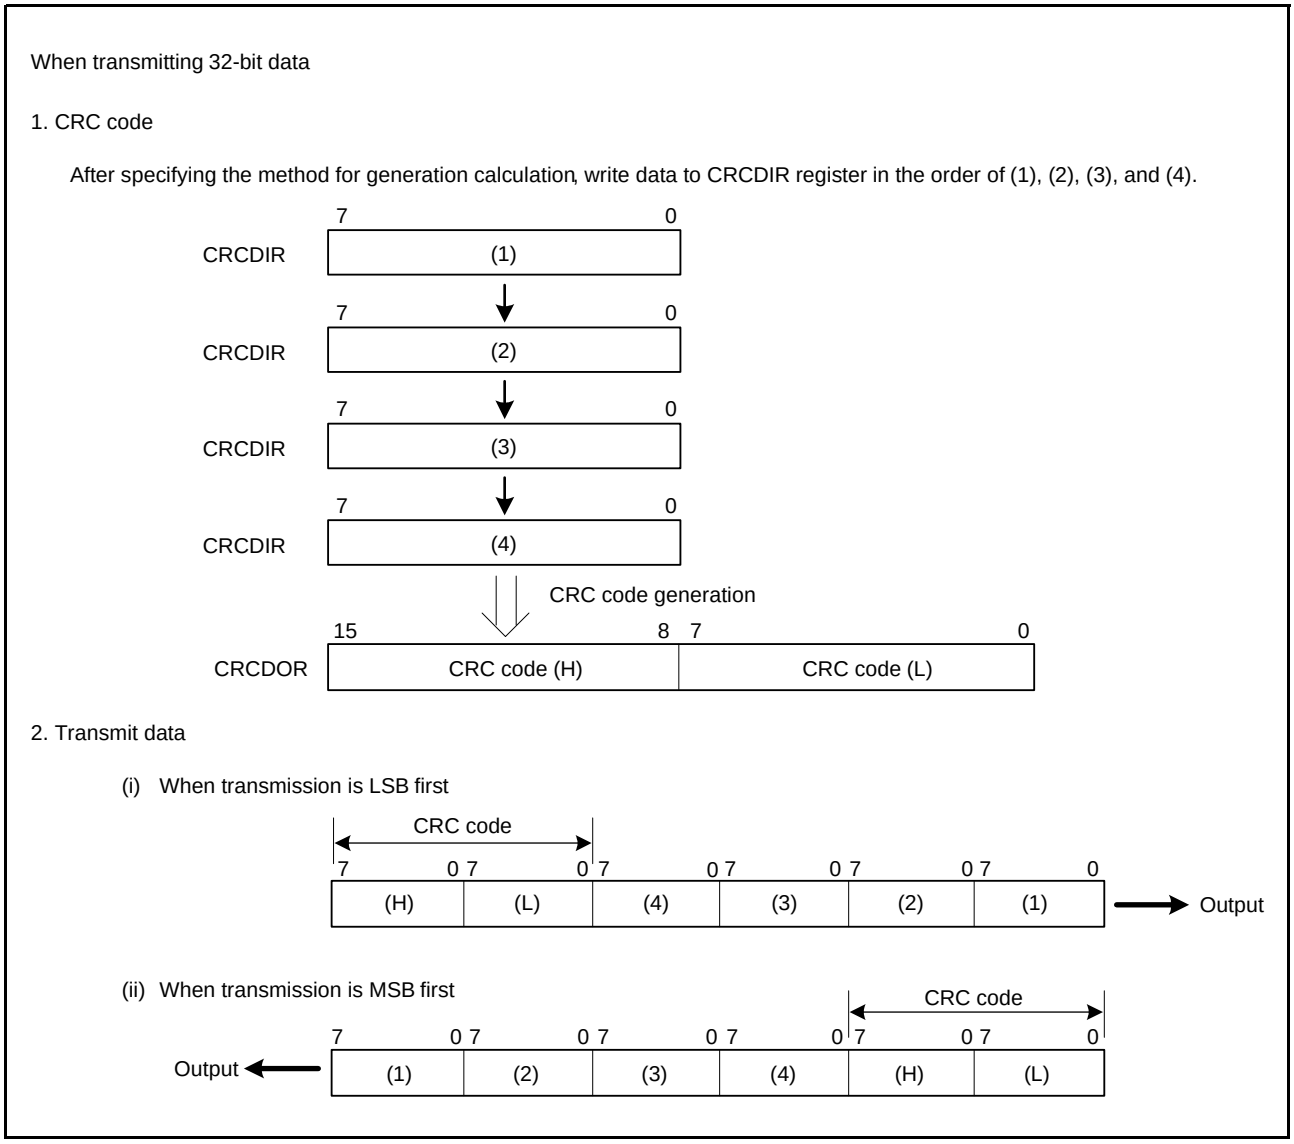


Figure 46.6 LSB First and MSB First Data Transmission

47. Serial Sound Interface (SSI)

This MCU integrates two channels of the serial sound interface (SSI) compliant with the I^{2}S bus specification. The SSI supports I^{2}S data format and MSB-first and left-justified/right-justified formats, so it can be used to send or receive audio data with various devices.

47.1 Overview

Table 47.1 SSI Specifications

Item	Specifications
Number of channels	Two channels (SSI0, SSI1)
Operating mode	Non-compressed mode
Transmission formats	• I^{2}S format supported • MSB-first supported Left-justified/right-justified formats selectable
Function	• Serves as both a transmitter and a receiver Channel 0 supports full-duplex communications. • Capable of various audio formats • SSISCKn (serial bit clock) can be selected from among 16, 32, 48, and 64 fs (fs: Sampling rate) (n = 0, 1) • The master clock (MCLK) is input from the master clock pin for audio (AUDIO_MCLK) (1 to 50 MHz) • Includes 8-stage FIFO buffers in transmitter and receiver • Capable of selecting whether to stop word select (SSIWSn) or not when data transmission is stopped
Interrupt sources	Three sources • Communication error Transmit underflow, transmit overflow, receive underflow, receive overflow, and idle • Receive data full • Transmit data empty
Low power consumption function	Module stop state can be set.

Figure 47.1 shows a block diagram of SSI (SSI0) and Figure 47.2 shows a block diagram of SSI (SSI1).

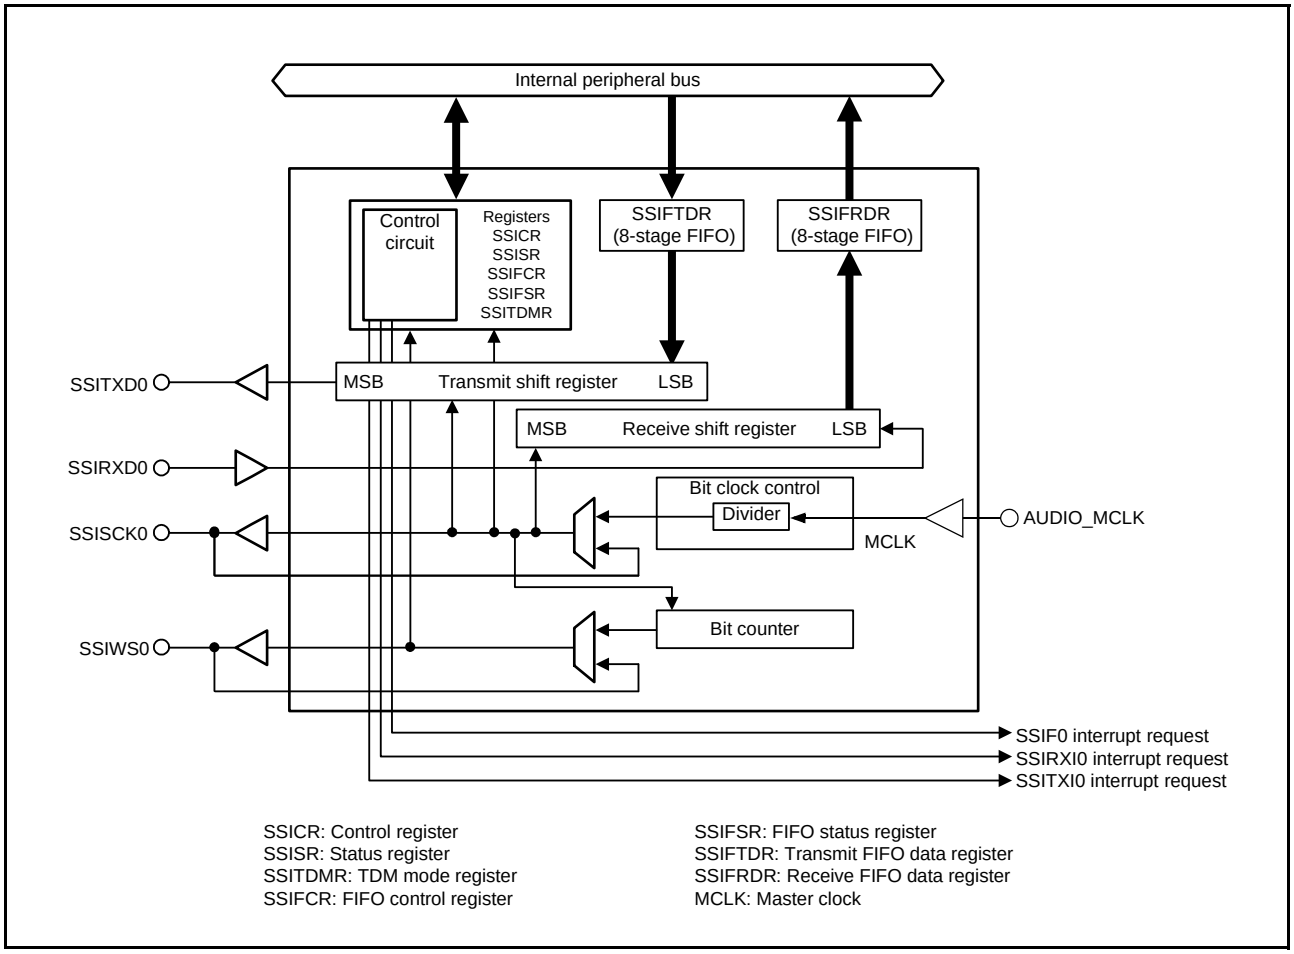

Figure 47.1 Block Diagram of SSI (SSI0)

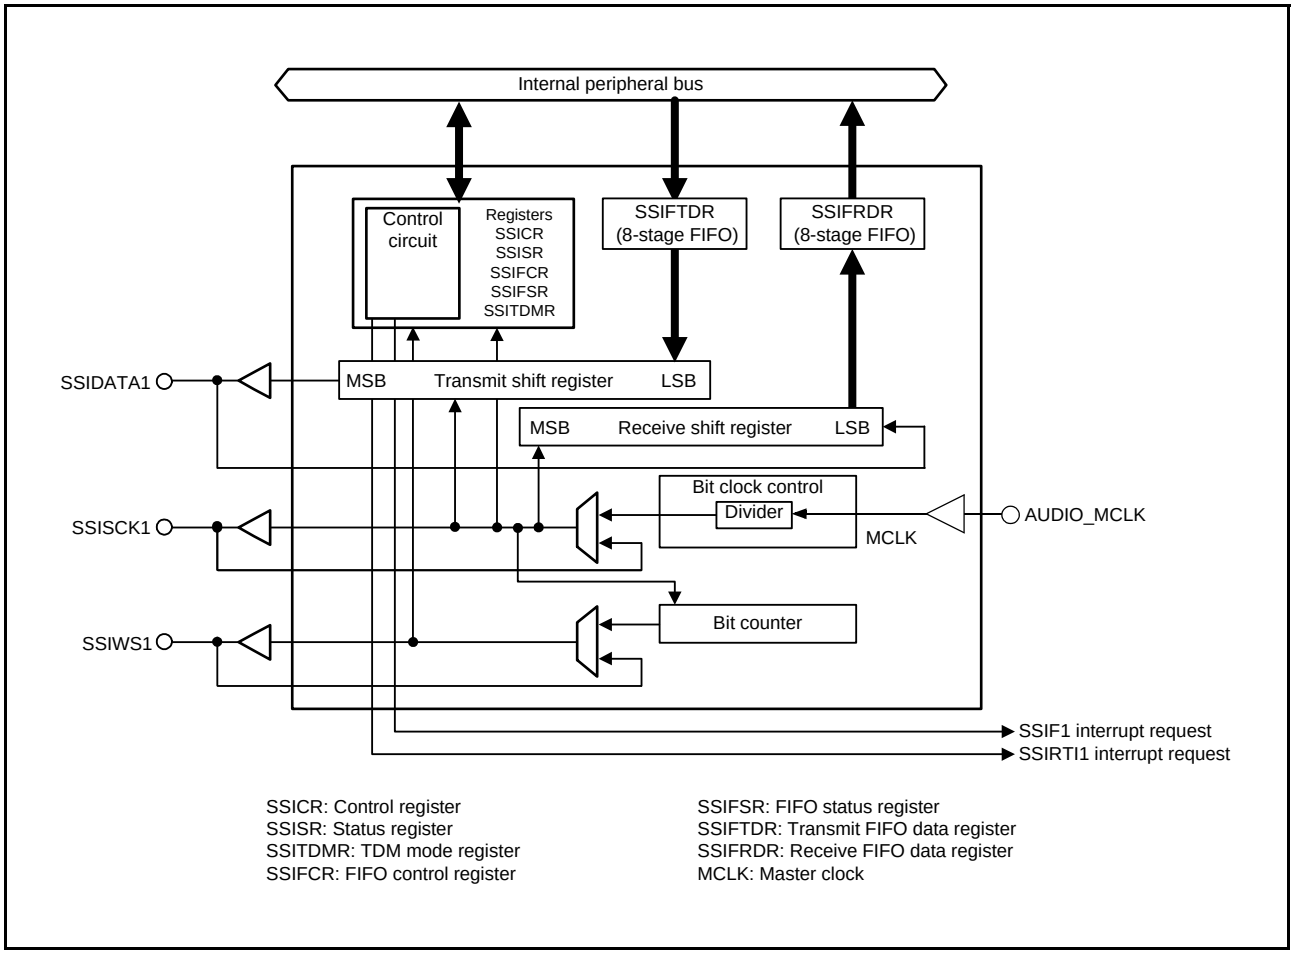

Figure 47.2 Block Diagram of SSI (SSI1)

Table 47.2 lists the I/O pins of the SSI.

Table 47.2 SSI I/O Pins

Channel	Pin Name	I/O	Description
SSI0	SSISCK0	I/O	Serial bit clock pin
	SSIWS0	I/O	Word selection pin
	SSITXD0	Output	Serial data output pin
	SSIRXD0	Input	Serial data input pin
SSI1	SSISCK1	I/O	Serial bit clock pin
	SSIWS1	I/O	Word selection pin
	SSIDATA1	I/O	Serial data input/output pin
SSI0, SSI1	AUDIO_MCLK	Input	Master clock for audio pin (input master clock)

47.2 Register Descriptions

47.2.1 Control Register (SSICR)

Address(es): SSI0.SSICR 0008 A500h, SSI1.SSICR 0008 A540h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	CKS	TUIEN	TOIEN	RUIEN	ROIEN	IIEN	—	CHNL[1:0]		DWL[2:0]			SWL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

b9	PDTA	Parallel Data Allocation*3	When data word length is 8 or 16 bits: 0: The lower bits of parallel data (SSIFTDR, SSIFRDR) are transferred prior to the upper bits. 1: The upper bits of parallel data (SSIFTDR, SSIFRDR) are transferred prior to the lower bits. When data word length is 18, 20, 22, or 24 bits: 0: Parallel data (SSIFTDR, SSIFRDR) is left-justified. 1: Parallel data (SSIFTDR, SSIFRDR) is right-justified.	R/W
b10	SDTA	Serial Data Alignment*3	0: Transmitting and receiving in the order of serial data and padding bits 1: Transmitting and receiving in the order of padding bits and serial data	R/W
b11	SPDP	Serial Padding Polarity*3	0: Padding data is 0. 1: Padding data is 1.	R/W

Bit	Symbol	Bit Name	Description	R/W
b12	SWSP	Word Select Polarity	0: SSIWSn is low for the 1st system word, high for the 2nd system word. 1: SSIWSn is high for the 1st system word, low for the 2nd system word.	R/W
b13	SCKP	Serial Bit Clock Polarity*3	0: SSIWSn, SSITXD0, and SSIDATA1 change at the SSISCKn falling edge (SSIWSn, SSIRXD0, and SSIDATA1 are sampled at the SSISCKn rising edge). 1: SSIWSn, SSITXD0, and SSIDATA1 change at the SSISCKn rising edge (SSIWSn, SSITXD0, and SSIDATA1 are sampled at the SSISCKn falling edge).	R/W
b14	SWSD	Word Select Direction*2, *3	0: SSIWSn pin is input (slave mode). 1: SSIWSn pin is output (master mode).	R/W
b15	SCKD	Serial Bit Clock Direction*2, *3	0: SSISCKn pin is input (slave mode). 1: SSISCKn pin is output (master mode).	R/W
b18 to b16	SWL[2:0]	System Word Length*3	Set the system word length to the bit clock frequency/2 fs. b18 b16 0 0 0: 8 bits (serial bit clock frequency = 16 fs) 0 0 1: 6 bits (serial bit clock frequency = 32 fs) 0 1 0: 24 bits (serial bit clock frequency = 48 fs) 0 1 1: 32 bits (serial bit clock frequency = 64 fs) Settings other than above are prohibited.	R/W
b21 to b19	DWL[2:0]	Data Word Length*3	b21 b19 0 0 0: 8 bits 0 0 1: 16 bits 0 1 0: 18 bits 0 1 1: 20 bits 1 0 0: 22 bits 1 0 1: 24 bits Settings other than above are prohibited.	R/W
b23, b22	CHNL[1:0]	Channels*3	b23 b22 0 0: One channel Settings other than above are prohibited.	R/W
b24	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b25	IIEN	Idle Interrupt Enable	0: Disables an idle interrupt. 1: Enables an idle interrupt.	R/W
b26	ROIEN	Receive Overflow Interrupt Enable	0: Disables a receive overflow interrupt. 1: Enables a receive overflow interrupt.	R/W
b27	RUIEN	Receive Underflow Interrupt Enable	0: Disables a receive underflow interrupt. 1: Enables a receive underflow interrupt.	R/W
b28	TOIEN	Transmit Overflow Interrupt Enable	0: Disables a transmit overflow interrupt. 1: Enables a transmit overflow interrupt.	R/W
b29	TUIEN	Transmit Underflow Interrupt Enable	0: Disables a transmit underflow interrupt. 1: Enables a transmit underflow interrupt.	R/W
b30	CKS	Audio Clock Select*3	0: AUDIO_MCLK input 1: Setting prohibited	R/W
b31	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. While this module is muted, low is transmitted regardless of the value of serial data, but data transmission is not stopped. Since the number of data in the transmit FIFO decreases, write dummy data to the SSIFTDR register to prevent the generation of a transmit underflow. When the MUEN bit is set to 1, the SSITXD0 and SSIDATA1 pins immediately become low without synchronizing SSIWSn pin.
Note 2. Set the SCKD and SWSD bits to the same value. Other settings are prohibited.
Note 3. Rewriting is allowed only in the idle state.

REN Bit (Receive Enable)

This bit enables or disables receive operation. Setting this bit to 1 starts receive operation.

TEN Bit (Transmit Enable)

This bit enables or disables transmit operation. Setting this bit to 1 starts transmit operation.
SSITXD0 pin of SSI0 is set as output while SSITXD0 is selected by the multi-function pin controller (MPC), regardless of the TEN bit setting. SSIDATA1 pin of SSI1 is set as output when the TEN bit is 1 and input when the TEN bit is 0 while SSIDATA1 is selected by MPC.

Table 47.3 SSITXD0, SSIRXD0, and SSIDATA1 Pin States

Register Settings			**SSI0**		**SSI1**
MPC setting	TEN	REN	SSITXD0	SSIRXD0	SSIDATA1
SSI function	0	0	Output	Input	Input
	0	1	Output	Input	Input
	1	0	Output	Input	Output
	1	1	Output	Input	—
Other than SSI function	x	x	Depends on the selected function	Depends on the selected function	Depends on the selected function

x: Don't care
—: Settings prohibited.

CKDV[3:0] Bits (Serial Bit Clock Frequency Setting)

These bits select the frequency of the serial bit clock in master mode. Since the input clock from the SSISCKn pin is used in slave mode, the setting of these bits is ignored (n = 0, 1). The serial bit clock is used as the operating clock of the shift register.

Calculation Example:
When fs (sampling rate) = the SSIWSn frequency = 96 kHz and the system word length = 32 bits
The bit clock frequency = 96 kHz × 32 bits × 2 = 6.144 MHz is necessary, so set CKDV[3:0] = 0001b (MCLK/2) when MCLK = 12.288 MHz.

PDTA Bit (Parallel Data Allocation)

The setting of this bit specifies the allocation of data to be stored in the SSIFRDR register in receive mode and the SSIFTDR register in transmit mode.
During receive operation, the SSI stores the data received from the serial bus in the SSIFRDR register according to the PDTA bit setting.
During transmit operation, the SSI stores the data stored in the SSIFTDR register in the transmit shift register, and transmits the data to the serial bus according to the PDTA bit setting.

(1) When PDTA bit is 0

DWL[2:0] Bits	SSIFTDR and SSIFRDR Registers
000b	31 24 23 16 15 8 7 0 4th word | 3rd word | 2nd word | 1st word
001b	31 16 15 0 2nd word | 1st word
010b	31 14 13 0 Valid | Invalid
011b	31 12 11 0 Valid | Invalid
100b	31 10 9 0 Valid | Invalid
101b	31 8 7 0 Valid | Invalid

(2) When PDTA bit is 1

DWL[2:0] Bits	SSIFTDR and SSIFRDR Registers
000b	31 24 23 16 15 8 7 0 1st word | 2nd word | 3rd word | 4th word
001b	31 16 15 0 1st word | 2nd word
010b	31 18 17 0 Invalid | Valid
011b	31 20 19 0 Invalid | Valid
100b	31 22 21 0 Invalid | Valid
101b	31 24 23 0 Invalid | Valid

SCKP Bit (Serial Bit Clock Polarity)

This bit is used to select the polarity of SSISCKn signal (n = 0, 1).
Table 47.4 lists the setting of SCKP bit and signal I/O timing.

Table 47.4 Setting of SCKP Bit and Signal Timing

	SCKP Bit = 0	SCKP Bit = 1
SSIRXD0 and SSIDATA1 input sampling timing for reception	SSISCKn rising edge	SSISCKn falling edge
SSITXD0 and SSIDATA1 output changing timing for transmission	SSISCKn falling edge	SSISCKn rising edge
SSIWSn input sampling timing in slave mode (SWSD bit = 0)	SSISCKn rising edge	SSISCKn falling edge
SSIWSn output changing timing in master mode (SWSD bit = 1)	SSISCKn falling edge	SSISCKn rising edge

CHNL[1:0] Bits (Channels)

These bits select the number of channels to be decoded in each system word. Set these bits to 00b in this module.

47.2.2 Status Register (SSISR)

Address(es): SSI0.SSISR 0008 A504h, SSI1.SSISR 0008 A544h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	TUIRQ	TOIRQ	RUIRQ	ROIRQ	IIRQ	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	TCHNO[1:0]		TSWNO	RCHNO[1:0]		RSWNO	IDST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	IDST	Idle Status Flag	0: SSI communication is in progress. 1: SSI communication is idle.	R
b1	RSWNO	Receive System Word Number Flag	Receive word number	R
b3, b2	RCHNO[1:0]	Receive Channel Number Flag	These bits are read as 00b.	R
b4	TSWNO	Transmit System Word Number Flag	Transmit word number	R
b6, b5	TCHNO[1:0]	Transmit Channel Number Flag	These bits are read as 00b.	R
b24 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25	IIRQ	Idle Interrupt Status Flag	0: Not in idle state 1: In idle state	R
b26	ROIRQ	Receive Overflow Interrupt Status Flag	0: No receive overflow has occurred. 1: A receive overflow has occurred.	R/(W) *1
b27	RUIRQ	Receive Underflow Interrupt Status Flag	0: No receive underflow has occurred. 1: A receive underflow has occurred.	R/(W) *1
b28	TOIRQ	Transmit Overflow Interrupt Status Flag	0: No transmit overflow has occurred. 1: A transmit overflow has occurred.	R/(W) *1
b29	TUIRQ	Transmit Underflow Interrupt Status Flag	0: No transmit underflow has occurred. 1: A transmit underflow has occurred.	R/(W) *1
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 0 after confirming the flag to be 1 clears the flag. To clear flags, write 0 only to the flags to be cleared; write 1 to the other flags. Do not write 0 to a status flag indicating 0.

IDST Flag (Idle Status Flag)

This status flag indicates that the SSI is in idle state where communication is stopped.

This flag is set to 0 when communication starts after the SSICR.TEN bit or SSICR.REN bit is set to 1. Also, this flag is set to 1 if both the TEN and REN bits are set to 0 and system word communication is completed.

If the external device stops inputting the serial bit clock before communication is completed, this flag is not set to 1.

RSWNO Flag (Receive System Word Number Flag)

The initial value of this flag is 1, and its value is inverted when the data is transferred from the receive shift register to the SSIFRDR register.

This flag is initialized to 1 when the SSICR.REN bit value is changed from 0 to 1.

When the data word length specified by the SSICR.DWL[2:0] bits is 18 bits or more, this flag indicates which system word the data in the SSIFRDR register represents.

TSWNO Flag (Transmit System Word Number Flag)

This status flag indicates the current word number.
The initial value of this is 1, and its value is inverted when the data is transferred from the SSIFTDR register to the transmit shift register.
This flag is initialized to 1 when the SSICR.TEN bit value is changed from 0 to 1.
When the data word length specified by the SSICR.DWL[2:0] bits is 18 bits or more, this flag indicates the system word that is in the data transferred from the SSIFTDR register to the transmit shift register.

IIRQ Flag (Idle Interrupt Status Flag)

This status flag indicates whether this module is in idle state.
This flag is set regardless of the value of the SSICR.IIEN bit to allow polling.
The interrupt can be masked by setting the SSICR.IIEN bit to 0, but the interrupt cannot be cleared by writing 0 to this flag.
If IIRQ flag = 1 and SSICR.IIEN bit = 1, an interrupt occurs.

ROIRQ Flag (Receive Overflow Interrupt Status Flag)

This status flag indicates that receive data was supplied at a higher rate than was required. If a receive overflow occurs, stop reception and start from the beginning of the flowchart again.
This flag is set to 1 regardless of the setting of the SSICR.ROIEN bit. This flag can be set to 0 by writing 0 after confirming it to be 1.
If ROIRQ flag = 1 and SSICR.ROIEN bit = 1, an interrupt occurs.
If ROIRQ flag = 1, the data was transferred from the transmit shift register to the SSIFRDR register while the receive FIFO is full (SSIFSR.RDC[3:0] flags = 8h). This may lead to the loss of data.

Note: When an overflow occurs, the current data in the data buffer of this module is overwritten by the next incoming data from the SSI interface.

RUIRQ Flag (Receive Underflow Interrupt Status Flag)

This status flag indicates that receive data was supplied at a lower rate than was required. If a receive underflow occurs, stop reception and start the flowchart again from the beginning.
This flag is set to 1 regardless of the setting of the SSICR.RUIEN bit. This flag can be set to 0 by writing 0 after confirming it to be 1.
If RUIRQ flag = 1 and SSICR.RUIEN bit = 1, an interrupt occurs.
If RUIRQ flag = 1, the SSIFRDR register was read while the receive FIFO is empty (SSIFSR.RDC[3:0] flags = 0h). This may cause invalid receive data to be stored.

TOIRQ Flag (Transmit Overflow Interrupt Status Flag)

This status flag indicates that transmit data was supplied at a higher rate than was required. If a transmit overflow occurs, stop transmission and start from the beginning of the flowchart again.
This flag is set to 1 regardless of the setting of the SSICR.TOIEN bit. This flag can be set to 0 by writing 0 after confirming it to be 1.
If TOIRQ flag = 1 and SSICR.TOIEN bit = 1, an interrupt occurs.
If TOIRQ flag = 1, the SSIFTDR register had data written to it while the transmit FIFO is full (SSIFSR.TDC[3:0] flags = 8h). This may lead to the loss of data.

TUIRQ Flag (Transmit Underflow Interrupt Status Flag)

This status flag indicates that transmit data was supplied at a lower rate than was required. If a transmit underflow occurs, stop transmission and start from the beginning of the flowchart again.
This flag is set to 1 regardless of the setting of the SSICR.TUIEN bit. This flag can be set to 0 by writing 0 after

confirming it to be 1.
If TUIRQ flag = 1 and SSICR.TUIEN bit = 1, an interrupt occurs.
If TUIRQ flag = 1, the SSIFTDR register did not have data written to it before it was required for transmission. This may lead to the same data being transmitted once more.

Note: When a transmit underflow occurs, the last data input to the SSIFTDR register is transmitted until this module is in the idle state after transmission is stopped.

47.2.3 FIFO Control Register (SSIFCR)

Address(es): SSI0.SSIFCR 0008 A510h, SSI1.SSIFCR 0008 A550h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	AUCKE	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SSIRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TTRG[1:0]		RTRG[1:0]		TIE	RIE	TFRST	RFRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFRST	Receive FIFO Data Register Reset*4	0: Release the receive FIFO data reset. 1: Initiates the receive FIFO data reset.	R/W
b1	TFRST	Transmit FIFO Data Register Reset*4	0: Release the transmit FIFO data reset. 1: Initiates the transmit FIFO data reset.	R/W
b2	RIE	Receive Data Full Interrupt Enable	0: Receive data full interrupt (RXI) request is disabled. 1: Receive data full interrupt (RXI) request is enabled.*1	R/W
b3	TIE	Transmit Data Empty Interrupt Enable	0: Transmit data empty interrupt (TXI) request is disabled. 1: Transmit data empty interrupt (TXI) request is enabled.*2	R/W
b5, b4	RTRG[1:0]	Receive FIFO Threshold Setting *4	b5 b4 0 0: 1 0 1: 2 1 0: 4 1 1: 6	R/W
b7, b6	TTRG[1:0]	Transmit FIFO Threshold Setting *4	b7 b6 0 0: 7 (1)*3 0 1: 6 (2)*3 1 0: 4 (4)*3 1 1: 2 (6)*3	R/W
b15 to b8	—	Reserved	These bits are read as undefined. The write value should be 0.	R/W
b16	SSIRST	SSI Software Reset	0: Clears the SSI software reset. 1: Initiates the SSI software reset.	R/W
b30 to b17	—	Reserved	These bits are read as undefined. The write value should be 0.	R/W
b31	AUCKE	Master Clock Enable*4	0: The master clock is disabled. 1: The master clock is enabled.	R/W

Note 1. The RXI request can be cleared by setting the SSIFSR.RDF flag to 0 (see the description of the SSIFSR.RDF flag for details) or RIE bit to 0.
Note 2. The TXI request can be cleared by setting the SSIFSR.TDE flag to 0 (see the description of the SSIFSR.TDE flag for details) or TIE bit to 0.
Note 3. The values in parenthesis are the number of empty stages in SSIFTDR at which the SSIFSR.TDE flag is set.
Note 4. Rewriting is allowed only in the idle state.

The SSIFCR register resets the number of the data bytes stored in the SSIFTDR and SSIFRDR registers, and specifies transmit FIFO and receive FIFO threshold values.

RFRST Bit (Receive FIFO Data Register Reset)

This bit invalidates the data in the SSIFRDR register to reset the FIFO to an empty state.

TFRST Bit (Transmit FIFO Data Register Reset)

This bit invalidates the data in the SSIFTDR register to reset the FIFO to an empty state.

RIE Bit (Receive Data Full Interrupt Enable)

This bit enables or disables generation of receive data full interrupt (RXI) requests when the SSIFSR.RDF flag is set to 1 during reception.

TIE Bit (Transmit Data Empty Interrupt Enable)

This bit enables or disables generation of transmit data empty interrupt (TXI) requests when the SSIFSR.TDE flag is set to 1 during transmit operation.

RTRG[1:0] Bits (Receive FIFO Threshold Setting)

These bits specify the receive FIFO threshold value. When the number of received data bytes stored in the SSIFRDR register (receive FIFO) has become equal to or greater than the value specified by the RTRG[1:0] bits, the SSIFSR.RDF flag is set to 1 and reading the received data is requested. If the SSIFCR.RIE bit is 1 at this time, a receive data full interrupt (RXI) request is generated.

TTRG[1:0] Bits (Transmit FIFO Threshold Setting)

These bits specify the transmit FIFO threshold value. When the number of transmit data bytes stored in the SSIFTDR register (transmit FIFO) has become equal to or less than the value specified by the TTRG[1:0], the SSIFSR.TDE flag is set to 1 and writing the transmit data is requested. If the SSIFCR.TIE bit is 1 at this time, a transmit data empty interrupt (TXI) request is generated.

SSIRST Bit (SSI Software Reset)

Writing 1 to this bit initializes the SSI internal status, registers other than the SSIFCR register, and bits other than this bit in the SSIFCR register. Since this bit is not automatically cleared to 0, confirm that 1 is written to it before writing 0. Do not write 0 to this bit and 1 to other bits at the same time. After modifying this bit, confirm that its value is modified before proceeding to the next processing.

47.2.4 FIFO Status Register (SSIFSR)

Address(es): SSI0.SSIFSR 0008 A514h, SSI1.SSIFSR 0008 A554h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	TDC[3:0]				—	—	—	—	—	—	—	TDE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	RDC[3:0]				—	—	—	—	—	—	—	RDF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RDF	Receive Data Full Flag	0: Number of received data bytes in the SSIFRDR register is less than the specified receive FIFO threshold value. 1: Number of received data bytes in the SSIFRDR register is equal to or greater than the specified receive FIFO threshold value.	R/(W) *1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11 to b8	RDC[3:0]	Receive Data Indicate Flag	Indicate the number of data units stored in the SSIFRDR register.	R
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	TDE	Transmit Data Empty Flag	0: Number of data bytes for transmission in the SSIFTDR register is greater than the specified transmit FIFO threshold value. 1: Number of data bytes for transmission in the SSIFTDR register is equal to or less than the specified transmit FIFO threshold value.*2	R/(W) *1
b23 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b27 to b24	TDC[3:0]	Transmit Data Indicate Flag	Indicate the number of data units stored in the SSIFTDR register.	R
b31 to b28	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 0 after confirming the flag to be 1 clears the flag. To clear flags, write 0 only to the flags to be cleared; write 1 to the other flags. Do not write 0 to a status flag indicating 0.

Note 2. Since the SSIFTDR register is an 8-stage FIFO register, the amount of data that can be written to it while TDE flag = 1 is “8 - specified transmit FIFO threshold value” bytes at maximum. Writing more data will be ignored. The number of data bytes in the SSIFTDR register is indicated in the TDC[3:0] flags.

The SSIFSR register consists of status flags indicating the operating status of the SSIFTDR register and SSIFRDR register.

RDF Flag (Receive Data Full Flag)

This flag indicates that, when the received data is transferred to the SSIFRDR register, the number of data bytes in the SSIFRDR register has become equal to or greater than the receive FIFO threshold value, and thus reading the received data from the SSIFRDR register has been enabled.

[Setting condition]

- The number of receive data bytes that is equal to or greater than the value specified by the SSIFCR.RTRG[1:0] bits is stored in the SSIFRDR register.

[Clearing conditions]

- 0 is written to the RDF flag after the RDF flag is confirmed to be 1.
- Received data is read from the SSIFRDR register using DMA or DTC transfer (transfer of the last block in block transfer). Do not clear the RDF flag to 0 during DMA or DTC transfer.

Note: Since the SSIFRDR register is a 32-byte FIFO register, the maximum number of data bytes that can be read from it while the RDF flag is 1 is indicated in the RDC[3:0] flags. If reading data from the SSIFRDR register is continued after all the data is read, undefined values will be read.

RDC[3:0] Flags (Receive Data Indicate Flag)

These flags indicate the number of data bytes stored in the SSIFRDR register.
RDC[3:0] flags = 0h indicates no received data. RDC[3:0] flags = 8h indicates that 32 bytes of received data is stored in the SSIFRDR register.

TDE Flag (Transmit Data Empty Flag)

This flag indicates that, when data is transferred from the SSIFTDR register to the transmit shift register, the number of data bytes in the SSIFTDR register has become less than the transmit FIFO threshold value, and thus writing transmit data to the SSIFTDR register has been enabled.
[Setting condition]

- The number of the transmit data bytes written to the SSIFTDR register is equal to or less than the value specified by the SSIFCR.TTRG[1:0] bits.

[Clearing conditions]

- 0 is written to the TDE flag after the TDE flag is confirmed to be 1.
- Transmit data is written to the SSIFTDR register using DMA or DTC transfer (transfer of the last block in block transfer). Do not clear the TDE flag to 0 during DMA or DTC transfer.

Note: Since the SSIFTDR register is a 32-byte FIFO register, the maximum number of bytes that can be written to it while the TDE flag is 1 is 8 – TDC[3:0]. If writing data to the SSIFTDR register is continued after all the data is written, writing will be invalid and an overflow occurs.

TDC[3:0] Flags (Transmit Data Indicate Flag)

These flags indicate the number of data bytes stored in the SSIFTDR register.
TDC[3:0] flags = 0h indicates no data for transmission. TDC[3:0] flags = 8h indicates that 32 bytes of data for transmission is stored in the SSIFTDR register.

47.2.5 Transmit FIFO Data Register (SSIFTDR)

Address(es): SSI0.SSIFTDR 0008 A518h, SSI1.SSIFTDR 0008 A558h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

The SSIFTDR register is a write-only FIFO register consisting of eight stages of 32-bit registers for storing transmit data. Write transmit data to the SSIFTDR register in 64-bit (two stages of FIFO) units regardless of the data word length setting. If transmit data ends on a 32-bit boundary, write 00000000h for the other 32 bits, and stop transmission while 64-bit writing is completed. When the transmit shift register is empty, the SSI transfers the transmit data written to the SSIFTDR register to start serial transmission, which can be continued until the SSIFTDR register becomes empty. Note that when the SSIFTDR register is full of data (32 bytes), the next data cannot be written to it. If writing is attempted, it will be ignored and an overflow occurs.

47.2.6 Receive FIFO Data Register (SSIFRDR)

Address(es): SSI0.SSIFRDR 0008 A51Ch, SSI1.SSIFRDR 0008 A55Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

The SSIFRDR register is a read-only FIFO register consisting of eight stages of 32-bit registers for storing received data. Each time 4 bytes of serial data is received, the SSI stores the received serial data in the SSIFRDR register from the receive shift register according to the PDTA bit setting. Receive operation can be continued until a maximum 32 bytes of data have been stored to in the SSIFRDR register. The SSIFRDR register can be read but cannot be written to. Note that when the SSIFRDR register is read when it stores no received data, undefined values will be read and a receive underflow occurs.
After the SSIFRDR register becomes full of received data, the data received thereafter will be lost and a receive overflow occurs.

47.2.7 TDM Mode Register (SSITDMR)

Address(es): SSI0.SSITDMR 0008 A520h, SSI1.SSITDMR 0008 A560h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CONT	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	CONT	WS Continue Mode*1	0: Disables WS continue mode. 1: Enables WS continue mode.	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. This bit can be set only in master mode (SSICR.SCKD bit = 1 and SSICR.SWSD bit = 1).

The SSITDMR register is a readable/writable 32-bit register that enables or disables WS continue mode.

47.3 Operation

47.3.1 Bus Format

This module can operate as a transmitter or a receiver and can be configured into many serial bus formats in either mode. The bus format can be selected from one of the six modes shown in Table 47.5.

Table 47.5 Bus Format

	TEN	REN	SCKD	SWSD	MUEN	IIEN	TOIEN	TUIEN	ROIEN	RUIEN	CONT	SWSP	DEL	PDTA	SDTA	SPDP	SCKP	SWL[2:0]	DWL[2:0]	CHNL[1:0]
Non-compression slave receiver	0	1	0	0	Control bits							Configuration bits								
Non-compression slave transmitter	1	0	0	0																
Non-compression slave transceiver	1	1	0	0																
Non-compression master receiver	0	1	1	1																
Non-compression master transmitter	1	0	1	1																
Non-compression master transceiver	1	1	1	1																

47.3.2 Non-Compressed Mode

This SSI supports non-compressed mode only. It supports the I^2S compatible format as well as MSB-first and left-justified/right-justified.

(1) Slave Receiver

This mode allows the module to receive serial data from another device. The clock and word select signal used for the serial data stream is also supplied from an external device. If these signals do not conform to the format specified in the configuration fields of this module, operation is not guaranteed.

(2) Slave Transmitter

This mode allows the module to transmit serial data to another device. The clock and word select signal used for the serial data stream is also supplied from an external device. If these signals do not conform to the format specified in the configuration fields of this module, operation is not guaranteed.

(3) Slave Transceiver

This mode allows serial data transmission and reception between this module and another device. The clock and word select signal used for the serial data stream is also supplied from an external device. If these signals do not conform to the format specified in the configuration fields of this module, operation is not guaranteed.

(4) Master Receiver

This mode allows the module to receive serial data from another device. The clock and word select signals are internally derived from the master clock. The format of these signals is defined in the configuration fields of this module. If the incoming data does not follow the configured format, operation is not guaranteed.

(5) Master Transmitter

This mode allows the module to transmit serial data to another device. The clock and word select signals are internally derived from the master clock. The format of these signals is defined in the configuration fields of this module.

(6) Master Transceiver

This mode allows serial data transmission and reception between this module and another device. The clock and word select signals are internally derived from the master clock. The format of these signals is defined in the configuration fields of this module.

(7) Operating Settings Related to Word Length

All bits related to the SSICR register's word length are valid in non-compressed modes. There are many configurations this module supports, but some of the combinations are shown below for the I²S compatible format, MSB-first and left-justified format, and MSB-first and right-justified format.
In this section SSITXD0, SSIRXD0, and SSIDATA1 are referred to SSIDATA.

- I²S Compatible Format

Figure 47.3 and Figure 47.4 show the I²S compatible format both without and with padding.
Padding occurs when the data word length is smaller than the system word length.

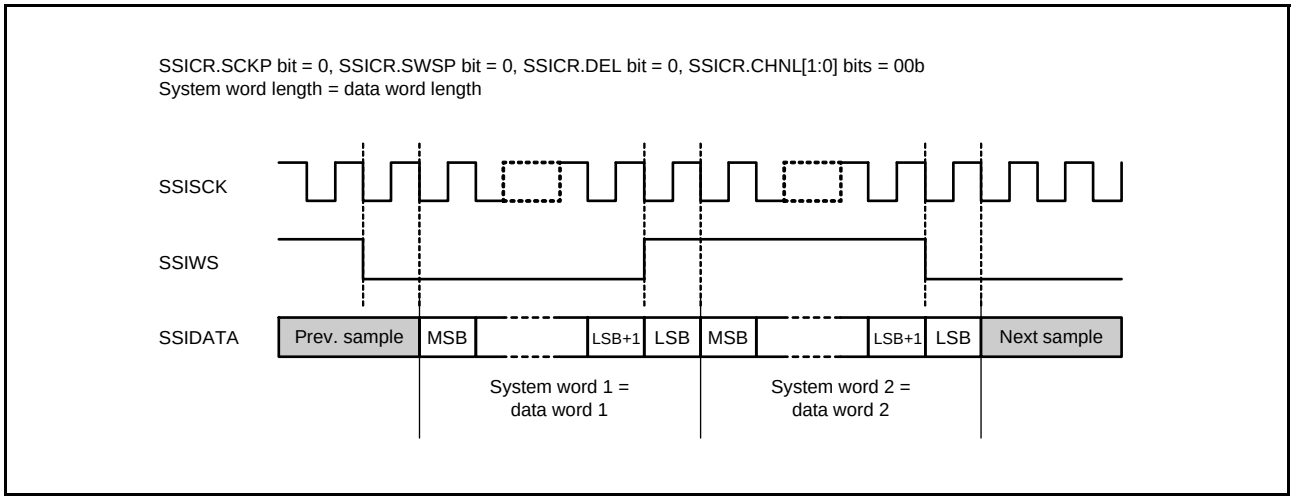

Figure 47.3 I²S Compatible Format (without Padding)

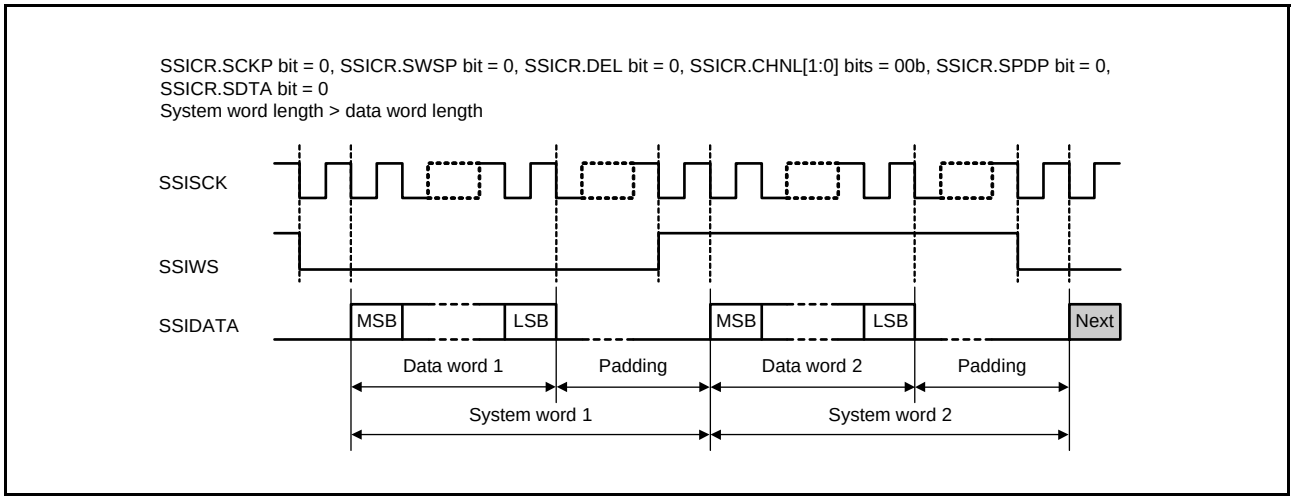

Figure 47.4 I²S Compatible Format (with Padding)

- MSB-First and Left-Justified Format

Figure 47.5 shows the MSB-first and left-justified format with padding.

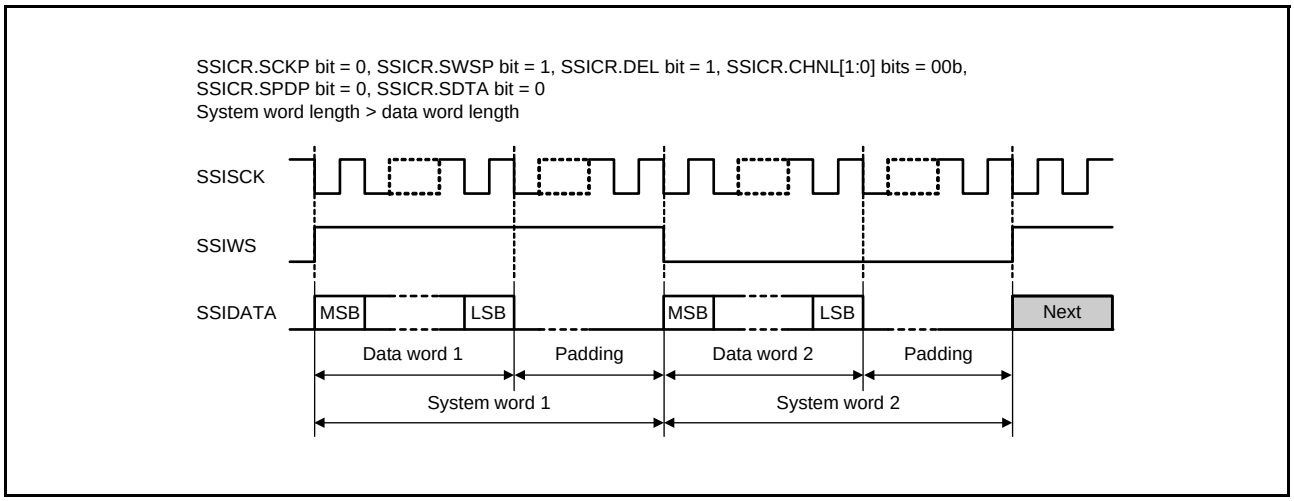

Figure 47.5 MSB-First and Left-Justified Format (Transmitted and Received in the Order of Serial Data and Padding Bits)

- MSB-First and Right-Justified Format

Figure 47.6 shows the MSB-first and right-justified format with padding.

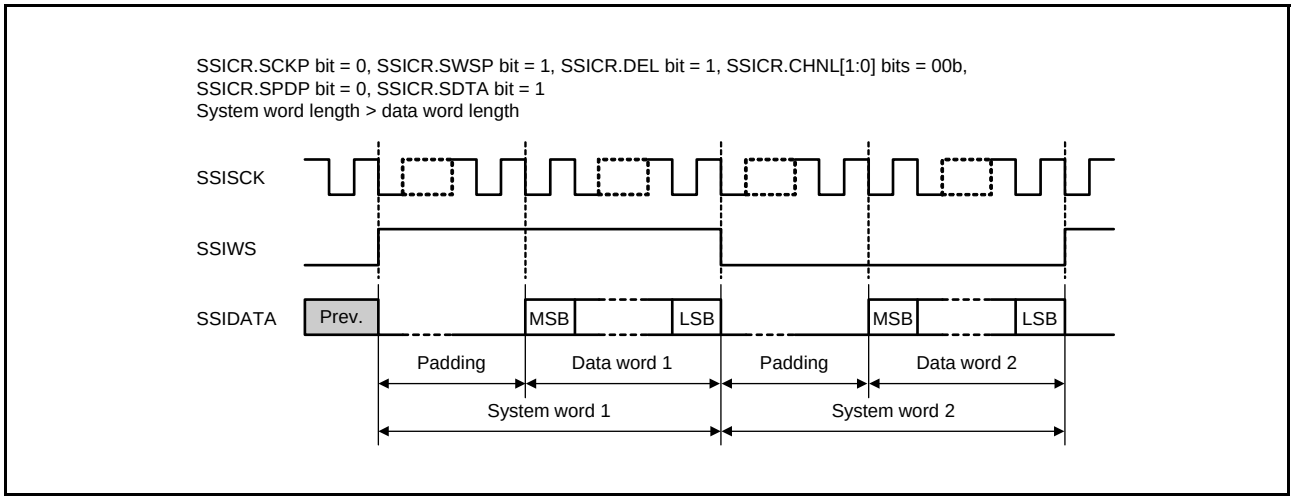

Figure 47.6 MSB-First and Right-Justified Format (Transmitted and Received in the Order of Padding Bits and Serial Data)

Table 47.6 shows the number of padding bits for each of the valid setting.

Table 47.6 Number of Padding Bits per System Word for Each Valid Setting

SSICR.CHNL[1:0] Bits (Decoded Channels per System Word)		SSICR.SWL[2:0] Bits (System Word Length)		SSICR.DWL[2:0] Bits (Data Word Length)					
				000b	001b	010b	011b	100b	101b
				8 bits	16 bits	18 bits	20 bits	22 bits	24 bits
00b	1 channel	000b	8 bits	0	—	—	—	—	—
		001b	16 bits	8	0	—	—	—	—
		010b	24 bits	16	8	6	4	2	0
		011b	32 bits	24	16	14	12	10	8

(8) Operating Settings Other than Word Length Related Settings

Several more configuration bits in non-compressed mode are shown below. These bits are not mutually exclusive, but some combinations may not be useful.

These configuration bits are described below with reference to the basic format sample in Figure 47.7.
In Figure 47.7 to Figure 47.15, a system word length of 6 bits and a data word length of 4 bits are used for simplification of these figures.

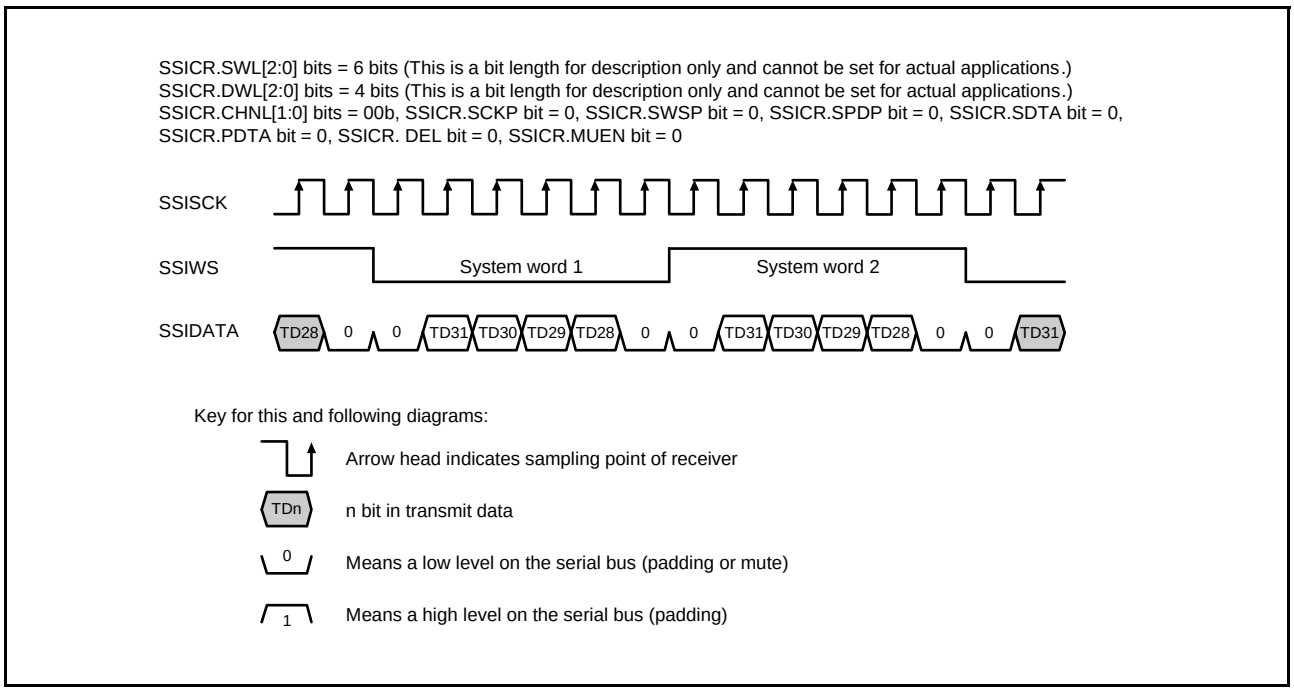

Figure 47.7 Basic Format Sample (Transmit Mode)

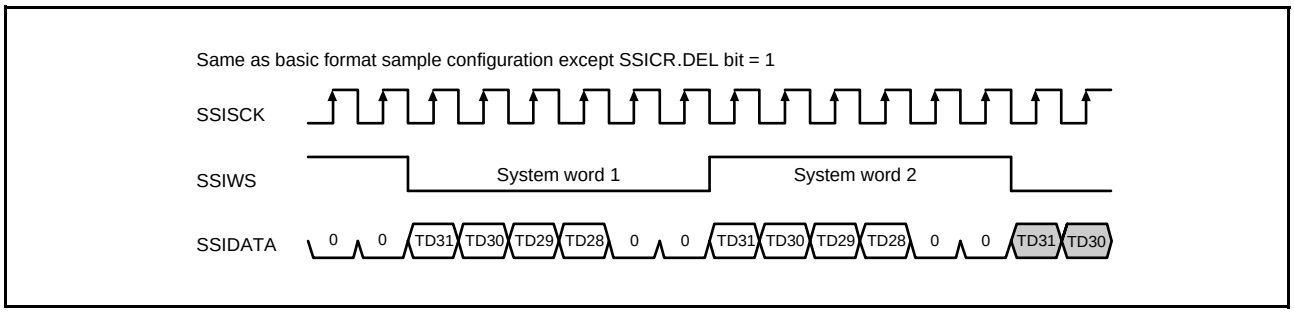

Figure 47.13 Transmitting and Receiving in the Order of Serial Data and Padding Bits; without Delay

- Parallel Right-Justified with Delay

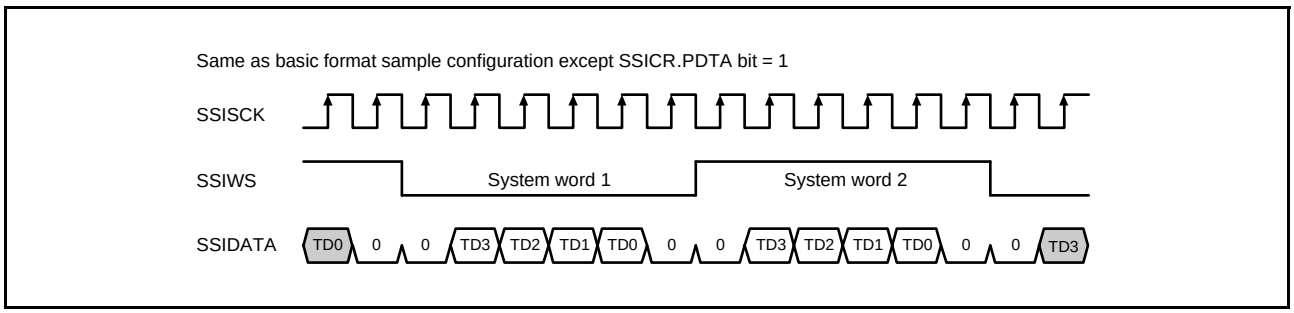

Figure 47.14 Parallel Right-Justified with Delay

- Mute Enabled

When the SSICR.MUEN bit is set to 1, the SSITXD0 and SSIDATA1 pins become low (0) without synchronizing SSIWSn (n = 0, 1).

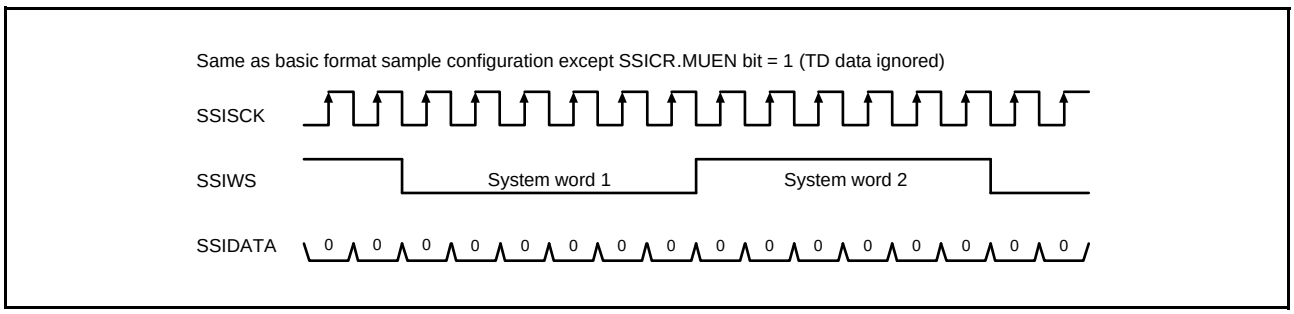

Figure 47.15 Mute Enabled

47.3.3 WS Continue Mode

In WS continue mode, the SSIWSn signal continues to be toggled irrespective whether data transmission is enabled or disabled (n = 0, 1). This mode can be set using the SSITDMR.CONT bit. With this mode enabled, the SSIWSn signal does not stop but continues toggling even if the SSICR.TEN and REN bits are both set to 0 (transmission disabled). With this mode disabled, the SSIWSn signal stops if the SSICR.TEN and REN bits are both set to 0.

Figure 47.16 and Figure 47.17 show the operations with WS continue mode enabled and disabled, respectively.

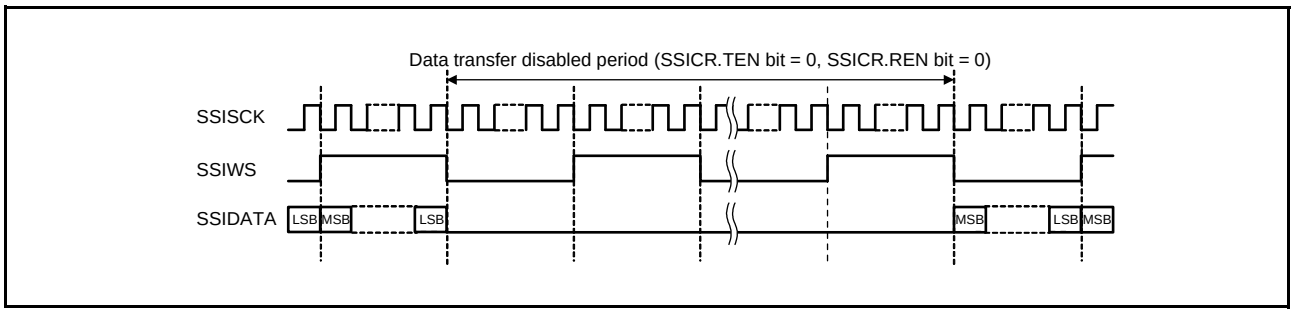

Figure 47.16 WS Continue Mode Enabled

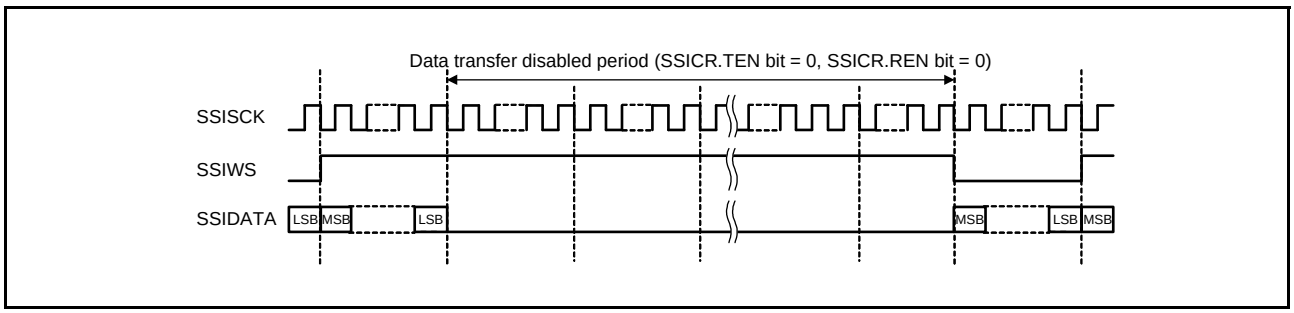

Figure 47.17 WS Continue Mode Disabled

47.3.4 Operating States

There are three states of operation: idle, communication, and waiting for idle. Figure 47.18 shows the operating state transitions.

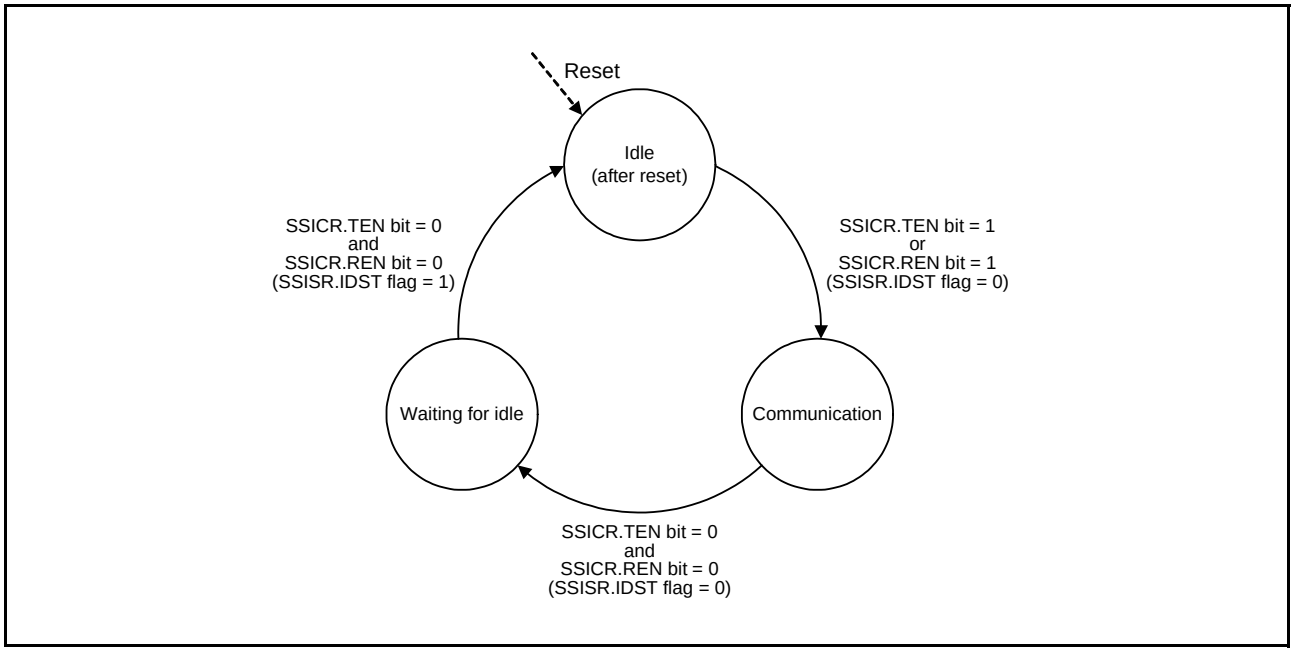

Figure 47.18 Operating State Transitions

(1) Idle State

This module enters this state when the MSTPCRD.MSTPD14 and MSTPD15 bits are set to 0 after a reset is released. All required configuration fields in the control register should be defined in this state. After the settings are made, the module enters communication state when the SSICR.TEN bit or SSICR.REN bit is set to 1.

(2) Communication State

Communication in this state depends on the selected operating state. For details, refer to section 47.3.5, Transmit Operation and section 47.3.6, Receive Operation.

(3) Waiting for Idle

This module enters this state when both the SSICR.TEN and SSICR.REN bits are set to 0 in communication state. If system word communication is completed in this state, the SSISR.IDST flag is set to 1 and this module enters the idle state.

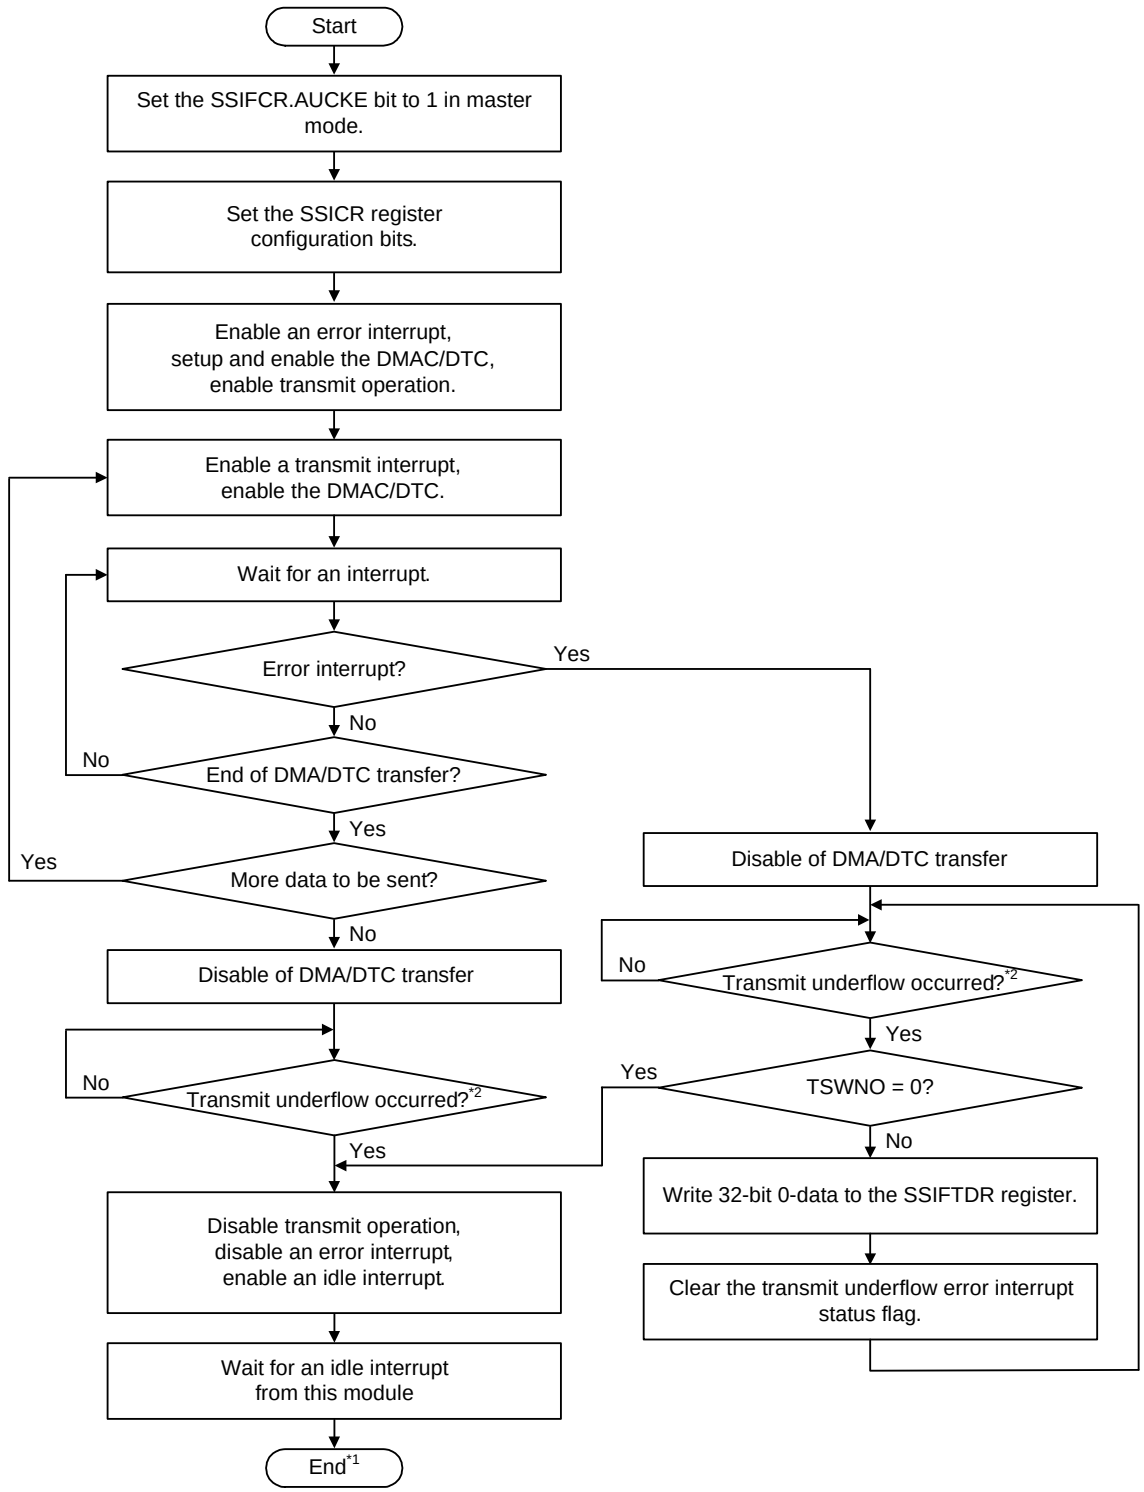
47.3.5 Transmit Operation

Transmission can be controlled either by DMA/DTC transfer or interrupt.
DMAC/DTC control is preferred to reduce the processor load. In transmission using the DMAC/DTC, the processor will only receive interrupts if there is an underflow or overflow of data or if DMA/DTC transfer has been completed. In transmission using DMA/DTC transfer, set the number of DMA/DTC transfers to multiples of 2 to write transmit data to the SSIFTDR register in 64-bit (two stages of FIFO) units.
The alternative method is using the interrupts that this module generates to supply data as required. In transmission using interrupts, write transmit data in 64-bit units regardless of the data format. If transmit data ends on a 32-bit boundary, write 00000000h after the last transmit data is written, and complete writing on a 64-bit boundary.
When stopping transmission, stop writing to the SSIFTDR register while 64-bit writing is completed. After writing is stopped, wait until a transmit underflow occurs before setting the SSICR.TEN bit to 0. During transmit underflow, the last data input to SSIFTDR register is continuously transmitted until this module enters the idle state. After setting the TEN bit to 0, continue to supply the clock*1 until the SSISR.IIRQ flag becomes 1 (in idle state). If a transmit underflow error or transmit overflow error occurs during data transmission, transmit data to SSIFTDR register may not be written in a 64-bit units. In that case, stop writing data, wait until a transmit underflow error occurs, and check the SSISR.TSWNO flag when the transmit underflow has occurred. When the TSWNO flag is 1, write 00000000h to SSIFTDR register and wait until an underflow occurs again. Once the TSWNO flag is confirmed to be 0, Set the TEN bit to 0 and continue to supply the clock*1 until the SSISR.IIRQ flag becomes 1 (in idle state).

Figure 47.19 shows transmission flow using the DMA/DTC, and Figure 47.20 shows transmission flow using interrupts.

Note 1. Input clock from the SSISCKn pin when SSICR.SCKD bit = 0 (n = 0, 1).
Master clock when SSICR.SCKD bit = 1.

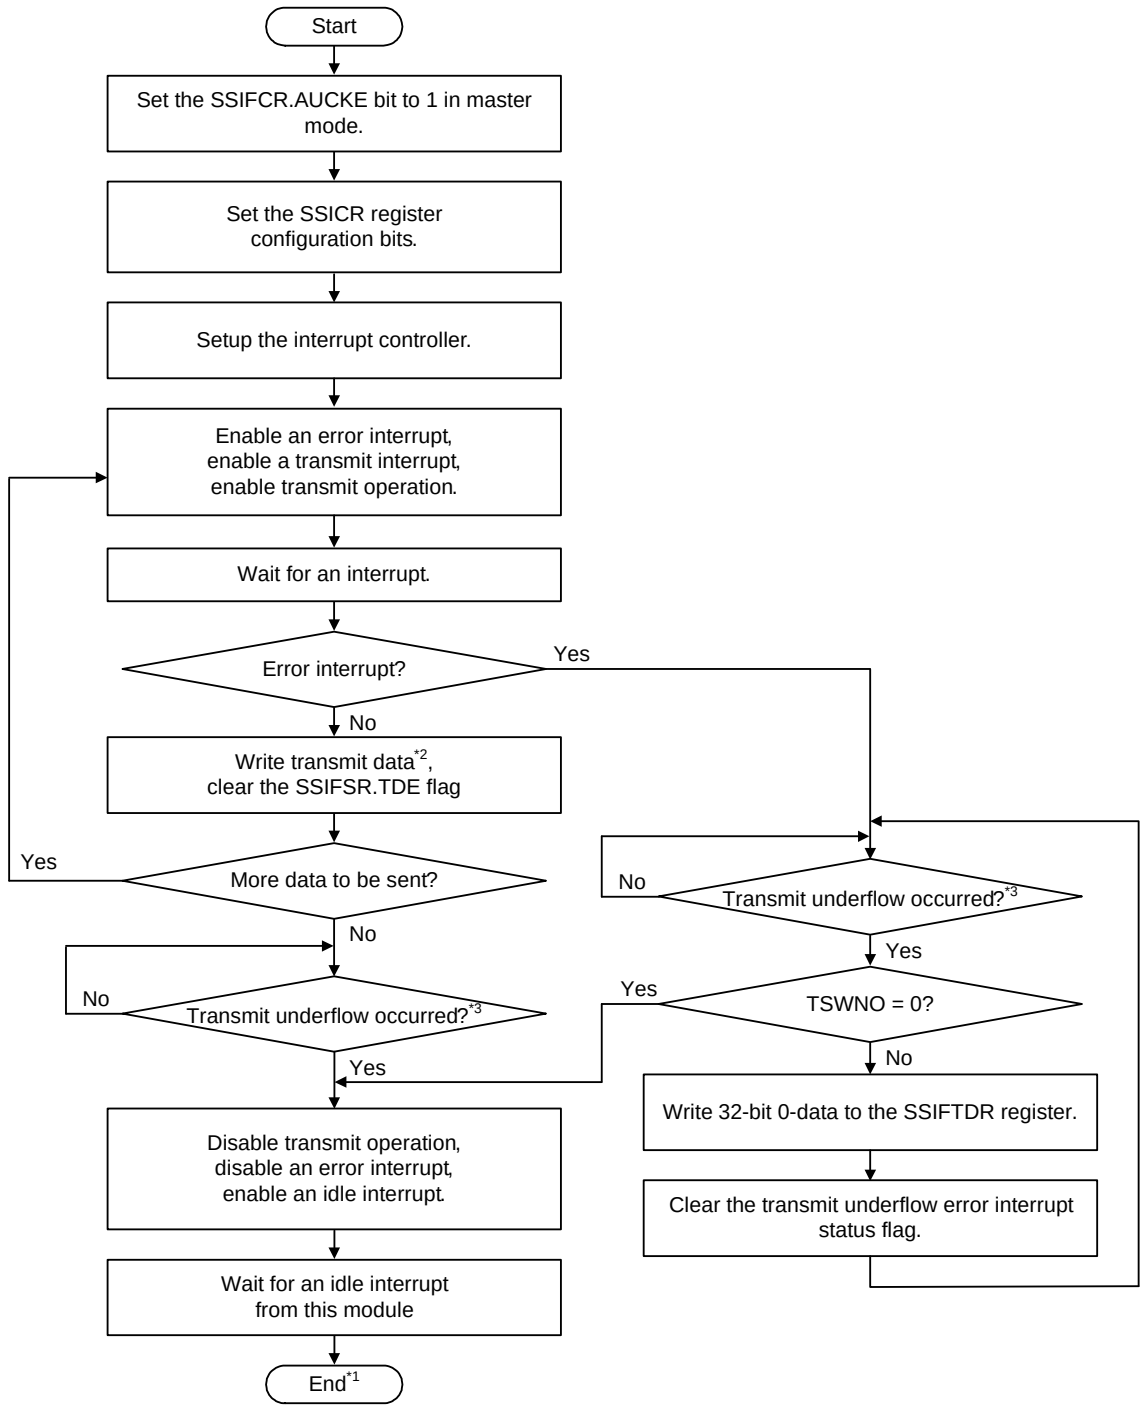
(1) Transmission Using the DMAC/DTC



Note 1. When restarting transmission after transmit operation is disabled (TEN = 0) while WS continue mode is disabled, execute a software reset and go back to the start of the flowchart again.
Note 2. Stop writing transmit data to the SSIFTDR register and wait until a transmit underflow occurs. During transmit underflow, the last data input to SSIFTDR register is continuously transmitted until the module is in the idle state.

Figure 47.19 Transmission Using the DMAC/DTC

(2) Transmission Using Interrupts



Note 1. When restarting transmission after transmit operation is disabled (TEN = 0) while WS continue mode is disabled, execute a software reset and go back to the start of the flowchart again.
Note 2. Write transmit data in 64-bit units regardless of the data word setting.
Note 3. Stop writing transmit data to the SSIFTDR register and wait until a transmit underflow occurs. During transmit underflow, the last data input to SSIFTDR register is continuously transmitted until the module is in the idle state.

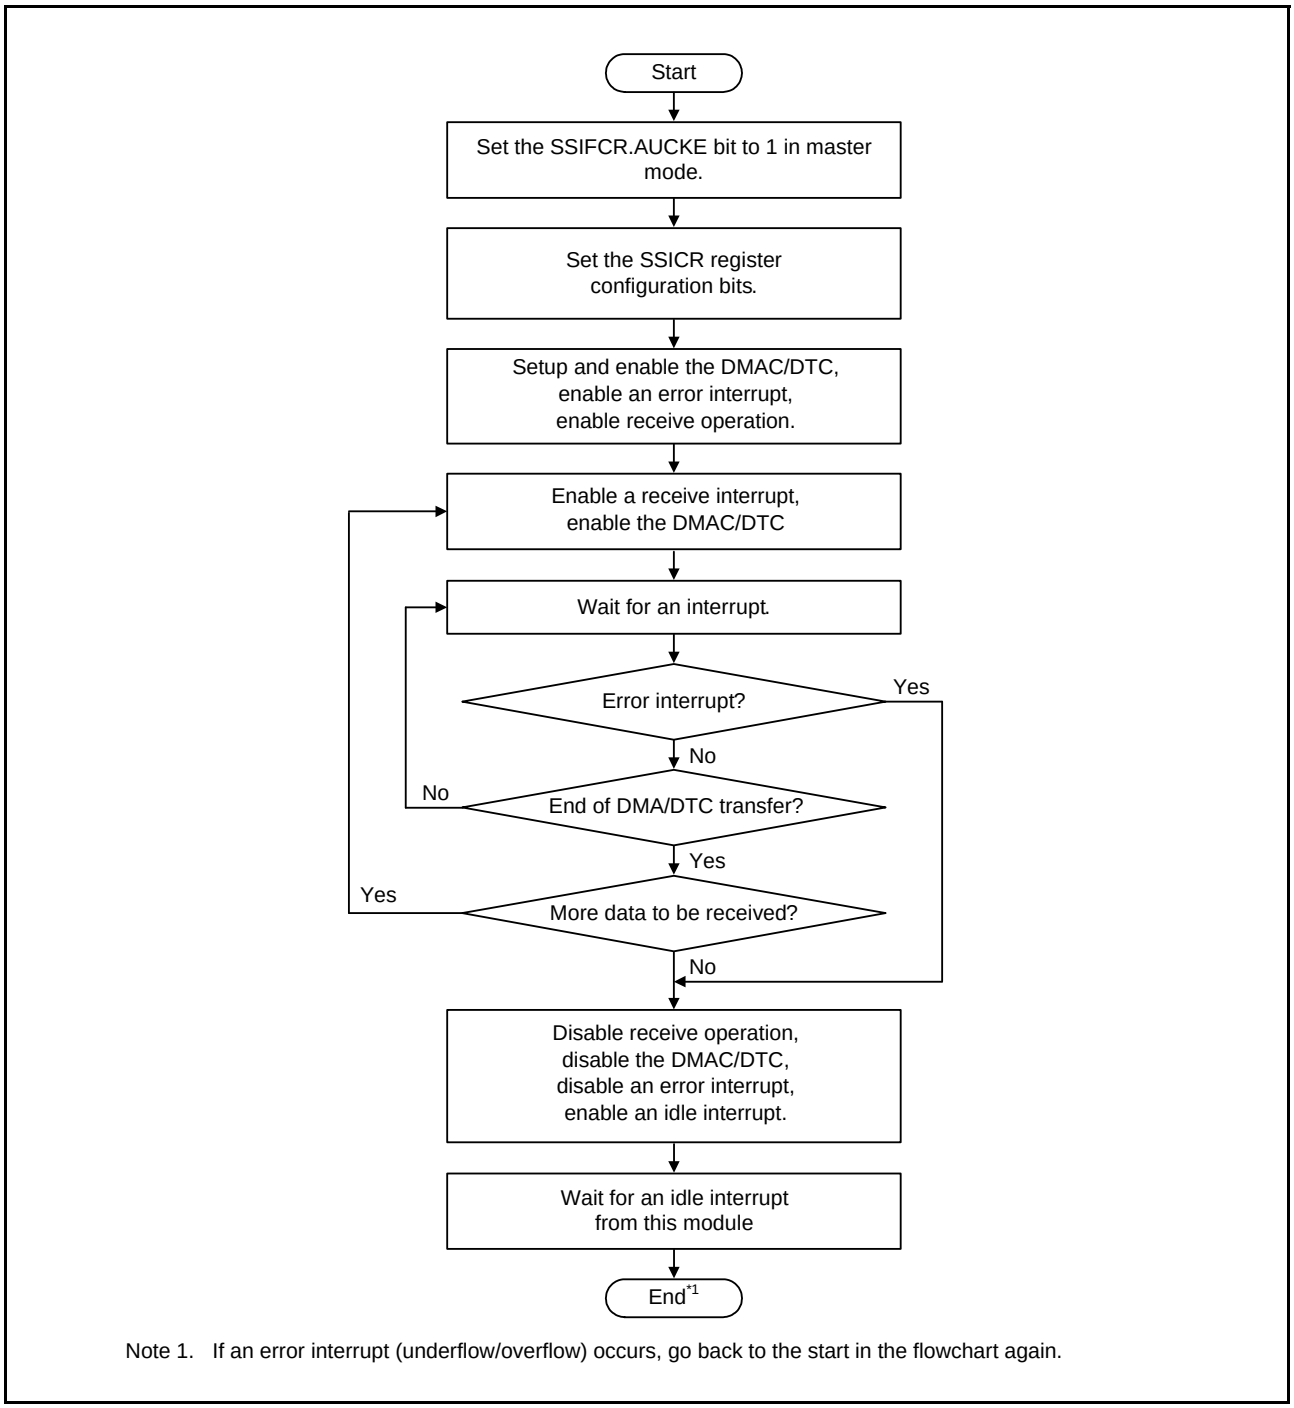
Figure 47.20 Transmission Using Interrupts

47.3.6 Receive Operation

Like transmission, reception can be controlled either by DMA/DTC transfer or interrupt.
Figure 47.21 and Figure 47.22 show the flow of operation.
When stopping reception, set the SSICR.REN bit to 0 and continue to supply the clock*1 until the SSISR.IIRQ flag becomes 1 (in idle state).

Note 1. Input clock from the SSISCKn pin when SSICR.SCKD bit = 0 (n = 0, 1).
Master clock when SSICR.SCKD bit = 1.

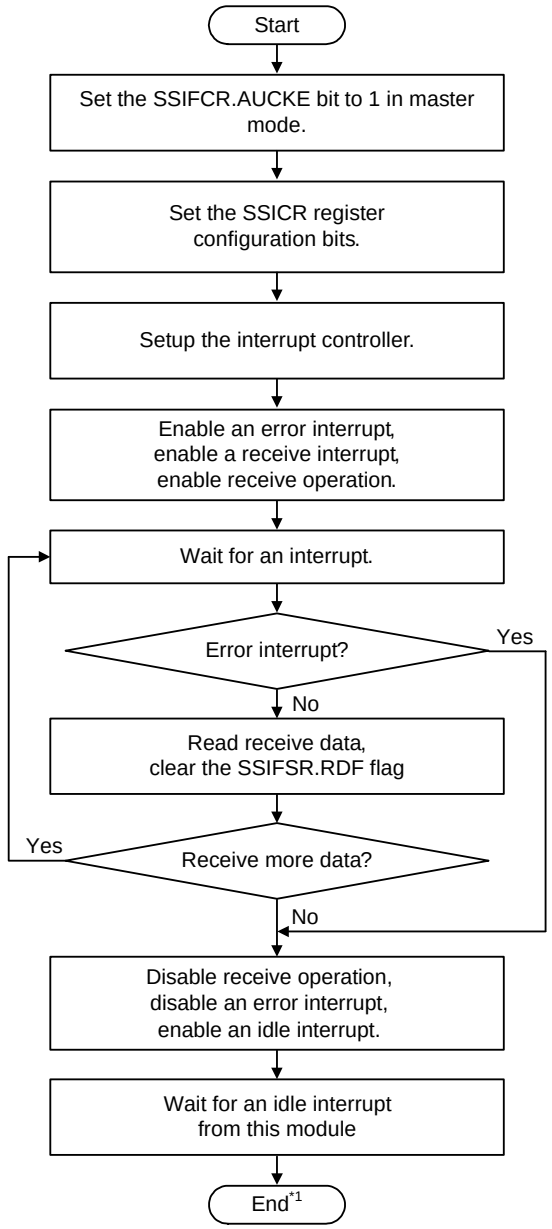
(1) Reception Using the DMAC/DTC



Note 1. If an error interrupt (underflow/overflow) occurs, go back to the start in the flowchart again.

Figure 47.21 Reception Using the DMAC/DTC

(2) Reception Using Interrupts



Note 1. If an error interrupt (underflow/overflow) occurs, go back to the start in the flowchart again.

Figure 47.22 Reception Using Interrupts

47.3.7 Serial Bit Clock Control

The SSI controls and selects the serial bit clock, according to the SSICR.SCKD and CKDV[3:0] bits setting.
If the serial bit clock direction is set to input (SCKD bit = 0), this module is in slave mode and the shift register uses the clock that was input to the SSISCKn pin as the bit clock (n = 0, 1).

If the serial bit clock direction is set to output (SCKD bit = 1), this module is in master mode, and the shift register uses the master clock (MCLK) or a divided master clock as the bit clock. The master clock is divided by the ratio specified by the SSICR.CKDV[3:0] bits for use as the bit clock by the shift register.
In either case the module pin, SSISCKn, is the same as the bit clock.

47.4 Interrupt Sources

Table 47.7 lists the interrupt sources of the SSI. Each interrupt source can be enabled or disabled by the SSICR.TUIEN, TOIEN, RUIEN, ROIEN and IIEN bits, and the SSIFCR.TIE and RIE bits.

Table 47.7 SSI Interrupt Sources

Channel	Interrupt Source	Description	Interrupt Status Flag	Interrupt Enable Bit	DMAC/DTC Start Trigger
SSI0	SSIF0	Transmit underflow interrupt Transmit overflow interrupt Receive underflow interrupt Receive overflow interrupt Idle interrupt	SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIRQ SSISR.IIRQ	SSICR.TUIEN SSICR.TOIEN SSICR.RUIEN SSICR.ROIEN SSICR.IIEN	Not available
	SSIRXI0	Receive data full interrupt (RXI)	SSIFSR.RDF	SSIFCR.RIE	Available
	SSITXI0	Transmit data empty interrupt (TXI)	SSIFSR.TDE	SSIFCR.TIE	Available
SSI1	SSIF1	Transmit underflow interrupt Transmit overflow interrupt Receive underflow interrupt Receive overflow interrupt Idle interrupt	SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIRQ SSISR.IIRQ	SSICR.TUIEN SSICR.TOIEN SSICR.RUIEN SSICR.ROIEN SSICR.IIEN	Not available
	SSIRTI1	Receive data full interrupt (RXI) Transmit data empty interrupt (TXI)	SSIFSR.RDF SSIFSR.TDE	SSIFCR.RIE SSIFCR.TIE	Available

47.5 Usage Notes

47.5.1 Setting the Module Stop Function

Module stop state can be entered or released using the MSTPCRD register. The initial setting of the SSI is in the module stop state. SSI register access is enabled by releasing the module stop state.
For details on the MSTPCRD register, refer to section 11, Low Power Consumption.

47.5.2 Notes on Changing Transmission Modes

For mode transitions between the transmitter, receiver, and transceiver while WS continue mode is disabled (SSITDMR.CONT = 0), set the SSICR.TEN and SSICR.REN bits to 0 and make a transition to the idle state once. Set the SSICR.TEN and SSICR.REN bits again while the module is in the idle state and restart transmission.

47.5.3 Limits on WS Continue Mode

If WS continue mode setting is changed, the operation of the SSISCKn and SSIWSn signals immediately after switching are not guaranteed (n = 0, 1). If it affects the device to be connected, do not change the setting dynamically.

47.5.4 Notes Regarding Clearing the Status Flag

The ROIRQ, RUIRQ, TOIRQ, and TUIRQ flags in the SSISR register can be set to 0 for only those that are read as 1. However, when reading any register in Table 47.8 while any of the flags is 1, the condition of reading the value 1 is satisfied even through the SSISR register is not read.
As a result, writing 0 to the applicable flag clears to the flag.
Similarly, regarding the RDF and TDE flags in the SSIFSR register, reading any register in Table 47.9 while either of the flag is 1, the condition of reading the value 1 is satisfied even though the SSIFSR register is not read. Just writing 0 to the applicable flag clears the flag.
Writing 0 only to the flag which is read as 1 when reading to clear the status flag.

Table 47.8 Registers that Satisfy the Condition of Reading the SSISR Register

Address	Module Symbol	Register Name	Register Symbol
0008 8004h	CMT0	Compare Match Timer Counter	CMCNT

48. Sample Rate Converter (SRC)

The sample rate converter is a module to convert the sample rate for data produced by various decoders such as WMA, MP3, or AAC.

48.1 Overview

Table 48.1 shows the specifications of the sample rate converter.

Table 48.1 Specifications of Sample Rate Converter

Item		Function
Data size		16 bits (stereo/monaural)
Sample rates	Input	8, 11.025, 12, 16, 22.05, 24, 32, 44.1, or 48 kHz is selectable.
	Output	8*1, 16*1, 32, 44.1, or 48 kHz is selectable.
Processing capacity		A sample output interval is a maximum of 7.7 µs (PCLKB = 60 MHz, 462 clocks).
SNR		80 dB or higher
Interrupt sources		Five Input FIFO empty, output FIFO full, output FIFO overflow, output FIFO underflow, and conversion end
DMA/DTC transfer sources		Two Input FIFO empty and output FIFO full
Module stop function		Power consumption can be reduced by stopping clock supply to this module when not used.

Note 1. Only when input of 44.1 kHz is selected.

Figure 48.1 shows a block diagram of the sample rate converter.

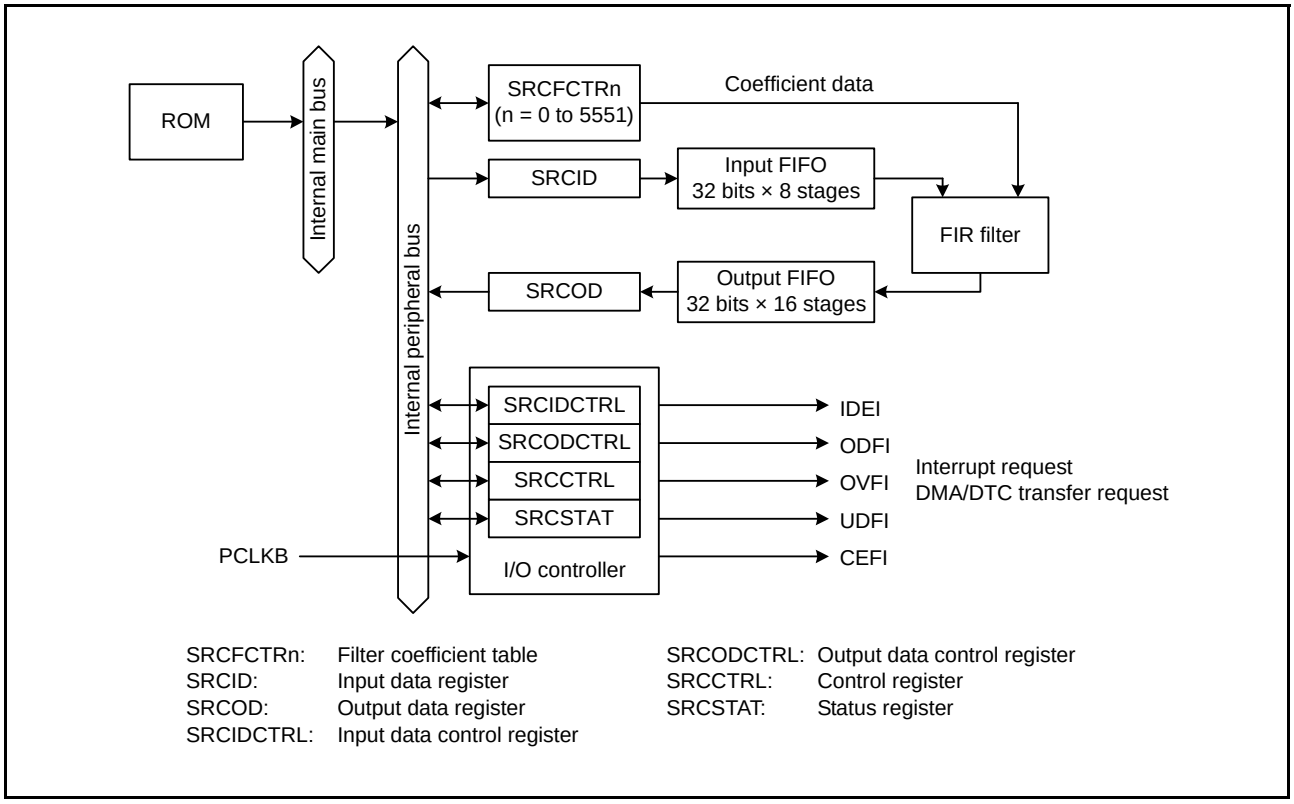

Figure 48.1 Block Diagram of Sample Rate Converter

48.2 Register Descriptions

48.2.1 Input Data Register (SRCID)

Address(es): SRC.SRCID 0009 DFF0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The SRCID register is a 32-bit readable/writable register that is used to input the data before sample rate conversion. This register is read as 0000 0000h. The data input to the SRCID register is stored in the 8-stage input FIFO. When the number of data in the input FIFO is 8, writing to the SRCID register has no effect.

For stereo data, bits 31 to 16 are for left channel data, and bits 15 to 0 are for right channel data. For monaural data, prepare valid data in bits 31 to 16 and dummy data in bits 15 to 0 before writing to the SRCID register in 32 bit units. The data arrangement must be changed by the setting of the SRCIDCTRL.IED bit when data to be converted are set to the SRCID register. Set the IED bit to 0 if the input data arrangement and the endian setting of the CPU are the same; set to 1 if these are different. For details on the endian setting of CPU, refer to section 7.2.5, Endian Select Register (MDE).

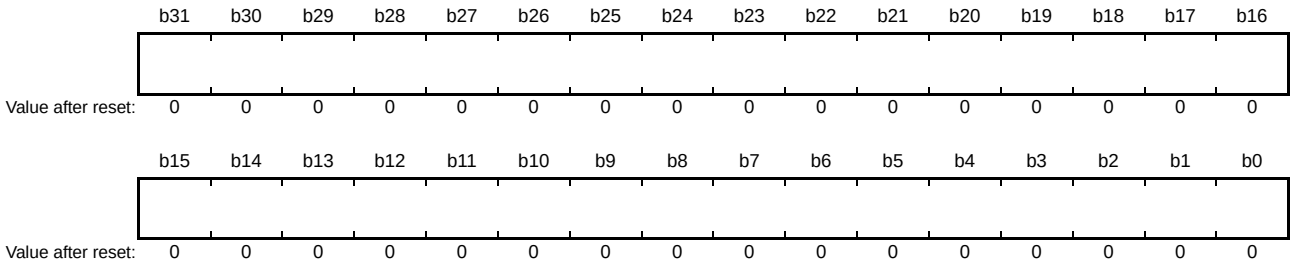
Table 48.2 shows the correspondence between the IED bit setting and data arrangement.

Table 48.2 Data Arrangement in the SRCID Register

SRCIDCTRL register	SRCID register			
IED bit	**b31 to b24**	**b23 to b16**	**b15 to b8**	**b7 to b0**
0	Lch[15:8]	Lch[7:0]	Rch[15:8]	Rch[7:0]
1	Lch[7:0]	Lch[15:8]	Rch[7:0]	Rch[15:8]

48.2.2 Output Data Register (SRCOD)

Address(es): 0009 DFF4h



The SRCOD register is a 32-bit read-only register used to output the data after sample rate conversion. The data in the 16-stage output FIFO is read through the SRCOD register. When the number of data in the output FIFO is zero after the start of conversion, the value previously read is read again.

The data arrangement in the SRCOD register depends on the settings of the OCH and OED bits in the SRCODCTRL register. Set the OED bit to 0 if the output data arrangement and the endian setting of the CPU are the same; set to 1 if these are different. For details on the endian setting of the CPU, refer to section 7.2.5, Endian Select Register (MDE).

Table 48.3 shows the correspondence between the OCH and OED bit setting and data arrangement in the SRCOD register.

Table 48.3 Data Arrangement in the SRCOD Register

SRCODCTRL register		SRCOD register			
OCH bit	**OED bit**	**b31 to b24**	**b23 to b16**	**b15 to b8**	**b7 to b0**
0	0	Lch[15:8]	Lch[7:0]	Rch[15:8]*1	Rch[7:0]*1
	1	Lch[7:0]	Lch[15:8]	Rch[7:0]*1	Rch[15:8]*1
1*2	0	Rch[15:8]	Rch[7:0]	Lch[15:8]	Lch[7:0]
	1	Rch[7:0]	Rch[15:8]	Lch[7:0]	Lch[15:8]

Note 1. When processing monaural data, the data in these bits is invalid. Discard the invalid data after reading from the SRCOD register in 32-bit units.

Note 2. When processing monaural data, do not set this bit to 1.

48.2.3 Input Data Control Register (SRCIDCTRL)

Address(es): SRC.SRCIDCTRL 0009 DFF8h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	IED	IEN	—	—	—	—	—	—	IFTRG[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	IFTRG[1:0]	Input FIFO Data Triggering Number	b1 b0 0 0: 0 0 1: 2 1 0: 4 1 1: 6	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	IEN	Input FIFO Empty Interrupt Enable	0: Disables input FIFO empty interrupt requests. 1: Enables input FIFO empty interrupt requests.	R/W
b9	IED	Input Data Endian*2	0: Does not switch the byte endian (when the endian setting of the CPU (MDE*1) is the same as the endian of the input data). 1: Switch the byte endian (when the endian setting of the CPU (MDE*1) is different from the endian of the input data).	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. For MDE settings, refer to section 7.2.5, Endian Select Register (MDE).
Note 2. This bit should be rewritten while the SRCCTRL.SRCEN bit is 0.

The SRCIDCTRL register is a 16-bit readable/writable register that specifies the byte endian of input data, enables/disables the interrupt requests, and specifies the triggering number of data.

IFTRG[1:0] Bits (Input FIFO Data Triggering Number)

These bits specify the condition in terms of the number on which the SRCSTAT.IINT flag is set to 1. When the number of data stored in the input FIFO becomes equal to or less than the specified triggering number, the IINT flag is set to 1.

IEN Bit (Input FIFO Empty Interrupt Enable)

Enables/disables the input FIFO empty interrupt request to be issued when the number of data in the input FIFO becomes equal to or less than the triggering number specified by the IFTRG[1:0] bits, thus resulting in the SRCSTAT.IINT flag being set to 1.

IED Bit (Input Data Endian)

Specifies the byte endian of the input data. Set this bit to 0 if the endian of the input data is the same as the endian setting of the CPU; set to 1 if these are different. For details on the endian setting of the CPU, refer to section 7.2.5, Endian Select Register (MDE).

48.2.4 Output Data Control Register (SRCODCTRL)

Address(es): SRC.SRCODCTRL 0009 DFFAh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	OCH	OED	OEN	—	—	—	—	—	—	OFTRG[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	OFTRG[1:0]	Output FIFO Data Trigger Number	b1 b0 0 0: 1 0 1: 4 1 0: 8 1 1: 12	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	OEN	Output FIFO Full Interrupt Enable	0: Disables output FIFO full interrupt requests. 1: Enables output FIFO full interrupt requests.	R/W
b9	OED	Output Data Endian	0: Does not switch the byte endian (when the endian setting of the CPU (MDE*1) is the same as the endian of the output data). 1: Switch the byte endian (when the endian setting of the CPU (MDE*1) is different from the endian of the output data).	R/W
b10	OCH	Output Data Channel Switching*2	0: Does not switch the data arrangement of the left and right channels (the same order of the input data) 1: Switch the data arrangement of the right and left channels (the reversed order of the input data)	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. For MDE settings, refer to section 7.2.5, Endian Select Register (MDE).
Note 2. This bit should be rewritten while the SRCCTRL.SRCEN bit is 0.

The SRCODCTRL register is a 16-bit readable/writable register that specifies whether to switch the channels for the output data, specifies the byte endian of output data, enables/disables the interrupt requests, and specifies the triggering number of data.

OFTRG[1:0] Bits (Output FIFO Data Trigger Number)

These bits specify the condition in terms of the number on which the SRCSTAT.OINT flag is set to 1. When the number of data in the output FIFO becomes equal to or greater than the specified triggering number, the OINT flag is set to 1.

OEN Bit (Output FIFO Full Interrupt Enable)

Enables/disables the output FIFO full interrupt request to be issued when the number of data in the output FIFO becomes equal to or greater than the number specified by the OFTRG[1:0] bits, thus resulting in the SRCSTAT.OINT flag being set to 1.

OED Bit (Output Data Endian)

Specifies the byte endian of the output data. Set this bit to 0 if the endian of the output data is the same as the endian setting of the CPU; set to 1 if these are different. For details on the endian setting of the CPU, refer to section 7.2.5, Endian Select Register (MDE).

OCH Bit (Output Data Channel Switching)

Specifies whether to switch the data arrangement of the left and right channels for the output data register (SRCOD). When processing monaural data, set this bit to 0.

48.2.5 Control Register (SRCCTRL)

Address(es): SRC.SRCCTRL 0009 DFFCh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b2 to b0	OFS[2:0]	Output Sample Rate	b2 b1 b0 0 0 0: 44.1 kHz 0 0 1: 48.0 kHz 0 1 0: 32.0 kHz 1 0 0: 8.0 kHz*1 1 0 1: 16.0 kHz*1 Settings other than above are prohibited.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7 to b4	IFS[3:0]	Input Sample Rate	b7 b6 b5 b4 0 0 0 0 : 8.0 kHz 0 0 0 1 : 11.025 kHz 0 0 1 0 : 12.0 kHz 0 1 0 0 : 16.0 kHz 0 1 0 1 : 22.05 kHz 0 1 1 0 : 24.0 kHz 1 0 0 0 : 32.0 kHz 1 0 0 1 : 44.1 kHz 1 0 1 0 : 48.0 kHz Settings other than above are prohibited.	R/W
b8	CL	Internal Work Memory Clear	Writing 1 to this bit clears the input FIFO, output FIFO, input buffer memory, intermediate memory, and accumulator.	R/W
b9	FL	Internal Work Memory Flush	Writing 1 to this bit starts converting the sample rate of all data in the input FIFO, input buffer memory, and intermediate memory (i.e., flush processing).	R/W
b10	OVEN	Output FIFO Overflow Interrupt Enable	0: Disables output FIFO overflow interrupt requests. 1: Enables output FIFO overflow interrupt requests.	R/W
b11	UDEN	Output FIFO Underflow Interrupt Enable	0: Disables output FIFO underflow interrupt requests. 1: Enables output FIFO underflow interrupt requests.	R/W
b12	SRCEN	Module Enable	0: Disables this module operation. 1: Enables this module operation.*2	R/W
b13	CEEN	Conversion End Interrupt Enable	0: Disables conversion end interrupt requests. 1: Enables conversion end interrupt requests.	R/W
b14	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b15	FICRAE	Filter Coefficient Table Access Enable	0: Reading/writing to filter coefficient table RAM is disabled. 1: Reading/writing to filter coefficient table RAM is enabled.	R/W

Note 1. Valid only when the IFS[3:0] bits are 1001b.
Note 2. When the SRCEN bit is 1, do not change the settings of the following bits:
SRCIDCTRL.IED bit, SRCODCTRL.OED and OCH bits, SRCCTRL.OFS[2:0], IFS[3:0], and FICRAE bits.

The SRCCTRL register is a 16-bit readable/writable register that enables/disables the access to the filter coefficient table, module operations, and interrupt requests, and specifies flush processing, clear processing of the internal work memory, and the input and output sample rates.

OFS[2:0] Bits (Output Sample Rate)

These bits specify the output sample rate.

IFS[3:0] Bits (Input Sample Rate)

These bits specify the input sample rate.

CL Bit (Internal Work Memory Clear)

Writing 1 to this bit clears the input FIFO, output FIFO, input buffer memory, intermediate buffer memory, and accumulator, then the CL bit is set to 0. This bit is read as 0. Even if the SRCEN bit is 0, writing 1 to this bit clears the processing.

FL Bit (Internal Work Memory Flush)

Writing 1 to this bit starts converting the sample rate of all data in the input FIFO, input buffer memory, and intermediate memory (i.e., flush processing). This bit is read as 0. When the SRCEN bit is 0, writing 1 to this bit does not trigger flush processing.
In addition, when 1 is written to the FL bit if the number of the input data is less than the values shown in Table 48.6, the effective output data cannot be obtained. Thus the internal work memory is cleared without triggering the flush processing.

OVEN Bit (Output FIFO Overflow Interrupt Enable)

Enables/disables the output FIFO overflow interrupt request to be issued when the SRCSTAT.OVF flag is set to 1.
When the OVEN bit is 1: Conversion processing is stopped until the OVF flag is cleared by the CPU accessing to SRCSTAT when the output FIFO overflow interrupt is generated. At this time, conversion result writing to the output FIFO is also stopped.
When the OVEN bit is 0: The OVF flag is automatically cleared when the output FIFO has space, and conversion processing can be continued.

UDEN Bit (Output FIFO Underflow Interrupt Enable)

Enables/disables the output FIFO underflow interrupt to be generated when the SRCSTAT.UDF flag is set to 1.

SRCEN Bit (Module Enable)

Enables/disables this module operation. Rewriting the SRCEN bit from 0 to 1 clears the internal work memory.

CEEN Bit (Conversion End Interrupt Enable)

Enables/disables a conversion end interrupt request to be issued when the SRCSTAT.CEF flag is set to 1 after flush processing is completed and all output data is read.

FICRAE Bit (Filter Coefficient Table Access Enable)

Enables/disables the access to the filter coefficient table RAM.

After flush processing has been completed, the number of output data obtained as a result of conversion can be calculated by using the following formula.
The value of n can be obtained from Table 48.4. The number of input data should be equal to or greater than the values in Table 48.5.

$$\frac{\text{Number of output data} - 1}{\text{Output sample rate}} = \frac{\text{Number of input data} \times n - 1}{\text{Input sample rate} \times n}$$

$$\text{Number of output data} = \left[(\text{Number of input data} \times n - 1) \times \frac{\text{Output sample rate}}{\text{Input sample rate} \times n} \right] + 1$$

Table 48.4 Sample Rate Settings and the Value of n

OFS[2:0] Bit Setting (Output Sample Rate [kHz])	IFS[3:0] Bit Setting (Input Sample Rate [kHz])								
	0000b (8.0)	0001b (11.025)	0010b (12.0)	0100b (16.0)	0101b (22.05)	0110b (24.0)	1000b (32.0)	1001b (44.1)	1010b (48.0)
000b (44.1)	6	4	4	3	2	2	3	—	1
001b (48.0)	6	4	4	3	2	2	3	1	—
010b (32.0)	4	8	4	2	4	2	—	2	1
100b (8.0)	—	—	—	—	—	—	—	1	—
101b (16.0)	—	—	—	—	—	—	—	1	—

Conversion processing is not started and thus output data is not obtained until the specified number of data are input. The minimum number of input data necessary for obtaining the first output data depends on the IFS[3:0] and OFS[2:0] bit settings. Table 48.5 shows the relation between the settings of the IFS[3:0] and OFS[2:0] bits and the number of initial input data required. Table 48.6 shows the relation between the settings of the IFS[3:0] and OFS[2:0] bits and the number of initial input data required for flush processing.

Table 48.5 Relation between Sample Rate Settings and Number of Initial Input Data Required

48.2.6 Status Register (SRCSTAT)

Address(es): SRC.SRCSTAT 0009 DFFEh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OFDN[4:0]					IFDN[3:0]				—	CEF	FLF	UDF	OVF	IINT	OINT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	OINT	Output FIFO Full Interrupt Request Flag	0: Number of data in the output FIFO has not become equal to or greater than the specified triggering number. 1: Number of data in the output FIFO has become equal to or greater than the specified triggering number.	R/(W) *1
b1	IINT	Input FIFO Empty Interrupt Request Flag	0: Number of data in the input FIFO has not become equal to or smaller than the specified triggering number. 1: Number of data in the input FIFO has become equal to or smaller than the specified triggering number.	R/(W) *1
b2	OVF	Output FIFO Overflow Interrupt Request Flag	0: No output FIFO overflow 1: An output FIFO overflow has occurred.	R/(W) *1
b3	UDF	Output FIFO Underflow Interrupt Request Flag	0: No output FIFO underflow 1: An output FIFO underflow has occurred.	R/(W) *1
b4	FLF	Flush Processing Status Flag	0: Flush processing is completed. 1: Flush processing is in progress.	R
b5	CEF	Conversion End Flag	0: All of the output data has not been read out. 1: All of the output data has been read out.	R/(W) *1
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b10 to b7	IFDN[3:0]	Input FIFO Data Count	Indicate the number of data in the input FIFO.	R
b15 to b11	OFDN[4:0]	Output FIFO Data Count	Indicate the number of data in the output FIFO.	R

Note 1. Only 0 can be written after having read as 1.

The SRCSTAT register is a 16-bit readable/writable register that indicates the number of data in the input and output FIFOs, whether the various interrupt sources have been generated or not, and the flush processing status.

OINT Flag (Output FIFO Full Interrupt Request Flag)

Indicates that the number of data in the output FIFO has become equal to or greater than the triggering number specified by the SRCODCTRL.OFTRG[1:0] bits.

[Setting condition]

- When the number of data in the output FIFO has become equal to or greater than the specified triggering number.

[Clearing conditions]

- When 0 has been written to the OINT flag after confirming the OINT flag is 1.
- When the last DMA/DTC transfer is executed.
- When 1 has been written to the SRCCTRL.CL bit.
- When the SRCCTRL.SRCEN bit has been rewritten from 0 to 1.

IINT Flag (Input FIFO Empty Interrupt Request Flag)

Indicates that the number of data in the input FIFO has become equal to or smaller than the triggering number specified by the SRCIDCTRL.IFTRG[1:0] bits.

[Setting conditions]

- When the number of data in the input FIFO has become equal to or smaller than the specified triggering number.
- When 1 has been written to the SRCCTRL.CL bit.

- When the SRCCTRL.SRCEN bit has been rewritten from 0 to 1.

[Clearing conditions]

- When 0 has been written to the IINT flag after confirming the IINT flag is 1.
- When the last DMA/DTC transfer is executed.

OVF Flag (Output FIFO Overflow Interrupt Request Flag)

Indicates that data has been written when the output FIFO is full. The conversion is stopped until the OVF flag is cleared.

[Setting condition]

- When data has been written when the output FIFO is full.

[Clearing conditions]

- If the SRCCTRL.OVEN bit is 1, when 0 has been written to the OVF flag after confirming the OVF flag is 1.
- If the SRCCTRL.OVEN bit is 0, when the number of data in the output FIFO decreases after reading the SRCOD register.
- When 1 has been written to the SRCCTRL.CL bit.
- When the SRCCTRL.SRCEN bit has been rewritten from 0 to 1.

UDF Flag (Output FIFO Underflow Interrupt Request Flag)

Indicates that data has been read when the output FIFO is empty.

[Setting condition]

- When data has been read when the output FIFO is empty.

[Clearing conditions]

- When 0 has been written to the UDF flag after confirming the UDF flag is 1.
- When 1 has been written to the SRCCTRL.CL bit.
- When the SRCCTRL.SRCEN bit has been rewritten from 0 to 1.

FLF Flag (Flush Processing Status Flag)

Indicates whether flush processing is in progress or not.

[Setting condition]

- When 1 has been written to the SRCCTRL.FL bit.
  (When flush processing is not in progress, however, the FLF flag is not set to 1).

[Clearing conditions]

- When flush processing has been completed.
- When 1 has been written to the SRCCTRL.CL bit.
- When the SRCCTRL.SRCEN bit has been rewritten from 0 to 1.

CEF Flag (Conversion End Flag)

Indicates that all output data is read after flush processing is completed.

[Setting condition]

- When the number of data in the output FIFO is zero on completion of flush processing.

[Clearing conditions]

- When 0 has been written to the CEF flag after confirming the CEF flag is 1.
- When 1 has been written to the SRCCTRL.CL bit.
- When the SRCCTRL.SRCEN bit has been rewritten from 0 to 1.

IFDN[3:0] Bits (Input FIFO Data Count)

These bits indicate the number of data in the input FIFO.

OFDN[4:0] Bits (Output FIFO Data Count)

These bits indicate the number of data in the output FIFO.

48.2.7 Filter Coefficient Table n (SRCFCTRn) (n = 0 to 5551)

Address(es): SRC.SRCFCTR0 to SRC.SRCFCTR5551 0009 8000h to 0009 D6BFh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	SRCFCOE[21:16]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SRCFCOE[15:0]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

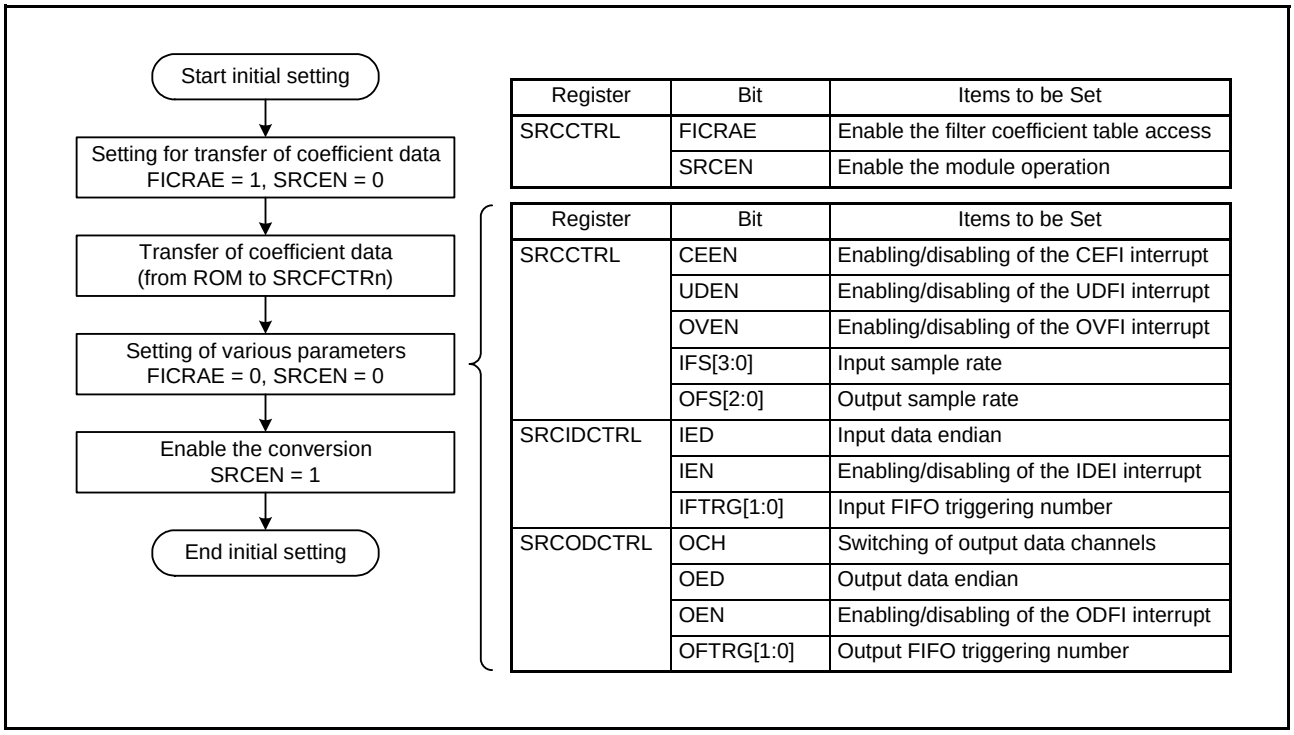
Bit	Symbol	Bit Name	Description	R/W
b21 to b0	SRCFCOE[21:0]	Filter Coefficient Table	Stores a filter coefficient value.	R/W
b31 to b22	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SRCFCTR0 to SRCFCTR5551 are 32-bit readable/writable RAM that store the filter coefficient to be used for sample rate conversion. This RAM can be read from and written to through the peripheral bus only when the SRCCTRL.FICRAE bit is 1 and the SRCCTRL.SRCEN bit is 0.

48.3 Operation

48.3.1 Initial Setting

Figure 48.2 shows a sample flowchart for initial setting. After the module stop state is released, the filter coefficient data stored in ROM and other areas needs to be transferred to the filter coefficient table (SRCFCTRn) before SRC conversion starts. When the filter coefficient data has been already stored in the filter coefficient table, skip the transfer mentioned above and set the various necessary parameters to start the conversion.



Register	Bit	Items to be Set
SRCCTRL	FICRAE	Enable the filter coefficient table access
	SRCEN	Enable the module operation

Register	Bit	Items to be Set
SRCCTRL	CEEN	Enabling/disabling of the CEFI interrupt
	UDEN	Enabling/disabling of the UDFI interrupt
	OVEN	Enabling/disabling of the OVFI interrupt
	IFS[3:0]	Input sample rate
	OFS[2:0]	Output sample rate
SRCIDCTRL	IED	Input data endian
	IEN	Enabling/disabling of the IDEI interrupt
	IFTRG[1:0]	Input FIFO triggering number
SRCODCTRL	OCH	Switching of output data channels
	OED	Output data endian
	OEN	Enabling/disabling of the ODFI interrupt
	OFTRG[1:0]	Output FIFO triggering number

Figure 48.2 Sample Flowchart for Initial Setting

48.3.2 Data Input

Figure 48.3 is a sample flowchart for data input.

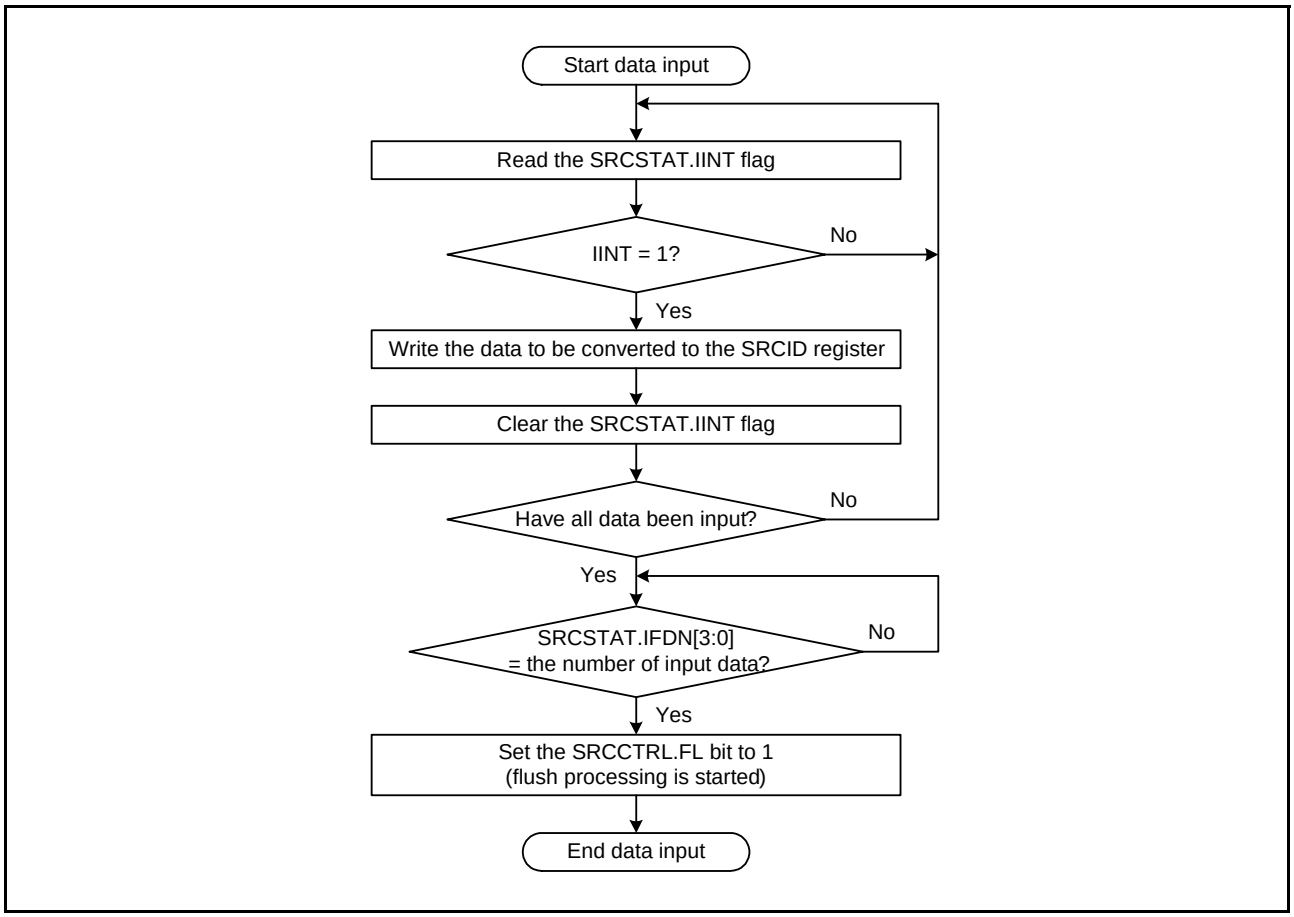


Figure 48.3 Flowchart for Data Input

(1) When Interrupts are Issued to CPU

1. Set the SRCIDCTRL.IEN bit to 1.
2. When the SRCSTAT.IINT flag is set to 1, the IDEI interrupt request is generated. In the interrupt processing routine, confirm that the IINT flag is 1, write data to the SRCID register, and write 0 to the IINT flag. Then return from the interrupt processing routine.
3. Repeat step 2 to complete input of all data.
4. Confirm that the value of the SRCSTAT.IFDN[3:0] bits matches with the number of data written to the SRCID register.
5. Write 1 to the SRCCTRL.FL bit.

(2) When Interrupts are Used to Activate DMAC

1. Set the request source for one of the channels of the DMAC as an IDEI interrupt request of this module.
2. Set the SRCIDCTRL.IEN bit to 1.
3. When the SRCSTAT.IINT flag is set to 1, an IDEI interrupt request is generated and the DMAC starts. When data is written to the SRCID register using DMA transfer and the number of data in the input FIFO exceeds the triggering number specified by the SRCIDCTRL.IFTRG[1:0] bits, the SRCSTAT.IINT flag becomes 0.
4. Repeat step 3 to complete input of all data, and write 1 to the SRCCTRL.FL bit.

(3) When Serial Sound Interface Interrupts are Used for Starting DMAC to Transfer Input Data from Serial Sound Interface

1. Set the request source for one of the channels of the DMAC as the serial sound interface. Set the SSIFRDR register of the serial sound interface as a transfer source and the SRCID register of the sample rate converter as a transfer destination, and set the serial sound interface to enable receive operation.
2. When the SSIFSR.RDF flag is set to 1, the serial sound interface interrupt request is generated and the DMAC starts. The DMAC then reads data from the SSIFRDR register and writes the data to the SRCID register.
3. Repeat step 2 to complete input of all data, and write 1 to the SRCCTRL.FL bit.

Note: The input FIFO has eight stages. The number of the data that can be transferred (i.e., the empty space in the FIFO) when an IDEI interrupt request is generated depends on the settings of the SRCIDCTRL.IFTRG[1:0] bits. Since the input FIFO is not equipped with a function to prevent or detect an overflow, the transferred data will be destroyed when an overflow occurs. When setting the number of consecutive data transfers by the DMAC, consider the settings of the SRCCTRL.IFTRG[1:0] bits.

48.3.3 Data Output

Figure 48.3 is a sample flowchart for data output.

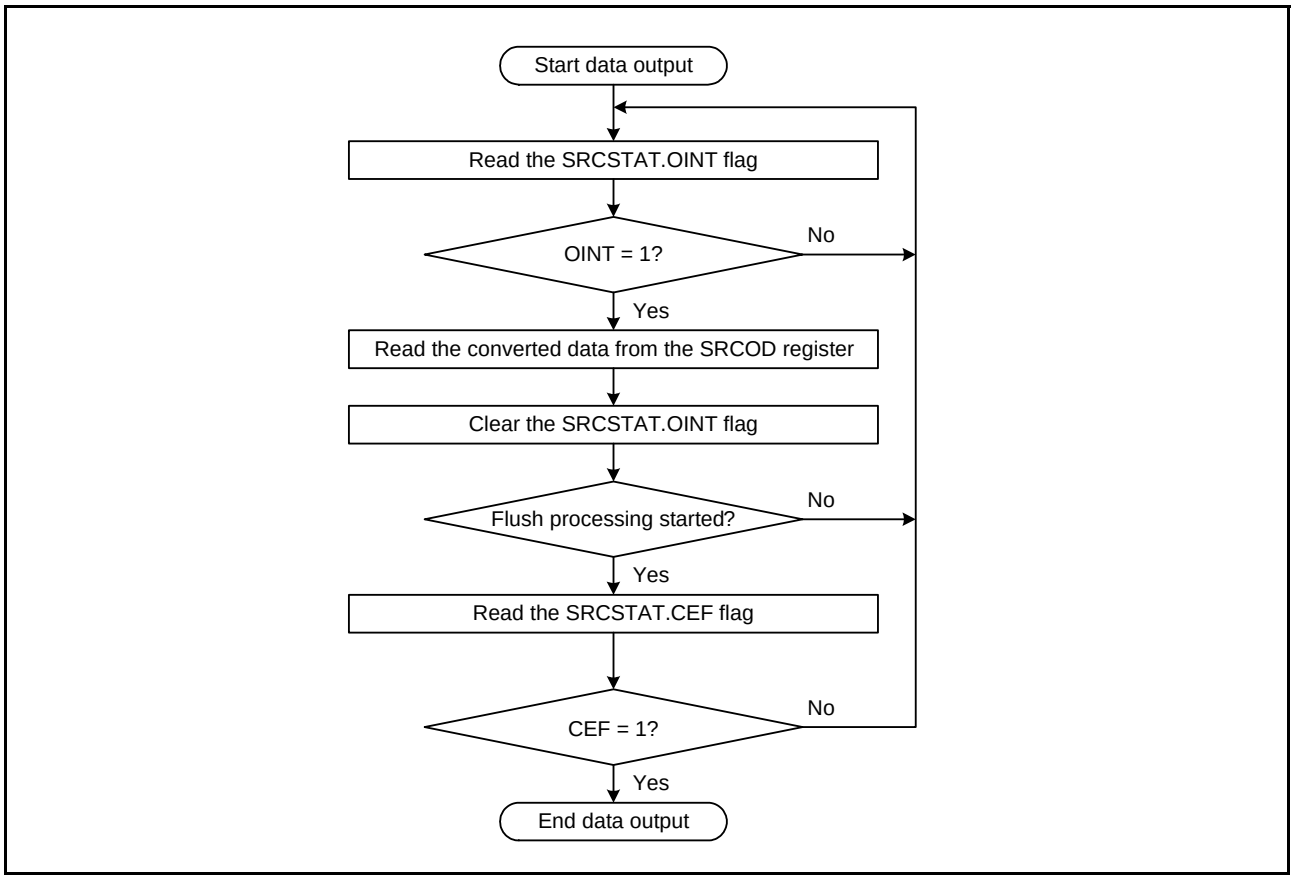

Figure 48.4 Flowchart for Data Output

(1) When Interrupts are Issued to CPU

1. Set the SRCODCTRL.OEN bit to 1.
2. When the SRCSTAT.OINT flag is set to 1, the ODFI interrupt request is generated. In the interrupt processing routine, confirm that the OINT flag is 1, read data from the SRCOD register, and write 0 to the OINT flag. Then return from the interrupt processing routine.
3. After flush processing starts, repeat step 2 until the SRCSTAT.CEF flag is read as 1.

(2) When Interrupts are Used to Activate DMAC

1. Assign the ODFI interrupt request of this module to one channel of the DMAC as a DMA transfer request source.
2. Set the SRCODCTRL.OEN bit to 1.
3. When the SRCSTAT.OINT flag is set to 1, the ODFI interrupt request is generated and the DMAC starts. When data is read from the SRCOD register using DMA transfer and the number of data in the output data FIFO becomes equal to or less than the triggering number specified by the SRCODCTRL.OFTRG[1:0] bits, the SRCSTAT.OINT flag becomes 0.
4. After flush processing starts, repeat step 3 until the SRCSTAT.FLF flag is read as 0.

(3) When Serial Sound Interface Interrupts are Used for Starting DMAC to Transfer Output Data to Serial Sound Interface

1. Set the SRCCTRL.OVEN bit to 0 to disable the OVFI interrupt request generation.
2. Assign the serial sound interface to one channel of the DMAC as a DMA transfer request source. Set the SRCOD register of the sample rate converter as a transfer source and the SSIFTDR register of the serial sound interface as a transfer destination, and set the serial sound interface to enable transmit operation.
3. When the SSIFSR.TDE flag is set to 1, the serial sound interface interrupt request is generated and the DMAC starts. The DMAC then reads data from the SRCOD register and writes the data to the SSIFTDR register.
4. After flush processing starts, repeat step 3 until the SRCSTAT.CEF flag is read as 1.

Note 1. The output FIFO has 16 stages. The conversion will be stopped when no data is read and overflow occurs in the output FIFO. Even in the state with overflow, data can be read from the output FIFO, but the procedure to restart conversion may be required depending on the settings. (For details, see the SRCCTRL.OVEN bit).

Note 2. When the number of data in the output FIFO is zero, incorrect data will be read. Thus take the settings of the SRCODCTRL.OFTRG[1:0] bits into consideration when setting the number of data to be continuously transferred by the DMAC.

48.4 Interrupts

This module has five interrupt sources: input FIFO empty (IDEI), output FIFO full (ODFI), output FIFO overflow (OVFI), output FIFO underflow (UDFI), and conversion end (CEFI). Table 48.7 lists interrupt request types and generation conditions.

Table 48.7 Interrupt Requests and Generation Conditions

Interrupt Request	Abbreviation	Interrupt Condition	DMA/DTC Request
Input FIFO empty	IDEI	(IINT = 1), (IEN = 1), and (SRCEN = 1)	Possible
Output FIFO full	ODFI	(OINT = 1), (OEN = 1), and (SRCEN = 1)	Possible
Output FIFO overflow	OVFI	(OVF = 1), (OVEN = 1), and (SRCEN = 1)	Not possible
Output FIFO underflow	UDFI	(UDF = 1), (UDEN = 1), and (SRCEN = 1)	Not possible
Conversion end	CEFI	(CEF = 1), (CEEN = 1), and (SRCEN = 1)	Not possible

When the condition for interrupt generation is satisfied, an interrupt request is output to the ICU.
The IDEI and ODFI interrupts can start the DMA/DTC transfer. If the DMAC or DTC is selected as an interrupt request destination, the interrupts from this module are not sent to the CPU.
Do not clear the IINT and OINT flags through writing by the CPU (i.e., writing 0 after reading 1) during the DMA/DTC transfer.

48.5 Usage Notes

48.5.1 Notes on Accessing Registers (1)

The specifications of access cycles depends on the register or filter coefficient table (RAM). For the number of access cycles, refer to section 5.1, I/O Register Addresses (Address Order).

48.5.2 Notes on Accessing Registers (2)

It takes three cycles of the peripheral module clock (PCLKB) from writing to the SRCCTRL register to updating the SRCSTAT register in the following cases:

- Until the SRCSTAT.FLF flag becomes 1 after 1 is written to the SRCCTRL.FL bit
- Until each bit in the SRCSTAT register is initialized after 1 is written to the SRCCTRL.CL bit
- Until each bit in the SRCSTAT register is initialized after the SRCCTRL.SRCEN bit has been rewritten from 0 to 1

On the other hand, since the CPU executes any subsequent instruction without waiting for the completion of writing to a register, the updated state of the SRCSTAT register cannot be correctly read out by an instruction immediately after the writing instruction to the SRCCTRL register. To check the updated state of the SRCSTAT register, perform a dummy read of the SRCCTRL or SRCSTAT register after the writing instruction to the SRCCTRL register.

48.5.3 Notes on Flush Processing

When 1 is written to the SRCCTRL.FL bit, this module adds dummy data of 0000 0000h after the data that have been input and continues flush processing. Perform flush processing when the last audio data has been input and there is no subsequent data.
To perform conversion again after flush processing, clear the internal work memory in either of the following ways.

- Write 1 to the SRCCTRL.CL bit.
- Write 0 and then 1 to the SRCCTRL.SRCEN bit.

48.5.4 Notes on DMA/DTC Transfer

When the DMAC or DTC is used for data transfer to the SRCID register or from the SRCOD register, do not clear the SRCSTAT.IINT or OINT flag by the CPU (writing 0 after reading 1) during the DMA/DTC transfer.

48.5.5 Notes on SRC Operation

Do not access the filter coefficient table when the SRC is operating (SRCCTRL.SRCEN = 1).

48.5.6 Conversion immediately after the Data Set in the SRCID Register

Confirm that the value of the SRCSTAT.IFDN[3:0] bits matches with the number of data written to the SRCID register when performing conversion immediately after setting the data in the SRCID register.

48.5.7 Module Stop Function Setting

Operation of the SRC can be disabled or enabled by module stop control register D (MSTPCRD). After a reset, operation of the SRC is stopped. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

49. SD Host Interface (SDHI)

This MCU incorporates an SD host interface (SDHI) which is compliant with the SD Specifications. When developing host devices that are compliant with the SD Specifications, the user must enter into the SD Host/Ancillary Product License Agreement (SD HALA).

49.1 Overview

Table 49.1 lists the SDHI specifications.

Table 49.1 SDHI Specifications

Item	Description
SD bus interface	• Compatible with SD memory card and SDIO card (**NOT** compatible with the SPI bus interface, embedded SDIO shared bus, 8-bit SD bus, or SDIO suspend/resume functions) • Transfer bus mode selectable from 4-bit wide bus mode or 1-bit default bus mode • Compatible with SD, SDHC, and SDXC formats
Transfer modes	Selectable from high-speed mode or default speed mode
SDHI clock	The SDHI clock is generated by dividing peripheral module clock B (PCLKB) by *n*, where *n* = 2, 4, 8, 16, 32, 64, 128, 256, or 512
Error check functions	• CRC7 (command/response) • CRC16 (transfer data)
Interrupt sources	• Card access interrupt (CACI) • SDIO access interrupt (SDACI) • Card detection interrupt (CDETI) • SD buffer access interrupt (SBFAI)
DMA transfer sources	• DMAC and DTC triggerable by the SBFAI interrupt • SD buffer is read and write accessible using the DMAC and DTC
Other functions	• Card detection • Write protection

Figure 49.1 shows a block diagram of the SDHI.

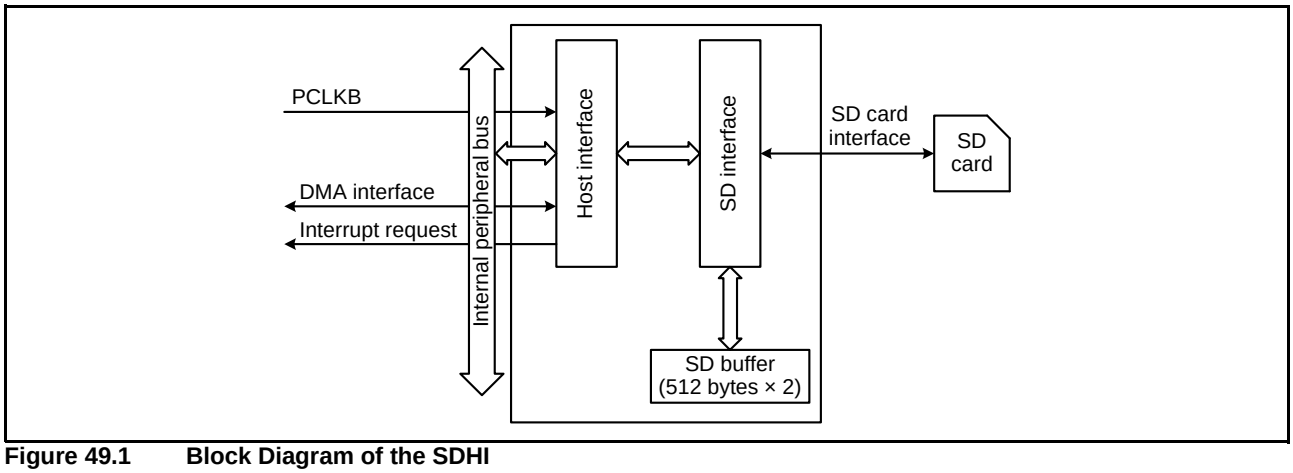

Figure 49.1 Block Diagram of the SDHI

Table 49.2 lists the pin configuration of the SDHI.

Table 49.2 Pin Configuration of the SDHI

Pin Name	I/O	Description
SDHI_CLK	Output	SDHI clock
SDHI_CMD	I/O	Command output, response input
SDHI_D0	I/O	Data 0 (DAT0)
SDHI_D1	I/O	Data 1 (DAT1), SDIO access interrupt
SDHI_D2	I/O	Data 2 (DAT2), read wait
SDHI_D3	I/O	Data 3 (DAT3), SD card detection
SDHI_CD	Input	SD card detection
SDHI_WP	Input	SD card write protection

49.2 Register Details

49.2.1 Command Register (SDCMD)

Address(es): SDHI.SDCMD 0008 AC00h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CMD12AT[1:0]		TRSTP	CMDRW	CMDTP	RSPTP[2:0]			ACMD[1:0]		CMDIDX[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	CMDIDX[5:0]	Command Index Field Value Select	These bits configure the command index field value. The examples below include the bit values for the ACMD[1:0] bits. b7 b0 0 0 0 0 0 1 1 0: CMD6 0 0 0 1 0 0 1 0: CMD18 0 1 0 0 1 1 0 1: ACMD13	R/W
b7, b6	ACMD[1:0]	Command Type Select	b7 b6 0 0: CMD 0 1: ACMD Only set the values listed above.	R/W
b10 to b8	RSPTP[2:0]	Response Type Select *1	b10 b8 0 0 0: Normal mode. Depending on the command, the response type and transfer method are selected by setting the ACMD[1:0] bits and CMDIDX[5:0] bits. At this time, the values for b15 to b11 in this register are invalid. 0 1 1: Expansion mode and no response 1 0 0: Expansion mode and R1, R5, R6, or R7 response 1 0 1: Expansion mode and R1b response 1 1 0: Expansion mode and R2 response 1 1 1: Expansion mode and R3 or R4 response Only set the values listed above.	R/W
b11	CMDTP	Data Transfer Select *2	0: Command does not include data transfer (bc, bcr, or ac) 1: Command includes data transfer (adtc)	R/W
b12	CMDRW	Data Transfer Direction Select *3	0: Write data to the SD card 1: Read data from the SD card	R/W
b13	TRSTP	Block Transfer Select *3	0: Single block transferred 1: Multiple blocks transferred	R/W
b15, b14	CMD12AT[1:0]	CMD12 Automatic Issue Select *4	b15 b14 0 0: CMD12 is automatically issued during multi-block transfer 0 1: CMD12 is not automatically issued during multi-block transfer Only set the values listed above.	R/W
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Some commands cannot be used in normal mode. Refer to Table 49.3 and set the RSPTP[2:0] bits.
Note 2. The CMDTP bit is valid only when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b.
Note 3. Bits CMDRW and TRSTP are valid only when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b, and the CMDTP bit is 1.
Note 4. The CMD12AT[1:0] bits are valid only when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b, and the TRSTP bit is 1.

The command type and response type are set in the SDCMD register. The command type and transfer mode must be set when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b. The sequence starts when a value is written to this register. Refer to Table 49.3 for setting examples. Do not write to the SDCMD register when the SDSTS2.CBSY flag is 1.

Table 49.3 lists examples of SDCMD register settings.

Table 49.3 Examples of SDCMD Register Settings

Type	Command Symbol	SDCMD Register Setting	Remarks
CMD	CMD0	0000 0000h	
	CMD2	0000 0002h	
	CMD3	0000 0003h	
	CMD4	0000 0004h	
	CMD5	0000 0705h or 0000 0005h	
	CMD6	0000 1C06h or 0000 0006h	
	CMD7	0000 0007h	When the card is deselected, the SD card does not return a response, so the SDSTS2.RSPTO flag becomes 1.
	CMD8	0000 0408h or 0000 0008h	
	CMD9	0000 0009h	
	CMD10	0000 000Ah	
	CMD11	0000 040Bh or 0000 000Bh	
	CMD12	0000 000Ch	
	CMD13	0000 000Dh	
	CMD15	0000 000Fh	
	CMD16	0000 0010h	
	CMD17	0000 0011h	
	CMD18	0000 0012h	
	CMD20	0000 0514h or 0000 0014h	
	CMD24	0000 0018h	
	CMD25	0000 0019h	
	CMD27	0000 001Bh	
	CMD28	0000 001Ch	
	CMD29	0000 001Dh	
	CMD30	0000 001Eh	
	CMD32	0000 0020h	
	CMD33	0000 0021h	
	CMD38	0000 0026h	
	CMD42	0000 002Ah	
	CMD52	0000 0434h or 0000 0034h	
	CMD53	0000 1C35h	Single block read
		0000 0C35h	Single block write
		0000 7C35h	Multi-block read
		0000 6C35h	Multi-block write
		0000 0035h	The setting to the left can be used regardless of the transfer being single block or multi-block. However, the MSB in the SDARG register (RW flag) must be set to 0 when reading and 1 when writing.
	CMD55	0000 0037h	
	CMD56	0000 0038h	
ACMD	ACMD6	0000 0046h

49.2.2 Argument Register (SDARG)

Address(es): SDHI.SDARG 0008 AC08h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The SDARG register is used for setting the argument field value. Set the SDARG register before setting the SDCMD register. The argument field value of the automatically issued CMD12 is 0000 0000h regardless of the SDARG register value.

49.2.3 Data Stop Register (SDSTOP)

Address(es): SDSTOP 0008 AC10h

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	—	—	—	—	SDBLKCNTEN
Value after reset:	0	0	0	0	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	STP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STP	Transfer Stop	Data transfer stops when this bit is set to 1.	R/W
b7 to b1	—	Reserved	These bits are 0 when read and cannot be modified.	R
b8	SDBLKCNTEN	Block Count Register Value Select *1	0: SDBLKCNT register value is invalid 1: SDBLKCNT register value is valid	R/W
b31 to b9	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite this bit when the SDSTS2.CBSY flag is 1.

The SDSTOP register stops data transfer. During a multi-block transfer sequence, the SDBLKCNT register value (number of blocks to be transferred) can be set to valid or invalid by setting the SDSTOP register.

STP Bit (Transfer Stop)

When setting the STP bit to 1, set it after the SDSTS1.RSPEND flag becomes 1; when setting the STP bit to 0, set it after the SDSTS1.ACEND flag becomes 1. After a command sequence is complete, the SDHI does not issue CMD12 and the SDSTS1.ACEND flag does not become 1 even if the STP bit is set to 1. When the SDHI is in the busy state after receiving the R1b response, the SDHI does not issue CMD12 even if the STP bit is 1, and after the SDHI is released from

the busy state, the SDSTS1.ACEND flag becomes 1.

- Performing a multi-block transfer
  When the STP bit is set to 1, the SDHI issues CMD12, and the command sequence is stopped. The SD buffer can be accessed even after the STP bit is set to 1, but a buffer access error occurs and the SDSTS2.ILW flag or SDSTS2.ILR flag becomes 1. If the command sequence stops due to a communication error or a timeout, the SDHI does not issue CMD12.
- Performing a single block transfer
  When the STP bit is set to 1 during a single block write access, if there is no data in the SD buffer, the SDSTS1.ACEND flag becomes 1. If there is data in the SD buffer, after the SDHI is released from the busy state, the SDSTS1.ACEND flag becomes 1. When the STP bit is set to 1 during a single block read access, the SDSTS1.ACEND flag becomes 1. Also, CMD12 is not issued even if the STP bit is set to 1 during a single block read access or single block write access.

SDBLKCNTEN Bit (Block Count Register Value Select)

If the SDBLKCNTEN bit is 1 during a multi-block transfer sequence, the SDHI automatically issues CMD12. When the SDCMD.RSPTP[2:0] bits are set to 000b and CMD18 or CMD25 is issued, or if the SDCMD.RSPTP[2:0] bits are set to 011b, 100b, 101b, 110b, or 111b and the SDCMD.TRSTP bit is 1 (multiple blocks transferred), if the SDCMD.CMD12AT[1:0] bits are 00b (CMD12 is automatically issued during multi-block transfer), and the number of transfer blocks reaches the value set in the SDBLKCNT register, the SDHI automatically issues CMD12.
If the command sequence is stopped by a communication error or a timeout, CMD12 is not automatically issued.

49.2.4 Block Count Register (SDBLKCNT)

Address(es): SDHI.SDBLKCNT 0008 AC14h

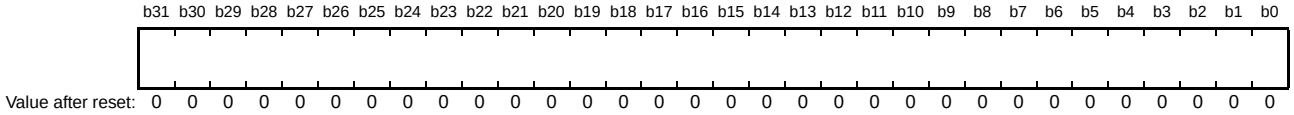
	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

When performing a multi-block transfer, SDBLKCNT is a readable/writable register used to set the number of blocks to be transferred. For example, when the register value is 0000 0001h, 1 block is transferred; when the register value is 0000 FFFFh, 65,535 blocks are transferred; and when the register value is FFFF FFFFh, 4,294,967,295 blocks are transferred. Do not set this register to 0000 0000h. Do not rewrite the SDBLKCNT register when the SDSTS2.CBSY flag is 1.

49.2.5 Response Register 10 (SDRSP10), Response Register 32 (SDRSP32), Response Register 54 (SDRSP54), Response Register 76 (SDRSP76)

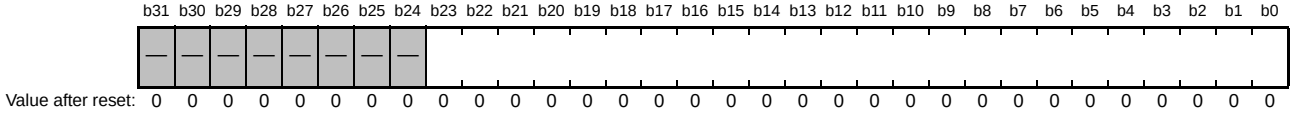
- SDRSP10, SDRSP32, SDRSP54

Address(es): SDHI.SDRSP10 0008 AC18h, SDHI.SDRSP32 0008 AC20h, SDHI.SDRSP54 0008 AC28h



- SDRSP76

Address(es): SDHI.SDRSP76 0008 AC30h



Bit	Symbol	Bit Name	Description	R/W
b23 to b0	—	—	This register stores the response from the SD card.	R
b31 to b24	—	Reserved	These bits are 0 when read.	R

Registers SDRSP10, SDRSP32, SDRSP54, and SDRSP76 are read-only registers that store the response from the SD card. Depending on the type of response from the SD card, the SDHI divides and stores the response among the four registers.

Table 49.4 lists the correspondence between the response type and its storage destination.

Table 49.4 Correspondence Between the Response Type and Its Storage Destination

Response Type	SDRSP10 Register	SDRSP32 Register	SDRSP54 Register	SDRSP76 Register
R1	[39:8]	—	[39:8] *1	—
R1b	[39:8]	—	[39:8] *1	—
R2	[39:8]	[71:40]	[103:72]	[127:104]
R3	[39:8]	—	—	—
R4	[39:8]	—	—	—
R5	[39:8]	—	—	—
R6	[39:8]	—	—	—
R7	[39:8]	—	—	—

Note 1. The response for CMD18 and CMD25 is stored in registers SDRSP10 and SDRSP54. Therefore, even if the SDRSP10 register is overwritten with the response for the automatically transmitted CMD12, the response for CMD18 or CMD25 can be confirmed by reading the SDRSP54 register.

49.2.6 SD Status Register 1 (SDSTS1)

Address(es): SDHI.SDSTS1 0008 AC38h

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	—	—	SDD3MON	SDD3IN	SDD3RM
Value after reset:	0	0	0	0	0	x	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	SDWPMON	—	SDCDMON	SDCDIN	SDCDRM	ACEND	—	RSPEND
Value after reset:	x	0	x	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RSPEND	Response End Detection Flag	0: Response end is not detected 1: Response end is detected	R(/W) *1
b1	—	Reserved	This bit is 0 when read and cannot be modified.	R
b2	ACEND	Access End Detection Flag	0: Access end is not detected 1: Access end is detected	R(/W) *1
b3	SDCDRM	SDHI_CD Removal Flag	0: SD card removal not detected by the SDHI_CD pin 1: SD card removal detected by the SDHI_CD pin	R(/W) *1
b4	SDCDIN	SDHI_CD Insertion Flag	0: SD card insertion not detected by the SDHI_CD pin 1: SD card insertion detected by the SDHI_CD pin	R(/W) *1
b5	SDCDMON	SDHI_CD Pin Monitor Flag	0: SDHI_CD pin level is high *2 1: SDHI_CD pin level is low *2	R
b6	—	Reserved	This bit is 0 when read and cannot be modified.	R
b7	SDWPMON	SDHI_WP Pin Monitor Flag	0: SDHI_WP pin level is high 1: SDHI_WP pin level is low	R
b8	SDD3RM	SDHI_D3 Removal Flag	0: SD card removal not detected by the SDHI_D3 pin 1: SD card removal detected by the SDHI_D3 pin	R(/W) *1
b9	SDD3IN	SDHI_D3 Insertion Flag	0: SD card insertion not detected by the SDHI_D3 pin 1: SD card insertion detected by the SDHI_D3 pin	R(/W) *1
b10	SDD3MON	SDHI_D3 Pin Monitor Flag	0: SDHI_D3 pin level is low 1: SDHI_D3 pin level is high	R
b31 to b11	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. The flag does not change even if set to 1. Writing 0 changes the flag value to 0.
Note 2. The flag changes when the pin level continues for the period set in the SDOPT.CTOP[3:0] bits or longer.

The SDSTS1 register indicates the detection of a response end or access end for a command sequence. The SDSTS1 register also indicates the detection SD card insertion/removal, and indicates the write protection status.
During a multi-block transfer sequence, if CMD12 or CMD52 (SDIO abort) is issued, the ACEND flag becomes 1, but the RSPEND flag remains set to 0.
If the command sequence is stopped due to a communication error or timeout, the ACEND flag or RSPEND flag becomes 1.
After a reset is canceled, the SDD3MON bit, SDD3IN flag, and SDD3RM flag values are changed according to the status of the SDHI_D3 pin, and their values are changed when data is being transferred in wide bus mode.
Flags to be cleared should be set to 0; flags not being cleared should be set to 1.

RSPEND Flag (Response End Detection Flag)

— This flag becomes 1 under any of the following conditions:

- A response is received.
- A command that does not have a response is issued.
- After the R1b response is received, the SDHI is released from the busy state.
- During a multi-block transmission, after the SDIOMD.C52PUB bit is set to 1, the CMD52 response is received.
- A communication error or timeout causes the command sequence to abort.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

Note: When a command is issued that is absent of data transfer, the RSPEND flag becomes 1 after the command sequence ends.

ACEND Flag (Access End Detection Flag)

— This flag becomes 1 under any of the following conditions:

- During a single block read sequence, the SD buffer read access is completed.
- During a multi-block read sequence, the last block is read from the SD buffer.
- During a multi-block read sequence, if CMD12 is automatically issued, data is read from the SD buffer, and the response for CMD12 is received.
- During a single block write sequence, after a CRC status token is received, the SDHI is released from the busy state.
- During a multi-block write sequence, after a CRC status token is received for the last block, the SDHI is released from the busy state.
- During a multi-block write sequence, when CMD12 is automatically issued, a response busy of the automatically issued CMD12 is received.
- During a multi-block read sequence, when CMD12 is automatically issued, after setting the SDSTOP.STP bit to 1, a response of the automatically issued CMD12 is received.
- During a multi-block write sequence, when CMD12 is automatically issued, after setting the SDSTOP.STP bit to 1, a response busy of the automatically issued CMD12 is received.
- During a multi-block read sequence, after the SDIOMD.IOABT bit is set to 1, the response for CMD52 is received.
- During a multi-block write sequence, after the SDIOMD.IOABT bit is set to 1, the response for CMD52 is received.
- A communication error or timeout causes the command sequence to abort.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

Note: The ACEND flag becomes 1 after the command sequence ends.

SDCDRM Flag (SDHI_CD Removal Flag)

— This flag becomes 1 under the following condition:

- The SDHI_CD pin changes from low to high, and the high period is the period set in the SDOPT.CTOP[3:0] bits or longer.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

SDCDIN Flag (SDHI_CD Insertion Flag)

— This flag becomes 1 under the following condition:

- The SDHI_CD pin changes from high to low, and the low period is the period specified in the SDOPT.CTOP[3:0] bits or longer.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

SDD3RM Flag (SDHI_D3 Removal Flag)

— This flag becomes 1 under the following condition:

- The SDHI_D3 pin changes from high to low, and the low period is at least two PCLKB cycles.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

SDD3IN Flag (SDHI_D3 Insertion Flag)

— This flag becomes 1 under the following condition:

- The SDHI_D3 pin changes from low to high, and the high period is at least two PCLKB cycles.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

49.2.7 SD Status Register 2 (SDSTS2)

Address(es): SDHI.SDSTS2 0008 AC3Ch

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8
	ILA	CBSY	SDCLKCREN	—	—	—	BWE	BRE
Value after reset:	0	0	1	0	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	SDD0MON	RSPTO	ILR	ILW	DTO	ENDE	CRCE	CMDE
Value after reset:	x	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMDE	Command Error Detection Flag	0: Command error not detected 1: Command error detected	R(/W) *1
b1	CRCE	CRC Error Detection Flag	0: CRC error not detected 1: CRC error detected	R(/W) *1
b2	ENDE	End Bit Error Detection Flag	0: End bit error not detected 1: End bit error detected	R(/W) *1
b3	DTO	Data Timeout Detection Flag	0: Data timeout not detected 1: Data timeout detected	R(/W) *1
b4	ILW	SDBUFR Illegal Write Access Detection Flag	0: Illegal write access to the SDBUFR register not detected 1: Illegal write access to the SDBUFR register detected	R(/W) *1
b5	ILR	SDBUFR Illegal Read Access Detection Flag	0: Illegal read access to the SDBUFR register not detected 1: Illegal read access to the SDBUFR register detected	R(/W) *1
b6	RSPTO	Response Timeout Detection Flag	0: Response timeout not detected 1: Response timeout detected	R(/W) *1
b7	SDD0MON	SDHI_D0 Pin Status Flag	0: SDHI_D0 pin is low 1: SDHI_D0 pin is high	R
b8	BRE	SDBUFR Read Enable Flag	0: Read access to the SDBUFR register disabled 1: Read access to the SDBUFR register enabled	R(/W) *1
b9	BWE	SDBUFR Write Enable Flag	0: Write access to the SDBUFR register disabled 1: Write access to the SDBUFR register enabled	R(/W) *1
b10	—	Reserved	This bit is 0 when read and cannot be modified.	R
b11	—	Reserved	This bit is 0 when read. Set it to 1 when writing.	R/W
b12	—	Reserved	This bit is 0 when read and cannot be modified.	R
b13	SDCLKCREN	SDCLKCR Write Enable Flag	0: SD bus (CMD and DAT lines) is busy, so write access to the SDCLKCR.CLKEN bit and CLKSEL[7:0] bits is disabled. 1: SD bus (CMD and DAT lines) is not busy, so write access to the SDCLKCR.CLKEN bit and CLKSEL[7:0] bits is enabled.	R
b14	CBSY	Command Sequence Status Flag	0: Command sequence completed 1: Command sequence in progress (busy)	R
b15	ILA	Illegal Access Error Detection Flag	0: Illegal access error not detected 1: Illegal access error detected	R(/W) *1
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. The flag does not change even if set to 1. Writing 0 changes the flag value to 0.

The SDSTS2 register indicates the status of the SD buffer and the status of the SD card. Flags to be cleared should be set to 0; flags not being cleared should be set to 1.

CMDE Flag (Command Error Detection Flag)

The command sequence is stopped when a command error occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence will not be completed. Perform the error processing shown in section 49.3.6.8 or section 49.3.6.9 and complete the command sequence.

— This flag becomes 1 under any of the following conditions:

- The command index field value for the command transmitted differs from the command index field value for the response received.
- The command index field value for the automatically issued CMD12 or CMD52 (which are the commands to stop transfer) differs from the command index field value for the response received.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

CRCE Flag (CRC Error Detection Flag)

The command sequence is stopped when a CRC error occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence will not be completed. Perform the error processing shown in section 49.3.6.8 or section 49.3.6.9 and complete the command sequence.

— This flag becomes 1 under any of the following conditions:

- The received CRC status token is in error (the value of the CRC status is a value other than 010b).
- The read data contains a CRC error.
- The response contains a CRC error.
- The response for the automatically issued CMD12 or CMD52 (which are the commands to stop transfer) contains a CRC error.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

ENDE Flag (End Bit Error Detection Flag)

The command sequence is stopped when an end bit error occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence will not be completed. Perform the error processing shown in section 49.3.6.8 or section 49.3.6.9 and complete the command sequence.

— This flag becomes 1 under any of the following conditions:

- The response length is in error (the end bit could not be detected).
- The read data length is in error (the end bit of the enabled bit could not be detected).
- The CRC status token length is in error (the end bit could not be detected).
- The response length for the automatically issued CMD12 or CMD52 (which are the commands to stop transfer) contains an error (the end bit could not be detected).

— This flag becomes 0 under the following condition:

- The flag is set to 0.

DTO Flag (Data Timeout Detection Flag)

This flag indicates that the data expected to be received during the period specified (set in the SDOPT.TOP[3:0] bits) was not received. However, response timeouts are excluded. The command sequence stops when a data timeout occurs.

— This flag becomes 1 under any of the following conditions:

- After the R1b response is received, the SDHI is busy for the period specified or longer.
- After the CRC status token is received, the SDHI is busy for the period specified or longer.
- After data is written, the CRC status token is not received even after the period specified elapsed.
- After a read command is issued, the read data is not received even after the period specified elapsed.
- After CMD12 is issued during a command sequence, the SDHI is busy for the period specified or longer.
- After the read data is received, the next read data is not received even after the period specified elapsed.
- After the SDHI exits the read wait state, the next read data is not received even after the period specified elapsed.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

ILW Flag (SDBUFR Illegal Write Access Detection Flag)

— This flag becomes 1 under any of the following conditions:

- A value is written to the SDBUFR register while the SDHI is not in the data read or data write command state.
- A value is written to the SDBUFR register while the SD buffer is full.
- A value is written to the SDBUFR register while the CRC status token or CRC status token length is in error.
- After the CRC status token is received, a value is written to the SDBUFR register if the SDHI is busy for the period set in bits SDOPT.TOP[3:0] or longer.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

ILR Flag (SDBUFR Illegal Read Access Detection Flag)

— This flag becomes 1 under any of the following conditions:

- A value is set to the SDBUFR register while the SD buffer is empty.
- The value read from the SDBUFR register includes a CRC error or end error.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

RSPTO Flag (Response Timeout Detection Flag)

The command sequence is stopped when a response timeout occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence will not be completed. Perform the error processing shown in section 49.3.6.8 or section 49.3.6.9 and complete the command sequence.

— This flag becomes 1 under the following condition:

- A response is not received even after 640 SDHI clock cycles or more have elapsed (including the response for the automatically issued CMD12 or CMD52 (which are the commands to stop transfer)).

— This flag becomes 0 under the following condition:

- The flag is set to 0.

SDD0MON Flag (SDHI_D0 Pin Status Flag)

This flag indicates the status of the SDHI_D0 pin. After an erase command is issued, if the DTO flag is 1 and the RSPTO flag is 0, polling can be used to monitor the SDD0MON flag change from 0 to 1, and check that the erase command sequence is complete. If a communication error or timeout occurs during the write sequence, the SDHI_D0 pin may remain low. When the SDHI clock is stopped, the value before the SDHI clock was stopped is retained.

BRE Flag (SDBUFR Read Enable Flag)

— This flag becomes 1 under any of the following conditions:

- During a single block transfer, the data size set in the SDSIZE.LEN[9:0] bits is stored in the SD buffer.
- During a multi-block transfer, the data size set in the SDSIZE.LEN[9:0] bits is stored in one of the two SD buffers.

— This flag becomes 0 under any of the following conditions:

- The bit is set to 0.
- DMA transfer is used to read 1 block of data from the SD buffer.

If the CPU is used to read data from the SDBUFR register, set the BRE flag to 0 before reading the data size *1 set in the SDSIZE.LEN[9:0] bits. Even if the block of data read contains a CRC error or end bit error, the data is stored in the SD buffer and the BRE flag becomes 1.

Note 1. If the transfer data size set in the SDSIZE.LEN[9:0] bits is an odd number, the odd numbered byte is ignored. Refer to section 49.5.2, SDBUFR Register Illegal Write Error for details.

BWE Flag (SDBUFR Write Enable Flag)

— This flag becomes 1 under any of the following conditions:

- During a single block transfer, the SD buffer is empty.
- During a multi-block transfer, bank 1 or bank 2 of the SD buffer is empty.

— This flag becomes 0 under any of the following conditions:

- The flag is set to 0.
- A DMA transfer is used to write 1 block of data from the SD buffer.

If the CPU is used to write data to the SDBUFR register, set the BWE flag to 0 before writing the data size *1 set in the SDSIZE.LEN[9:0] bits.

Note 1. If the transfer data size set in the SDSIZE.LEN[9:0] bits is an odd number, the odd numbered byte is ignored. Refer to section 49.5.2, SDBUFR Register Illegal Write Error for details.

SDCLKCREN Flag (SDCLKCR Write Enable Flag)

When a value is written to the SDCMD register, the SDHI starts the command sequence, the SDSTS2.CBSY flag becomes 1, and the SDSTS2.SDCLKCREN flag becomes 0. When the command sequence is complete, after the SDSTS2.CBSY flag becomes 0, eight cycles of the SDHI clock elapse and then the SDSTS2.SDCLKCREN flag becomes 1.

ILA Flag (Illegal Access Error Detection Flag)

— This flag becomes 1 under any of the following conditions:

- A value is written to the SDCMD register when the SDSTS2.CBSY flag is 1.
- The SDCMD.CMDTP bit is set to 1 (command accompanying data transfer), the SDCMD.ACMD[1:0] bits are set to 00b, and the SDCMD.CMDIDX[5:0] bits are set to 001100b (CMD12).

— This flag becomes 0 under the following condition:

- The flag is set to 0.

49.2.8 SD Interrupt Mask Register 1 (SDIMSK1)

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	SDCDINM	SDCDRMM	ACENDM	—	RSPENDM
Value after reset:	0	0	0	1	1	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	RSPENDM	Response End Interrupt Request Mask	0: Response end interrupt request is not masked 1: Response end interrupt request is masked	R/W
b1	—	Reserved	This bit is 0 when read and cannot be modified.	R
b2	ACENDM	Access End Interrupt Request Mask	0: Access end interrupt request is not masked 1: Access end interrupt request is masked	R/W
b3	SDCDRMM	SDHI_CD Removal Interrupt Request Mask	0: SD card removal interrupt request by the SDHI_CD pin not masked 1: SD card removal interrupt request by the SDHI_CD pin masked	R/W
b4	SDCDINM	SDHI_CD Insertion Interrupt Request Mask	0: SD card insertion interrupt request by the SDHI_CD pin not masked 1: SD card insertion interrupt request by the SDHI_CD pin masked	R/W
b7 to b5	—	Reserved	These bits are 0 when read and cannot be modified.	R
b8	SDD3RMM	SDHI_D3 Removal Interrupt Request Mask	0: SD card removal interrupt request by the SDHI_D3 pin not masked 1: SD card removal interrupt request by the SDHI_D3 pin masked	R/W
b9	SDD3INM	SDHI_D3 Insertion Interrupt Request Mask	0: SD card insertion interrupt request by the SDHI_D3 pin not masked 1: SD card insertion interrupt request by the SDHI_D3 pin masked	R/W
b31 to b10	—	Reserved	These bits are 0 when read and cannot be modified.	R

The SDIMSK1 register enables and disables the interrupt requests from the status flags in the SDSTS1 register. Refer to Table 49.8, Interrupt Sources for details on the relationship between the status flags and the requested interrupt source.

49.2.9 SD Interrupt Mask Register 2 (SDIMSK2)

Address(es): SDHI.SDIMSK2 0008 AC44h

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8
	ILAM	—	—	—	—	—	BWEM	BREM
Value after reset:	1	0	0	0	1	0	1	1

	b7	b6	b5	b4	b3	b2	b1	b0
	—	RSPTOM	ILRM	ILWM	DTTOM	ENDEM	CRCEM	CMDEM
Value after reset:	0	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	CMDEM	Command Error Interrupt Request Mask	0: Command error interrupt request not masked 1: Command error interrupt request masked	R/W
b1	CRCEM	CRC Error Interrupt Request Mask	0: CRC error interrupt request not masked 1: CRC error interrupt request masked	R/W
b2	ENDEM	End Bit Error Interrupt Request Mask	0: End bit detection error interrupt request not masked 1: End bit detection error interrupt request masked	R/W
b3	DTTOM	Data Timeout Interrupt Request Mask	0: Data timeout interrupt request not masked 1: Data timeout interrupt request masked	R/W
b4	ILWM	SDBUFR Register Illegal Write Interrupt Request Mask	0: Illegal write detection interrupt request for the SDBUFR register not masked 1: Illegal write detection interrupt request for the SDBUFR register masked	R/W
b5	ILRM	SDBUFR Register Illegal Read Interrupt Request Mask	0: Illegal read detection interrupt request for the SDBUFR register not masked 1: Illegal read detection interrupt request for the SDBUFR register masked	R/W
b6	RSPTOM	Response Timeout Interrupt Request Mask	0: Response timeout interrupt request not masked 1: Response timeout interrupt request masked	R/W
b7	—	Reserved	This bit is 0 when read and cannot be modified.	R
b8	BREM	BRE Interrupt Request Mask	0: Read enable interrupt request for the SD buffer not masked 1: Read enable interrupt request for the SD buffer masked	R/W
b9	BWEM	BWE Interrupt Request Mask	0: Write enable interrupt request for the SDBUFR register not masked 1: Write enable interrupt request for the SDBUFR register masked	R/W
b10	—	Reserved	This bit is 0 when read and cannot be modified.	R
b11	—	Reserved	This bit is 1 when read and cannot be modified.	R
b14 to b12	—	Reserved	These bits are 0 when read and cannot be modified.	R
b15	ILAM	Illegal Access Error Interrupt Request Mask	0: Illegal access error interrupt request not masked 1: Illegal access error interrupt request masked	R/W
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. When the SDIMSK2.BWEM bit is 0 or the SDIMSK2.BREM bit is 0, set the SDDMAEN.DMAEN bit to 0. When the SDDMAEN.DMAEN bit is 1, set the SDIMSK2.BWEM bit to 1 and the SDIMSK2.BREM bit to 1.

The SDIMSK2 register enables and disables the interrupt requests from the status flags in the SDSTS2 register. Refer to Table 49.8 for details on the relationship between the status flags and the requested interrupt source.

49.2.10 SDHI Clock Control Register (SDCLKCR)

Address(es): SDHI.SDCLKCR 0008 AC48h

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	—	—	—	CLKCTRLEN	CLKEN
Value after reset:	0	0	0	0	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	CLKSEL[7:0]							
Value after reset:	0	0	1	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CLKSEL[7:0]	SDHI Clock Frequency Select *1	b7 b0 0 0 0 0 0 0 0 0: PCLKB divided by 2 0 0 0 0 0 0 0 1: PCLKB divided by 4 0 0 0 0 0 0 1 0: PCLKB divided by 8 0 0 0 0 0 1 0 0: PCLKB divided by 16 0 0 0 0 1 0 0 0: PCLKB divided by 32 0 0 0 1 0 0 0 0: PCLKB divided by 64 0 0 1 0 0 0 0 0: PCLKB divided by 128 0 1 0 0 0 0 0 0: PCLKB divided by 256 1 0 0 0 0 0 0 0: PCLKB divided by 512 Only set the values listed above.	R/W
b8	CLKEN	SDHI Clock Output Control *1	0: SDHI clock output is disabled (SDHI_CLK signal fixed low) 1: SDHI clock output enabled	R/W
b9	CLKCTRLEN	SDHI Clock Output Automatic Control Select	0: Automatic control of SDHI clock output disabled 1: Automatic control of SDHI clock output enabled	R/W
b31 to b10	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Bits CLKSEL[7:0] and CLKEN cannot be write accessed when the SDSTS2.SDCLKCREN flag is 0.

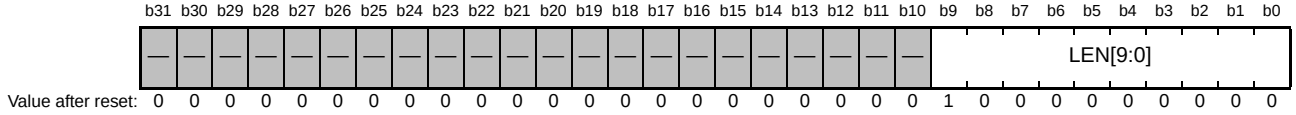
The SDCLKCR register controls the SDHI clock frequency settings and output. Set the CLKEN bit to 1 before writing to the SDCMD register to start a command sequence. Do not write access the SDCLKCR register when the SDSTS2.SDCLKCREN flag is 0.

CLKCTRLEN Bit (SDHI Clock Output Automatic Control Select)

The SDHI clock output automatic control is a function for starting and stopping SDHI clock output only during a command sequence. When this function is enabled, the SDHI starts outputting the SDHI clock after a value is set to the SDCMD register. After the command sequence is complete and eight cycles of the SDHI clock elapse, the SDHI stops outputting the SDHI clock. When the SDCLKCR.CLKEN bit is 0, output from the SDHI_CLK pin becomes low regardless of the CLKCTRLEN bit setting.

49.2.11 Transfer Data Size Register (SDSIZE)

Address(es): SDHI.SDSIZE 0008 AC4Ch



Bit	Symbol	Bit Name	Description	R/W
b9 to b0	LEN[9:0]	Transfer Data Size Setting	Set the transfer data size. *1	R/W
b11 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R
b31 to b12	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite these bits when the SDSTS2.CBSY flag is 1.

The SDSIZE register is used to set the transfer data size.

LEN[9:0] Bits (Transfer Data Size Setting)

When using single block transfer, the transfer data size can be set from 1 byte to 512 bytes. When CMD12 is automatically issued during a multi-block transfer sequence (CMD18 and CMD25), the transfer data size can only be set to 512 bytes. When CMD12 is not automatically issued during a multi-block transfer sequence, the transfer data size can be set to 32, 64, 128, 256, or 512 bytes. However, a 32-, 64-, 128-, or 256-byte multi-block read transfer can only be performed during an SDIO multi-block transfer (CMD53). Do not set these bits to 0 when using a command that includes data transfer.

49.2.12 Card Access Option Register (SDOPT)

Address SDHI.SDOPT 0008 AC50h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WIDTH	—	—	—	—	—	—	—	TOP[3:0]				CTOP[3:0]			
Value after reset	0	1	0	0	0	0	0	0	1	1	1	0	1	1	1	0

Bit	Symbol	Bit Name	Description		R/W
b3 to b0	CTOP[3:0]	Card Detection Time Counter *1	b3 b0 0 0 0 0: PCLKB × 2^{10} 0 0 0 1: PCLKB × 2^{11} 0 0 1 0: PCLKB × 2^{12} 0 0 1 1: PCLKB × 2^{13} 0 1 0 0: PCLKB × 2^{14} 0 1 0 1: PCLKB × 2^{15} 0 1 1 0: PCLKB × 2^{16} 0 1 1 1: PCLKB × 2^{17}	b3 b0 1 0 0 0: PCLKB × 2^{18} 1 0 0 1: PCLKB × 2^{19} 1 0 1 0: PCLKB × 2^{20} 1 0 1 1: PCLKB × 2^{21} 1 1 0 0: PCLKB × 2^{22} 1 1 0 1: PCLKB × 2^{23} 1 1 1 0: PCLKB × 2^{24} 1 1 1 1: Do not set this value.	R/W
b7 to b4	TOP[3:0]	Timeout Counter *1	b7 b4 0 0 0 0: SDHI clock × 2^{13} 0 0 0 1: SDHI clock × 2^{14} 0 0 1 0: SDHI clock × 2^{15} 0 0 1 1: SDHI clock × 2^{16} 0 1 0 0: SDHI clock × 2^{17} 0 1 0 1: SDHI clock × 2^{18} 0 1 1 0: SDHI clock × 2^{19} 0 1 1 1: SDHI clock × 2^{20}	b7 b4 1 0 0 0: SDHI clock × 2^{21} 1 0 0 1: SDHI clock × 2^{22} 1 0 1 0: SDHI clock × 2^{23} 1 0 1 1: SDHI clock × 2^{24} 1 1 0 0: SDHI clock × 2^{25} 1 1 0 1: SDHI clock × 2^{26} 1 1 1 0: SDHI clock × 2^{27} 1 1 1 1: Do not set this value.	R/W
b8	—	Reserved	This bit is 0 when read. Set it to 0 when writing.		R/W
b12 to b9	—	Reserved	These bits are 0 when read and cannot be modified.		R
b13	—	Reserved	This bit is 0 when read. Set it to 0 when writing.		R/W
b14	—	Reserved	This bit is 1 when read and cannot be modified.		R
b15	WIDTH	SD Bus Width Select *1	0: Wide bus mode (4 bits) 1: Default bus mode (1 bit)		R/W
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.		R

Note 1. Do not rewrite these bits when the SDSTS2.CBSY flag is 1.

The SD bus width and timeout counter are set in the SDOPT register.

49.2.13 SD Error Status Register 1 (SDERSTS1)

Address(es): SDHI.SDERSTS1 0008 AC58h

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8
	—	CRCTK[2:0]			CRCTKE	RDCRCE	RSPCRCE1	RSPCRCE0
Value after reset:	0	0	1	0	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	CRCLENE	RDLENE	RSPLENE1	RSPLENE0	CMDE1	CMDE0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMDE0	Command Error Flag 0	0: Command index field value for a command *1 response is error free 1: Command index field value for a command *1 response is in error	R
b1	CMDE1	Command Error Flag 1	0: Command index field value for a command *2 response is error free 1: Command index field value for a command *2 response is in error (by setting the SDCMD.CMDIDX[5:0] bits, the error that occurs by issuing CMD12 is indicated by the CMDE0 flag)	R
b2	RSPLENE0	Response Length Error Flag 0	0: Command *1 response length is error free 1: Command *1 response length is in error	R
b3	RSPLENE1	Response Length Error Flag 1	0: Command *2 response length is error free 1: Command *2 response length is in error (by setting the SDCMD.CMDIDX[5:0] bits, the error that occurs by issuing CMD12 is indicated by the RSPLENE0 flag)	R
b4	RDLENE	Read Data Length Error Flag	0: Read data length error did not occur 1: Read data length error occurred	R
b5	CRCLENE	CRC Status Token Length Error Flag	0: CRC status token length error did not occur 1: CRC status token length error occurred	R
b7, b6	—	Reserved	These bits are 0 when read.	R
b8	RSPCRCE0	Response CRC Error Flag 0	0: No CRC error detected in command *1 response 1: CRC error detected in command *1 response	R
b9	RSPLENE1	Response CRC Error Flag 1	0: No CRC error detected in command *2 response 1: CRC error detected in command *2 response (the error that occurs for CMD12 with the setting of the SDCMD.CMDIDX[5:0] bits is indicated by the RSPCRCE0 flag)	R
b10	RDCRCE	Read Data CRC Error Flag	0: No CRC error detected in read data 1: CRC error detected in read data	R
b11	CRCTKE	CRC Status Token Error Flag	0: No error detected in CRC status token 1: Error detected in CRC status token	R
b14 to b12	CRCTK[2:0]	CRC Status Token	Store the CRC status token value (normal value is 010b)	R
b31 to b15	—	Reserved	These bits are 0 when read.	R

Note 1. Command other than CMD12 or CMD52 which are automatically issued to stop data transfer.
Note 2. CMD12 or CMD52 which are automatically issued to stop data transfer.

The SDERSTS1 register indicates the CRC status token, CRC error, end bit error, and command error.

49.2.14 SD Error Status Register 2 (SDERSTS2)

Address(es): SDHI.SDERSTS2 0008 AC5Ch

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	—	CRCBSYTO	CRCTO	RDTO	BSYTO1	BSYTO0	RSPTO1	RSPTO0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RSPTO0	Response Timeout Flag 0	0: After a command *1 was issued, a response was received in less than 640 cycles of the SDHI clock. 1: After a command *1 was issued, a response was not received even after 640 cycles or more of the SDHI clock elapsed.	R
b1	RSPTO1	Response Timeout Flag 1	0: After a command *2 was issued, a response was received in less than 640 cycles of the SDHI clock. 1: After a command *2 was issued, a response was not received even after 640 cycles or more of the SDHI clock elapsed (by setting the SDCMD.CMDIDX[5:0] bits, the error that occurs by issuing CMD12 is indicated by the RSPTO0 flag).	R
b2	BSYTO0	Busy Timeout Flag 0	0: After the R1b response was received, the SDHI was released from the busy state during the specified period *3. 1: After the R1b response was received, the SDHI was in the busy state even after the specified period *3 elapsed.	R
b3	BSYTO1	Busy Timeout Flag 1	0: After CMD12 was automatically issued, the SDHI was released from the busy state during the specified period *3. 1: After CMD12 was automatically issued, the SDHI was in the busy state even after the specified period *3 elapsed (by setting the SDCMD.CMDIDX[5:0] bits, the error that occurs by issuing CMD12 is indicated by the BSYTO0 flag).	R
b4	RDTO	Read Data Timeout Flag	After a read command is issued, this flag becomes 1 when read data is not received even after the specified period *3 elapses. After read data is received, this flag becomes 1 when the next block of read data is not received even after the specified period *3 elapses. After the SDHI exits the read wait state, this flag becomes 1 when the next block of read data is not received even after the specified period *3 elapses.	R
b5	CRCTO	CRC Status Token Timeout Flag	0: After data was written to the SD card, a CRC status token was received during the specified period *3. 1: After CRC data was written to the SD card, a CRC status token was not received even after the specified period *3 elapsed.	R
b6	CRCBSYTO	CRC Status Token Busy Timeout Flag	0: After a CRC status token was received, the SDHI was released from the busy state during the specified period *3. 1: After a CRC status token was received, the SDHI is in the busy state even after the specified period *3 elapsed.	R
b31 to b7	—	Reserved	These bits are 0 when read.	R

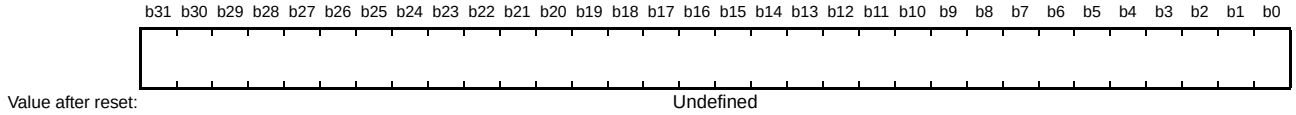
Note 1. Command other than CMD12 or CMD52 which are automatically issued to stop data transfer.
Note 2. CMD12 or CMD52 which are automatically issued to stop transfer.

Note 3. Set the SDOPT.TOP[3:0] bits to select the number of *n* cycles.

The SDERSTS2 register indicates the timeout status.

49.2.15 SD Buffer Register (SDBUFR)

Address(es): SDHI.SDBUFR 0008 AC60h



The SDBUFR register is used when writing data to the SD card and when reading data from the SD card. The SDBUFR register is connected to the SDHI's internal SD buffer. Refer to section 49.3.1, Data Block Format of the SD Card for details on the configuration of the SDBUFR register and the SD buffer.

49.2.16 SDIO Mode Control Register (SDIOMD)

Address(es): SDHI.SDIOMD 0008 AC68h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	C52PUB	IOABT	—	—	—	—	—	RWREQ	—	INTEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	INTEN	SDIO Interrupt Acceptance Enable *1	0: SDIO interrupt accept disabled 1: SDIO interrupt accept enabled	R/W
b1	—	Reserved	This bit is 0 when read and cannot be modified.	R
b2	RWREQ	Read Wait Request	0: SDHI exits read wait state 1: Request for SDHI to enter read wait state	R/W
b7 to b3	—	Reserved	These bits are 0 when read and cannot be modified.	R
b8	IOABT	SDIO Abort	If this bit is set to 1 during multi-block transfer triggered by CMD53, CMD52 is immediately issued, and the command sequence is aborted.	R/W
b9	C52PUB	SDIO None Abort	If this bit is set to 1 during multi-block transfer triggered by CMD53, CMD52 is issued before the transfer process is complete, and the command sequence is completed.	R/W
b31 to b10	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite this bit when the SDSTS2.CBSY flag is 1.

The SDIOMD register controls reception of the SDIO interrupt, controls CMD52 issuance during multi-block transfer, and controls the read wait request. Do not set bits C52PUB and IOABT to 1 at the same time.

RWREQ Bit (Read Wait Request)

If the RWREQ bit is set to 1 during a multi-block read sequence triggered by issuing CMD53, when the current block is done being read, the SDHI enters the read wait state. The method for exiting the read wait state is as follows.

- If the RWREQ bit is set to 0 while the SDHI is in the read wait state, the SDHI exits the read wait state.
- If the IOABT bit is set to 1 while the SDHI is in the read wait state, after CMD52 is issued, the RWREQ bit becomes 0 and the SDHI exits the read wait state.
- If bits C52PUB and RWREQ are simultaneously set to 1 during a multi-block read sequence triggered by issuing CMD53 *1, the SDHI does not automatically exit the read wait state, so after receiving the CMD52 response, set the RWREQ bit to 0.

Note 1. Set bits RWREQ and C52PUB to 1 simultaneously.

If the RWREQ bit is set to 1 while the last block is being transferred during a multi-block read sequence triggered by issuing CMD53, the SDHI will not enter the read wait state, the SDSTS1.ACEND flag becomes 1, and the RWREQ bit becomes 0. Set the RWREQ bit to 1 after the SDSTS1.RSPEND flag becomes 1.

IOABT Bit (SDIO Abort)

- If the IOABT bit is set to 1 during a multi-block transfer sequence triggered by issuing CMD53, the SDHI stops the CMD53 command sequence, and CMD52 is issued. If the command sequence is stopped due to a communication error or timeout, the SDHI does not issue CMD52. The SD buffer can be accessed even after the IOABT bit is set to 1, but the SDSTS2.ILR flag or ILW flag becomes 1, and a buffer access error occurs. Write a value to the SDARG register before setting the IOABT bit to 1.
- During a single block write, if there is no data in the SD buffer when the IOABT bit is set to 1, the SDHI does not issue CMD52, and the SDSTS1.ACEND flag becomes 1. If there is data in the SD buffer when the IOABT bit is set to 1, the SDHI does not issue CMD52, and after the SDHI exits the busy state, the SDSTS1.ACEND flag becomes 1.
- If the IOABT bit is set to 1 during a single block read, the SDHI does not issue CMD52, and the SDSTS1.ACEND flag immediately becomes 1.
- If the SDHI is in the busy state after the R1b response is received and the IOABT bit is set to 1, the SDHI does not issue CMD52, and after the SDHI exits the busy state, the SDSTS1.ACEND flag becomes 1.
- If the IOABT bit is set to 1 after the command sequence is completed, the SDHI does not issue CMD52, and the SDSTS1.ACEND flag does not become 1.
- Set the IOABT bit to 1 after the SDSTS1.RSPEND flag becomes 1.
- Set the IOABT bit to 0 after the SDSTS1.ACEND flag becomes 1.

C52PUB Bit (SDIO None Abort)

- If the C52PUB bit is set to 1 during a multi-block write sequence triggered by issuing CMD53, CMD52 is automatically issued when the SD buffer is empty and the current block write access is complete. The C52PUB bit becomes 0 after the response for CMD52 is received. If the C52PUB bit is 1 while the last block is being transferred, the SDHI does not issue CMD52, and after the SDSTS1.RSPEND flag becomes 1, the C52PUB bit is set to 0.
- If the C52PUB bit and RWREQ bit are set to 1 during a multi-block read sequence triggered by issuing CMD53, the SDHI enters the read wait state after the current block read access is complete, and the SDHI automatically issues CMD52. The C52PUB bit becomes 0 after the response for CMD52 is received. If the C52PUB bit is set to 1 while the last block is being transferred, the SDHI does not issue CMD52, and after the SDSTS1.RSPEND flag becomes 1, the C52PUB bit is set to 0.
- During a multi-block read sequence triggered by issuing CMD53, if the C52PUB bit is set to 1, also set the RWREQ bit to 1.
- Write a value to the SDARG register before setting the C52PUB bit to 1.
- Set the C52PUB bit to 1 after the SDSTS1.RSPEND flag becomes 1.

49.2.17 SDIO Status Register (SDIOSTS)

Address(es): SDHI.SDIOSTS 0008 AC6Ch

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8
	EXWT	EXPUB52	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	IOIRQ
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IOIRQ	SDIO Interrupt Status Flag	0: SDIO interrupt not accepted 1: SDIO interrupt accepted	R(/W) *1
b2, b1	—	Reserved	These bits are undefined when read. Set them to 1 when writing.	R/W
b13 to b3	—	Reserved	These bits are 0 when read and cannot be modified.	R
b14	EXPUB52	EXPUB52 Status Flag	Indicates the status of the EXPUB52	R(/W) *1
b15	EXWT	EXWT Status Flag	Indicates the status of the EXWT	R(/W) *1
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. The flag value does not change even when set to 1. If 0 is written to this flag, it becomes 0.

The SDIOSTS register indicates the status of the SDIO card access. When clearing a flag, bits to be cleared should be set to 0; bits not being cleared should be set to 1.

IOIRQ Flag (SDIO Interrupt Status Flag)

— This flag becomes 1 under the following condition:

- The SDIO interrupt from the SDIO card is accepted while the SDIOMD.INTEN bit is 1.

— This flag becomes 0 under the following condition:

- The flag is set to 0. *1

Note 1. Access the SDIO card, negate the SDIO interrupt from the SDIO card, and then set the IOIRQ flag to 0. If the SDIO interrupt from the SDIO card is not negated, the IOIRQ flag might become 1 again.

EXPUB52 Flag (EXPUB52 Status Flag)

— This flag becomes 1 under any of the following conditions:

- When multi-block transfer is triggered by CMD53 being issued, the SDIOMD.C52PUB bit is set to 1 while the last block is being transferred.
- When multi-block write is triggered by CMD53 being issued, the SDIOMD.C52PUB bit remains set to 1 while the last block is being transferred.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

EXWT Flag (EXWT Status Flag)

— This flag becomes 1 under the following condition:

- During a multi-block read sequence triggered by CMD53 being issued, the SDIOMD.RWREQ bit is set to 1 while the last block is being transferred.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

49.2.18 SDIO Interrupt Mask Register (SDIOIMSK)

Address(es): SDHI.SDIOIMSK 0008 AC70h

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8
	EXWTM	EXPUB52M	—	—	—	—	—	—
Value after reset:	1	1	0	0	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	IOIRQM
Value after reset:	0	0	0	0	0	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	IOIRQM	IOIRQ Interrupt Mask Control	0: IOIRQ interrupt not masked 1: IOIRQ interrupt masked	R/W
b2, b1	—	Reserved	These bits are 1 when read. Set them to 1 when writing.	R/W
b13 to b3	—	Reserved	These bits are 0 when read and cannot be modified.	R
b14	EXPUB52M	EXPUB52 Interrupt Request Mask Control	0: EXPUB52 interrupt request not masked 1: EXPUB52 interrupt request masked	R/W
b15	EXWTM	EXWT Interrupt Request Mask Control	0: EXWT interrupt request not masked 1: EXWT interrupt request masked	R/W
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

The SDIOIMSK register enables and disables the interrupt requests from the status flags in the SDIOSTS register. Refer to Table 49.8, Interrupt Sources for details on the relationship between the status flags and the requested interrupt source.

49.2.19 DMA Transfer Enable Register (SDDMAEN)

Address(es): SDHI.SDDMAEN 0008 ADB0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMAEN	—
Value after reset:	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b1	DMAEN	DMA Transfer Enable *1 *2	0: Using DMAC and DTC to access the SDBUFR register is disabled 1: Using DMAC and DTC to access the SDBUFR register is enabled	R/W
b3, b2	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R
b4	—	Reserved	This bit is 1 when read. Set it to 1 when writing.	R
b5	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b7, b6	—	Reserved	These bits are 0 when read and cannot be modified.	R
b9, b8	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b11, b10	—	Reserved	These bits are 0 when read and cannot be modified.	R
b12	—	Reserved	This bit is 1 when read. Set it to 1 when writing.	R
b31 to b13	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite this bit when the SDSTS2.CBSY bit is 1.
Note 2. When the SDIMSK2.BWEM bit is 0 or the SDIMSK2.BREM bit is 0, set the SDDMAEN.DMAEN bit to 0. When the SDDMAEN.DMAEN bit is 1, set the SDIMSK2.BWEM bit to 1 and the SDIMSK2.BREM bit to 1.

The SDDMAEN register enables and disables DMA transfer.

DMAEN Bit (DMA Transfer Enable)

When using DMA transfer to access the SD buffer, set the DMAEN bit to 1 before setting the SDCMD register.

49.2.20 SDHI Software Reset Register (SDRST)

Address(es): SDHI.SDRST 0008 ADC0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SDRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	SDRST	SDHI Software Reset Control	0: SDHI software reset 1: SDHI software reset canceled	R/W
b2, b1	—	Reserved	These bits are 1 when read. Set them to 1 when writing.	R
b31 to b3	—	Reserved	These bits are 0 when read and cannot be modified.	R

Table 49.5 lists the bits and flags initialized by the SDHI software reset.

Table 49.5 Bits and Flags Initialized by the SDHI Software Reset

Register	Bit/Flag
SDSTOP	SDBLKCNTEN
SDSTS1	RSPEND, ACEND
SDSTS2	CMDE, CRCE, ENDE, DTO, ILW, ILR, RSPTO, SDD0MON, BRE, BWE, SDCLKCREN, ILA
SDCLKCR	CLKEN
SDOPT	CTOP[3:0], TOP[3:0], WIDTH Bits b8 and b13 in the SDOPT register are also initialized by the SDHI software reset.
SDERSTS1	CMDE0, CMDE1, RSPLENE0, RSPLENE1, RDLENE, CRCLENE, RSPCRCE0, RSPCRCE1, RDCRCE, CRCTKE, CRCTK[2:0]
SDERSTS2	RSPTO0, RSPTO1, BSYTO0, BSYTO1, RDTO, CRCTO, CRCBSYTO
SDIOSTS	IOIRQ, EXPUB52, EXWT

49.2.21 Version Register (SDVER)

Address(es): SDHI.SDVER 0008 ADC4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CPRM	CLKRAT	—	—	IP2[3:0]				IP1[7:0]							
Value after reset:	1	0	0	0	1	0	1	0	0	0	0	0	1	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	IP1[7:0]	IP Version 1	IP version 1	R
b11 to b8	IP2[3:0]	IP Version 2	IP version 2	R
b13, b12	—	Reserved	These bits are 0 when read.	R
b14	CLKRAT	Operating Clock Condition	0: SDHI clock frequency = PCLKB frequency not supported 1: SDHI clock frequency = PCLKB frequency supported	R
b15	CPRM	CPRM Function Select	0: CPRM function is enabled 1: CPRM function is disabled	R
b31 to b16	—	Reserved	These bits are 0 when read.	R

The SDVER register indicates the SDHI version.

49.2.22 Swap Control Register (SDSWAP)

Address(es): SDHI.SDSWAP 0008 ADE0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	BRSWP	BWSWP	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is 0 when read and cannot be modified.	R
b1	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b2	—	Reserved	This bit is 0 when read and cannot be modified.	R
b4, b3	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b5	—	Reserved	This bit is 0 when read and cannot be modified.	R
b6	BWSWP	SDBUFR Swap Write *1	0: Normal write operation 1: Swap the byte endian before writing to the SDBUFR register	R/W
b7	BRSWP	SDBUFR Swap Read *1	0: Normal read operation 1: Swap the byte endian before reading the SDBUFR register	R/W
b10 to b8	—	Reserved	These bits are 0 when read and cannot be modified.	R
b12, b11	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b14, b13	—	Reserved	These bits are 0 when read and cannot be modified.	R
b15	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite this bit when the SDSTS2.CBSY flag is 1.

The SDSWAP register is used to select whether or not the byte endian is swapped when accessing the SDBUFR register. Refer to section 49.3.1 for details on the differences in accessing the SDBUFR register based on the SDSWAP register value.

49.3 SDHI Operation

49.3.1 Data Block Format of the SD Card

The SDHI has a default bus mode (1-bit width) that uses just the SDHI_D0 pin as a data line and a wide bus mode (4-bit width) that uses pins SDHI_D0 to SDHI_D3. Figure 49.2 shows the transfer format when the SDOPT.WIDTH bit is 1 (default bus mode), and Figure 49.3 shows the transfer format when the SDOPT.WIDTH bit is 0 (wide bus mode).

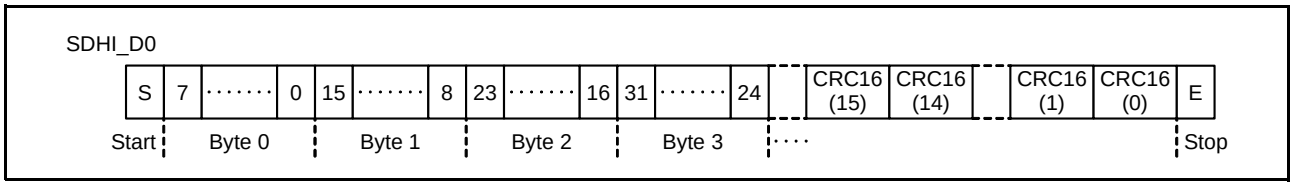


Figure 49.2 Transfer Format in Default Bus Mode

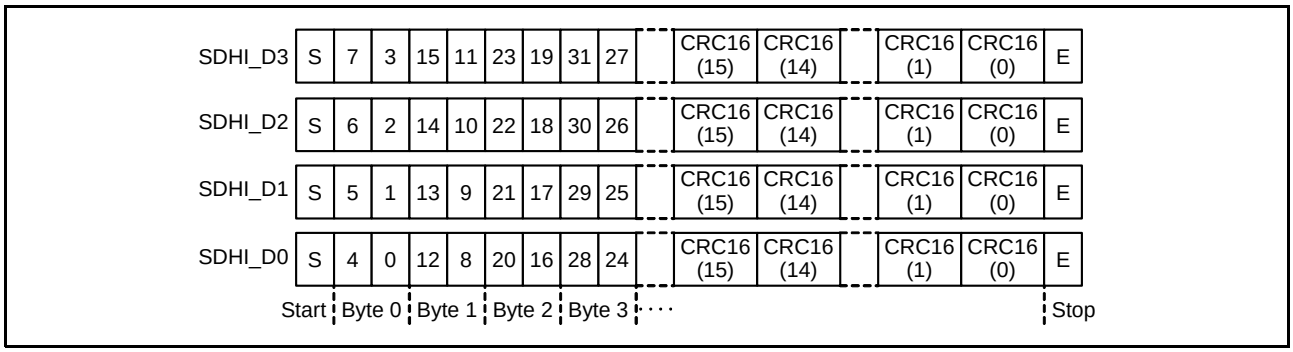

Figure 49.3 Transfer Format in Wide Bus Mode

49.3.2 SD Buffer and the SDBUFR Register

The SDHI transfers data to an SD card via its internal SD buffer. The SD buffer is comprised of a double buffer, and each buffer is 512 bytes. Figure 49.4 shows the data configuration of a single buffer of the SD buffer's double buffer.

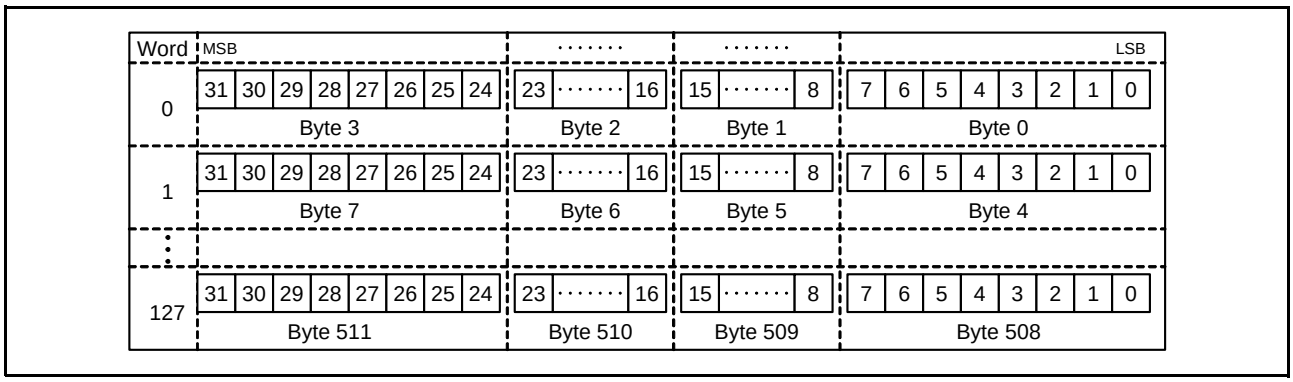

Figure 49.4 Data Configuration of Single Buffer in the SD Buffer

Access to the SD buffer is done via the SDBUFR register. If data is written to the SDBUFR register while the SDSWAP.BWSWP bit is 1, the SDHI swaps the endian for the byte, and stores the data in the SDBUFR register. If data is read from the SDBUFR register while the SDSWAP.BRSWP bit is 1, the data of the endian for the byte that was swapped can be read. Figure 49.5 shows the data alignment when reading the SDBUFR register.

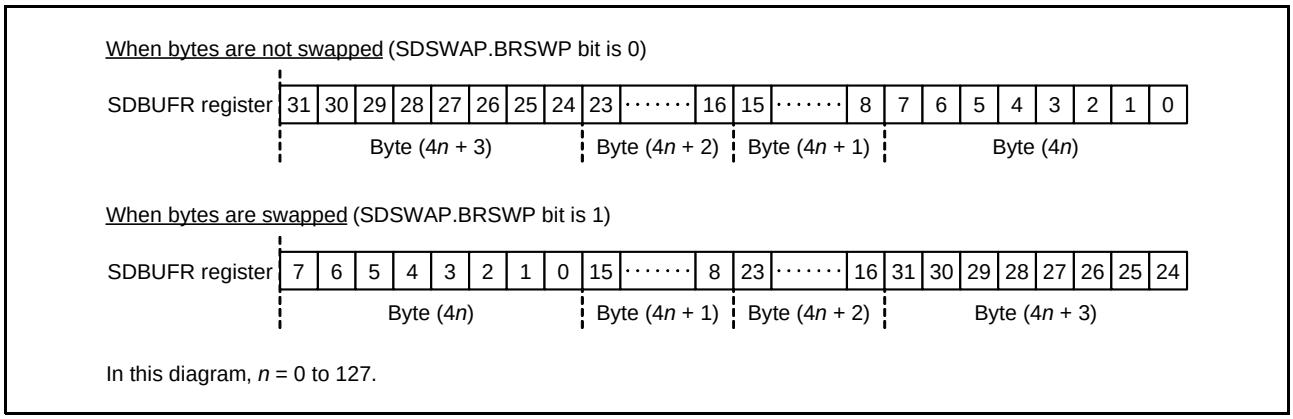

Figure 49.5 Data Alignment When Reading the SDBUFR Register

49.3.3 SD Card Detection

The SDHI can detect an SD card using either the SDHI_CD pin or SDHI_D3 pin.

49.3.3.1 Using the SDHI_CD Pin to Detect an SD Card

Figure 49.6 shows the timing chart for SD card detection using the SDHI_CD pin. The SDHI_CD pin is connected to the card detection switch of the SD card connector, and is pulled-up by the MCU. The pull-up resistance value is determined by the specifications of the host device. Note that there are some SD card sockets whose card detection switches become open when the SD card is inserted.

- Detecting SD card insertion
  The signal from the SDHI_CD pin becomes low when an SD card is inserted. This causes the SDSTS1.SDCDIN flag to become 1 if the SDHI_CD pin is low for the number of cycles set in the SDOPT.CTOP[3:0] bits. The SDSTS1.SDCDIN flag is cleared by setting it to 0.
- Detecting SD card removal
  The signal from the SDHI_CD pin becomes high when the SD card is removed. This causes the SDSTS1.SDCDRM flag to become 1 if the SDHI_CD pin is high for the number of cycles set in the SDOPT.CTOP[3:0] bits. The SDSTS1.SDCDRM flag is cleared by setting it to 0.

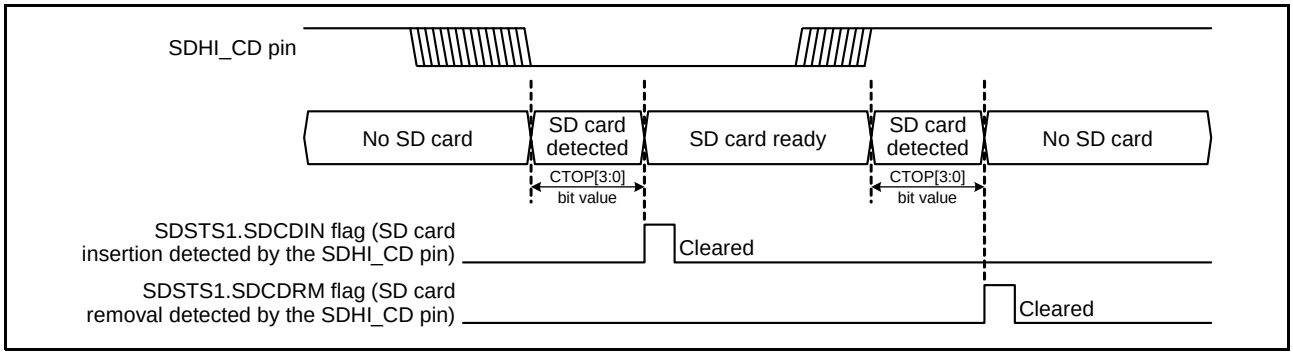

Figure 49.6 SD Card Detection Using the SDHI_CD Pin

49.3.3.2 Using the SDHI_D3 Pin to Detect an SD Card

Figure 49.7 shows the timing chart for SD card detection using the SDHI_D3 pin. The SDHI_D3 pin is pulled-down by the MCU. The pull-down resistance value is determined by the specifications of the host device.

- Detecting SD card insertion
  The signal from the SDHI_D3 pin becomes high when an SD card is inserted. This causes the SDSTS1.SDD3IN flag to become 1. The SDSTS1.SDD3IN flag is cleared by setting it to 0.
- Detecting SD card removal
  The signal from the SDHI_D3 pin becomes low when the SD card is removed. This causes the SDSTS1.SDD3RM flag to become 1. The SDSTS1.SDD3RM flag is cleared by setting it to 0.

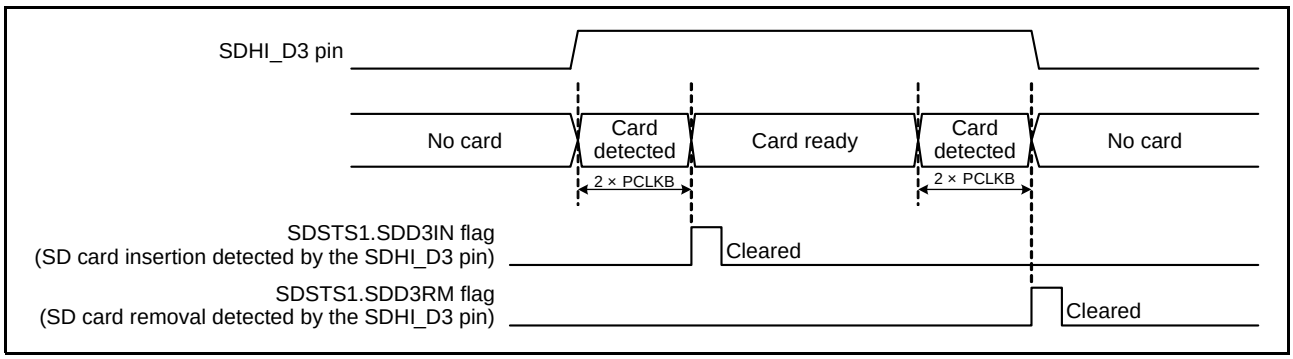

Figure 49.7 SD Card Detection Using the SDHI_D3 Pin

49.3.4 SD Card Write Protection

The SDHI can disable writing to an SD card via the SDHI_WP pin or a command.

49.3.4.1 Using the SDHI_WP Pin to Enable Write Protection

The SDHI_WP pin is connected to the WP detection switch of the SD card connector, and the SDHI_WP pin is pulled-down or pulled-up when an SD card is inserted. The resistance value and whether the SDHI_WP pin is pulled-up or pulled-down are determined by the specifications of the host device. The status of the SDHI_WP pin is reflected in the SDSTS1.SDWPMON flag. After an SD card is inserted, read the SDSTS1.SDWPMON flag to check if write protection is enabled or disabled.

49.3.4.2 Using a Command to Enable Write Protection

The SDHI uses the write protect command or the SD card lock command to disable writing to the SD card.

49.3.5 Communication Errors and Timeouts

When a communication error or timeout error occurs, depending on the type of error, the corresponding status flag in the SDSTS2 register becomes 1. Also, depending on the source of the error, the corresponding flag in the SDERSTS1 or SDERSTS2 register becomes 1.

The status flags in registers SDERSTS1 and SDERSTS2 become 0 by writing to the SDCMD register, or by setting the SDRST.SDRST bit to 0.

Table 49.6 Communication Errors

Communication Error	Interrupt Flag Register		Error Status Register		This Occurs When...
	Register symbol	Bit symbol	Register symbol	Bit symbol	
End bit error	SDSTS2	ENDE	SDERSTS1	CRCLENE	The CRC status token length is in error
				RDLENE	The read data length is in error
				RSPLENE1	The response length is in error *1
				RSPLENE0	The response length is in error *2
CRC error		CRCE		CRCTKE	The CRC status token is in error
				RDCRCE	There is a CRC error in the read data
				RSPCRCE1	There is a CRC error in the response *1
				RSPCRCE0	There is a CRC error in the response *2
Command error		CMDE		CMDE1	The command index field value for the transmitted command and received response do not match *1
				CMDE0	The command index field value for the transmitted command and received response do not match *2

Note 1. CMD12 or CMD52 which are automatically issued to stop transfer.
Note 2. A command other than CMD12 or CMD52 which are automatically issued to stop transfer.

Table 49.7 Timeouts

Timeout	Interrupt Flag Register		Error Status Register		This Occurs When...
	Register symbol	Bit symbol	Register symbol	Bit symbol	
Response timeout	SDSTS2	RSPTO	SDERSTS2	RSPTO1	A response is not received even after a minimum of 640 SDHI clock cycles elapse *1
				RSPTO0	A response is not received even after a minimum of 640 SDHI clock cycles elapse *2
Data timeout (excluding response timeout)		DTO		CRCBSYTO	After the CRC status token is received, the SDHI is busy for at least the period set *3
				CRCTO	After the write data is transmitted, the CRC status token is not received even after at least the period set *3 elapses
				RDTO	After the read command is issued, the read data is not received even after at least the period set *3 elapses
					After the read data is received, the next block read data is not received even after at least the period set *3 elapses
					After the SDHI exits the read wait state, the next block read data is not received even after at least the period set *3 elapses
				BSYTO1	After CMD12 is issued during the command sequence, the SDHI is busy for at least the period set *3
				BSYTO0	After the R1b response is received, the SDHI is busy for at least the period set *3 (a command other than CMD12 is issued during the command sequence)

Note 1. CMD12 or CMD52 which are automatically issued to stop transfer.
Note 2. A command other than CMD12 or CMD52 which are automatically issued to stop transfer.
Note 3. The period is set in the SDOPT.TOP[3:0] bits.

49.3.6 Examples of Issuing a Command

49.3.6.1 Command Absent of Response Reception and Data Transfer

Figure 49.8 shows an example of no response being received and no data being transferred after the SDHI issues a command.

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 49.5.5 for details on setting the SDCLKCR register.
3. After setting the argument field value to the SDARG register, write the command information to be sent to the SDCMD register. The SDHI issues a command when a value is written to the SDCMD register.
4. After a command is issued, the SDSTS1.RSPEND flag becomes 1, and a response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0.

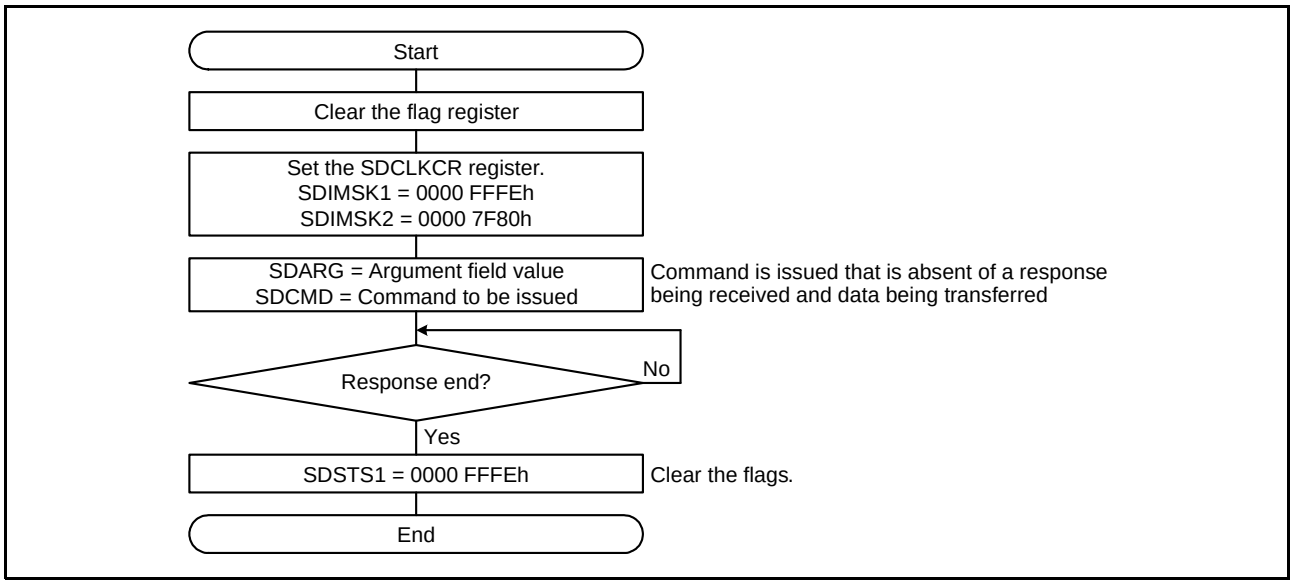

Figure 49.8 Command Issued That Is Absent of Response Reception and Data Transfer

49.3.6.2 Command Absent of Data Transfer

Figure 49.9 shows an example of no data being transferred after the SDHI issues a command.

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 49.5.5 for details on setting the SDCLKCR register.
3. After setting the argument field value in the SDARG register, write the information of the command to be issued to the SDCMD register. The SDHI issues a command when a value is written to the SDCMD register.
4. After a response is received, the SDSTS1.RSPEND flag becomes 1, and a response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0, and read the response stored in the SDRSP10 register.

Perform error processing (clear the interrupt flag) if a communication error or timeout occurs.

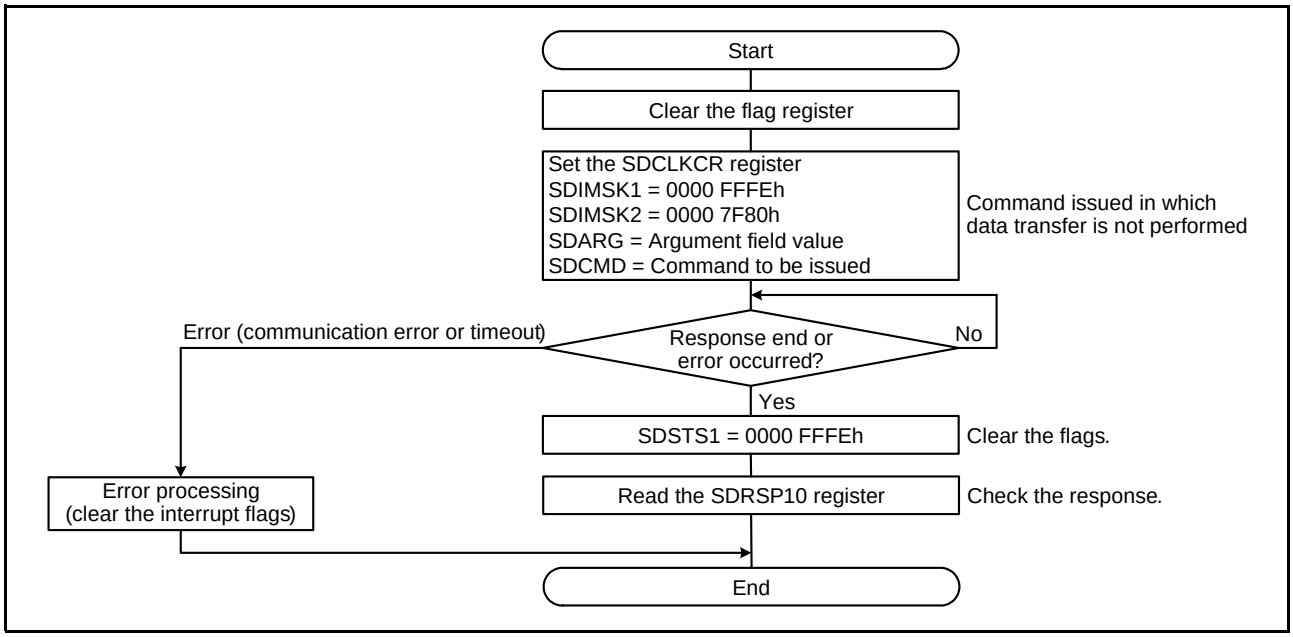

Figure 49.9 Command Issued That Is Absent of Data Transfer

49.3.6.3 Single Block Read Command (CMD17)

Figure 49.10 shows an example of issuing the single block read command (CMD17).

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 49.5.5 for details on setting the SDCLKCR register.
3. After setting the argument field value for CMD17 to the SDARG register, write 0000 0011h to the SDCMD register. The SDHI issues CMD17 when a value is written to the SDCMD register.
4. When the response is received, the SDSTS1.RSPEND flag becomes 1, and a response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0, and read the response stored in the SDRSP10 register. If the response read is in error, set the SDSTOP.STP bit or SDIOMD.IOABT bit to 1, and the command sequence can be stopped. When the command sequence is stopped, the SDSTS1.ACEND flag becomes 1. Note that CMD12 and CMD52 are not automatically issued by stopping this command sequence.
6. After the response is received, set the SDIMSK1.ACENDM bit to 0 and set the SDIMSK2.BREM bit to 0.
7. After the amount of data set in the SDSIZE.LEN[9:0] bits is received from the SD card, the SDSTS2.BRE flag becomes 1, and the BRE interrupt request is generated.
8. Set the SDSTS2.BRE flag to 0, and read the amount of data set in the SDSIZE.LEN[9:0] bits from the SDBUFR register.
9. After data has been read from the SDBUFR register, the SDSTS1.ACEND flag becomes 1, and the access end interrupt request is generated.
10. Set the SDSTS1.ACEND flag to 0.

Perform error processing (clear the interrupt flag) if a communication error or timeout occurs.

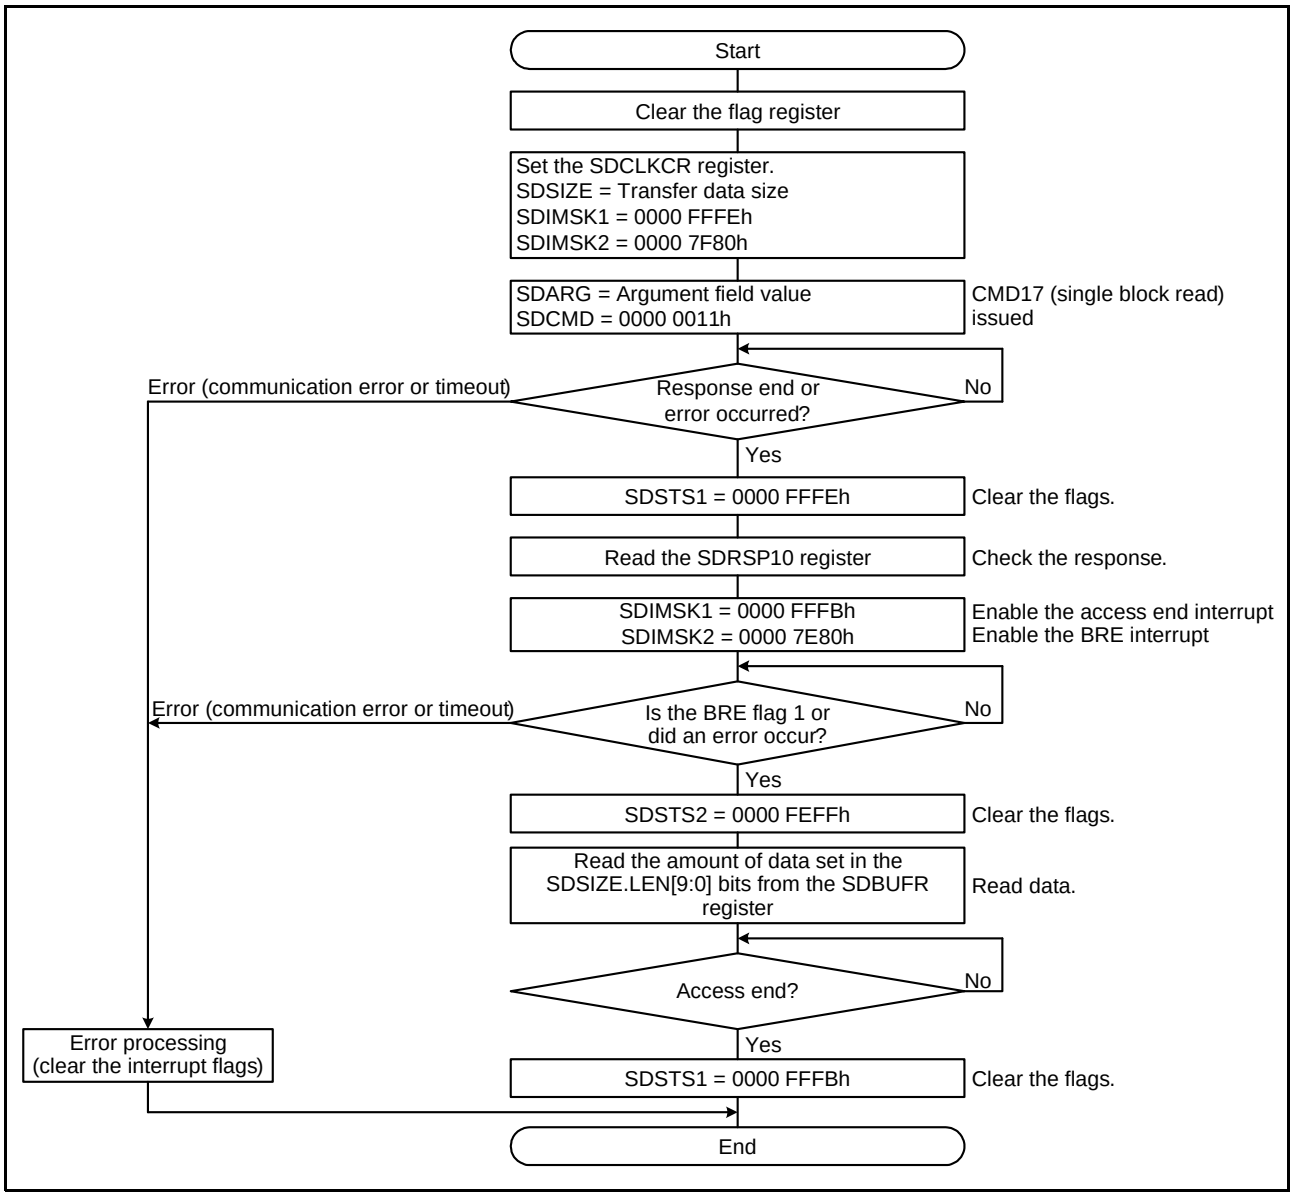

Figure 49.10 Issuing the Single Block Read Command

49.3.6.4 Single Block Write Command (CMD24)

Figure 49.11 shows an example of issuing the single block write command (CMD24).

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 49.5.5 for details on setting the SDCLKCR register.
3. After setting the argument field value for CMD24 to the SDARG register, write 0000 0018h to the SDCMD register. The SDHI issues CMD24 when a value is written to the SDCMD register.
4. When the response is received, the SDSTS1.RSPEND flag becomes 1, and the response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0 and read the response stored in the SDRSP10 register. If the read response is in error, set the SDSTOP.STP bit and SDIOMD.IOABT bit to 1, and the command sequence can be stopped. When the command sequence is stopped, the SDSTS1.ACEND flag becomes 1. Note that when this command sequence is stopped, CMD12 and CMD52 are not automatically issued.
6. After the response is received, set the SDIMSK1.ACENDM bit to 0, and set the SDIMSK2.BWEM bit to 0.
7. When the SDBUFR register becomes write accessible, the SDSTS2.BWE flag becomes 1, and the BWE interrupt request is generated.
8. Set the SDSTS2.BWE flag to 0, and write the amount of data set in the SDSIZE.LEN[9:0] bits to the SDBUFR register. After writing to the SDBUFR register, the SDHI transmits write data to the SD card. Also, after writing to the SDBUFR register, data transmission may cause a communication error or timeout to occur.
9. After all data has been written to the SD card, the SDHI receives the CRC status token, and the SDHI_D0 pin line becomes busy (low). Then, when the SDHI exits the busy state, the SDSTS1.ACEND flag becomes 1, and the access end interrupt request is generated.
10. Set the SDSTS1.ACEND flag to 0.

Perform error processing (clear the interrupt flag) if a communication error or timeout occurs.

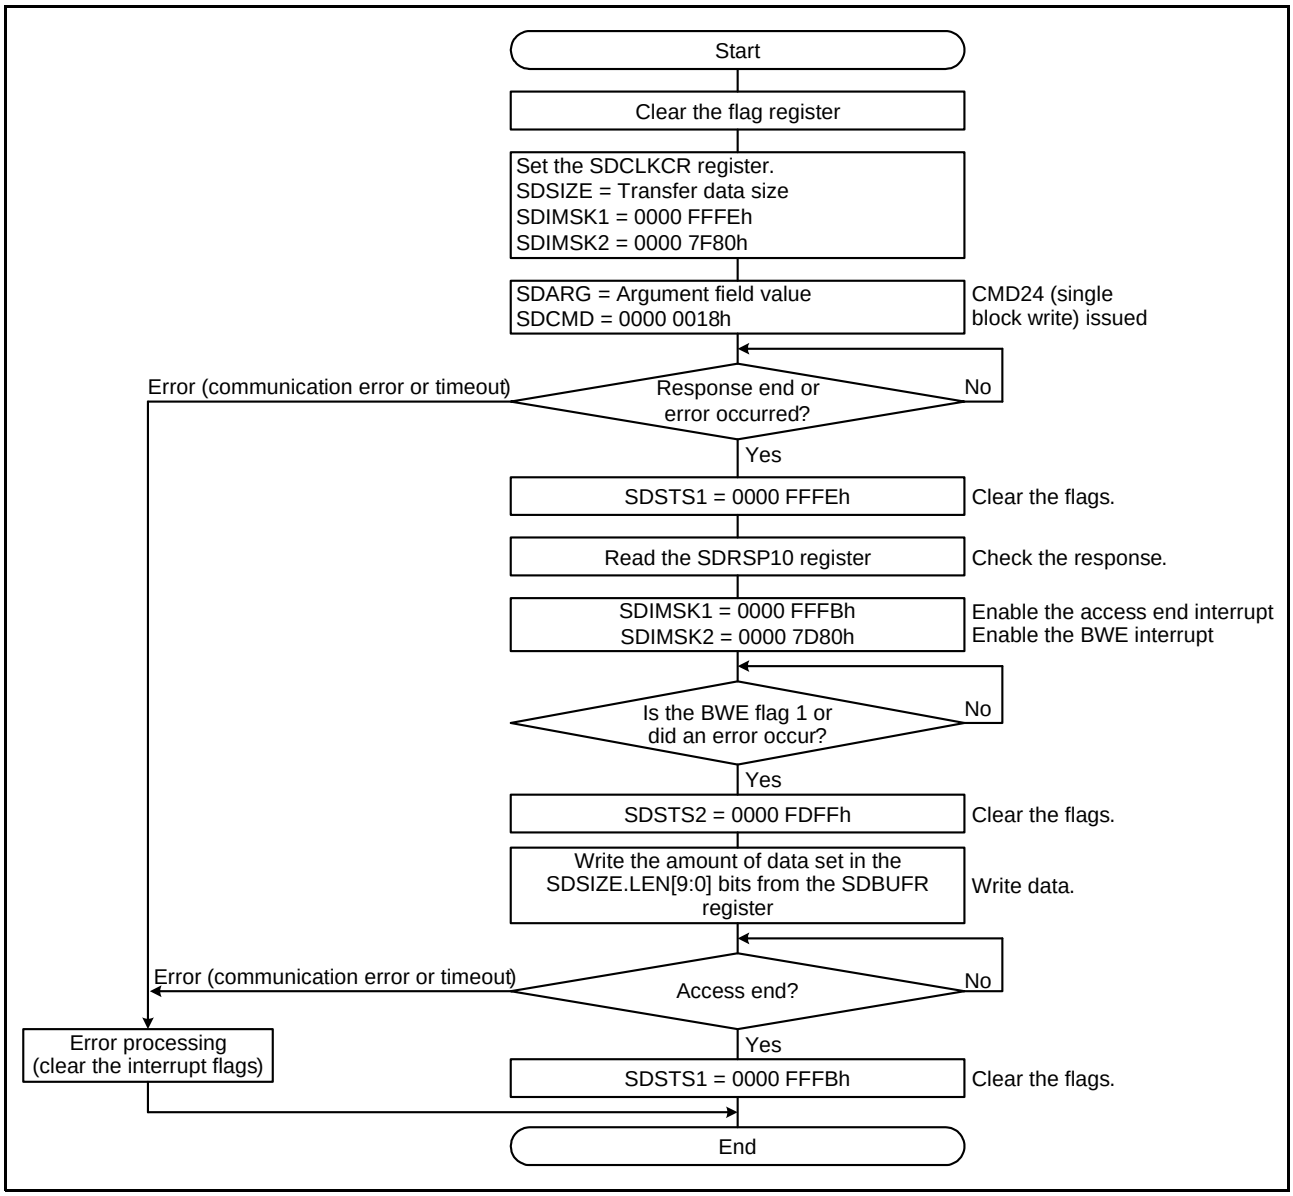

Figure 49.11 Issuing the Single Block Write Command

49.3.6.5 Multi-Block Read Command (CMD18)

Figure 49.12 shows an example of issuing the multi-block read command (CMD18).

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 49.5.5 for details on setting the SDCLKCR register. Set the SDSTOP.SDBLKCNTEN bit to 1, and set the number of transfer blocks in the SDBLKCNT register.
3. After setting the argument field value for CMD18 to the SDARG register, write 0000 0012h to the SDCMD register. The SDHI issues CMD18 when a value is written to the SDCMD register.
4. When the response is received, the SDSTS1.RSPEND flag becomes 1, and the response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0 and read the response stored in the SDRSP54 register. If the read response is in error, set the SDSTOP.STP bit to 1, and the command sequence can be stopped. When the SDSTOP.STP bit is set to 1, the SDHI automatically issues CMD12, and the response is received. At this point, the SDSTS1.ACEND flag becomes 1, and if the access end interrupt request is enabled, the access end interrupt request is generated. Next, set the SDSTS1.ACEND flag to 0 and read the response.
6. After the response is received, set the SDIMSK1.ACENDM bit to 0, and set the SDIMSK2.BREM bit to 0.
7. After receiving one block of data from the SD card, the SDSTS2.BRE bit becomes 1, and the BRE interrupt request is generated.
8. Set the SDSTS2.BRE flag to 0, and read the amount of data set in the SDSIZE.LEN[9:0] bits from the SDBUFR register. The read access to the SDBUFR register repeats for the amount of transfer blocks set in the SDBLKCNT register. Also, while reading the SDBUFR register, data reception may cause a communication error or timeout to occur. After the amount of transfer blocks set in the SDBLKCNT register have been read, the SDHI automatically issues CMD12, and the response is received. At this time, the SDHI automatically writes 0000 0000h to the SDARG register.
9. When all blocks have been received and the CMD12 response is received, the SDSTS1.ACEND flag becomes 1 and the access end interrupt request is generated.
10. Set the SDSTS1.ACEND flag to 0 and read the response.

Perform error processing (clear the interrupt flag) if a communication error or timeout occurs.

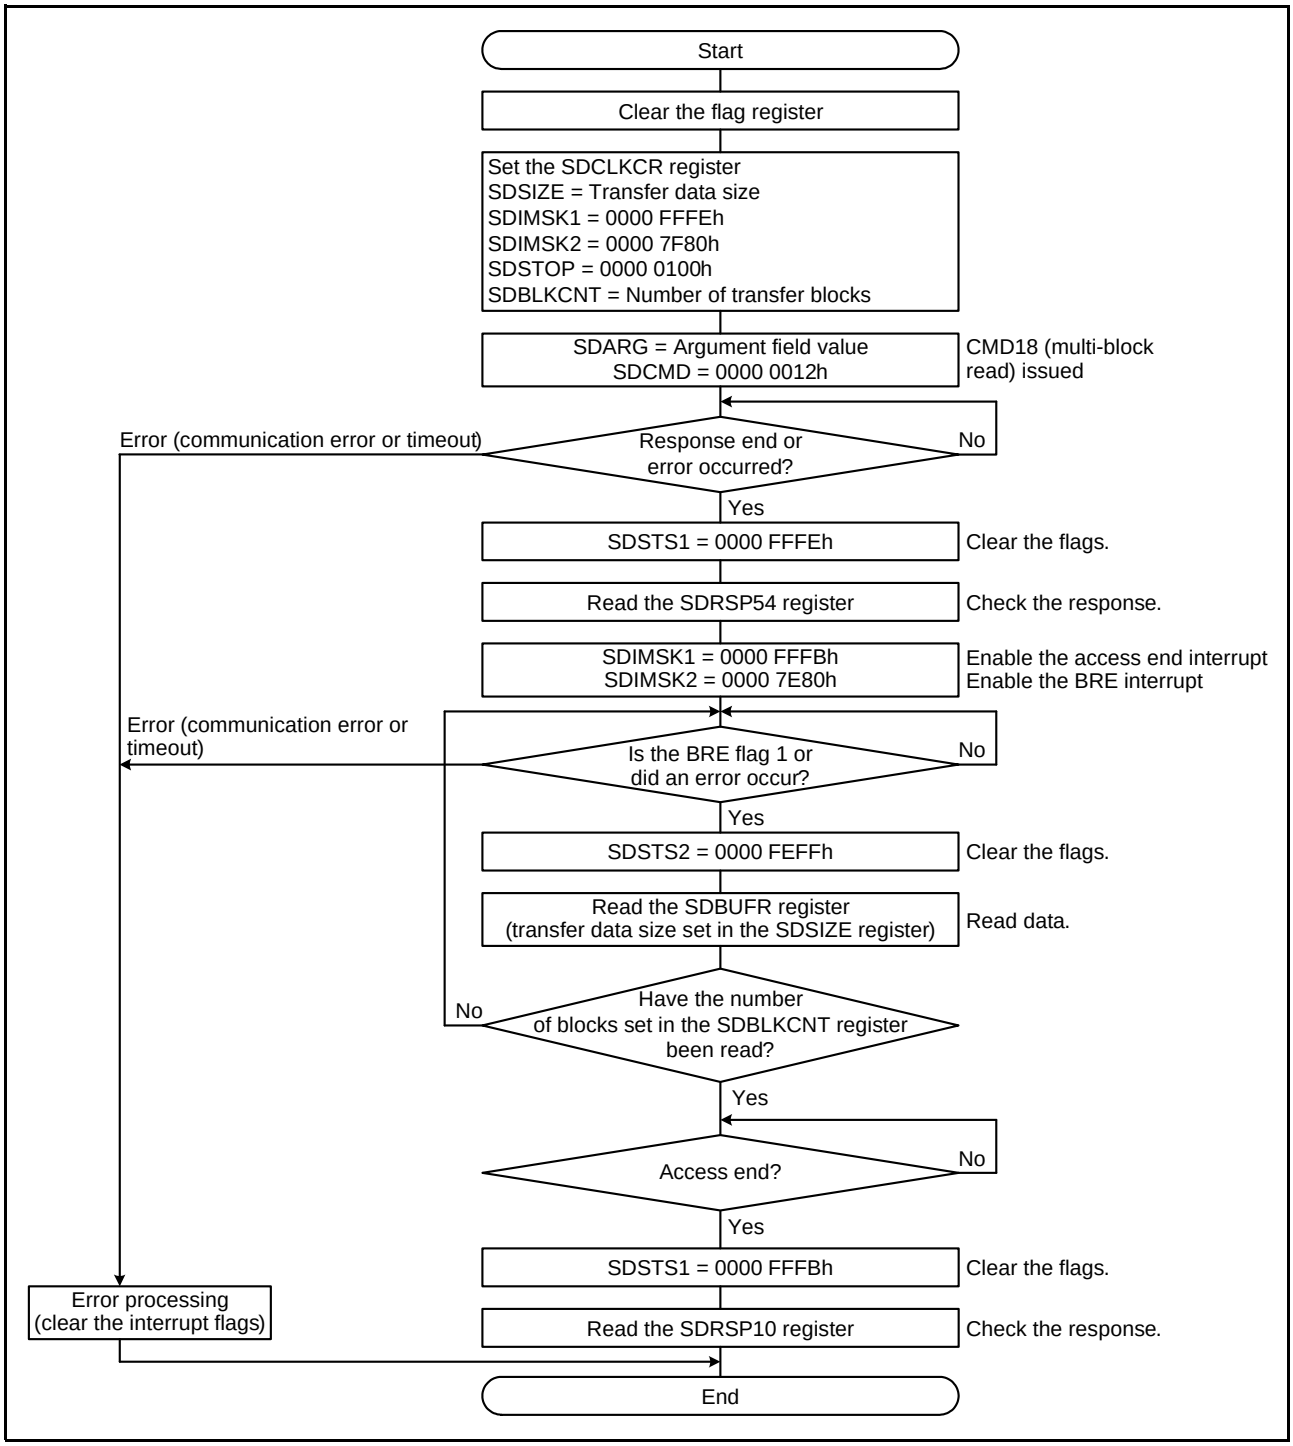

Figure 49.12 Issuing the Multi-Block Read Command

49.3.6.6 Multi-Block Write Command (CMD25)

Figure 49.13 shows an example of issuing the multi-block write command (CMD25).

1. Initialize the flags in registers SDSTS1 and SDSTS2.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 49.5.5 for details on setting the SDCLKCR register. Set the SDSTOP.SDBLKCNTEN bit to 1, and set the number of transfer blocks in the SDBLKCNT register.
3. After setting the argument field value for CMD25 to the SDARG register, write 0000 0019h to the SDCMD register. The SDHI issues CMD25 when a value is written to the SDCMD register.
4. When the response is received, the SDSTS1.RSPEND flag becomes 1, and the response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0 and read the response stored in the SDRSP54 register. If the read response is in error, set the SDSTOP.STP bit to 1, and the command sequence can be stopped. When the SDSTOP.STP bit is set to 1, the SDHI automatically issues CMD12, and the response is received. At this point, the SDSTS1.ACEND flag becomes 1, and if the access end interrupt request is enabled, the access end interrupt request is generated. Next, set the SDSTS1.ACEND flag to 0 and read the response.
6. After the response is received, configure the SDIMSK1 register to enable the access end interrupt request, and configure the SDIMSK2 register to enable the BWE interrupt request.
7. When the SDBUFR register becomes write accessible, the SDSTS2.BWE flag becomes 1, and the BWE interrupt request is generated.
8. Set the SDSTS2.BWE flag to 0, and write the amount of data set in the SDSIZE.LEN[9:0] bits to the SDBUFR register. After writing to the SDBUFR register, and after the SDHI transmits write data to the SD card, the CRC status token is received, and the SDHI_D0 pin line becomes busy (low). The write access to the SDBUFR register and CRC status token reception repeat for the amount of transfer blocks set in the SDBLKCNT register. Also, after writing to the SDBUFR register, data transmission may cause a communication error or timeout to occur. After the amount of transfer blocks set in the SDBLKCNT register have been written, the SDHI automatically issues CMD12, and the response is received. At that time, the SDHI automatically writes 0000 0000h to the SDARG register.
9. When all blocks have been transmitted and the CRC status token is received, the SDHI exits the busy state, the SDSTS1.ACEND flag becomes 1, and the access end interrupt request is generated.
10. Set the SDSTS1.ACEND flag to 0 and read the response.

Perform error processing (clear the interrupt flag) if a communication error or timeout occurs.

49.3.6.10 DMA Transfer

Figure 49.21 shows an example of data being transferred from the SDBUFR register after the CMD18 multi-block read command is issued.

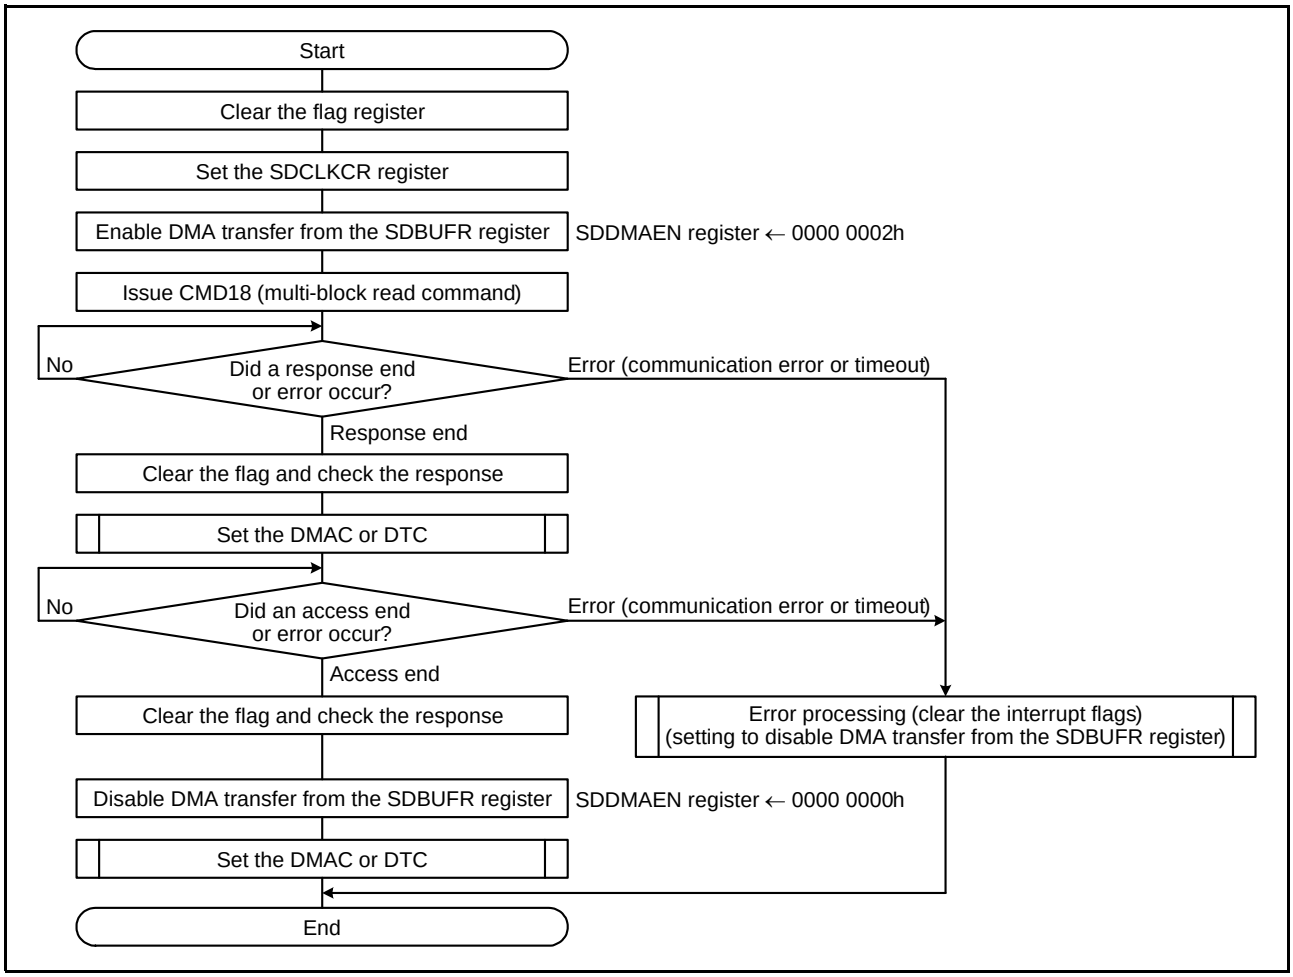

Figure 49.21 DMA Transfer After CMD18 is Issued

Figure 49.22 shows an example of data being DMA transferred to the SDBUFR register after the CMD25 multi-block write command is issued.

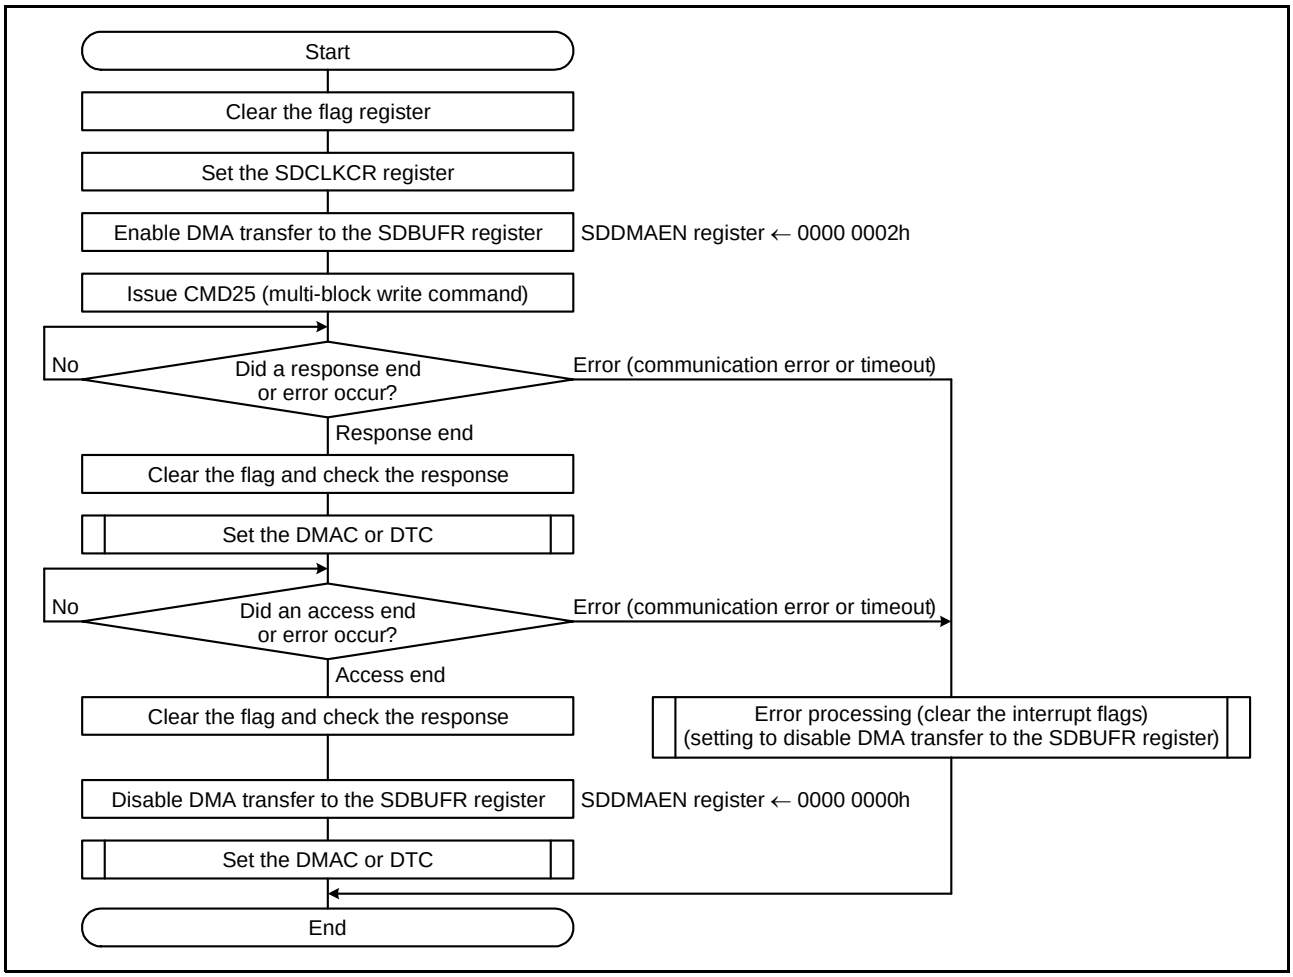

Figure 49.22 DMA Transfer After CMD25 is Issued

49.4 Interrupts

Table 49.8 lists the SDHI interrupt sources. When the status flags in registers SDSTS1, SDSTS2, and SDIOSTS become 1, if the corresponding bits in registers SDIMSK1, SDIMSK2, and SDIOIMSK are 0, the SDHI requests an interrupt. When clearing the status flags in registers SDSTS1, SDSTS2, and SDIOSTS, write 0 to the status flags to be cleared and write 1 to the states flags not being cleared.

Table 49.8 Interrupt Sources

Interrupt Source	Status Flag Register		Interrupt Mask/Enable Register		DMAC/DTC Triggerable
	Register symbol	Bit symbol	Register symbol	Bit symbol	
CACI	SDSTS1	ACEND	SDIMSK1	ACENDM	No
		RSPEND		RSPENDM	
	SDSTS2	ILA	SDIMSK2	ILAM	
		BWE		BWEM	
		BRE		BREM	
		RSPTO		RSPTOM	
		ILR		ILRM	
		ILW		ILWM	
		DTO		DTTOM	
		ENDE		ENDEM	
		CRCE		CRCEM	
		CMDE		CMDEM	
SDACI	SDIOSTS	EXWT	SDIOIMSK	EXWTM	No
		EXPUB52		EXPUB52M	
		IOIRQ		IOIRQM	
CDETI	SDSTS1	SDD3IN	SDIMSK1	SDD3INM	No
		SDD3RM		SDD3RMM	
		SDCDIN		SDCDINM	
		SDCDRM		SDCDRMM	
SBFAI	SDSTS2	BWE	SDDMAEN	DMAEN	Yes
		BRE			

49.4.1 DMA Transfer Triggered by Interrupt Requests

When the SBFAI interrupt is requested, DMA/DTC transfer can be used to write to or read the SDBUFR register. When using the SBFAI interrupt, set the SDDMAEN.DMAEN bit to 1, the SDIMSK2.BWEM bit to 1, and SDIMSK2.BREM bit to 1.

When the SDDMAEN.DMAEN bit is 1, if a write command is issued, the SDSTS2.BWE flag becomes 1; if a read command is issued, the SDSTS2.BRE flag becomes 1. At this point, the SBFAI interrupt request is output. When the last data of a block is transferred (one block is the transfer data size set in the SDSIZE.LEN[9:0] bits), the SBFAI interrupt request is canceled, and the SDSTS2.BWE flag or the SDSTS2.BRE flag becomes 0.

The SBFAI interrupt request is also canceled by following:

- The SDRST.SDRST bit is set to 0 (SDHI software reset).
- The SDSTOP.STP bit is set to 1.
- The SDIOMD.IOABT bit is set to 1.
- The SDDMAEN.DMAEN bit is set to 0.
  However, if the DMAEN bit is set to 1 again before the next command is written to the SDCMD register, the SBFAI interrupt request is output again.

The SDSTS2.BWE flag and BRE flag will not become 0 when a communication error or timeout occurs, nor will they become 0 when the SDSTOP.STP bit and SDIOMD.IOABT bit are set to 1. If the SDSTS2.BWE flag or BRE flag remain set to 1, even if a write command or read command is issued, the SBFAI interrupt request will not be output, and the SDSTS2.BWE flag and BRE flag must be set to 0 before issuing the next command.

Table 49.9 lists the DMAC and DTC settings when performing DMA transfer.

Table 49.9 DMAC and DTC Settings When Performing DMA Transfer

Item		Setting Description
Transfer mode		Block transfer mode
Transfer data	1 data	32 bits
	Block size	Size set in the SDSIZE.LEN[9:0] bits divided by 4
Number of block transfers		Number of transfers set in the SDBLKCNT register

49.5 Notes on Using the SDHI

49.5.1 Illegal Read Access During a Multi-Block Read and How To Avoid It

When the multi-block read command (CMD18) is issued to read one or two blocks, if the response to CMD18 stored in the SDRSP10 register is read, the timing of the read access may cause the response to be read incorrectly.
Figure 49.23 shows examples of a normal read and an illegal read when using CMD18 to read two blocks.

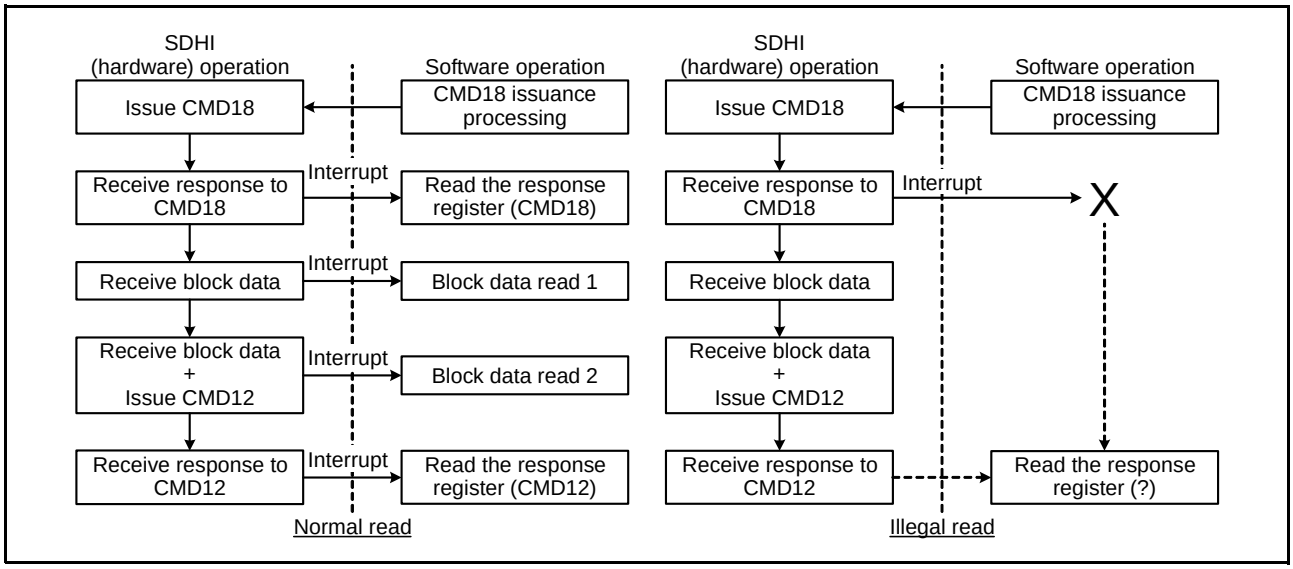

Figure 49.23 Multi-Block Read Processing When Reading Two Blocks

In the example of the illegal read, when the interrupt is generated by receiving the response to CMD18, the timing for reading the SDRSP10 register during the interrupt handling is delayed, and instead of the response for CMD18 being read, the response for CMD12 or the data during the response for CMD12 may be read.
This problem can be avoided by performing either of the following:

- When reading one block or two blocks, use a single block read command instead of a multi-block read command.
- When reading the response for CMD18, read the SDRSP54 register instead of the SDRSP10 register.

When using a multi-block read command to read three or more blocks, CMD12 will not be issued if no block data is read, which will prevent this problem from happening. Also, when using a multi-block write command, the above problem can be avoided by transmitting block data after reading the response to CMD25.

49.5.2 SDBUFR Register Illegal Write Error

When writing to the SDBUFR register after issuing a single block write command or a multi-block write command, write data for the size set by the SDSIZE.LEN[9:0] bits. If the amount of data written to the SDBUFR register is greater than the size set by the SDSIZE.LEN[9:0] bits, an illegal write error occurs in the SDBUFR register, and the SDSTS2.ILW flag becomes 1. However, the padding data included in the data being written to the SDBUFR register is ignored, so this error does not occur. For example, if the data size set by the SDSIZE.LEN[9:0] bits is an odd number, of the data written to the SDBUFR register, there is a remainder of 1 byte or 3 bytes. Although the extra data is written to the register, no error occurs. If the data size set by the SDSIZE.LEN[9:0] bits is an even number, and there is a remainder of 2 bytes, no error occurs even if these 2 bytes are written to the SDBUFR register.
If data written to the SDBUFR register is not transmitted, the SDSTS2.SDCLKCREN flag may remain set to 0. In this case, in order to set the SDSTS2.SDCLKCREN flag to 1, the SDRST.SDRST bit must be set to 0 and then set back to 1.

49.5.3 Automatic Control of the SDHI Clock Output

As per the SD card specifications, after MCU power-on, 74 cycles of the SDHI clock must be output from the host to the SD card before the card initialization command (CMD0) can be issued. Therefore, 74 cycles of the SDHI clock should be output from the SDHI to the SD card before enabling automatic control of the SDHI clock output.
When automatic control of the SDHI clock output is enabled, SDHI clock output stops if the command sequence is ended by a communication error or timeout. Therefore, if it is necessary to change the internal status of the SD card even after the command sequence ends, disable automatic control of the SDHI clock output and output the SDHI clock to the SD card.

49.5.4 Restrictions on Setting the C52PUB Bit During a Multi-Block Write Sequence

During a CMD53 multi-block write sequence, if the SDIOMD.C52PUB bit is set to 1, the SDHI issues CMD52 after the SD buffer becomes empty. To immediately issue CMD52, perform one of the procedures below to suspend writing to the SD buffer, and set the C52PUB bit to 1.

Procedure to suspend writing to the SD buffer when not performing DMA transfer (interrupt used)

1. Set the SDIMSK2.BWEM bit to 1 to disable the interrupt, and suspend writing to the SDBUFR register.
2. Set the SDIOMD.C52PUB bit to 1. Then, when the SD buffer becomes empty, the SDHI issues CMD52.
3. After receiving the response for CMD52, set the SDIMSK2.BWEM bit to 0 to enable the interrupt, and resume writing to the SDBUFR register.

Procedure to suspend writing to the SD buffer when performing DMA transfer

1. Configure settings to perform DMA transfer every [SDSIZE register setting value × *n* blocks], and suspend writing to the SDBUFR register before setting the SDIOMD.C52PUB bit (*n* = 1, 2, ...).
2. Set the SDIOMD.C52PUB bit to 1. Then, when the SD buffer becomes empty, the SDHI issues CMD52.
3. After receiving the response for CMD52, resume DMA transfer to the SDBUFR register.

49.5.5 Note on Setting the SDCLKCR Register

The SDCLKCR register cannot be written when the SDSTS2.SDCLKCREN flag is 0. Set the SDSTS2.SDCLKCREN flag to 1 before writing to the SDCLKCR register.

49.5.6 Writing to the SDSTOP Register During a Multi-Block Read Sequence

When the SDSTOP.SDBLKCNTEN bit is 1 during a multi-block read sequence, if the SDSTOP.STP bit is set to 1 and the command sequence is stopped, the command sequence may not be completed depending on when the SDSTOP.STP bit is set to 1. To avoid this problem, set the SDSTOP.STP bit and the SDSTOP.SDBLKCNTEN bit to 0 simultaneously. Note that at this time, the SDSTOP.SDBLKCNTEN bit should be set to 0 even if the SDSTS2.SDCLKCREN bit is 0.
If the SDSTOP.SDBLKCNTEN bit is not set to 0, the command sequence can be completed by setting the SDRST.SDRST bit to 0.
During a CMD53 multi-block transfer, when stopping data transfer by setting the SDIOMD.IOABT bit to 1, the SDSTOP.SDBLKCNTEN bit should remain set to 1.

49.5.7 Controlling Module Operation

SDHI operation is controlled by setting the MSTPCRD.MSTPD19 bit. Setting the MSTPD19 bit to 0 enables the SDHI; setting the MSTPD19 bit to 1 disables the SDHI. The SDHI is disabled after a reset. Registers in the SDHI can be accessed by setting the MSTPD19 bit to 0. Refer to section 11, Low Power Consumption for details.

50. MultiMediaCard Interface (MMCIF)

50.1 Overview

This MCU incorporates a MultiMediaCard interface (MMCIF) that conforms to the JEDEC Standard JESD84-A441. Table 50.1 lists the specifications of the MMCIF.

Table 50.1 MMCIF Specifications

Item	Function
MMC bus interface	Transfer bus width selectable from 1, 4, or 8 bits
Transfer modes	• Backward compatible mode or high-speed mode selectable • Supports the single data rate • Supports block transfer (stream read and stream write operations are not supported)
Clocks	The MMCIF clock is generated by dividing peripheral module clock B (PCLKB) by *n*, where *n* = 2, 4, 8, 16, 32, 64, 128, 256, 512, or 1,024.
Boot operation mode	The MMCIF clock frequency is switchable during boot operation (alternative boot operation is not supported).
MMCIF buffers	512 bytes × 2
Interrupt sources	• Normal operation interrupt (ACCIO) • Error/timeout interrupt (ERRIO) • MMC detection interrupt (CDETIO) • MMCIF buffer access interrupt (MBFAI)
DMA transfer requests	• MBFAI interrupt can be used to trigger the DMAC and DTC • DMAC or DTC can be used to read and write to the MMCIF buffer
Other functions	• MMC detection • Supports background operations • Supports the high priority interrupt (HPI) during CMD6, CMD24, CMD25 (pre-defined), and CMD38 command sequences

Figure 50.1 shows a Block Diagram of the MMCIF.

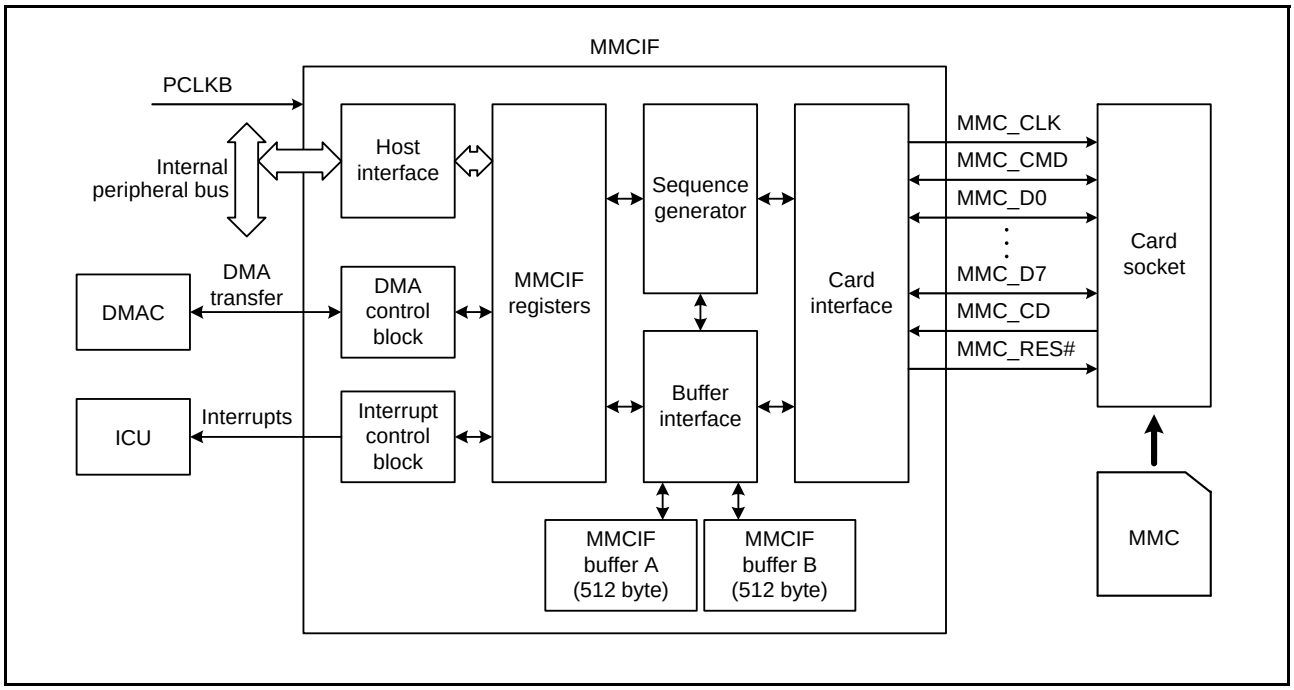

Figure 50.1 Block Diagram of the MMCIF

Table 50.2 lists the MMCIF I/O Pins.

Table 50.2 MMCIF I/O Pins

Pin Name	I/O	Description
MMC_CLK	Output	MMCIF clock
MMC_CMD	I/O	Command output and response input
MMC_D0 to MMC_D7	I/O	Transfer data (DAT0 to DAT7)
MMC_CD	Input	MMC detection *1
MMC_RES#	Output	MMC reset *2

Note 1. Check the specifications of the card socket to be used before connecting the pins to the MMC.
Note 2. Similar reset control is possible with a general purpose port.

50.2 Register Descriptions

50.2.1 Command Setting Register (CECMDSET)

Address 0008 8500h

Bit	b31	b30	b29	b28	b27	b26	b25	b24
Symbol	—	BOOT	CMD[5:0]					
Value after reset	0	0	0	0	0	0	0	0

Bit	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	TBIT	OPDM	—	—	SBIT	—	DATW[1:0]	
Value after reset	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0 *1	DATW[1:0]	Data Bus Width Select	b1 b0 0 0 : 1-bit data bus width 0 1 : 4-bit data bus width 1 0 : 8-bit data bus width 1 1 : Do not set this value.	R/W
b2	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b3 *2	SBIT	Read Data Start Bit Detection Setting	0: When the MMC_D*n* pins corresponding to the data bus width set in the DATW[1:0] bits are all low, this bit is detected as a start bit (*n* = 0, 0 to 3, or 0 to 7) 1: When the MMC_D0 pin is low, this bit is detected as a start bit	R/W
b5, b4	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b6	OPDM	MMC_CMD Output Select	0: Normal output from the MMC_CMD pin 1: Open-drain output from the MMC_CMD pin	R/W
b7	TBIT	Transmission Bit Setting	0: Transmission bit is set to 1 1: Transmission bit is set to 0	R/W
b8 *3	CRCSTE	CRC Status Token Reception	0: CRC status token received 1: CRC status token not received (set to 1 when CMD19 is issued)	R/W
b9	BOOTACK	Boot Acknowledge Reception	0: Boot acknowledge not received 1: Boot acknowledge received	R/W
b10 *2	CRC16C	CRC16 Check During Reception	0: Check CRC16 in the transfer data 1: Do not check CRC16 in the transfer data (set to 1 when CMD14 is issued)	R/W
b11	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b13, b12	RCRC7C[1:0]	Response CRC7 Check	b13 b12 0 0 : Performs an error check on CRC7 field value (set the RTYP[1:0] bits to 01b) 0 1 : Confirms that the field values for the response check bits are all 1 (set the RTYP[1:0] bits to 01b) 1 0 : Performs an error check on internal CRC7 field value (set the RTYP[1:0] bits to 10b) 1 1 : Error check not performed on response's CRC7 field value	R/W
b15, b14	RIDXC[1:0]	Response Index Check	b15 b14 0 0 : The command index field value checks to see if the command matches the response. 0 1 : Checks to see if the check bits in the response are all 1 1 0 : Response's command index field value is not checked 1 1 : Do not set this value.	R/W
b16	CMD12EN	CMD12 Automatic Issue Setting	0: CMD12 is not automatically issued during a multiple block transfer 1: CMD12 is automatically issued during a multiple block transfer	R/W
b17 *1	CMLTE	Transfer Type Select	0: Single block transfer 1: Multiple block transfer	R/W

Bit	Symbol	Bit Name	Description	R/W
b18 *1	DWEN	MMC Access Select	0: Read data from the MMC 1: Write data to the MMC	R/W
b19	WDAT	Data Presence Determination	0: No data present in the MMC 1: Data present in the MMC	R/W
b20	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b21	RBSY	MMC Response	0: No response busy 1: Response busy is included (R1b)	R/W
b23, b22	RTYP[1:0]	Response Type Select	b23 b22 0 0 : No response 0 1 : 6-byte response (R1, R1b, R3, R4, R5) 1 0 : 17-byte response (R2) 1 1 : Do not set this value.	R/W
b29 to b24	CMD[5:0]	Command Index	Set the command index field value.	R/W
b30	BOOT	Boot Operations	0: Command sequence when not performing boot operations 1. Command sequence when performing boot operations	R/W
b31	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W

Note 1. The DATW[1:0], CMLTE, and DWEN bit values are valid when the WDAT bit is 1.
Note 2. The SBIT and CRC16C bit values are valid when the WDAT bit is 1 and the DWEN bit is 0.
Note 3. The CRCSTE bit value is valid when bits WDAT and DWEN are both 1.

The CECMDSET register defines the command sequence. The command sequence starts when a value is written to the CECMDSET register. The CECMDSET register cannot be write accessed when the CEHOSTSTS1.CMDSEQ bit is 1. Table 50.3 lists the setting values for the CECMDSET register.

CMD12EN Bit (CMD12 Automatic Issue Setting)

Set this bit to select whether CMD12 is automatically issued or not during a multiple block transfer. When the CMD12EN bit is 1 and CMD12 automatic issuance is enabled, set the RBSY bit to 0 and set the CEBLOCKSET.BLKSIZ[15:0] bits to 200h (512 bytes). For details on CMD12 automatic issuance, refer to section 50.3.4, Automatically Issuing CMD12.

RBSY Bit (MMC Response)

Set this bit to enable or disable the busy signal when receiving a response.

Table 50.3 Setting Values for the CECMDSET Register

Command	Response	CECMDSET Register Setting Value																						Remark
		—	BOOT	CMD[5:0]	RTYP[1:0]	RBSY	—	WDAT	DWEN	CMLTE	CMD12EN	RIDXC[1:0]	RCRC7C[1:0]	—	CRC16C	BOOTACK	CRCSTE	TBIT	OPDM	—	—	SBIT	—	DATW[1:0]

50.2.2 Argument Register (CEARG)

Address 0008 8508h

Bit	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol																																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CEARG register defines the argument field value for the command issued. Set a value to the CEARG register before starting the command sequence. The argument field value for an automatically issued CMD12 should be set in the CEARGCMD12 register.

50.2.3 Automatically Issued CMD12 Argument Register (CEARGCMD12)

Address 0008 850Ch

Bit	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol																																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CEARGCMD12 register defines the argument field value of an automatically issued CMD12. This register is only accessible when CMD12 is automatically issued during a multiple block transfer. Set a value to the CEARGCMD12 register before starting the command sequence. For details on CMD12 automatic issuance, refer to section 50.3.4, Automatically Issuing CMD12.

50.2.4 Command Control Register (CECMDCTRL)

Address 0008 8510h

Bit	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Symbol	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BREAK
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

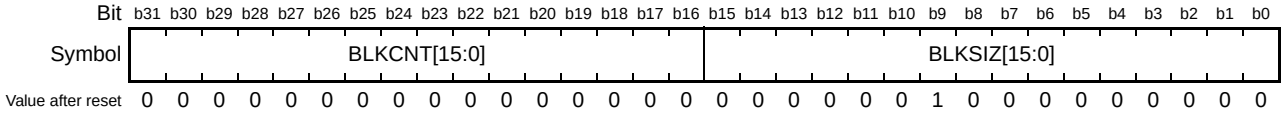
Bit	Symbol	Bit Name	Description	R/W
b0	BREAK	Command Sequence Force Stop	Writing 1 to this bit stops the command sequence. This bit will not automatically revert to 0, so after setting it to 1, set it back to 0.	R/W
b31 to b1	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

BREAK Bit (Command Sequence Force Stop)

To stop the command sequence, when the BREAK bit is 0, set it to 1 and then to 0 in succession. Then confirm that the CEHOSTSTS1.CMDSEQ flag is 0, set the CEVERSION.SWRST bit to 1, and perform an MMCIF software reset. When an MMCIF software reset is performed, registers associated with the MMCIF module become their value after reset values, so initial settings are required.

50.2.5 Transfer Block Setting Register (CEBLOCKSET)

Address 0008 8514h



Bit	Symbol	Bit Name	Description	R/W
b15 to b0	BLKSIZ[15:0]	Transfer Block Size	These bits define the transfer block size. When performing a single block transfer, values equivalent to 1 to 512 (bytes) can be set. When performing a multiple block transfer, set a value equivalent to 512 (bytes).	R/W
b31 to b16	BLKCNT[15:0]	Number of Transfer Blocks *1	These bits define the number of transfer blocks.	R/W

Note 1. These bits are accessible during a multiple block transfer.

The CEBLOCKSET register defines the block size of the data to be transferred, and the number of blocks. Set a value to the CEBLOCKSET register before starting the command sequence.

50.2.6 Clock Control Register (CECLKCTRL)

Address 0008 8518h

Bit	b31	b30	b29	b28	b27	b26	b25	b24
Symbol	MMCBUSBSY	—	—	—	—	—	—	CLKEN
Value after reset	0	0	0	0	0	0	0	0

Bit	b23	b22	b21	b20	b19	b18	b17	b16
Symbol	—	—	—	—	CLKDIV[3:0]			
Value after reset	0	0	0	0	0	0	0	0

Bit	b15	b14	b13	b12	b11	b10	b9	b8
Symbol	—	—	SRSPTO[1:0]		SRBSYTO[3:0]			
Value after reset	0	0	0	0	0	0	0	0

Bit	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	SRWDTO[3:0]				—	—	—	—
Value after reset	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description		R/W
b3 to b0	—	Reserved	These bits are 0 when read. Set them to 0 when writing.		R/W
b7 to b4	SRWDTO[3:0]	Write Data Timeout/Read Data Timeout Setting	b7 b4 0 0 0 0: MMCIF × 2^{14} 0 0 0 1: MMCIF × 2^{15} 0 0 1 0: MMCIF × 2^{16} 0 0 1 1: MMCIF × 2^{17} 0 1 0 0: MMCIF × 2^{18} 0 1 0 1: MMCIF × 2^{19} 0 1 1 0: MMCIF × 2^{20} 0 1 1 1: MMCIF × 2^{21}	b7 b4 1 0 0 0: MMCIF × 2^{22} 1 0 0 1: MMCIF × 2^{23} 1 0 1 0: MMCIF × 2^{24} 1 0 1 1: MMCIF × 2^{25} 1 1 0 0: MMCIF × 2^{26} 1 1 0 1: MMCIF × 2^{27} 1 1 1 0: MMCIF × 2^{28} 1 1 1 1: MMCIF × 2^{29}	R/W
b11 to b8	SRBSYTO[3:0]	Response Busy Timeout Setting	b11 b8 0 0 0 0: MMCIF × 2^{14} 0 0 0 1: MMCIF × 2^{15} 0 0 1 0: MMCIF × 2^{16} 0 0 1 1: MMCIF × 2^{17} 0 1 0 0: MMCIF × 2^{18} 0 1 0 1: MMCIF × 2^{19} 0 1 1 0: MMCIF × 2^{20} 0 1 1 1: MMCIF × 2^{21}	b11 b8 1 0 0 0: MMCIF × 2^{22} 1 0 0 1: MMCIF × 2^{23} 1 0 1 0: MMCIF × 2^{24} 1 0 1 1: MMCIF × 2^{25} 1 1 0 0: MMCIF × 2^{26} 1 1 0 1: MMCIF × 2^{27} 1 1 1 0: MMCIF × 2^{28} 1 1 1 1: MMCIF × 2^{29}	R/W
b13, b12	SRSPTO[1:0]	Response Timeout Setting	b13 b12 0 0 : MMCIF clock × 64 0 1 : MMCIF clock × 128	b13 b12 1 0 : MMCIF clock × 256 1 1 : Do not set this value.	R/W
b15, b14	—	Reserved	These bits are 0 when read. Set them to 0 when writing.		R/W
b19 to b16	CLKDIV[3:0]	MMCIF Clock Frequency Select	b19 b16 0 0 0 0: PCLKB/2 0 0 0 1: PCLKB/2^2 0 0 1 0: PCLKB/2^3 0 0 1 1: PCLKB/2^4 0 1 0 0: PCLKB/2^5	b19 b16 0 1 0 1: PCLKB/2^6 0 1 1 0: PCLKB/2^7 0 1 1 1: PCLKB/2^8 1 0 0 0: PCLKB/2^9 1 0 0 1: PCLKB/2^{10}	R/W
			Only set the values listed above.		
b23 to b20	—	Reserved	These bits are 0 when read. Set them to 0 when writing.		R/W
b24	CLKEN	MMCIF Clock Output Control	0: MMCIF clock is not output from the MMC_CLK pin (low level output) 1: MMCIF clock is output from the MMC_CLK pin		R/W
b30 to b25	—	Reserved	These bits are 0 when read. Set them to 0 when writing.		R/W
b31	MMCBUSBSY	MMC Bus Status Flag	0: MMC bus is not busy 1: MMC bus is busy		R

Note 1. Do not rewrite the CLKEN or CLKDIV[3:0] bits when the MMCBUSBSY flag is 1.

The CECLKCTRL register controls the MMCIF clock and defines the timeout value. Do not rewrite the CECLKCTRL register during the command sequence.

MMCBUSBSY Flag (MMC Bus Status Flag)

When writing a value to the CECMDSET register and starting the command sequence, the CEHOSTSTS1.CMDSEQ flag and MMCBUSBSY flag become 1 simultaneously. When the command sequence is complete and the CEHOSTSTS1.CMDSEQ flag becomes 0, 10 cycles of the MMCIF clock are output before the MMCBUSBSY flag becomes 0.

50.2.7 Buffer Access Setting Register (CEBUFACC)

Address 0008 851Ch

Bit	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Symbol	—	—	—	—	—	DMATYP	DMAWEN	DMAREN	—	—	—	—	—	—	—	ATYP
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b16	ATYP	Buffer Access Select	0: When accessing the CEDATA register, the byte endian is not switched 1: When accessing the CEDATA register, the byte endian is switched	R/W
b23 to b17	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b24	DMAREN	Enable DMA Transfer Request to Read the CEDATA Register	0: CEDATA register cannot be read using DMA transfer 1: CEDATA register can be read using DMA transfer	R/W
b25	DMAWEN	Enable DMA Transfer Request to Write to the CEDATA Register	0: CEDATA register cannot be written to using DMA transfer 1: CEDATA register can be written to using DMA transfer	R/W
b26	DMATYP	DMA Transfer Method Select	Set this bit to 1 when the DMAREN or DMAWEN bit is 1 (enabled).	R/W
b31 to b27	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

The CEBUFACC register is used to select a method of accessing the CEDATA register, and to set the DMAC and DTC transfer method. Do not rewrite the CEBUFACC register during the command sequence. For details on the MMCIF buffer, refer to section 50.3.3, MMCIF Buffer Structure and Access Method.

50.2.8 Response Register 0 (CERESP0), Response Register 1 (CERESP1), Response Register 2 (CERESP2), Response Register 3 (CERESP3)

Addresses CERESP0 0008 852Ch, CERESP1 0008 8528h, CERESP2 0008 8524h, CERESP3 0008 8520h

Bit	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol																																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Registers CERESP0 to CERESP3 are read-only registers used for storing response values from the MMC. Depending on the type of response received, the MMCIF divides and stores the responses in their appropriate registers. Table 50.4 lists the Response Value Storage Destinations. Refer to section 50.3.1, Command and Response Formats for details on the format of the response value.

Table 50.4 Response Value Storage Destinations

Response Type	CERESP3 Register	CERESP2 Register	CERESP1 Register	CERESP0 Register
R1	—	—	—	[39:8]
R1b *1	—	—	—	[39:8]
R2	[127:96]	[95:64]	[63:32]	[31:0]
R3	—	—	—	[39:8]
R4	—	—	—	[39:8]
R5	—	—	—	[39:8]

Note 1. The response for an automatically issued CMD12 is stored in the CERESPCMD12 register.

50.2.9 Automatically Issued CMD12 Response Register (CERESPCMD12)

Address 0008 8530h

Bit	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol																																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CERESPCMD12 is a read-only register that stores the response from the MMC when CMD12 is automatically issued.

50.2.10 Data Register (CEDATA)

Address 0008 8534h

Bit	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol																																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CEDATA data register is used for accessing the MMCIF buffer. Refer to section 50.3.2, Data Block Format for details on the format of the read and write data.

50.2.11 Boot Operation Setting Register (CEBOOT)

Address 0008 853Ch

Bit	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b27 to b24	SBTACKTO[3:0]	Boot Acknowledge Timeout Setting	b27 b24 0 0 0 0: 2^{14} × MMCIF clock cycle 0 0 0 1: 2^{15} × MMCIF clock cycle 0 0 1 0: 2^{16} × MMCIF clock cycle 0 0 1 1: 2^{17} × MMCIF clock cycle 0 1 0 0: 2^{18} × MMCIF clock cycle 0 1 0 1: 2^{19} × MMCIF clock cycle 0 1 1 0: 2^{20} × MMCIF clock cycle 0 1 1 1: 2^{21} × MMCIF clock cycle	b27 b24 1 0 0 0: 2^{22} × MMCIF clock cycle 1 0 0 1: 2^{23} × MMCIF clock cycle 1 0 1 0: 2^{24} × MMCIF clock cycle 1 0 1 1: 2^{25} × MMCIF clock cycle 1 1 0 0: 2^{26} × MMCIF clock cycle 1 1 0 1: 2^{27} × MMCIF clock cycle 1 1 1 0: 2^{28} × MMCIF clock cycle 1 1 1 1: 2^{29} × MMCIF clock cycle	R/W
b31 to b28	SBTCLKDIV[3:0]	MMCIF Clock Frequency During Boot Operations	b31 b28 0 0 0 0: PCLKB/2 0 0 0 1: PCLKB/4 0 0 1 0: PCLKB/8 0 0 1 1: PCLKB/16 Only set the values listed above.		R/W

The CEBOOT register is used for selecting the MMCIF clock frequency during boot operations, and for setting timeout values. Do not rewrite this register during a command sequence or during boot operations.

SBTCLKDIV[3:0] Bits (MMCIF Clock Frequency During Boot Operations)

The SBTCLKDIV[3:0] bit setting value must be the equal to or lower than the MMCIF clock frequency selected in the CECLKCTRL.CLKDIV[3:0] bits (the MMCIF clock frequency during boot operations must be equal to or greater than the MMCIF clock frequency in normal mode).

Refer to section 50.3.5, MMCIF Clock Frequency During Boot Operations for details on the MMCIF clock frequency during boot operation.

50.2.12 Interrupt Status Flag Register (CEINT)

Address 0008 8540h

b25	CMD12RBE	Automatically Issued CMD12 Response Busy Complete Flag	0: Response reception and response busy triggered by automatically issued CMD12 are incomplete 1: Response reception and response busy triggered by automatically issued CMD12 are complete	R(/W) *1

Bit	Symbol	Bit Name	Description	R/W
b26	CMD12DRE	Automatically Issued CMD12 Response Busy and MMCIF Buffer Read Complete Flag	0: Response busy and MMCIF buffer read access triggered by automatically issued CMD12 are incomplete 1: Response busy and MMCIF buffer read access triggered by automatically issued CMD12 are complete	R(/W) *1
b31 to b27	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. This flag cannot be set to 1 by the user. This flag becomes 0 when set to 0 by the user.

The CEINT register indicates the various states in the command sequence. When clearing a flag, set the flag to be cleared to 0 and set the other flags to 1. Refer to section 50.3.8, MMCIF Processing When an Error or Timeout Occurs for details on MMCIF operation when errors and timeouts occur.

RSPTO Flag (Response Timeout Flag)

This flag indicates that a response or boot acknowledge was not received within the specified period. Note that the command sequence does not stop even if the RSPTO flag becomes 1.

— When not performing a boot operation, this flag becomes 1 under the following condition:
- After a command is issued (including an automatically issued CMD12), a response is not received even after the number of clocks selected in the CECLKCTRL.SRSPTO[1:0] bits have been output.

— When performing a boot operation, this flag becomes 1 under the following condition:
- When the CECMDSET.BOOTACK bit is set to 1 (boot acknowledge received), a boot acknowledge is not received even after the number of clocks selected in the CEBOOT.SBTACKTO[3:0] bits have been output.

— This flag becomes 0 under the following condition:
- The flag is set to 0.

RBSYTO Flag (Response Busy Timeout Flag)

This flag indicates that the response is in a busy state longer than the specified period. Note that the command sequence does not stop even if the RBSYTO flag becomes 1.

— This flag becomes 1 under the following condition:
- After a command is issued (including an automatically issued CMD12), the response is in the busy state even after the number of clocks selected in the CECLKCTRL.SRBSYTO[3:0] bits have been output.

— This flag becomes 0 under the following condition:
- The flag is set to 0.

RDATTO Flag (Read Data Timeout Flag)

This flag indicates that data was not received within the specified period. Note that the command sequence does not stop even if the RDATTO flag becomes 1.

— When not performing a boot operation, this flag becomes 1 under any of the following conditions:
- After a read command is issued, data is not received even after the number of clocks selected in the CECLKCTRL.SRWDTO[3:0] bits have been output.
- After read data is received, data is not received even after the number of clocks selected in the CECLKCTRL.SRWDTO[3:0] bits have been output.

— When performing a boot operation, this flag becomes 1 under any of the following conditions:
- The first data is not received even after the number of clocks selected in the CEBOOT.SFSTBTDATTO[3:0] bits have been output.
- After read data is received, the next data is not received even after the number of clocks selected in the CEBOOT.SBTDATTO[3:0] bits have been output.

— This flag becomes 0 under the following condition:
- The flag is set to 0.

WDATTO Flag (Write Data Timeout Flag)

During a data write access, this flag indicates that the MMC was in the busy state longer than the specified period. Note that the command sequence does not stop even when the WDATTO flag becomes 1.

— This flag becomes 1 under the following condition:
- After a CRC status token is received, the MMC is in a busy state even after the number of clocks selected in the CECLKCTRL.SRWDTO[3:0] bits have been output.

— This flag becomes 0 under the following condition:
- The flag is set to 0.

CRCSTO Flag (CRC Status Timeout Flag)

This flag indicates that a CRC status token was not received. Note that the command sequence does not stop even if the CRCSTO flag becomes 1.

— This flag becomes 1 under the following condition:
- A CRC status token is not received.

— This flag becomes 0 under the following condition:
- The flag is set to 0.

RSPERR Flag (Response Error Flag)

This flag indicates that the response or boot acknowledge is in error. Note that the command sequence stops when the RSPERR flag becomes 1.

— When not performing a boot operation, this flag becomes 1 under any of the following conditions:
- The response's transmission bit is 1.
- The response's end bit is in error.
- Bits [7:1] of the response are in error (content to be checked is specified in the CECMDSET.RCRC7C[1:0] bits).

— When performing a boot operation, this flag becomes 1 under any of the following conditions:
- The bit pattern of the boot acknowledge is in error.
- The end bit of the boot acknowledge is in error.

— This flag becomes 0 under the following condition:
- The flag is set to 0.

RIDXERR Flag (Response Index Error Flag)

This flag indicates that the command index or check bits for the response is in error. Note that the command sequence stops when the RIDXERR flag becomes 1.

— This flag becomes 1 under the following condition:
- The response's command index field value or check bits field value is in error (content to be checked is specified in the CECMDSET.RIDXC[1:0] bits).

— This flag becomes 0 under the following condition:
- The flag is set to 0.

RDATERR Flag (Read Data Error Flag)

This flag indicates that the read data is in error. Note that the command sequence stops when the RDATERR flag becomes 1.

— This flag becomes 1 under any of the following conditions:
- CMD16 of the read data is in error.
- The end bit of the read data is in error.

— This flag becomes 0 under the following condition:
- The flag is set to 0.

WDATERR Flag (Write Data Error Flag)

This flag indicates that the write data is in error. Note that the command sequence stops when the WDATERR flag becomes 1.

— This flag becomes 1 under any of the following conditions:
- The status of the CRC status token is in error.
- The end bit of the CRC status token is in error.

— This flag becomes 0 under the following condition:
- The flag is set to 0.

BUFVIO Flag (MMCIF Buffer Access Error Flag)

This flag indicates illegal accesses to the MMCIF buffer. Note that the command sequence does not stop even if the BUFVIO flag becomes 1.

— This flag becomes 1 under any of the following conditions:
- The CEDATA register was accessed more times than the block size set in the CEBLOCKSET.BLKSIZ[15:0] bits.
- Despite the BUFREN bit not being set to 1 (during DMA transfer, the MMCIF buffer read DMA transfer is not requested), the CEDATA register was accessed while data was being read from the MMC.
- Despite the BUFWEN bit not being set to 1 (during DMA transfer, the MMCIF buffer write DMA transfer is not requested), the CEDATA register was accessed while data was being written to the MMC.

— This flag becomes 0 under the following condition:
- The flag is set to 0.

Note: If the MMCIF buffer is accessed after a communication error occurs, the BUFVIO flag may become 1.

CMDVIO Flag (Command Issue Error Flag)

This flag indicates that registers CECMDSET and CEBLOCKSET were set illegally.

— This flag becomes 1 under any of the following conditions:
- A value is set to the CECMDSET.CMD[5:0] bits during a command sequence (the command sequence does not automatically stop).
- A value is set to the CECMDSET.CMD[5:0] bits when one of the following is in agreement with the CECMDSET and CEBLOCKSET register setting:
  - — The RTYP[1:0] bits are 00b (no response), and the RBSY bit is 1 (response busy).
  - — The RTYP[1:0] bits are 00b, the WDAT bit is 1 (data present), and the BOOT bit is 0 (command sequence when not performing boot operations).
  - — The WDAT bit is 0 (no data present), and the CMD12EN bit is 1 (CMD12 is automatically issued).
  - — The WDAT bit is 1, the CMLTE bit is 0 (single block transfer), and the CMD12EN bit is 1.
  - — The WDAT bit is 1, the RBSY bit is 1 (response busy), and the CMD12EN bit is 1.
  - — The WDAT bit is 1, and the BLKSIZ[15:0] bits (transfer block size) are 00h.
  - — The WDAT bit is 1, and the BLKSIZ[15:0] bits are greater than 512.
  - — The WDAT bit is 1, the CMLTE bit is 1 (multiple block transfer), and the BLKCNT[15:0] bits (number of transfer blocks) are 00h.
  - — The BOOT bit is 1 (command sequence when performing boot operations), and the WDAT bit is 0 (no data present).
  - — The BOOT bit is 1, and the DWEN bit is 1 (write data to the MMC).
  - — The BOOT bit is 1, and the RBSY bit is 1.
  - — The BOOT bit is 1, and the CMD12EN bit is 1.
  - — The BOOTACK bit is 1 (boot acknowledge received), and the BOOT bit is 0 (command sequence when not performing boot operations).

— This flag becomes 0 under the following condition:
- The flag is set to 0.

CRSPE Flag (Command Response Complete Flag)

This flag indicates when command issuance or response reception is complete. The response complete flag for the automatically issued CMD12 is the CMD12CRE flag.

— When not performing a boot operation, this flag becomes 1 under any of the following conditions:
- A command is issued when no response is configured.
- A response is received when a 6-byte response and 17-byte response are set.

— When performing a boot operation, this flag becomes 1 under the following condition:
- A boot acknowledge is received while the CECMDSET.BOOTACK bit is set to 1 (boot acknowledge received).

— This flag becomes 0 under the following condition:
- The flag is set to 0.

RBSYE Flag (Response Busy Complete Flag)

This flag indicates that the response busy is complete. Note that when the RBSYE flag becomes 1, the CRSPE flag also becomes 1. The response busy complete flag for the automatically issued CMD12 is the CMD12RBE flag.

— This flag becomes 1 under the following condition:
- Response reception and response busy reception are complete.

— This flag becomes 0 under the following condition:
- The flag is set to 0.

BUFREN Flag (MMCIF Buffer Read Enable Flag)

This flag indicates that the MMCIF buffer has become read accessible. When using the CPU to read data from the CEDATA register, set the BUFREN flag to 0 before reading the amount of data set in the CEBLOCKSET.BLKSIZ[15:0] bits. If the CEBUFACC.DMAREN bit is 1, the BUFREN flag will not become 1.

— This flag becomes 1 under the following condition:
- The transfer block size amount of data is stored in the MMCIF buffer and the MMCIF buffer becomes read accessible.

— This flag becomes 0 under the following condition:
- The flag is set to 0.

BUFWEN Flag (MMCIF Buffer Write Enable Flag)

This flag indicates that the MMCIF buffer has become write accessible. When using the CPU to write data to the CEDATA register, set the BUFWEN flag to 0 before writing the amount of data set in the CEBLOCKSET.BLKSIZ[15:0] bits. If the CEBUFACC.DMAWEN bit is 1, the BUFWEN flag will not become 1.

— This flag becomes 1 under the following condition:
- The MMCIF buffer becomes empty and becomes write accessible.

— This flag becomes 0 under the following condition:
- The flag is set to 0.

BUFRE Flag (MMCIF Buffer Read Complete Flag)

This flag indicates that the read access of the MMCIF is complete.

— When not performing a boot operation, this flag becomes 1 under the following condition:
- All data in all blocks is received, the read access of the MMCIF buffer is finished, and the MMCIF buffer is empty.

— When performing a boot operation, this flag becomes 1 under the following condition:
- All data in all blocks is received, the read access of the MMCIF buffer is finished, the MMC_CMD pin changes from low to high, and the amount of time it takes 48 MMCIF clock cycles to elapse has passed.

— This flag becomes 0 under the following condition:
- The flag is set to 0.

DTRANE Flag (Data Transmit Complete Flag)

This flag indicates the all data in all blocks has been transmitted.

— This flag becomes 1 under any of the following conditions:

- When receiving a CRC status token, the busy status is complete after the CRC status token is received.
- When not receiving a CRC status token, data transmission is complete.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

CMD12CRE Flag (Automatically Issued CMD12 Response Complete Flag)

This flag indicates that the response for the automatically issued CMD12 was received.

— This flag becomes 1 under the following condition:

- A response is received for the automatically issued CMD12.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

CMD12RBE Flag (Automatically Issued CMD12 Response Busy Complete Flag)

This flag indicates that the response busy for the automatically issued CMD12 is complete. Note that when the CMD12RBE flag becomes 1, the CMD12CRE flag also becomes 1. When the CMD12RBE flag becomes 1 during a multiple block write, the DTRANE flag also becomes 1.

— This flag becomes 1 under the following condition:

- A response is received for the automatically issued CMD12, and the response busy is complete.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

CMD12DRE Flag (Automatically Issued CMD12 Response Busy and MMCIF Buffer Read Complete Flag)

This flag indicates that the response busy for the automatically issued CMD12 is complete, and the MMCIF buffer read access is complete. Note that when the CMD12DRE flag becomes 1, the CMD12RBE, CMD12CRE, and BUFRE flags also become 1.

— This flag becomes 1 under the following condition:

- The response busy for the automatically issued CMD12 is complete, and the read access from the MMCIF buffer is complete.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

b31 to b27	—	Reserved	These bits are 0 when read and cannot be modified.	R

When the status flags in the CEINT register become 1, the CEINTEN register controls whether or not to generate an interrupt request. When bits in this register are 1 and the corresponding status flag in the CEINT register is 1, then an interrupt request is generated. Refer to section 50.5, Interrupts for details on interrupt requests.

50.2.14 Status Register 1 (CEHOSTSTS1)

Address 0008 8548h

Bit	b31	b30	b29	b28	b27	b26	b25	b24

b23 to b16	DATSIG[7:0]	MMC_D[7:0] Pin Status Flag	Indicates the status of pins MMC_D7 to MMC_D0 0: Pin level is low 1: Pin level is high	R
b29 to b24	RSPIDX[5:0]	Response Index	Indicates the command index field value or the check bits field value of the response	R
b30	CMDSIG	MMC_CMD Pin Status Flag	Indicates the status of the MMC_CMD pin 0: Pin level is low 1: Pin level is high	R
b31	CMDSEQ	Command Sequence Status Flag	0: Command sequence is in its initial state 1: Command sequence in progress	R

The CEHOSTSTS1 register indicates the number of blocks that have been transferred, indicates the status of the MMC_CMD pin and pins MMC_D0 to MMC_D7, indicates the index of the response received, and indicates the status of the command sequence.

RCVBLK[15:0] Bits (Number of Blocks Transferred Flag)

These bits indicate the number of blocks that have been transferred.
When the CECMDSET.DWEN bit is 0, these bits indicate the number of blocks read from the MMC.
When the CECMDSET.DWEN bit is 1, these bits indicate the number of blocks written to the MMC.

DATSIG[7:0] Bits (MMC_D[7:0] Pin Status Flag)

These bits indicate the status of pins MMC_D0 to MMC_D7.

Note: If a communication error or timeout occurs, the MMC_D0 pin may remain low.

50.2.15 Status Register 2 (CEHOSTSTS2)

b31	CRCSTE	CRC Status Error Flag	0: CRC status error did not occur 1: CRC status error occurred	R

The CEHOSTSTS2 register indicates the status of various timeouts and errors.

BTDATTO Flag (Boot Operation Timeout Flag)

When performing boot operations, after read data is received, if the next data is not received even after the period set in the CEBOOT.SBTDATTO[3:0] bits elapses, this flag becomes 1.

FSTBTDATTO Flag (First Boot Data Timeout Flag)

When performing boot operations, if the first data is not received even after the period set in the CEBOOT.SFSTBTDATTO[3:0] bits elapses, this flag becomes 1.

BTACKTO Flag (Boot Acknowledge Timeout Flag)

When performing boot operations, if the boot acknowledge is not received even after the period set in the CEBOOT.SBTDATTO[3:0] bits elapses, this flag becomes 1.

STRSPTO Flag (Response Timeout Flag)

After issuing a command other than the automatically issued CMD12, if the response is not received even after the period set in the CECLKCTRL.SRSPTO[1:0] bits elapses, this flag becomes 1.

AC12RSPTO Flag (Automatically Issued CMD12 Response Timeout Flag)

After CMD12 is automatically issued, if the response is not received even after the period set in the CECLKCTRL.SRSPTO[1:0] bits elapses, this flag becomes 1.

RSPBSYTO Flag (Response Busy Timeout Flag)

After issuing a command other than the automatically issued CMD12, if the busy status continues even after the period set in the CECLKCTRL.SRBSYTO[3:0] bits elapses, this flag becomes 1.

AC12BSYTO Flag (Automatically Issued CMD12 Response Busy Timeout Flag)

After CMD12 is automatically issued, if the busy status continues even after the period set in the CECLKCTRL.SRBSYTO[3:0] bits elapses, this flag becomes 1.

CRCSTTO Flag (CRC Status Timeout Flag)

This flag becomes 1 if the CRC status token is not received.

DATBSYTO Flag (Data Busy Timeout Flag)

After the CRC status token is received, if the busy status continues even after the period set in the CECLKCTRL.SRWDTO[3:0] bits elapses, this flag becomes 1.

STRDATTO Flag (Read Data Timeout Flag)
After a read command is issued, if data is not received even after the period set in the CECLKCTRL.SRWDTO[3:0] bits elapses, this flag becomes 1. After data is received, if the next data is not received even after the period set in the CECLKCTRL.SRWDTO[3:0] bits elapses, this flag becomes 1.

CRCST[2:0] Flags (CRC Status Indicator Flag)
When the CECMDSET.BOOT bit is 0, these bits indicate the status of the received CRC status token.
When the CECMDSET.BOOT bit is 1, these bits indicate the bit pattern of the boot acknowledge.

BTACKEBE Flag (Boot Acknowledge End Bit Error Flag)
This flag becomes 1 if the end bit of the boot acknowledge is in error.

BTACKPATE Flag (Boot Acknowledge Pattern Error Flag)
This flag becomes 1 if the bit pattern of the boot acknowledge is in error.

RSPIDXE Flag (Command Response Index Error Flag (Other Than Automatically Issued CMD12))
If the command index field value of the response, or the check bits field value is in error, this flag becomes 1. The content of the error is defined in the CECMDSET.RIDXC[1:0] bits.

AC12IDXE Flag (Automatically Issued CMD12 Response Index Error Flag)
If the command index field value of the response for the automatically issued CMD12 is in error, this flag becomes 1. The content of the error is defined in the CECMDSET.RIDXC[1:0] bits.

RSPEBE Flag (Command Response End Bit Error Flag (Other Than Automatically Issued CMD12))
If the end bit of the response for a command other than the automatically issued CMD12 is in error, this flag becomes 1.

AC12REBE Flag (Automatically Issued CMD12 Response End Bit Error Flag)
This flag becomes 1 if the end bit of the response for the automatically issued CMD12 is in error.

RDATEBE Flag (Read Data End Bit Error Flag)
This flag becomes 1 if the end bit for the read data is in error.

CRCSTEBE Flag (CRC Status End Bit Error Flag)
This flag becomes 1 if the end bit of the CRC status token is in error.

RSPCRC7E Flag (Command Response CMD7 Error Flag (Other Than Automatically Issued CMD12))
If bits [7:1] of a response for a command other than the automatically issued CMD12 are in error, this flag becomes 1. The content of the error is stored in the CECMDSET.RCRC7C[1:0] bits.

AC12CRCE Flag (Automatically Issued CMD12 Response CMD7 Error Flag)
If bits [7:1] of the response for the automatically issued CMD12 are in error, this bit becomes 1. The content of the error is stored in the CECMDSET.RCRC7C[1:0] bits.

CRC16E Flag (Read Data CMD16 Error Flag)
This flag becomes 1 when CRC16 of the read data is in error.

CRCSTE Flag (CRC Status Error Flag)
This flag becomes 1 when the CRC status value is in error.

50.2.16 MMC Detection and Port Control Register (CEDETECT)

Address 0008 8570h

b11	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b12	CDFALL	MMC_CD Pin Falling Edge Detection Flag	0: Falling edge on the MMC_CD pin not detected 1: Falling edge on the MMC_CD pin detected	R/W *1
b13	CDRISE	MMC_CD Pin Rising Edge Detection Flag	0: Rising edge on the MMC_CD pin not detected 1: Rising edge on the MMC_CD pin detected	R/W *1
b14	CDSIG	MMC_CD Pin Status Indication Flag	This flag indicates the status of the MMC_CD pin. 0: Pin level is low 1: Pin level is high	R
b31 to b15	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. This flag cannot be set to 1 by the user. This flag becomes 0 when set to 0 by the user.

The CEDETECT register controls detection of the MMC. Refer to section 50.5, Interrupts for details on the MMC detection interrupt request.

CDFALL Flag (MMC_CD Pin Falling Edge Detection Flag)

— This flag becomes 1 under the following condition:
- The MMC_CD pin changes from high to low.

— This flag becomes 0 under the following condition:
- The flag is set to 0.

CDRISE Flag (MMC_CD Pin Rising Edge Detection Flag)

— This flag becomes 1 under the following condition:
- The MMC_CD pin changes from low to high.

— This flag becomes 0 under the following condition:
- The flag is set to 0.

50.2.17 Special Mode Setting Register (CEADDMODE)

Address 0008 8574h

Bit	b31	b30	b29	b28	b27	b26	b25	b24
Symbol	—	—	—	—	—	—	—	—

Value after reset	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b18 to b0	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b19	CLKMAIN	MMCIF Internal Clock Control	0: Normal mode 1: Low power consumption mode (possible only when MMC is detected)	R/W
b20	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b21	RESNOUT	Reset Output *1	0: MMC_RES# pin is high 0: MMC_RES# pin is low	R/W
b31 to b22	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. The same functions can be performed using a general-use I/O port.

The CEADDMODE register controls the MMCIF internal clock.

50.2.18 Version Register (CEVERSION)

Address 0008 857Ch

Bit	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	VERSION[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	VERSION[15:0]	Version Indicator	These bits indicate the version of the MMCIF.	R
b30 to b16	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b31	SWRST	MMCIF Software Reset	0: MMCIF exits the MMCIF software reset and enters normal operation 1: MMCIF is in the MMCIF software reset state	R/W

The CEVERSION register indicates the MMCIF version and controls the MMCIF software reset.

SWRST Bit (MMCIF Software Reset)

When the SWRST bit is set to 1, the MMCIF is reset, and all register values in the MMCIF become their value after reset (except for the SWRST bit).

50.3 MMCIF Operation

50.3.1 Command and Response Formats

Figure 50.2 shows the Command Format. The command index field value set in the CECMDSET.CMD[5:0] bits is reflected in bits [45:40] of the command, and the argument field value set in the CEARG register is reflected in bits [39:8] of the command.

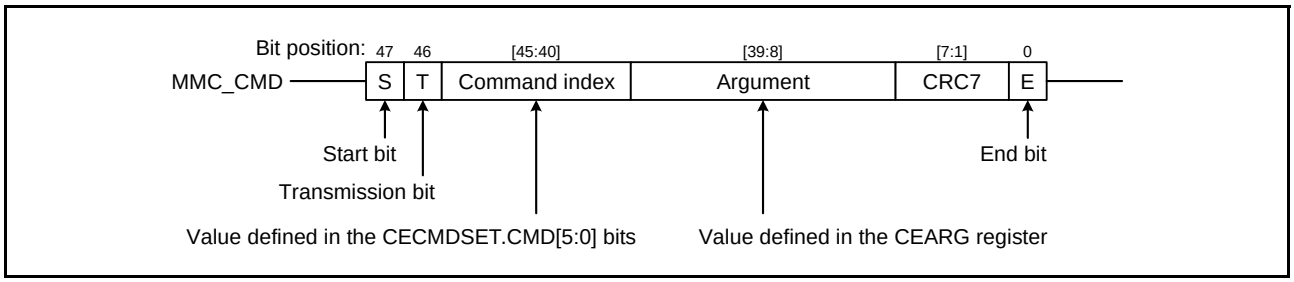

Figure 50.2 Command Format

Figure 50.3 shows the format of a 6-byte response (response other than the R2 response), and Figure 50.4 shows the format of a 17-byte response (R2 response). The command index field value or check bits field value of the response is stored in the CEHOSTSTS1.RSPIDX[5:0] flags. For a 6-byte response, bits [39:8] of the response are stored in the CERESP0 register, and for a 17-byte response, bits [127:0] of the response are stored in registers CERESP3 to CERESP0.

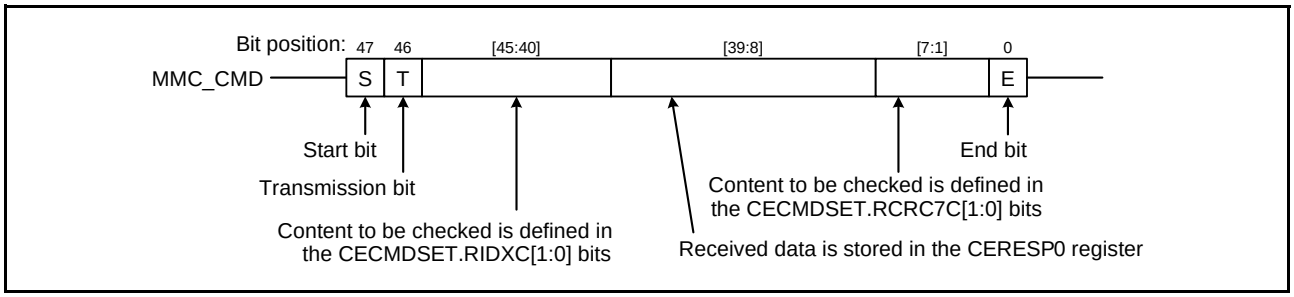

Figure 50.3 6-Byte Response Format (Response Other Than the R2 Response)

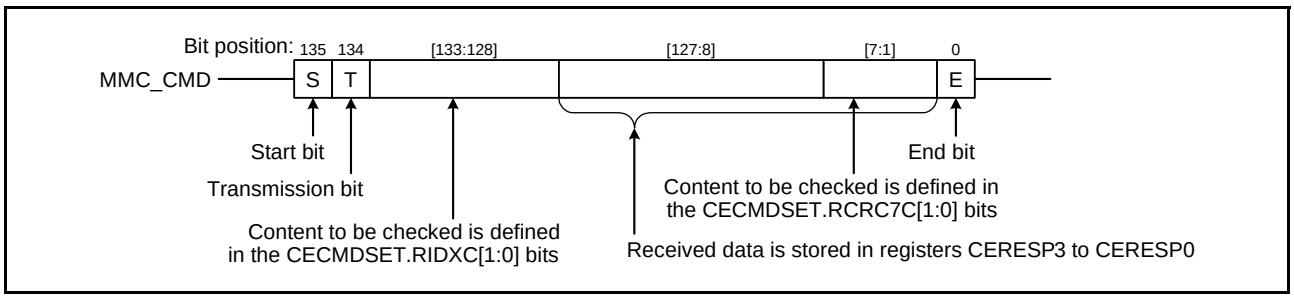

Figure 50.4 17-Byte Response Format (R2 Response)

50.3.2 Data Block Format

Figure 50.5 shows the data block format. Refer to section 50.3.3, MMCIF Buffer Structure and Access Method for details on data 0 to data 3 shown in the figure. When writing data to an MMC, data stored in the MMCIF buffer is transmitted. When reading data from an MMC, data received from the MMC is stored in the MMCIF buffer.

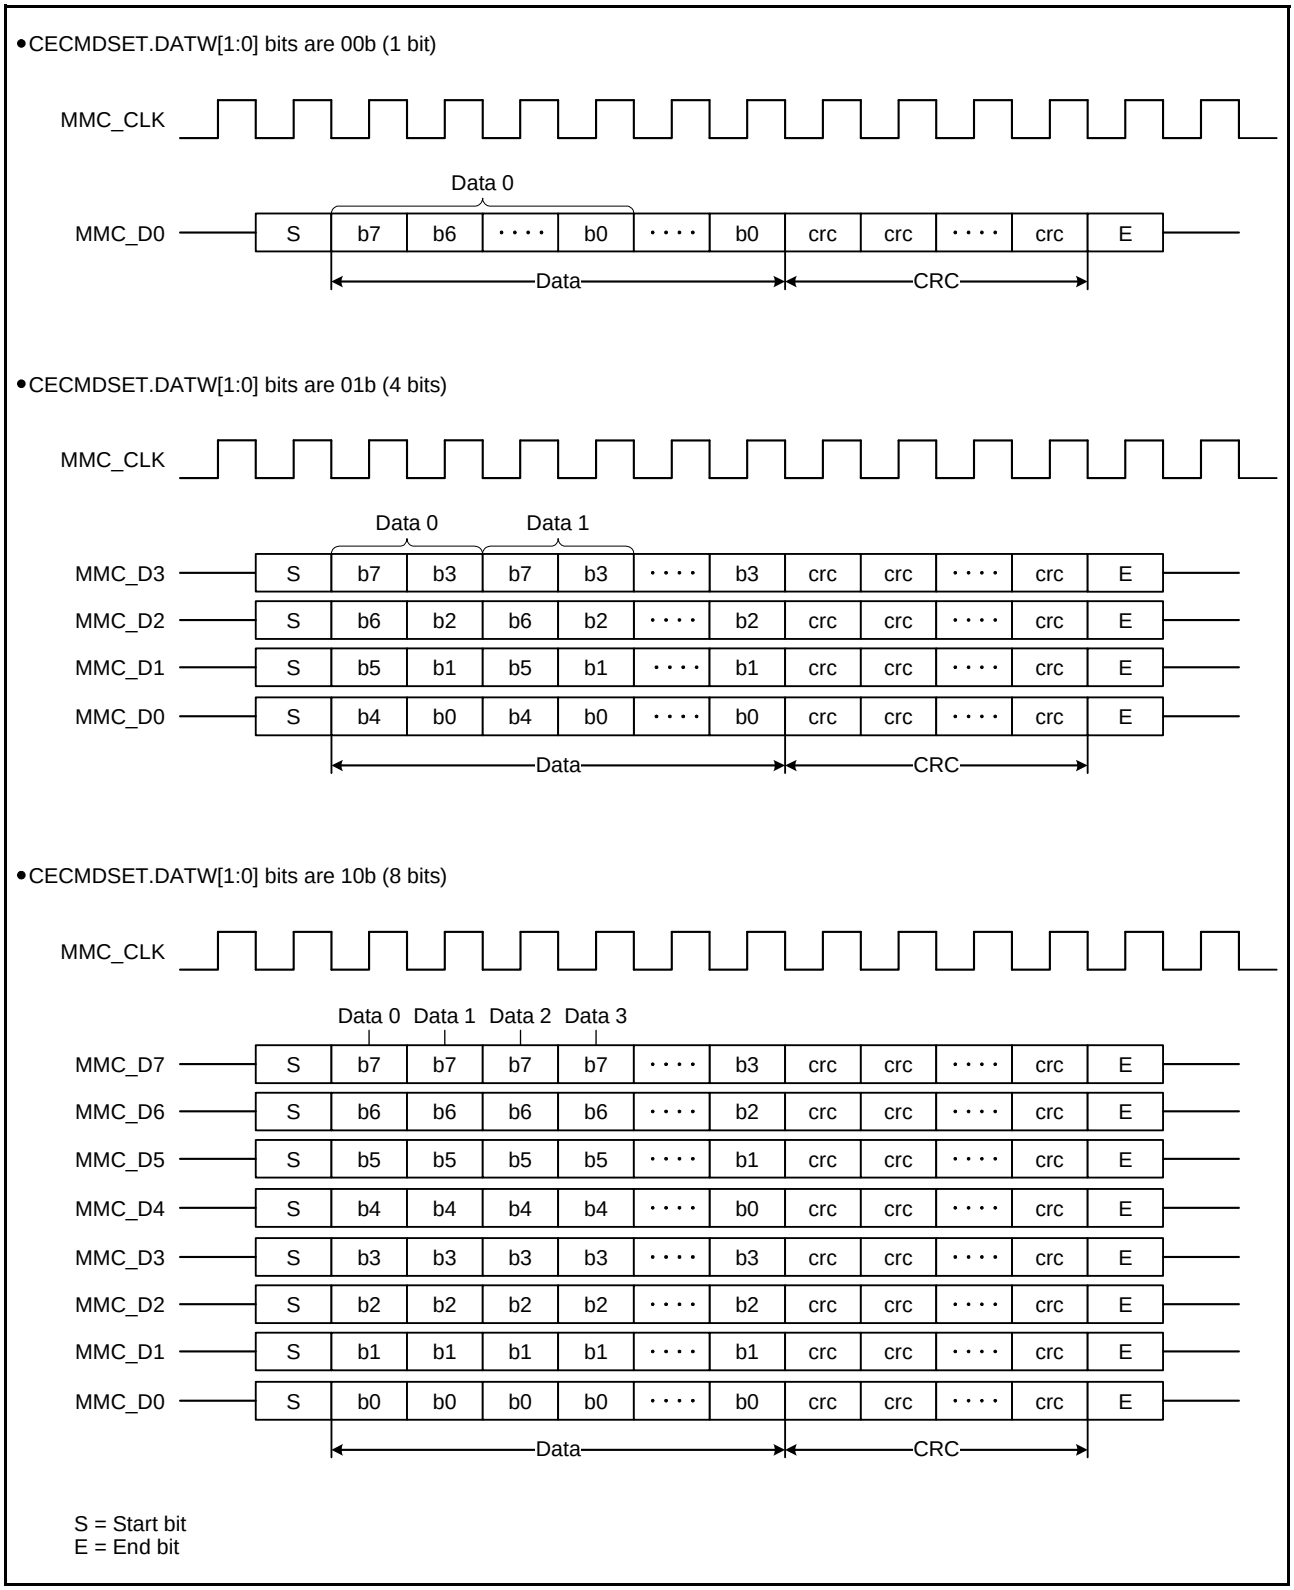

Figure 50.5 Data Block Format

50.3.3 MMCIF Buffer Structure and Access Method

Figure 50.6 shows the structure of the MMCIF buffer. The MMCIF buffer is a double buffer structure, and each buffer is 512 bytes. During a multi-block write operation, after transmitting one block of data (512 bytes) from the data stored in the MMCIF buffer, if the other buffer is full, the next block of data can be transmitted. During a multi-block read operation, even if one block of receive data (512 bytes) is stored in the MMCIF buffer, if the other MMCIF buffer is empty, the next block of receive data can be stored in the MMCIF buffer. If neither buffer is empty when performing a multi-block read operation, the MMCIF stops the MMCIF clock and pauses data reception. Then, when one of the buffers becomes empty, the MMCIF starts supplying the MMCIF clock and data reception resumes.
The CEDATA register is used to access the MMCIF buffer. If the transfer block size is set to 4*n* + 1 bytes, 4*n* + 2 bytes, or 4*n* + 3 bytes, access the CEDATA register for 4(*n* + 1) bytes (*n* = 0 to 127).

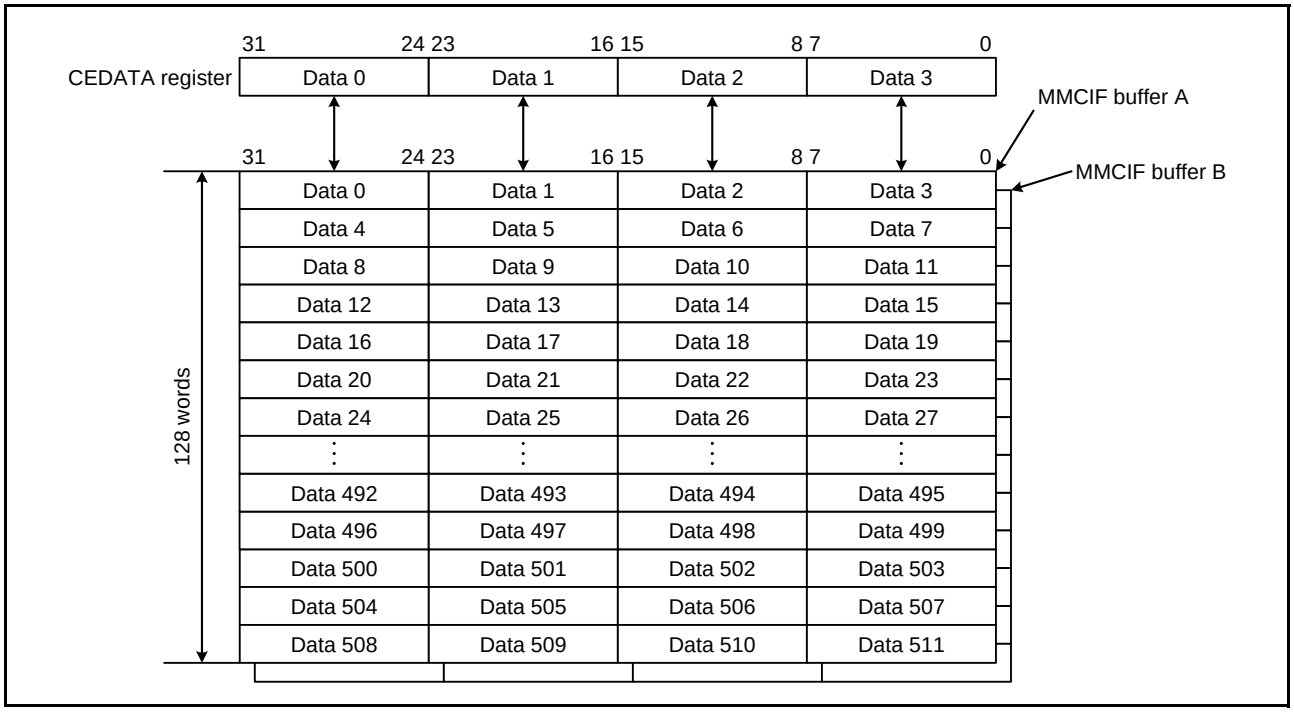

Figure 50.6 MMCIF Buffer Structure (32-Bit Access)

If the CEBUFACC.ATYP bit is set to 1, when data is written from the CEDATA register to the MMCIF buffer, or when data read from the MMCIF buffer and written to the CEDATA register, the data endian can be swapped in 1-byte units. An overview of data being swapped in 1-byte units is shown in Figure 50.7.

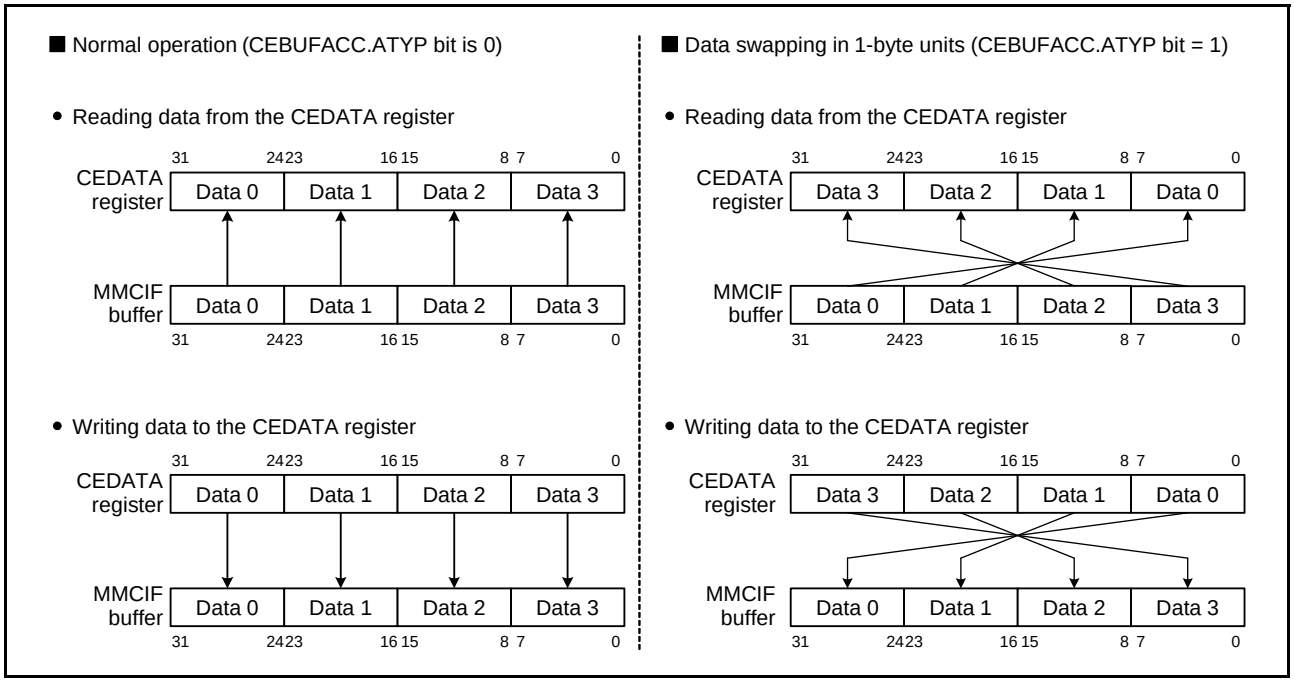

Figure 50.7 Overview of Data Swapping in 1-Byte Units (32-Bit Access)

50.3.4 Automatically Issuing CMD12

When the CECMDSET.CMD12EN bit is set to 1 and a multiple block transfer is performed, the MMCIF automatically issues CMD12. Figure 50.8 shows the Timing for Automatically Issuing CMD12 During a Multi-Block Read Operation (1-Bit Data Bus Width). CMD12 is issued such that the end bit of the command is sent 2 bits before the end bit of the data during reception of the last block.

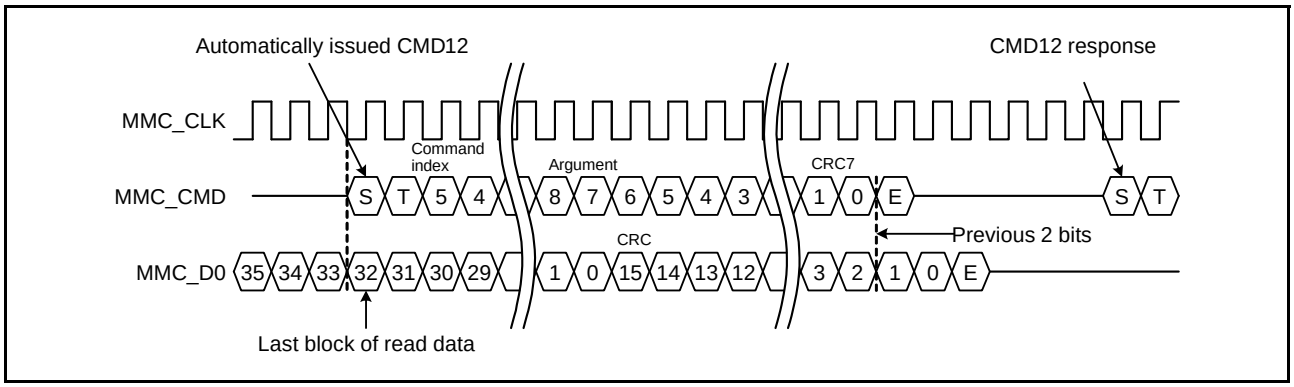

Figure 50.8 Timing for Automatically Issuing CMD12 During a Multi-Block Read Operation (1-Bit Data Bus Width)

Figure 50.9 shows the Timing for Automatically Issuing CMD12 During a Multi-Block Write Operation (1-Bit Data Bus Width). CMD12 is issued after the last block is transferred and the busy state is completed.

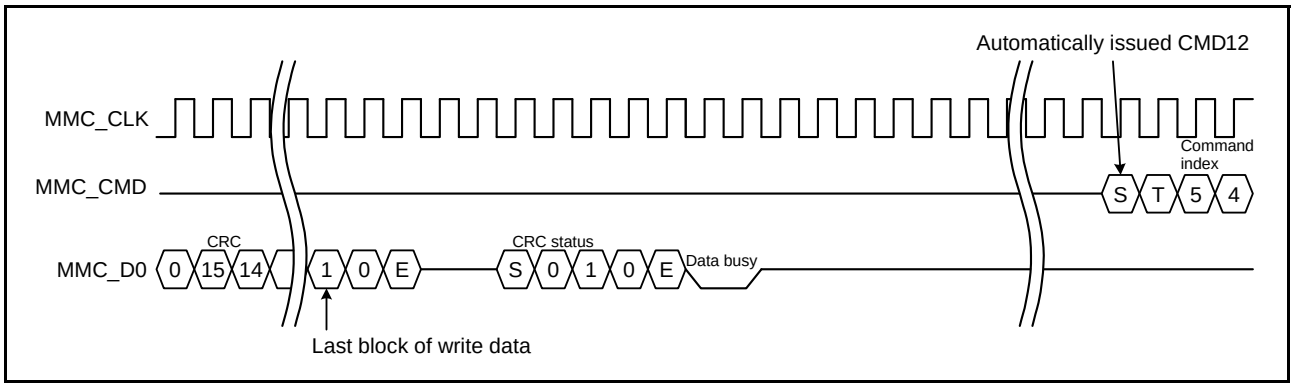

Figure 50.9 Timing for Automatically Issuing CMD12 During a Multi-Block Write Operation (1-Bit Data Bus Width)

The argument field value of the automatically issued CMD12 is set in the CEARGCMD12 register. The value for bits [39:8] of the CMD12 response are stored in the CERESPCMD12 register. Then, the response is received and the MMCIF enters the busy state.

50.3.5 MMCIF Clock Frequency During Boot Operations

Figure 50.9 shows Switching the MMCIF Clock Frequency During Boot Operations. During boot operations, when the MMC_CMD pin changes from high to low, 74 cycles of the MMCIF clock are output before the MMCIF clock frequency set in the CEBOOT.SBTCLKDIV[3:0] bits changes. After the MMC_CMD pin changes from low to high, 48 cycles of the MMCIF clock are output before the MMCIF returns to the MMCIF clock frequency set in the CECLKCTRL.CLKDIV[3:0] bits.

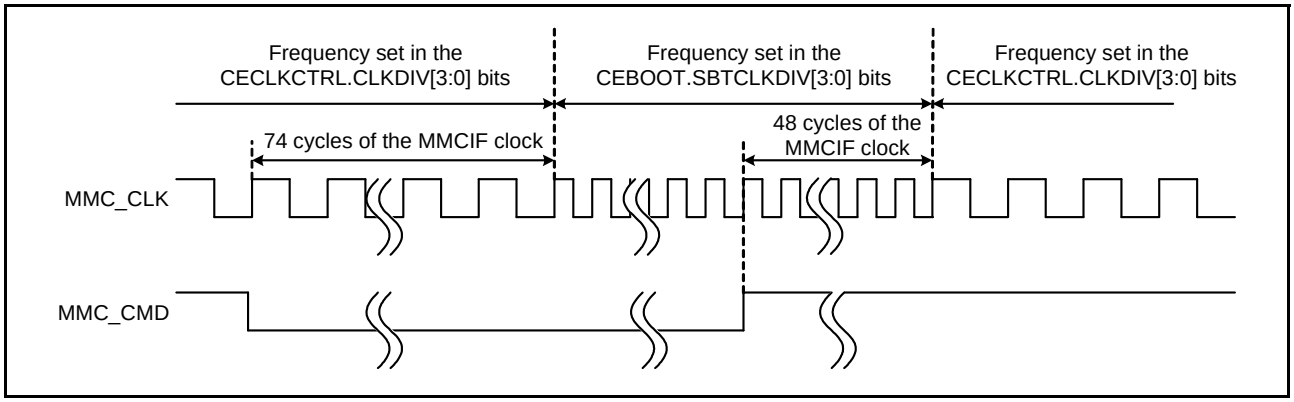

Figure 50.10 Switching the MMCIF Clock Frequency During Boot Operations

50.3.6 High Priority Interrupt (HPI)

The MMCIF supports the HPI in the sequence of CMD6, CMD24, CMD25 (pre-defined), and CMD38.
The following procedures are for HPI processing.

(1) Executing an HPI while writing to the MMC

1. Forcibly stop the command sequence.
2. Wait until the CEHOSTSTS1.CMDSEQ flag becomes 0.
3. Issue CMD12 (R1) and transition the state of the MMC from rcv to prg. If the state of the MMC is already in prg at this time, the MMC will not output a response.
4. Issue CMD13 (R1).
5. Issue the HPI command (i.e. CMD12 (R1b) or CMD13 (R1b), depending on which e.MMC is connected).

(2) Executing an HPI when not writing to the MMC an while the response is busy

1. Forcibly stop the command sequence.
2. Wait until the CEHOSTSTS1.CMDSEQ bit becomes 0.
3. Issue CMD13 (R1).
4. Issue the HPI command (i.e. CMD12 (R1b) or CMD13 (R1b), depending on which e.MMC is connected).

50.3.7 Background Operations (BGOs)

To execute BGOs, issue CMD6 (R1) and write to the BKOPS_START field in the EXT_CSD register of the MMC. To stop BGOs, issue CMD6 (R1) followed by CMD13 (R1), and either confirm that the device state is in tran, or confirm that the MMC_D0 pin is high. The HPI is used to interrupt BGOs. Refer to section 50.3.6, High Priority Interrupt (HPI) for details.

50.3.8 MMCIF Processing When an Error or Timeout Occurs

When an error occurs, the MMCIF may not stop. If an error occurs during a command sequence (the CEHOSTSTS1.CMDSEQ flag is 1), after forcibly stopping the command sequence, perform a MMCIF software reset. When an error occurs, note that transmit data and receive data stored in the MMCIF buffer is not guaranteed.
When a timeout occurs, the MMCIF will not stop. After a timeout occurs, before issuing the next command, forcibly stop the command sequence, perform an MMCIF software reset, and then issue the next command.

50.4 Examples of Issuing Commands

50.4.1 Issuing a Command Where a Response is Not Received and Data is Not Transferred

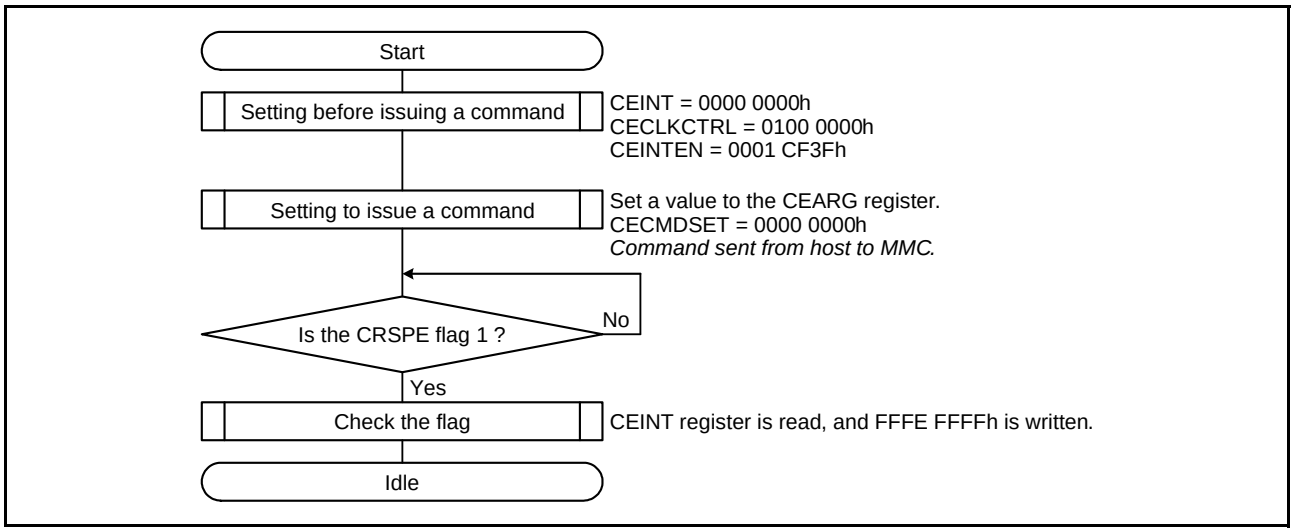

Figure 50.11 Issuing a Command Where a Response is Not Received and Data is Not Transferred (CMD0)

50.4.2 Issuing a Command Where Data is Not Transferred

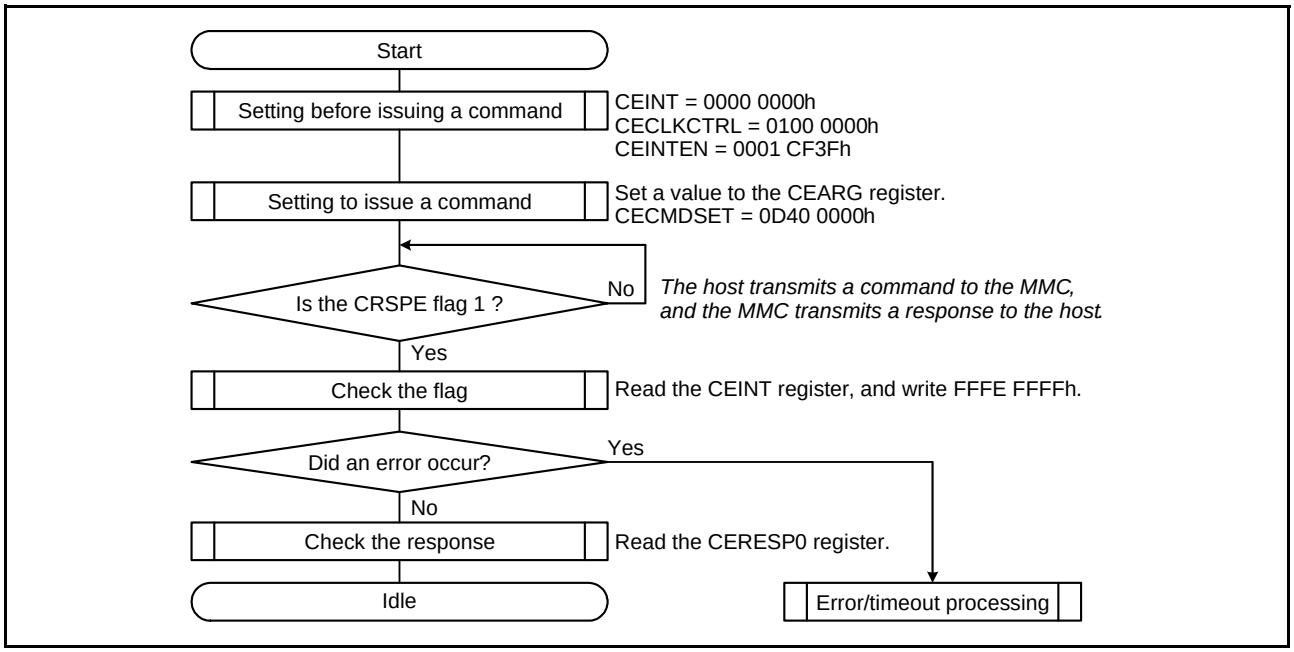

Figure 50.12 Issuing a Command Where Data is Not Transferred (CMD13)

50.4.3 Issuing a Command Where Data is Not Transferred and the Busy Signal is Used

(1) Example where the busy time is less than the period set in bits CECLKCTRL.SRBSYTO[3:0]

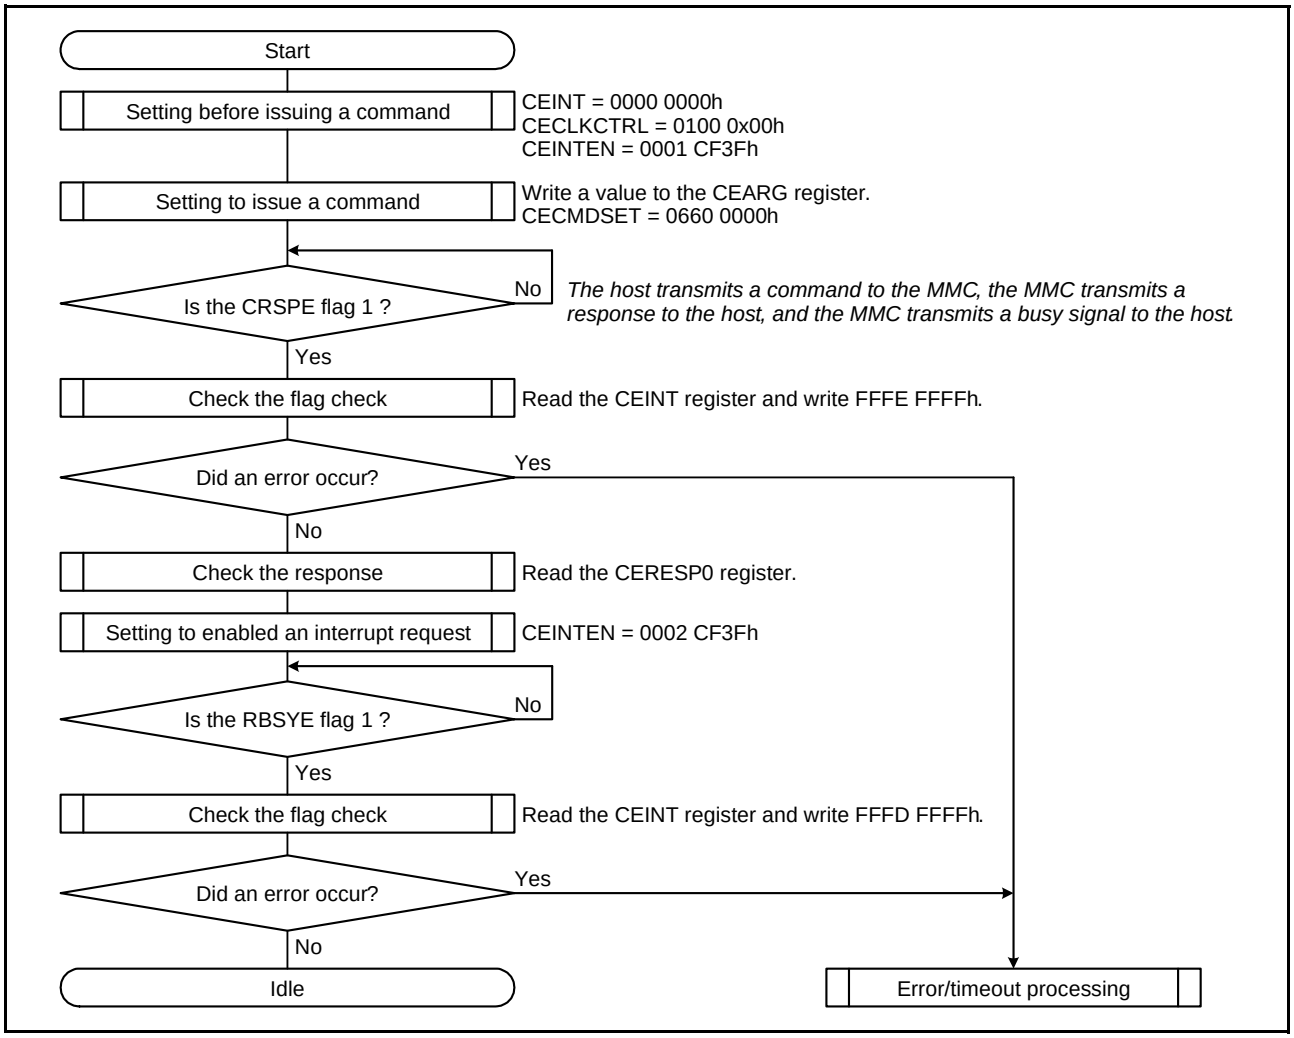

Figure 50.13 Issuing a Command Where Data is Not Transferred and the Busy Signal is Used (CMD6)

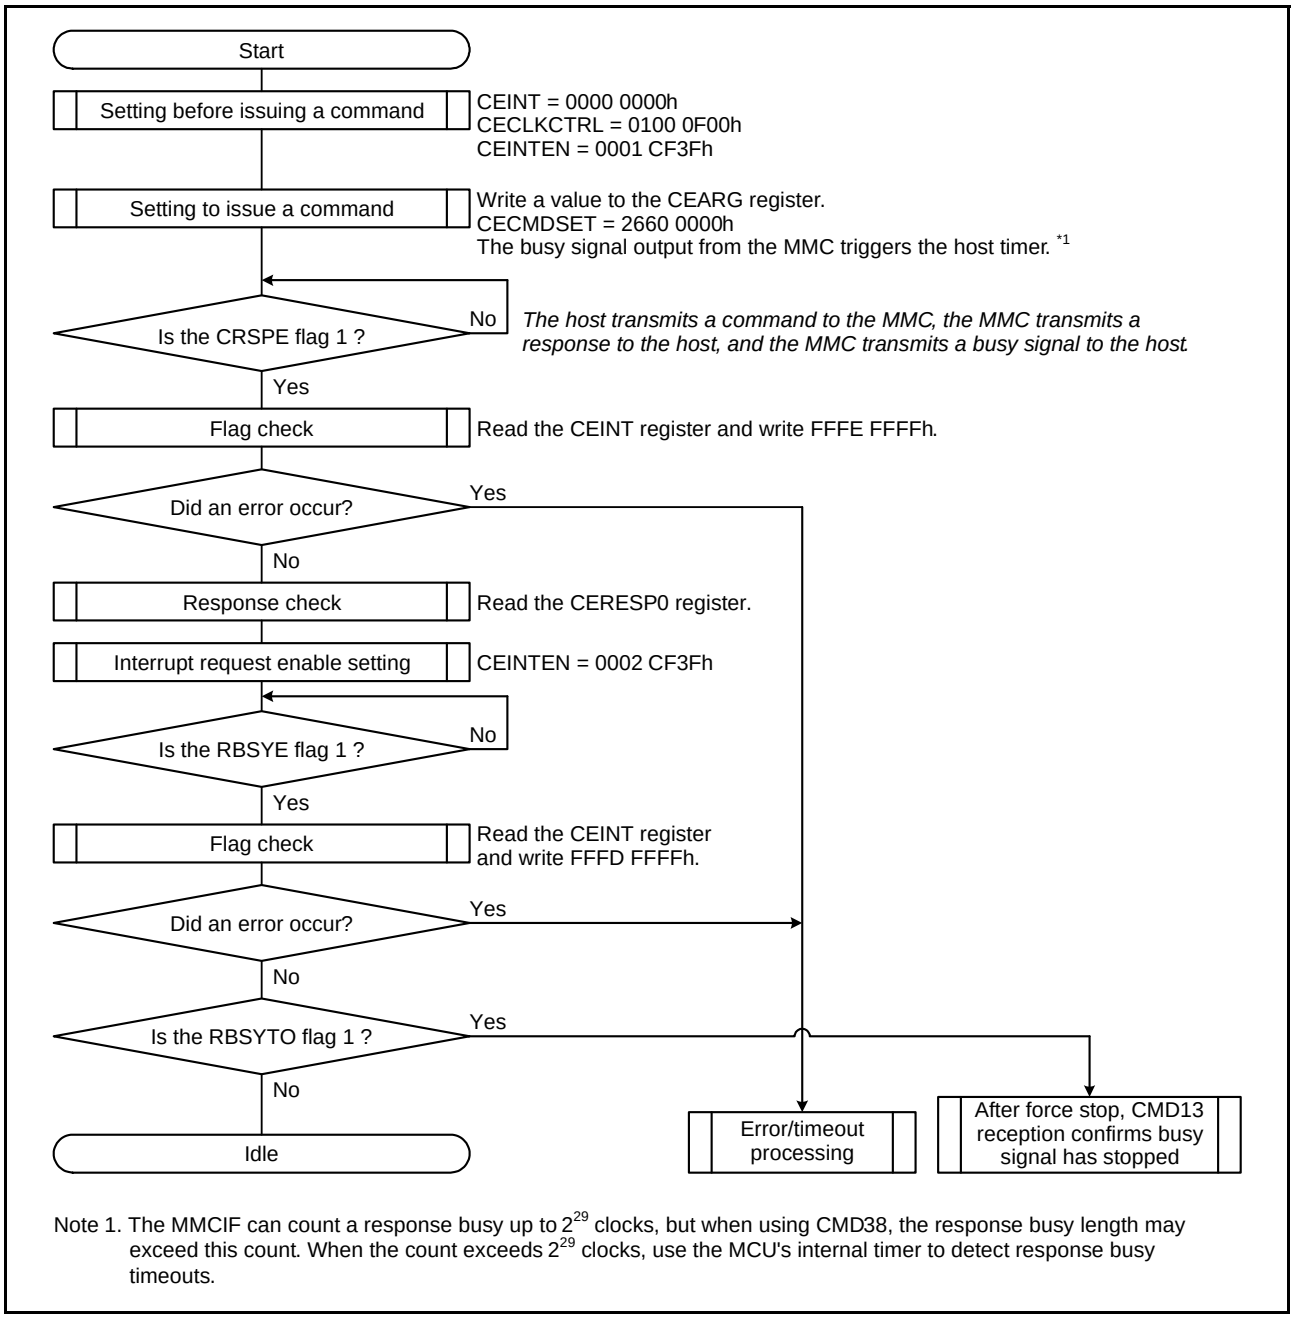
(2) Example where the busy time is equal to or more than the period set in bits CECLKCTRL.SRBSYTO[3:0]



Note 1. The MMCIF can count a response busy up to 2^{29} clocks, but when using CMD38, the response busy length may exceed this count. When the count exceeds 2^{29} clocks, use the MCU's internal timer to detect response busy timeouts.

Figure 50.14 Issuing a Command Where Data is Not Transferred and Busy Signal is Used (CMD38)

50.4.4 Issuing a Single Block Read Command (CMD17)

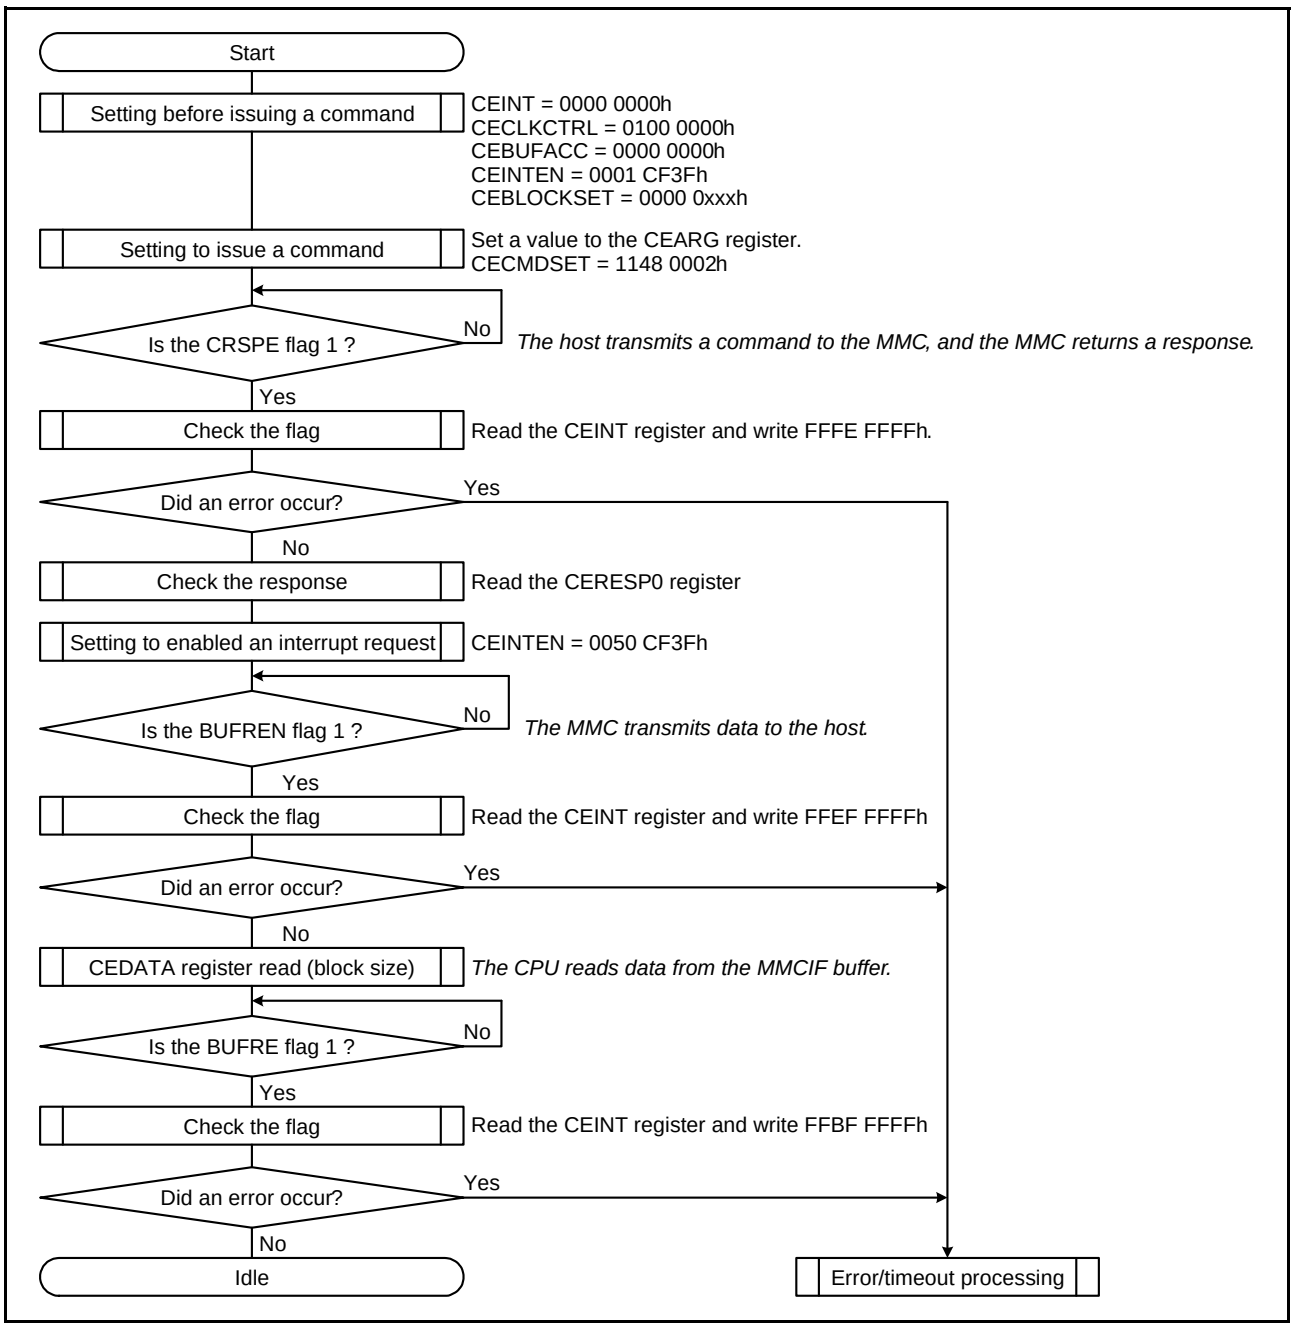


Figure 50.15 Issuing a Single Block Read Command (CMD17)

50.4.5 Issuing a Multi-Block Read Command (CMD18)

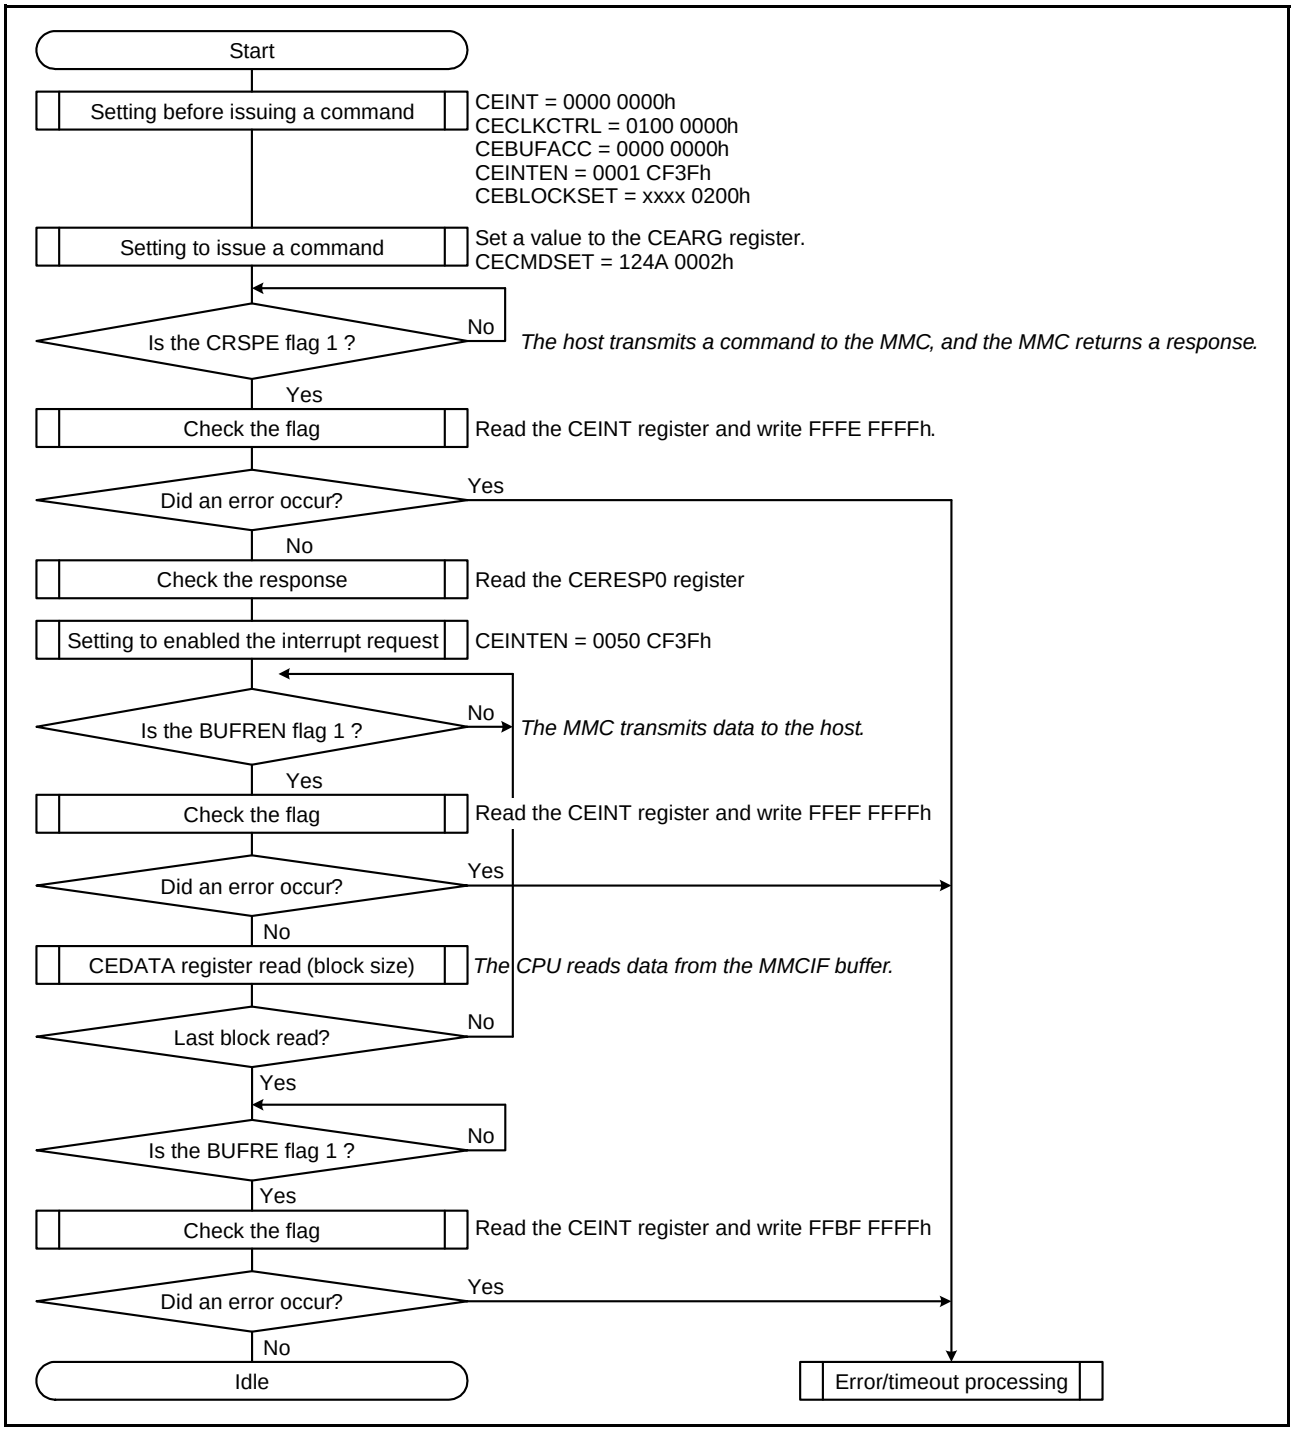

Figure 50.16 Issuing a Multi-Block Read Command (CMD18 Pre-Defined)

50.4.6 Issuing a Multi-Block Read Command (CMD18 With Automatically Issued CMD12)

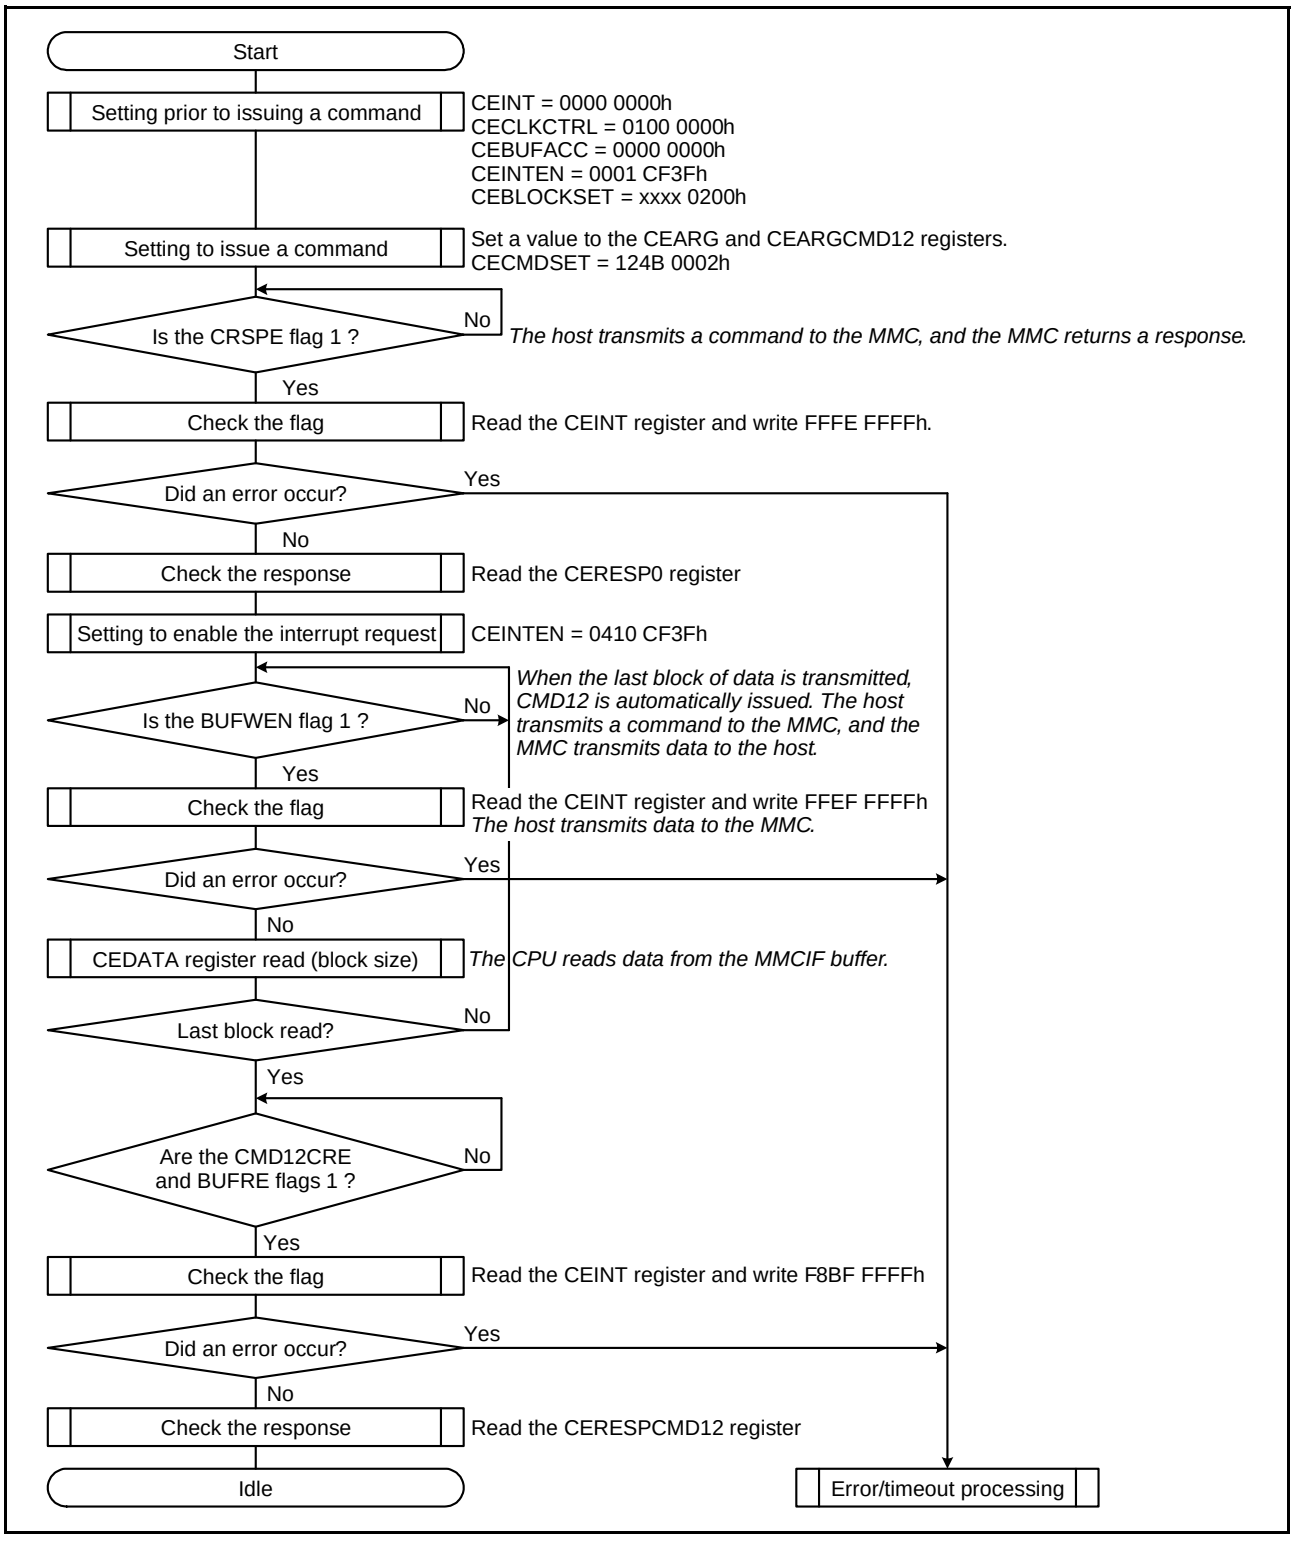

Figure 50.17 Issuing a Multi-Block Read Command (CMD18 Open-Ended)

50.4.7 Issuing a Single Block Write Command (CMD24)

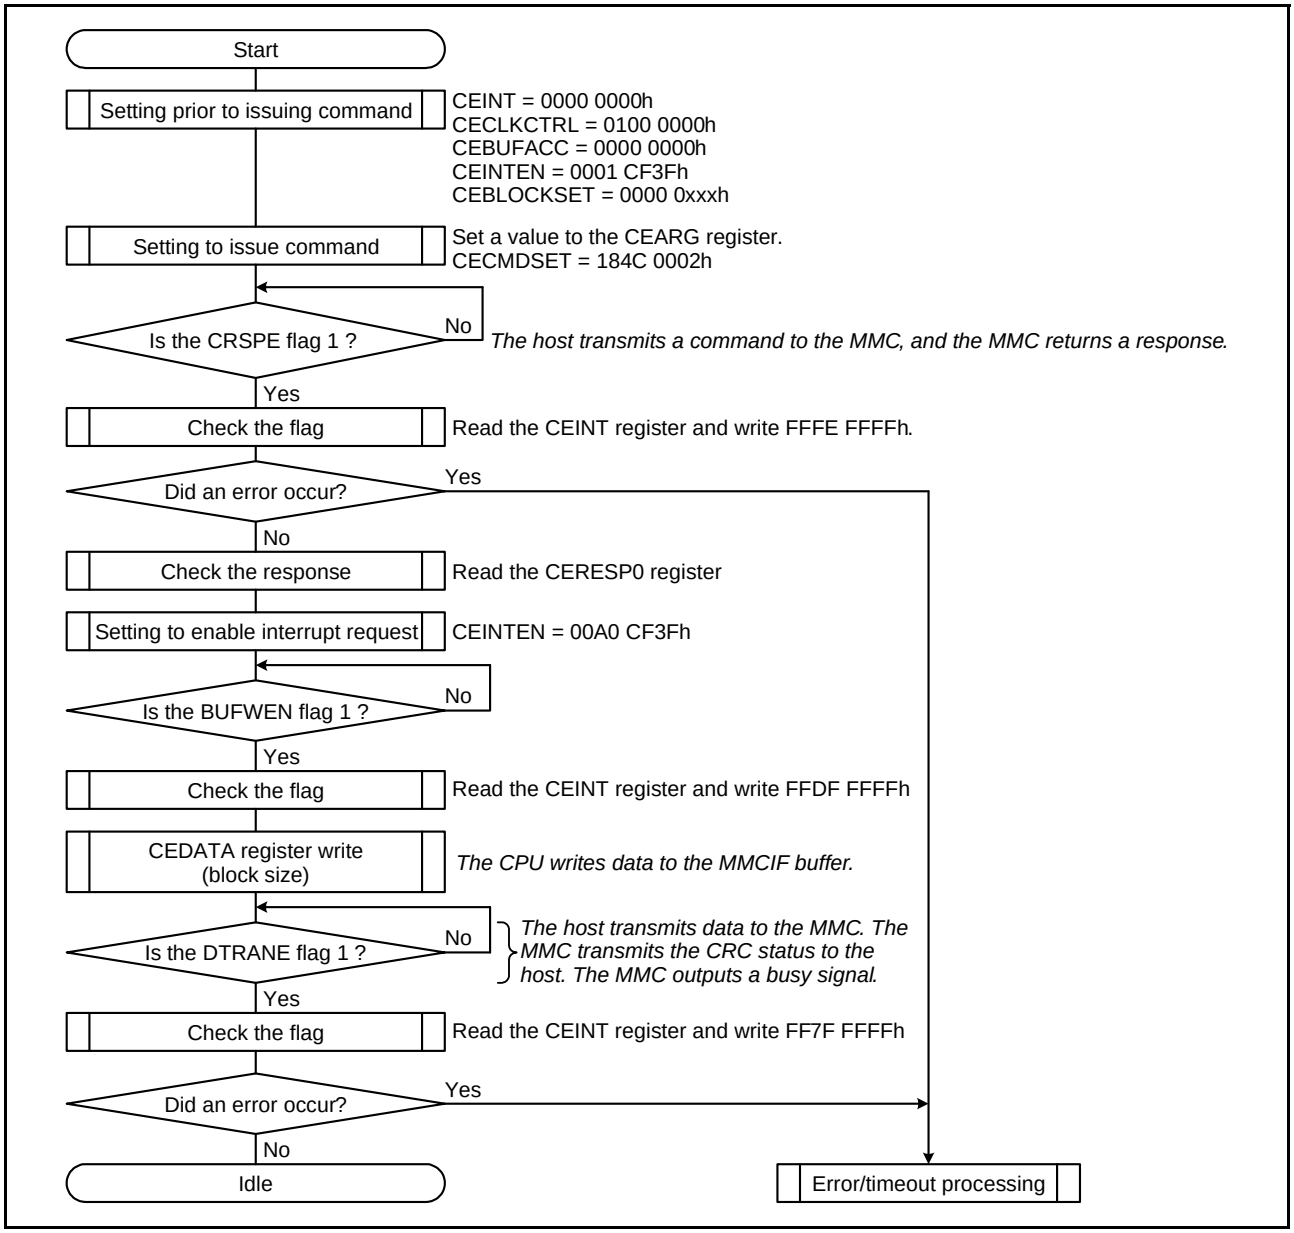

Figure 50.18 Issuing a Single Block Write Command (CMD24)

50.4.8 Issuing a Multi-Block Write Command (CMD25)

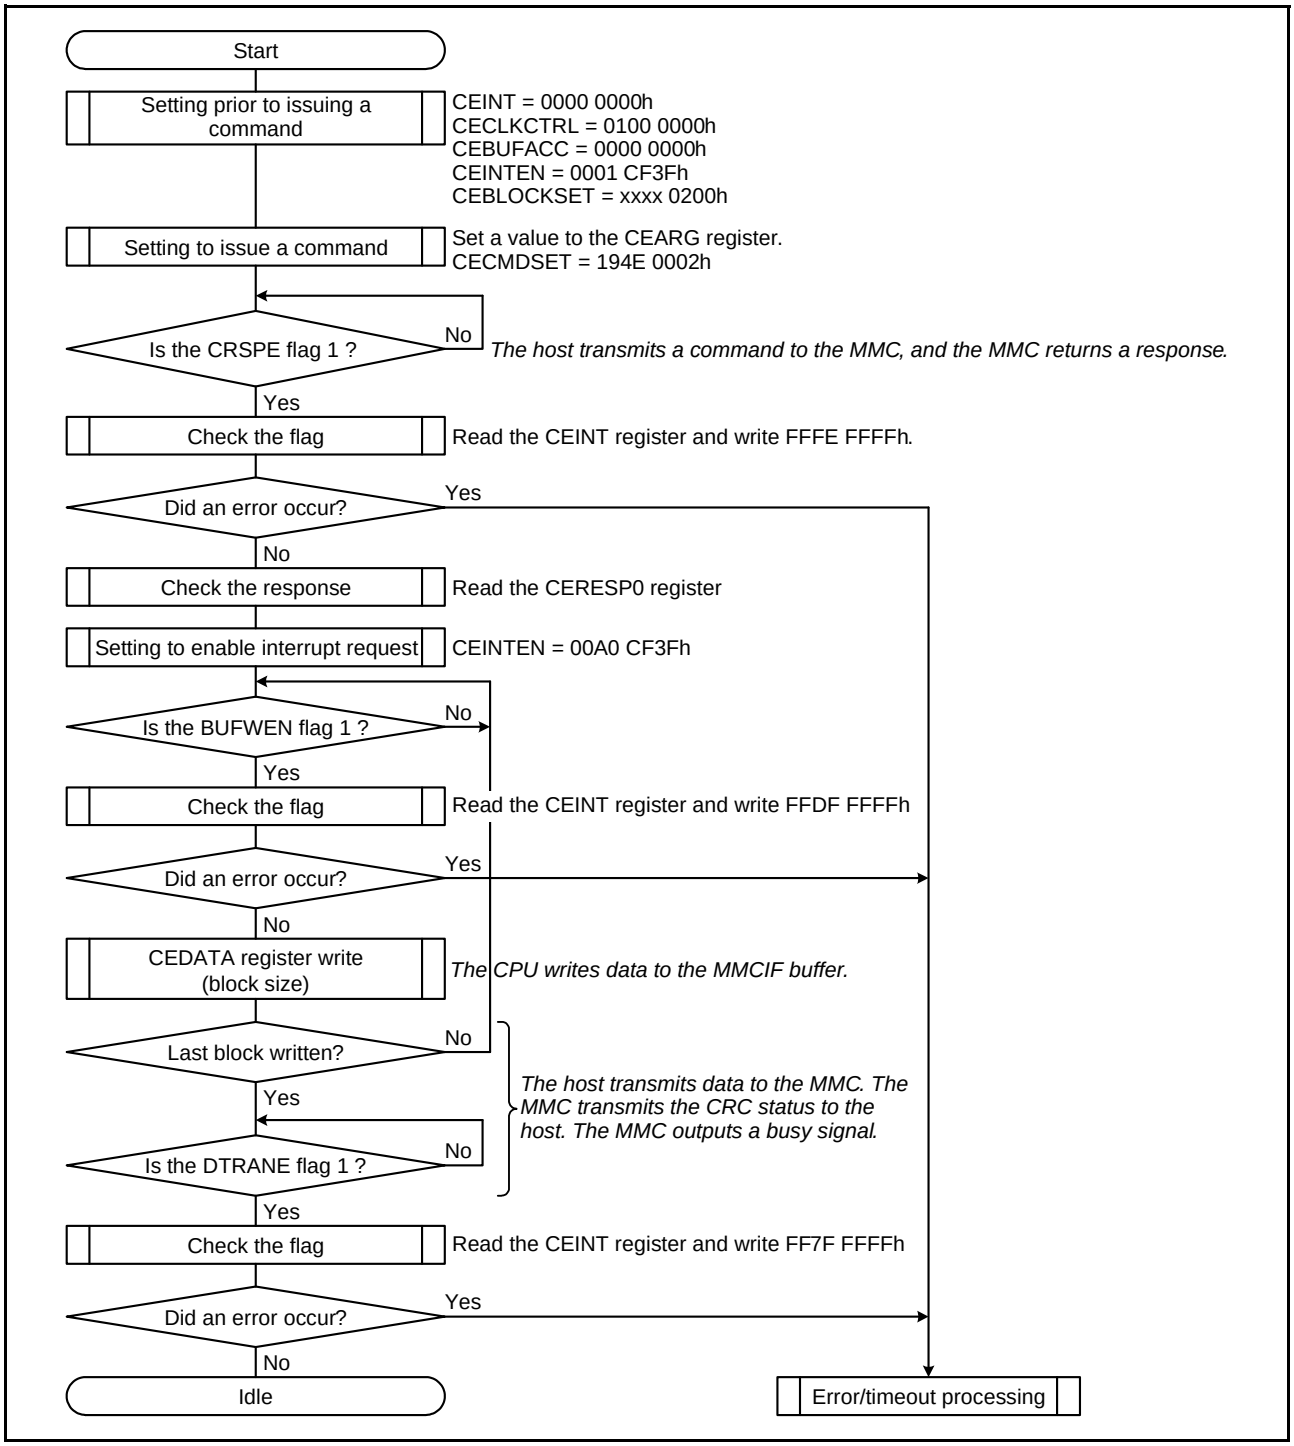

Figure 50.19 Issuing a Multi-Block Write Command (CMD25 Pre-Defined)

50.4.9 Issuing a Multi-Block Write Command (CMD25 With Automatically Issued CMD12)

50.4.10 Boot Operations

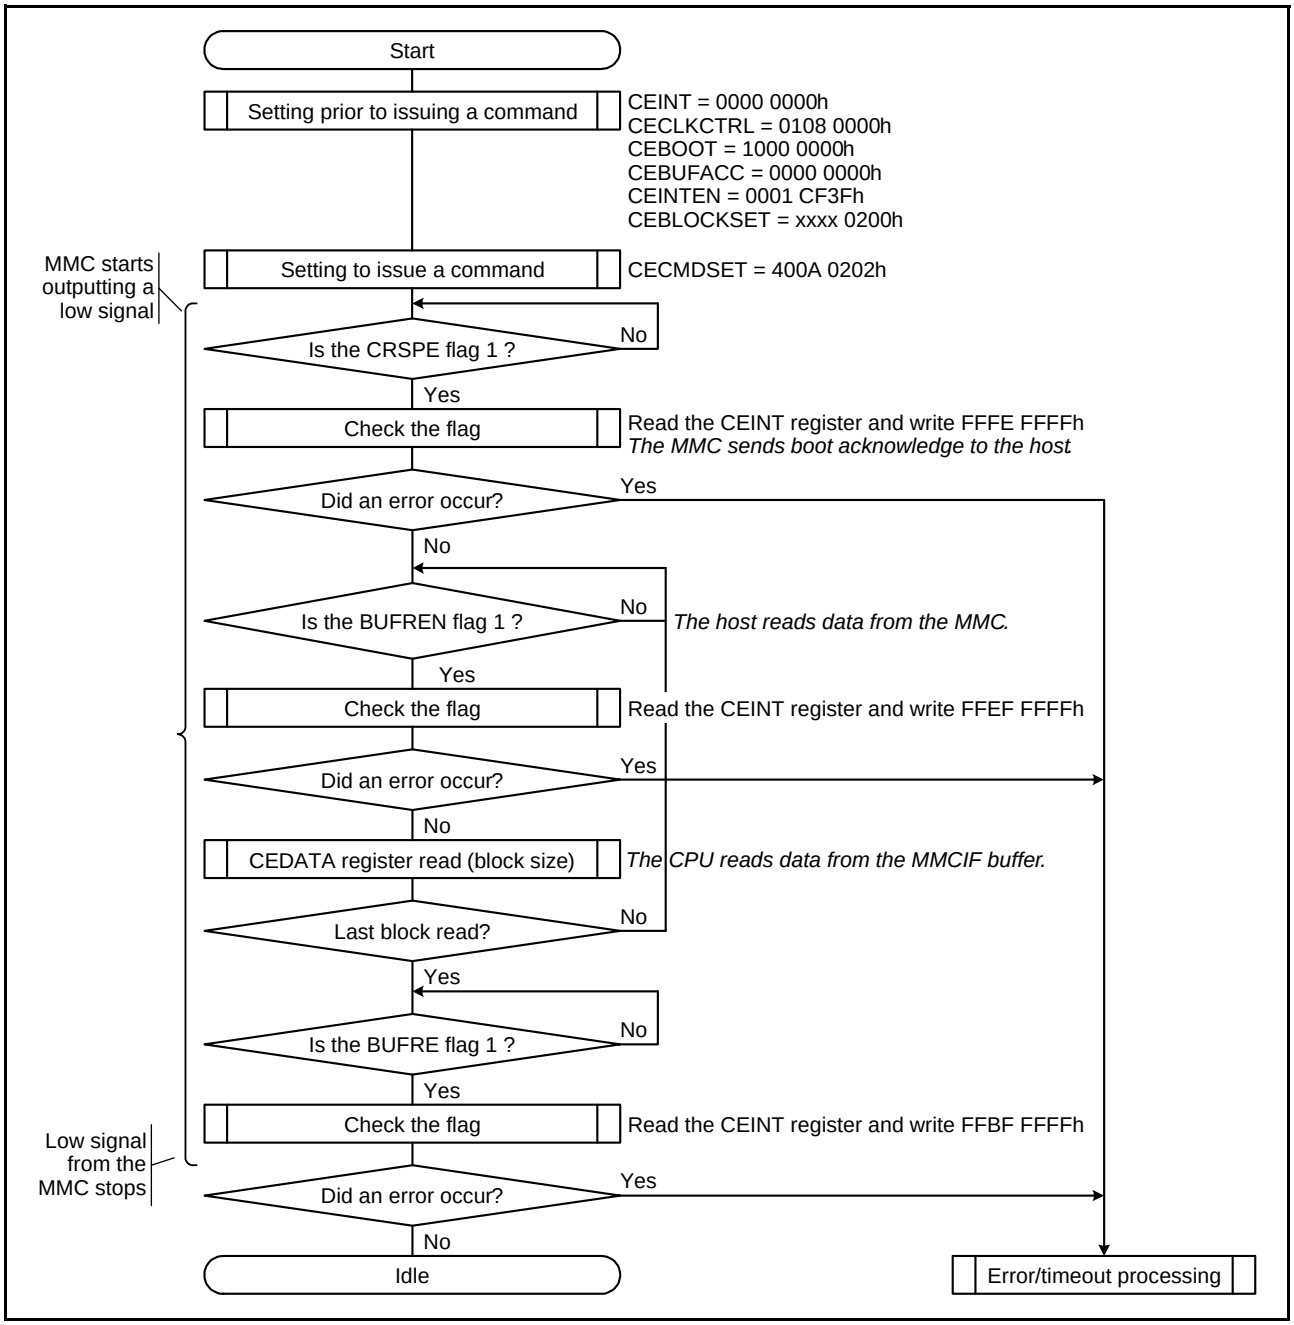

Figure 50.21 Boot Operation With Boot Acknowledge

50.4.11 Command Sequence Force Stop

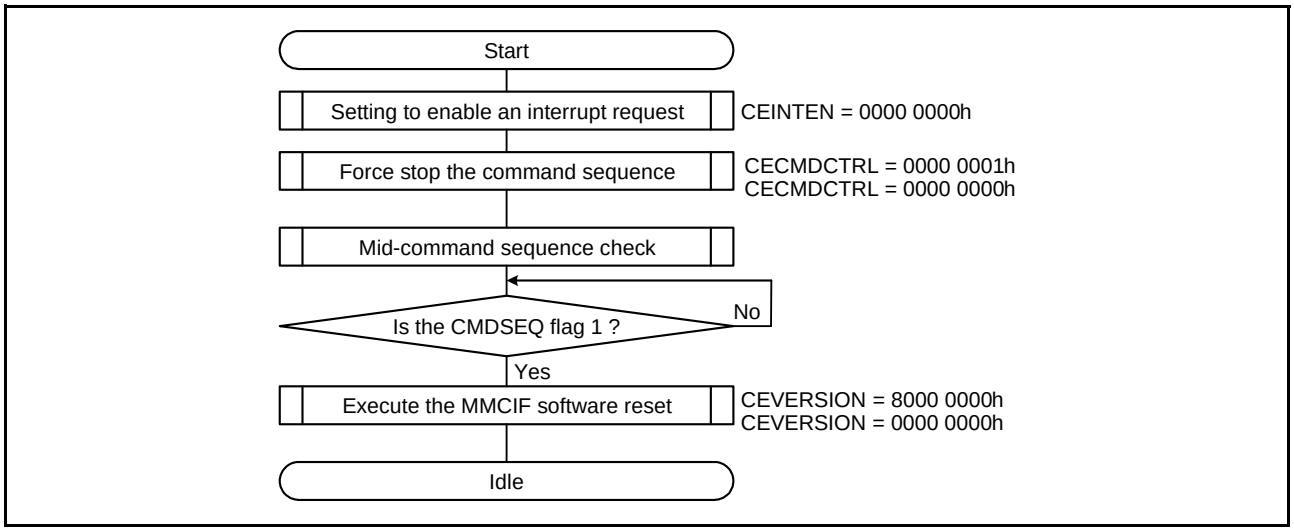

Figure 50.22 Command Sequence Force Stop

50.5 Interrupts

Table 50.5 lists the MMCIF Interrupt Sources. The MMCIF generates four types of interrupt requests: normal operation interrupt, error/timeout interrupt, MMC detection interrupt, and the MMCIF buffer access interrupt. When an interrupt status flag in the CEINT register becomes 1, if the corresponding bit in the CEINTEN register is 1, the MMCIF interrupt request is generated.

Table 50.5 MMCIF Interrupt Sources

Interrupt Source	Interrupt Status Flags		Interrupt Request Enable Register		DMAC/DTC Triggerable
	Register symbol	Bit symbol	Register symbol	Bit symbol	
Normal operation interrupt (ACCIO)	CEINT	CMD12DRE	CEINTEN	MCMD12DRE	No
		CMD12RBE		MCMD12RBE	
		CMD12CRE		MCMD12CRE	
		DTRANE		MDTRANE	
		BUFRE		MBUFRE	
		BUFWEN		MBUFWEN	
		BUFREN		MBUFREN	
		RBSYE		MRBSYE	
		CRSPE		MCRSPE	
Error/timeout interrupt (ERRIO)		CMDVIO		MCMDVIO	No
		BUFVIO		MBUFVIO	
		WDATERR		MWDATERR	
		RDATERR		MRDATERR	
		RIDXERR		MRIDXERR	
		RSPERR		MRSPERR	
		CRCSTO		MCRCSTO	
		WDATTO		MWDATTO	
		RDATTO		MRDATTO	
		RBSYTO		MRBSYTO	
		RSPTO		MRSPTO	
MMC detection interrupt (CDETIO)	CEDETECT	CDRISE	CEDETECT	MCDRISE	No
		CDFALL		MCDFALL	
MMCIF buffer access interrupt (MBFAI)	—	—	CEBUFACC	DMAREN (when reading)	Yes
				DMAWEN (when writing)	

50.5.1 DMA Transfer Interrupt Requests

The MBFAI interrupt can be used to trigger DMA transfer for writing data to and reading data from the CEDATA register. When the CEBUFACC.DMAWEN bit is set to 1, if the MMCIF buffer is empty, the MBFAI interrupt request is generated. This interrupt request triggers the DMAC or DTC, and data can be transferred to the MMCIF buffer. At this point, the CEINT.BUFWEN flag does not become 1. When the CEBUFACC.DMAREN bit is set to 1, if the amount of data in the MMCIF buffer is the size specified in the CEBLOCKSET.BLKSIZ[15:0] bits, the MBFAI interrupt request is generated. This interrupt request triggers the DMAC or DTC, and data can be transferred from the MMCIF buffer. At this point, the CEINT.BUFREN flag does not become 1.

The MBFAI interrupt request is asserted for (block size set in the CEBLOCKSET.BLKSIZ[15:0] bits × number of blocks set in the CEBLOCKSET.BLKCNT[15:0] bits), and when the last block is transferred, it is negated. During DMA transfer, if an error occurs or if the command sequence is forcibly ended, the command sequence is stopped, so the MBFAI interrupt request is canceled.

Table 50.6 lists the DMAC and DTC Settings When Performing DMA Transfer.

Table 50.6 DMAC and DTC Settings When Performing DMA Transfer

Item		Settings
Transfer mode		Block transfer mode
Transfer data	1 data	32 bits
	Block size	Size set in the CEBLOCKSET.BLKSIZ[15:0] bits divided by 4
Block transfer count		Number of times set in the CEBLOCKSET.BLKCNT[15:0] bits

50.6 Notes On Using the MMCIF

50.6.1 MMC Detection

Insertion and removal of an MMC can be detected by monitoring the CEDETECT.CDRISE flag and CDFALL flag. However, as the MMCIF does not include hardware to eliminate chattering that occurs when the MMC is inserted and removed, chattering must be eliminated with software.

50.6.2 Multiple Block Transfer

Using a pre-defined multiple block transfer is recommended to increase data transfer rates.

50.6.3 Module-Stop Function Settings

Set the MSTPCRD.MSTPD21 bit to enable and disable MMCIF operation. MMCIF operation is stopped after a reset. Registers in the MMCIF can be accessed by exiting the module-stop state. Refer to section 11, Low Power Consumption for details.

51. Parallel Data Capture Unit (PDC)

51.1 Overview

This MCU includes a single parallel data capture unit (PDC).
The PDC has the function of communicating with the external I/O devices including image sensors, and specifically transferring parallel data such as an image output from the external I/O devices via the DTC or DMAC to the on-chip RAM and external address spaces (the CS and SDRAM areas).

Table 51.1 PDC Specifications

Item	Description
Capture Range	• Desired amounts of parallel data within the following ranges in the vertical and horizontal directions. Vertical direction: 1 to 4095 lines Horizontal direction: 4 to 4095 bytes
Parallel data transfer clock (PIXCLK)	• Operating frequency: 1 to 27 MHz*1
Interrupt Sources	• Receive data ready • Frame end • Overrun • Underrun • Error in the setting for the number of lines • Error in setting for the number of bytes per line
Startup of DTC/DMAC	• The receive data ready interrupt is capable of starting the DTC or DMAC
Parallel data transfer clock output (PCKO)	• Operating frequency: 1 to 30 MHz*2 • Clock source: Peripheral module clock B (PCLKB) • Frequency division ratio: Selectable from 2, 4, 6, 8, 10, 12, 14, and 16.
Others	• PDC reset function • Selectable active sense for the VSYNC and HSYNC signals • Monitoring of the VSYNC and HSYNC signals • Endian selection
Reducing Power Consumption	• The PDC can be placed in the module stop state.
Internal Bus Interface	• The PDC is connected with internal peripheral bus 3

Note 1. The frequency of the parallel data transfer clock (PIXCLK) should be equal to or less than 0.6 × PCLKB (peripheral module clock).
Note 2. The operating frequency is 30 MHz when that of the peripheral module clock B (PCLKB) is 60 MHz and the frequency division ratio is 2.

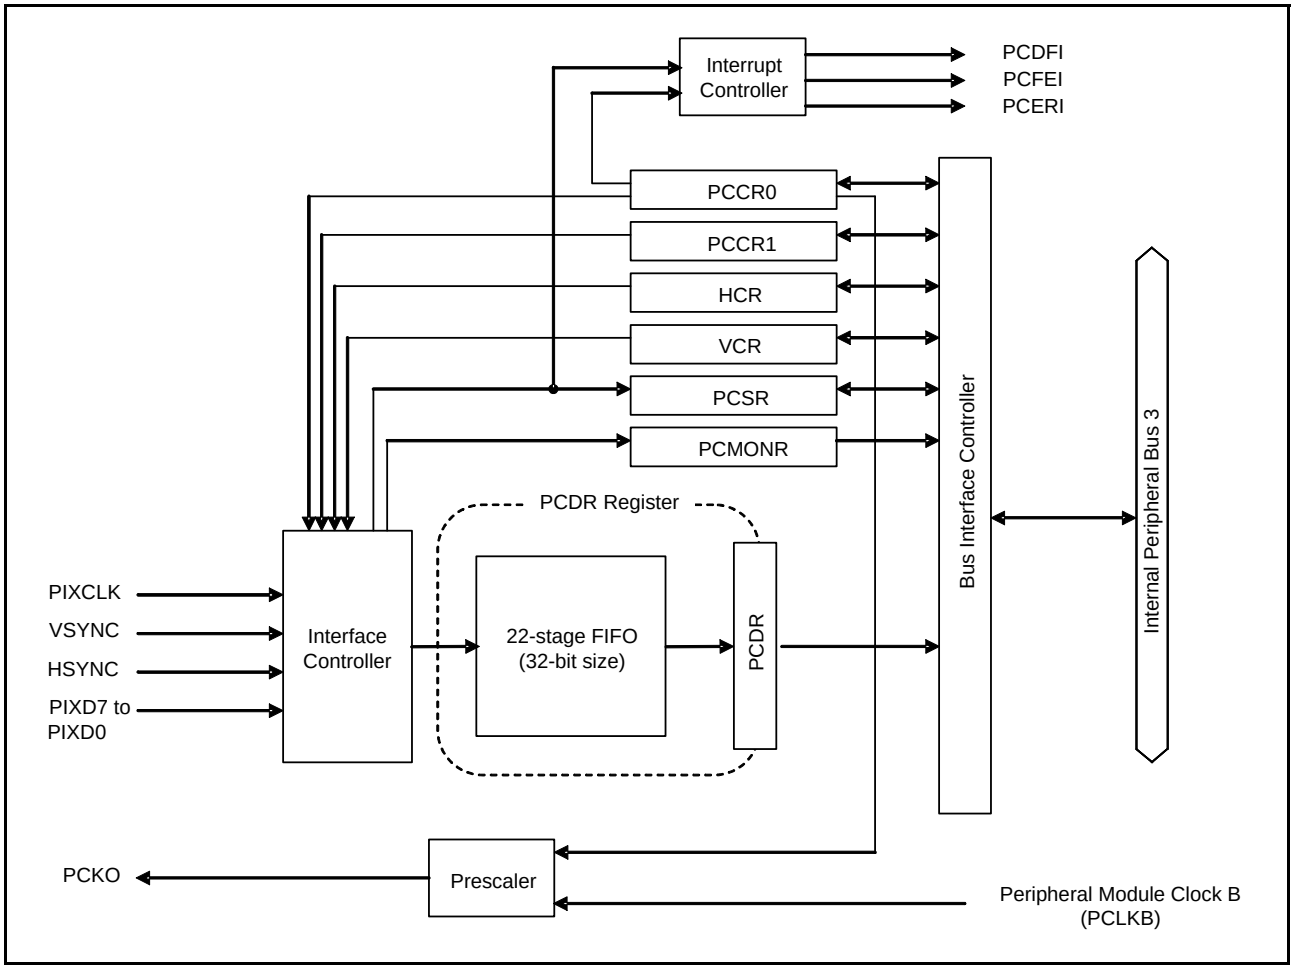

Figure 51.1 Block Diagram of the PDC

Table 51.2 Input and Output Pins of the PDC

Pin Name	Input/Output	Description
PIXCLK	Input	Parallel data transfer clock
VSYNC	Input	Vertical synchronization signal
HSYNC	Input	Horizontal synchronization signal
PIXD7 to PIXD0	Input	8-bit data
PCKO	Output	Output of the parallel data transfer clock

51.2 Register Descriptions

51.2.1 PDC Control Register 0 (PCCR0)

Address(es): 000A 0500h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	EDS	PCKDIV[2:0]			PCKOE	HERIE	VERIE	UDRIE	OVIE	FEIE	DFIE	PRST	HPS	VPS	PCKE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit Name	Symbol	Bit Name	Description	R/W
b0	PCKE	PIXCLK Input Enable	0: PIXCLK input is disabled. 1: PIXCLK input is enabled.	R/W
b1	VPS	VSYNC Signal Polarity Select	0: VSYNC signal is active high. 1: VSYNC signal is active low.	R/W
b2	HPS	HSYNC Signal Polarity Select	0: HSYNC signal is active high. 1: HSYNC signal is active low.	R/W
b3	PRST	PDC Reset	0: PDC reset is not applied. 1: PDC is reset.	R/(W) *1
b4	DFIE	Receive Data Ready Interrupt Enable	0: Generation of receive data ready interrupt requests is disabled. 1: Generation of receive data ready interrupt requests is enabled.	R/W
b5	FEIE	Frame End Interrupt Enable	0: Generation of frame end interrupt requests is disabled. 1: Generation of frame end interrupt requests is enabled.	R/W
b6	OVIE	Overrun Interrupt Enable	0: Generation of overrun interrupt requests is disabled. 1: Generation of overrun interrupt requests is enabled.	R/W
b7	UDRIE	Underrun Interrupt Enable	0: Generation of underrun interrupt requests is disabled. 1: Generation of underrun interrupt requests is enabled.	R/W
b8	VERIE	Vertical Line Number Setting Error Interrupt Enable	0: Generation of vertical line number setting error interrupt requests is disabled. 1: Generation of vertical line number setting error interrupt requests is enabled.	R/W
b9	HERIE	Horizontal Byte Number Setting Error Interrupt Enable	0: Generation of horizontal byte number setting error interrupt requests is disabled. 1: Generation of horizontal byte number setting error interrupt requests is enabled.	R/W
b10	PCKOE	PCKO Output Enable	0: PCKO output is disabled (fixed to the high level) 1: PCKO output is enabled.	R/W
b13 to b11	PCKDIV[2:0]	PCKO Frequency Division Ratio Select	b13 b11 0 0 0: PCKO/2 0 0 1: PCKO/4 0 1 0: PCKO/6 0 1 1: PCKO/8 1 0 0: PCKO/10 1 0 1: PCKO/12 1 1 0: PCKO/14 1 1 1: PCKO/16	R/W
b14	EDS	Endian Select	0: Little endian 1: Big endian	R/W
b31 to b15	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 1 can be written to this bit.

The PCCR0 register should only be set while the PCE bit in the PCCR1 register is 0.

PCKE Bit (PIXCLK Input Enable)

This bit enables and disables the input through the PIXCLK pin.
Set this bit to 1 before enabling reception. After enabling input through the PIXCLK pin, use the PRST bit to initialize the PDC.
When setting this bit to 0, do so after disabling reception operations.

VPS Bit (VSYNC Signal Polarity Select)

This bit selects the active sense of the VSYNC signal.

HPS Bit (HSYNC Signal Polarity Select)

This bit selects the active sense of the HSYNC signal.

PRST Bit (PDC Reset)

This bit initializes the internal status of the PDC and the target registers of the PDC reset. See section 51.3.11, Reset State for the target registers.
The PDC should be reset after setting the PCKE bit to 1.
When 1 is written to the PRST bit, initialization is started in synchronization with the PIXCLK. After completion of the initialization, the PRST bit is automatically cleared to 0. When the PDC is reset, ensure that the PIXCLK pin has an input signal. Also, after 1 has been written to the PRST bit, do not proceed to the next step until verifying that the bit has returned to 0.
In the case of consecutive PDC resets, wait for at least one cycle of PIXCLK after verifying that the PRST bit has returned to 0.

DFIE Bit (Receive Data Ready Interrupt Enable)

This bit enables and disables the generation of receive data ready interrupt requests.

FEIE Bit (Frame End Interrupt Enable)

This bit enables and disables the generation of frame end interrupt requests.

OVIE Bit (Overrun Interrupt Enable)

This bit enables and disables the generation of overrun interrupt requests.

UDRIE Bit (Underrun Interrupt Enable)

This bit enables and disables the generation of underrun interrupt requests.

VERIE Bit (Vertical Line Number Setting Error Interrupt Enable)

This bit enables and disables the generation of vertical line number setting error interrupt requests.

HERIE Bit (Horizontal Byte Number Setting Error Interrupt Enable)

This bit enables and disables the generation of horizontal byte number setting error interrupt requests.

PCKOE Bit (PCKO Output Enable)

This bit enables and disables an output from PCKO.
When the PCKOE bit is cleared to 0 during low output of PCKO, it may cause high output at the time of clearing, resulting in spoiling the duty factor.

PCKDIV[2:0] Bits (PCKO Frequency Division Ratio Select)

This bit selects the frequency division ratio of the PCKO.

The PCKO output is a clock signal derived by dividing the PCLKB clock signal by the value from 2 to 16 corresponding to the setting of the PCKDIV[2:0] bits.

The operating frequency should be set in accord with that of PCLKB to a value within the range from 1 to 30 MHz.

EDS Bit (Endian Select)

This bit selects an endian for the captured data.

51.2.2 PDC Control Register 1 (PCCR1)

Address(es): 000A 0504h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PCE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit Name	Symbol	Bit Name	Description	R/W
b0	PCE	PDC Operation Enable	0: Operations for reception are disabled. 1: Operations for reception are enabled.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

PCE Bit (PDC Operation Enable)

This bit enables and disables operations for reception.

When the PCE bit is set to 1 during assertion of the VSYNC signal, the PDC starts operations for reception from the next effective edge of the VSYNC signal.

The PCE bit should only be cleared to 0 while operations for reception or continued reception are stopped, including the frame end interrupt and so on. Regarding operations for continued reception, see section 51.3.6, Operations for Continued Reception at the Time of Frame End.

51.2.3 PDC Status Register (PCSR)

Address(es): 000A 0508h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	HERF	VERF	UDRF	OVRF	FEF	FEMPF	FBSY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit Name	Symbol	Bit Name	Description	R/W
b0	FBSY	Frame Busy Flag	0: Operations for reception are stopped. 1: Operations for reception are ongoing.	R
b1	FEMPF	FIFO Empty Flag	0: FIFO is not empty. 1: FIFO is empty.	R
b2	FEF	Frame End Flag	0: Frame end has not been generated. 1: Frame end has been generated.	R/(W) *1
b3	OVRF	Overrun Flag	0: FIFO overrun has not been generated. 1: FIFO overrun has been generated.	R/(W) *1
b4	UDRF	Underrun Flag	0: Underrun has not been generated. 1: Underrun has been generated.	R/(W) *1
b5	VERF	Vertical Line Number Setting Error Flag	0: Vertical line number setting error has not been generated. 1: Vertical line number setting error has been generated.	R/(W) *1
b6	HERF	Horizontal Byte Number Setting Error Flag	0: Horizontal byte number setting error has not been generated. 1: Horizontal byte number setting error has been generated.	R/(W) *1
b31 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. 0 can only be written to these bits to clear these flags after they have been read out as 1.

FBSY Flag (Frame Busy Flag)

This flag indicates the state of PDC operations.

[Setting Condition]

- Detection of the effective edge of the VSYNC signal after the enabling of operations for reception.

[Clearing Conditions]

- Reception of one-frame of data according to the settings of the VCR and HCR registers being completed.*1
- When an error (overrun, underrun, vertical line number setting error, or horizontal byte number setting error) occurs
- When the PCCR1.PCE bit is 0

Note 1. This flag is 0 during operations for continued reception.

FEMPF Flag (FIFO Empty Flag)

This flag indicates the state of the FIFO.

This flag indicates the state of the FIFO at the time when a vertical line number setting error or a horizontal byte number setting error occurs and is 0 following an overrun and undefined following an underrun.

[Setting Conditions]*1

- Reading of the PCDR register while the FIFO is empty.
- Detection of an effective edge of the VSYNC signal.

- The PDC being reset.

[Clearing Condition]*1

- Storage of the data captured in the FIFO.

Note 1. This flag is undefined following an underrun, and is set to either 0 or 1.

FEF Flag (Frame End Flag)

This flag indicates the end of a frame.

[Setting Condition]

- Reception of one frame of data in accord with the settings of the VCR and HCR registers.*1

[Clearing Conditions]

- The PDC being reset.
- Writing of 0 to the bit after it has been read as 1.

Note 1. In the case of operations for continued reception, this flag will be 1 after their completion.

OVRF Flag (Overrun Flag)

This flag indicates an overrun.

[Setting Condition]

- Data for reception arriving while the FIFO is full.

[Clearing Conditions]

- The PDC being reset.
- Writing of 0 to the bit after it has been read as 1.

UDRF Flag (Underrun Flag)

This flag indicates an underrun.

[Setting Condition]

- Reading of the PCDR register while the FIFO is empty.

[Clearing Conditions]

- The PDC being reset.
- Writing of 0 to the bit after it has been read as 1.

VERF Flag (Vertical Line Number Setting Error Flag)

This flag indicates an error in the setting for the number of lines.

[Setting Condition]

- The VSYNC signal is negated because fewer lines have been captured than the value in the VCR register.

[Clearing Conditions]

- The PDC being reset.
- Writing of 0 to the bit after it has been read as 1.

HERF Flag (Horizontal Byte Number Setting Error Flag)

This flag indicates an error in the setting for the number of bytes in a line.

[Setting Condition]

- The HSYNC signal is negated because fewer bytes in a line have been captured than the value in the HCR register.

[Clearing Conditions]

- The PDC being reset.
- Writing of 0 to the bit after it has been read as 1.

51.2.4 PDC Pin Monitor Register (PCMONR)

Address(es): 000A 050Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	HSYNC	VSYNC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit Name	Symbol	Bit Name	Description	R/W
b0	VSYNC	VSYNC Signal Status Flag	0: VSYNC signal is at the low level. 1: VSYNC signal is at the high level.	R
b1	HSYNC	HSYNC Signal Status Flag	0: HSYNC signal is at the low level. 1: HSYNC signal is at the high level.	R
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R

VSYNC Flag (VSYNC Signal Status Flag)

This flag indicates the state of the VSYNC signal.

HSYNC Flag (HSYNC Signal Status Flag)

This flag indicates the state of the HSYNC signal.

51.2.5 PDC Receive Data Register (PCDR)

Address(es): 000A 0510h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The PDC includes a 32-bit, 22-stage FIFO buffer for the storage of captured data. The FIFO buffer is mapped to the 4-byte PCDR register, and captured data are read from this register in 4-byte units. The receive data ready flag is set for every 32 bytes of received data, and this also leads to a receive data ready interrupt if the DFIE bit in the PCCR0 register is set to 1. When a receive data ready interrupt is generated, read the PCDR register eight times. Figure 51.2 shows a schematic view of the PCDR register.

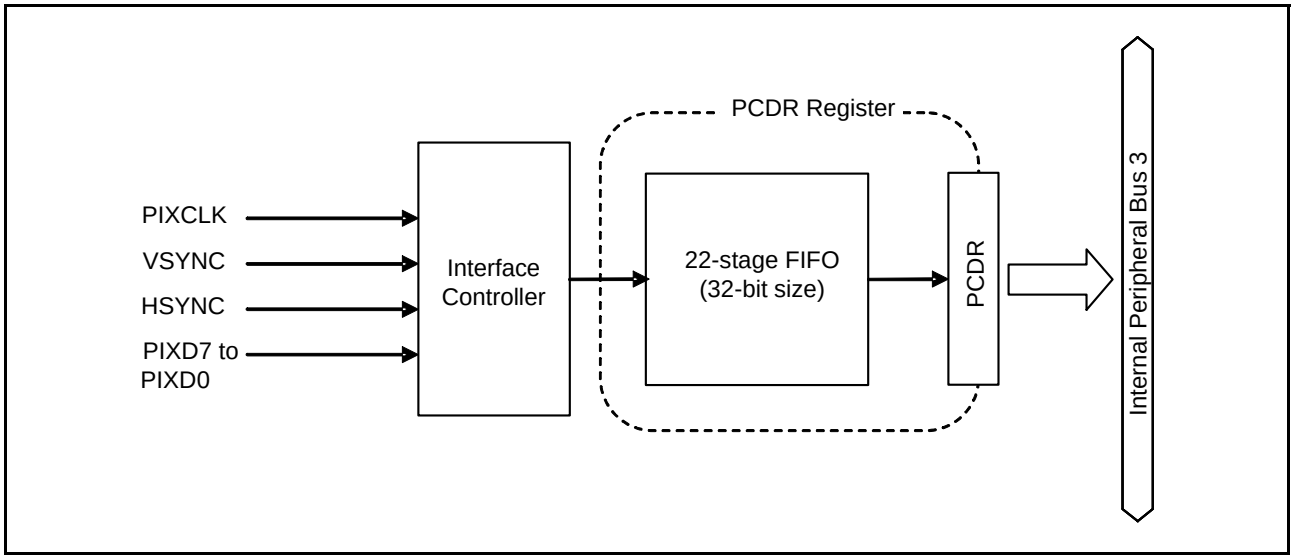

Figure 51.2 Schematic View of the PCDR Register

For the format of the captured data, either big or little endian can be selected by the EDS bit of the PCCR0 register. Figure 51.3 shows the arrangements of data according to the endian formats.

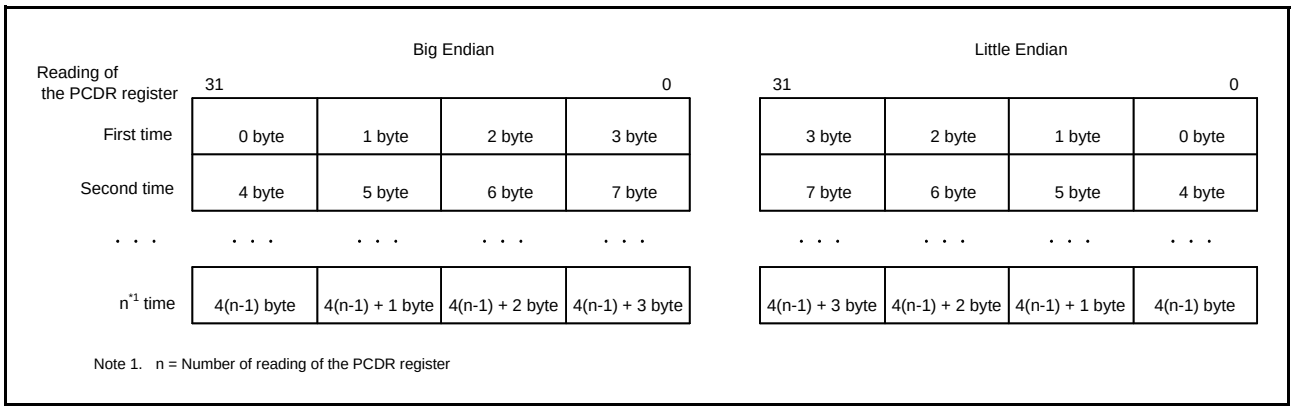

Figure 51.3 Endian Formats

51.2.6 Vertical Capture Register (VCR)

Address(es): 000A 0514h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	VSZ[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	VST[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit Name	Symbol	Bit Name	Description	R/W
b11 to b0	VST[11:0]	Vertical Capture Start Line Position	Number of the line where capture is to start.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b27 to b16	VSZ[11:0]	Vertical Capture Size	Number of lines to be captured.	R/W
b31 to b28	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

For the relationship between the VCR register setting and the captured range, see section 51.3.3, Settings of the VCR and HCR Registers and the Captured Range.
The VCR register should be set while the PCE bit in the PCCR1 register is 0.

VST[11:0] Bit (Vertical Capture Start Line Position)

These bits set the number of the line where capture is to start.
To set the first line, these bits should be 000h; to set the 4095th line, they should be FFEh.
The setting of the VST[11:0] bits should be within the range from 000h to FFEh and, in combination with that of the VSZ[11:0] bits, satisfy the following relation:
Setting range of the VST[11:0] bits: $1 \leq VST[11:0] + VSZ[11:0] \leq FFFh$.

VSZ[11:0] Bit (Vertical Capture Size)

These bits set the number of lines to be captured.
To set one line, these bits should be 001h; to set 4095 lines, they should be FFFh.
The setting of the VSZ[11:0] bits should be within the range from 001h to FFFh and, in combination with that of the VST[11:0] bits, satisfy the following relation:
Setting range of the VSZ[11:0] bits: $1 \leq VST[11:0] + VSZ[11:0] \leq FFFh$.

51.2.7 Horizontal Capture Register (HCR)

Address(es): 000A 0518h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	HSZ[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	HST[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit Name	Symbol	Bit Name	Description	R/W
b11 to b0	HST[11:0]	Horizontal Capture Start Byte Position	Horizontal position in bytes where capture is to start.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b27 to b16	HSZ[11:0]	Horizontal Capture Size	Number of bytes to be captured horizontally.	R/W
b31 to b28	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

For the relationship between the HCR register setting and the captured range, see section 51.3.3, Settings of the VCR and HCR Registers and the Captured Range.
The HCR register should be set while the PCE bit in the PCCR1 register is 0.

HST[11:0] Bit (Horizontal Capture Start Byte Position)

These bits set the horizontal position in bytes where capture is to start.
To set the first byte, these bits should be 000h; to set the 4092th byte, they should be FFBh.
The setting of the HST[11:0] bits should be within the range from 000h to FFBh and, in combination with that of the HSZ[11:0] bits, satisfy the following relation:
Setting range of the HST[11:0] bits: $4 \leq HST[11:0] + HSZ[11:0] \leq FFFh$.

HSZ[11:0] Bit (Horizontal Capture Size)

These bits set the number of bytes to be captured per line.
To set four bytes, these bits should be 004h; to set 4095 bytes, they should be FFFh.
The setting of the HSZ[11:0] bits should be within the range from 004h to FFFh and, in combination with that of the HST[11:0] bits, satisfy the following relation:
Setting range of the HSZ[11:0] bits: $4 \leq HST[11:0] + HSZ[11:0] \leq FFFh$.

51.3 Operation

51.3.1 Transfer Formats

The PDC supports the four transfer formats shown in Figure 51.4 to Figure 51.7. The format is determined by the setting of the VPS and HPS bits in the PCCR0 register.

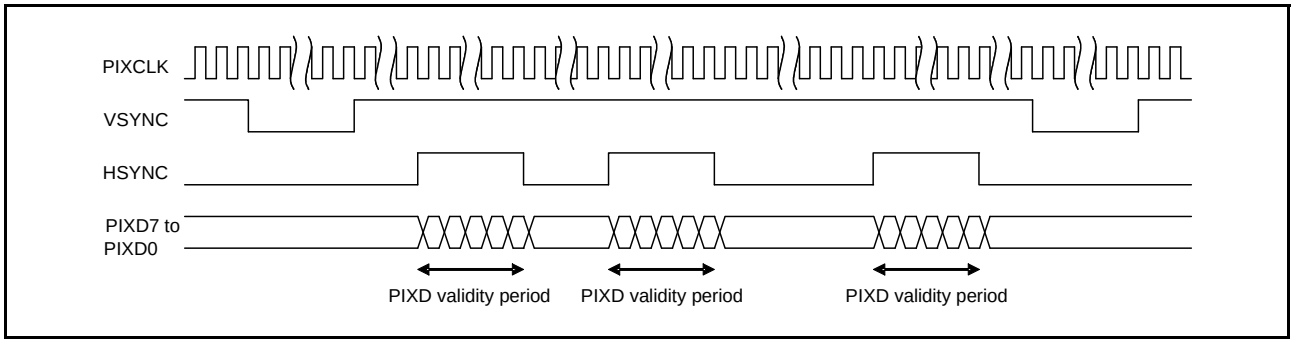

Figure 51.4 PDC Transfer Format (for VPS=0, HPS=0)

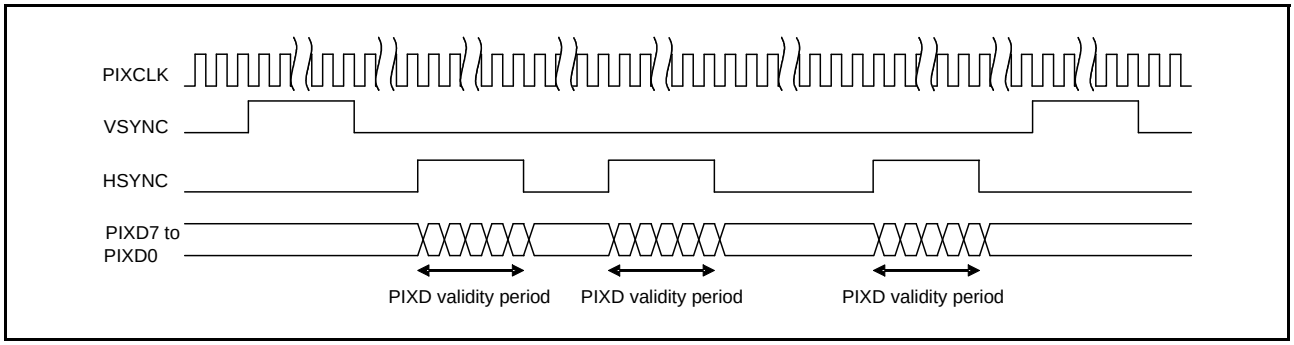

Figure 51.5 PDC Transfer Format (for VPS=1, HPS=0)

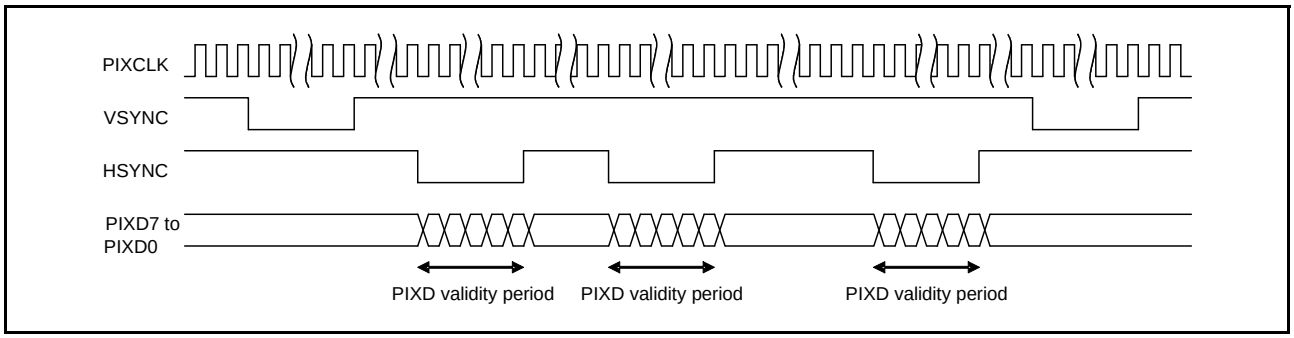

Figure 51.6 PDC Transfer Format (for VPS=0, HPS=1)

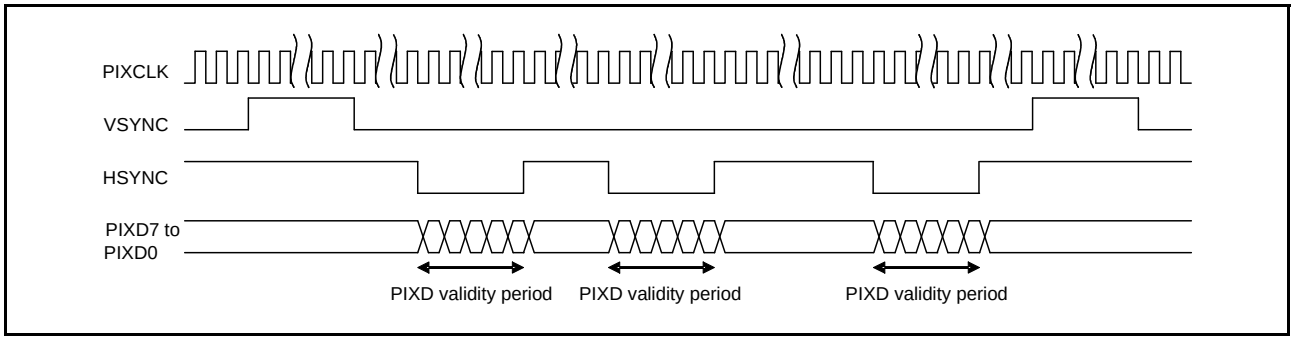

Figure 51.7 PDC Transfer Format (for VPS=1, HPS=1)

51.3.2 Transfer Timing

Figure 51.8 and Table 51.3 show the timing of transfer by the PDC.

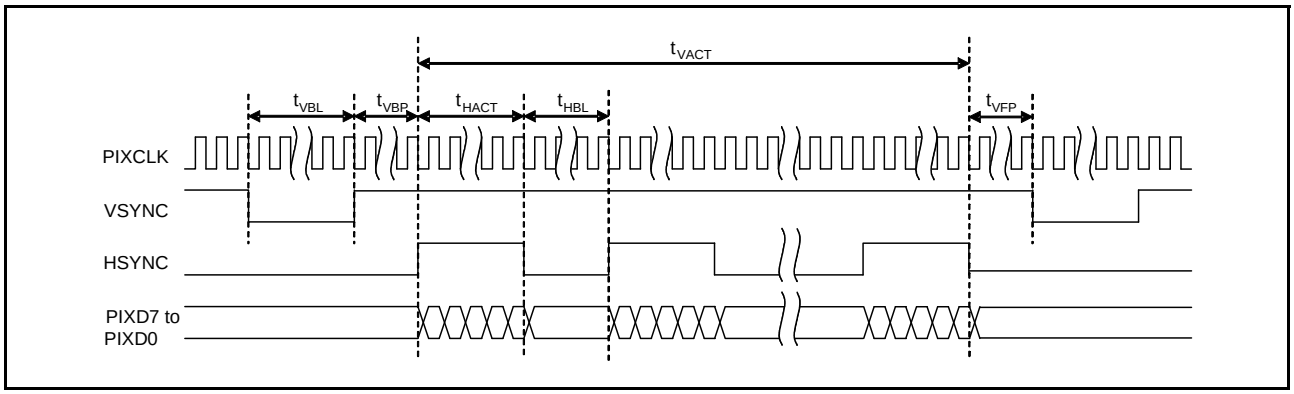

Figure 51.8 PDC Transfer Timing

Table 51.3 PDC Transfer Timing

Item	Symbol	Min*1	Max	Unit
Vertical Blanking Period	t_{VBL}	128	—	PIXCLK
Vertical Backporch	t_{VBP}	10	—	PIXCLK
Horizontal Valid Period	t_{HACT}	4	4095	PIXCLK
Horizontal Blanking Period	t_{HBL}	128	—	PIXCLK
Vertical Frontporch	t_{VFP}	10	—	PIXCLK
Vertical Valid Period	t_{VACT}	1	4095	Line

Note 1. The minimum values are the lowest of which this MCU circuit is capable. They are not values which guarantee the avoidance of overruns, vertical line number setting errors, or horizontal byte number setting errors.

51.3.3 Settings of the VCR and HCR Registers and the Captured Range

Figure 51.9 and Figure 51.10 show the relationship between the settings of the VCR and HCR registers and the captured range.

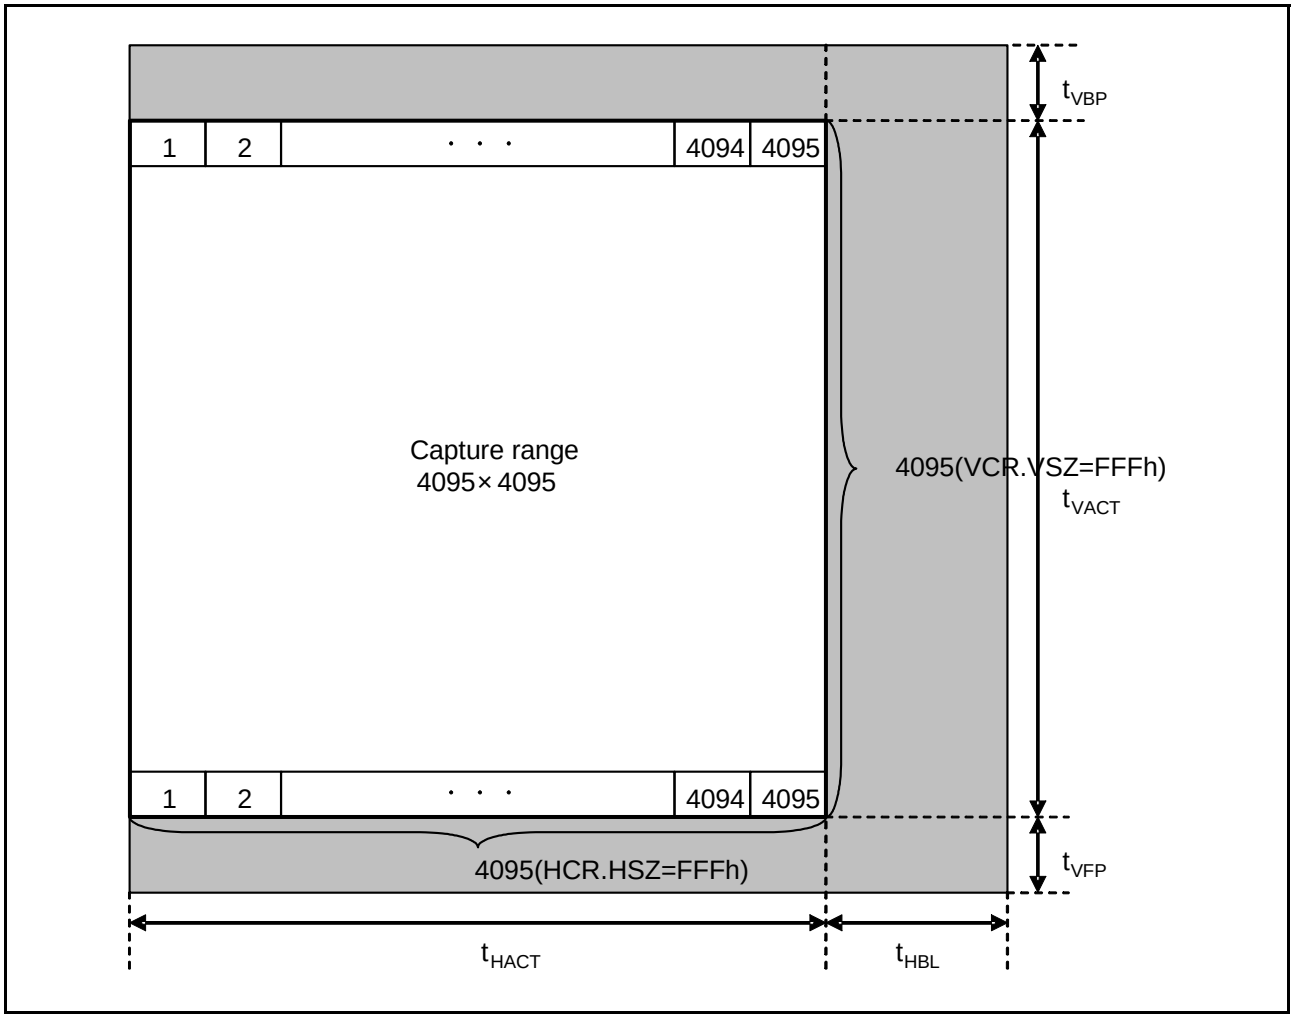

Figure 51.9 Settings of the VCR and HCR Registers and the Captured Range (VCR = 0FFF 0000h, HCR = 0FFF 0000h)

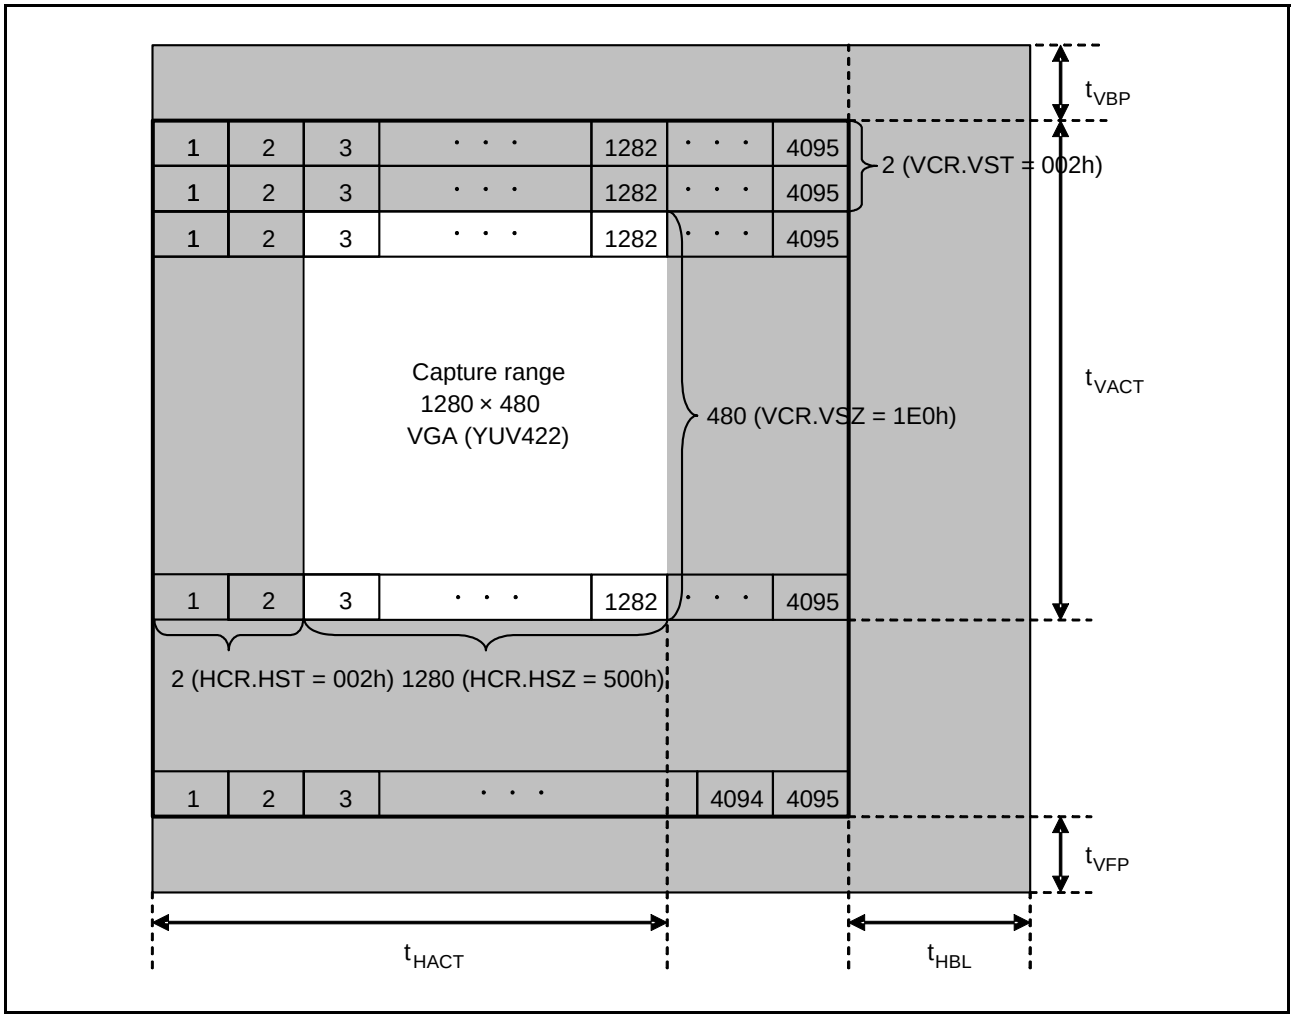

Figure 51.10 Settings of the VCR and HCR Registers and the Captured Range (VCR = 01E0 0002h, HCR = 0500 0002h)

51.3.4 Operations for Reception

Figure 51.11 shows an example of operations for reception when receive data ready interrupts (to start up the DTC or DMAC) and frame end interrupts are in use.

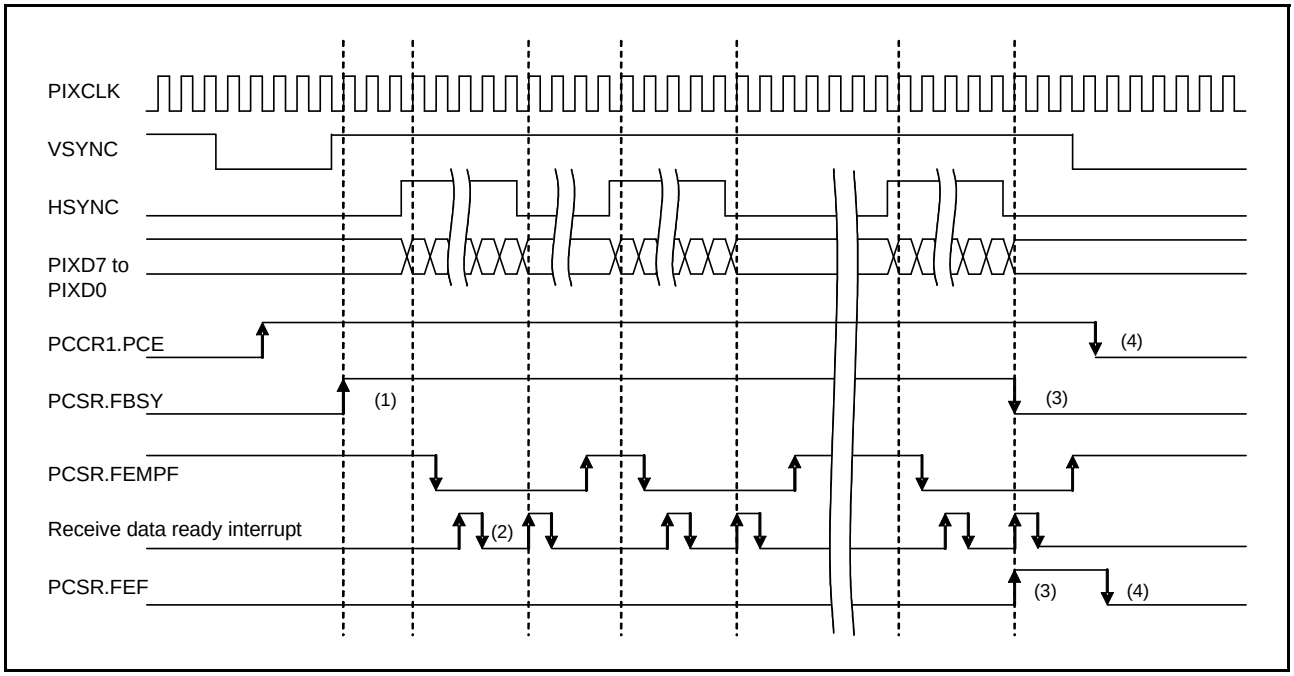

Figure 51.11 Example of Operations for Reception

The actual operations at the times indicated by (1), (2), (3), and (4) in Figure 51.11 are described below.

(1) When an effective edge of the VSYNC signal is detected after the PCE bit in the PCCR1 register is set to 1, the FEMPF flag in the PCSR register is set to 1 and the FIFO is initialized. Concurrently, the FBSY flag in the PCSR register is set to 1 and operations for reception start.

(2) When data within the range for capture set in the VCR and HCR registers is received, the data are stored in the FIFO. The PDC generates a receive data ready interrupt every time it receives 32 bytes of data, and the interrupt starts transfer of the captured data by the DTC or DMAC to the on-chip RAM or an external address space. The FIFO is likely to overrun if reading of the PCDR register takes more time than reception of the data. Check the OVRF flag in the PCSR register to verify an overrun.

(3) After reception of the last byte of data is completed, the FBSY flag in the PCSR register is cleared to 0 and the FEF flag in the PCSR register is set to 1 so that a receive data ready interrupt and frame end interrupt are generated.

(4) The FEMPF flag in the PCSR register is polled by the frame end interrupt, after which the completion of data transfer by the DTC or DMAC should be verified. After the PCE bit in the PCCR1 register is cleared to 0, the FEF flag in the PCSR register is also cleared to 0, and the reception of one frame of data is complete.
If an underrun occurs while the PCSR.FEMPF flag is being polled, setting of the PCSR.FEMPF flag may not proceed. Accordingly, also check the PCSR.UDRF flag during polling, and if an underrun occurs, run appropriate error processing.

If the FEF flag in the PCSR register has been set to 1 before the PCE bit in the PCCR1 register is set to 1, effective edges of the VSYNC signal are not detected and operations for reception will not be started. Clear the FEF flag in the PCSR register to 0 to start operations for data reception.

51.3.5 Operation during the Horizontal Blanking Period

If the horizontal blanking period begins but the number of the received data bytes has not reached 32 bytes since the previous receive data ready, the count of the number of received data bytes is retained and carried over to the next horizontal valid period. Figure 51.12 shows an example of operation during the horizontal blanking period.

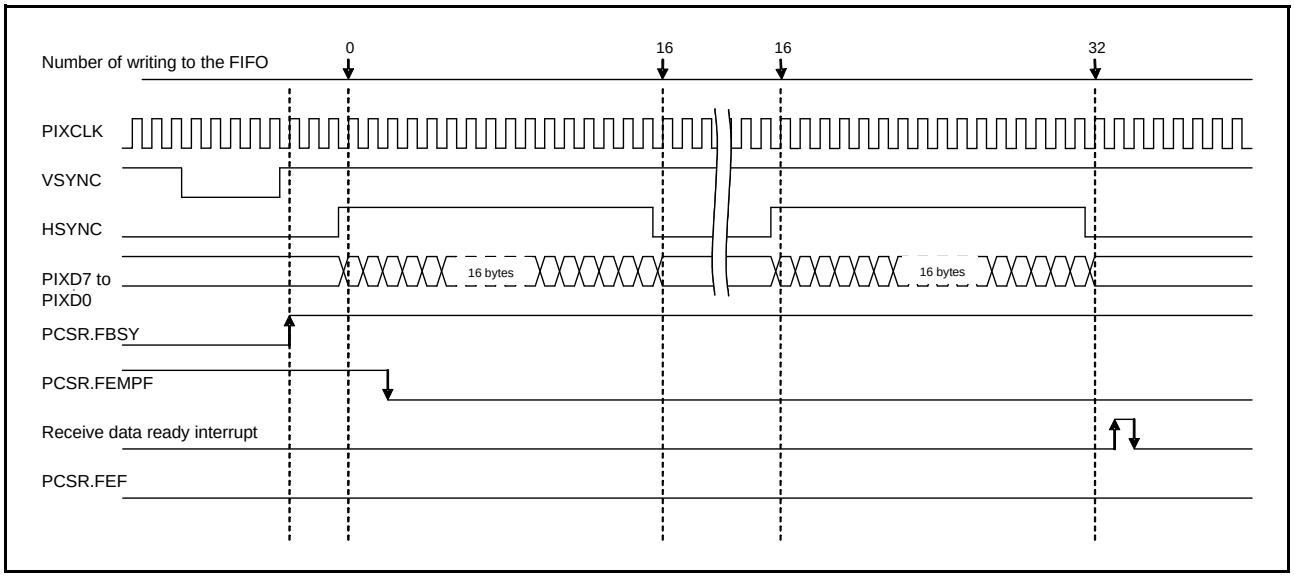

Figure 51.12 Example of Operation during the Horizontal Blanking Period

51.3.6 Operations for Continued Reception at the Time of Frame End

When the last of the data have been received but the number of bytes of data received since the previous receive data ready has not reached 32, the PDC continues to receive data (hereinafter referred to as “continued reception”) until the number reaches 32. After that, it generates a receive data ready and a frame end. The PIXCLK should be input during operations for continued reception. If the data stored in the FIFO are read out during operations for continued reception, the values read are undefined. Figure 51.13 shows an example of operations at the time of frame end.

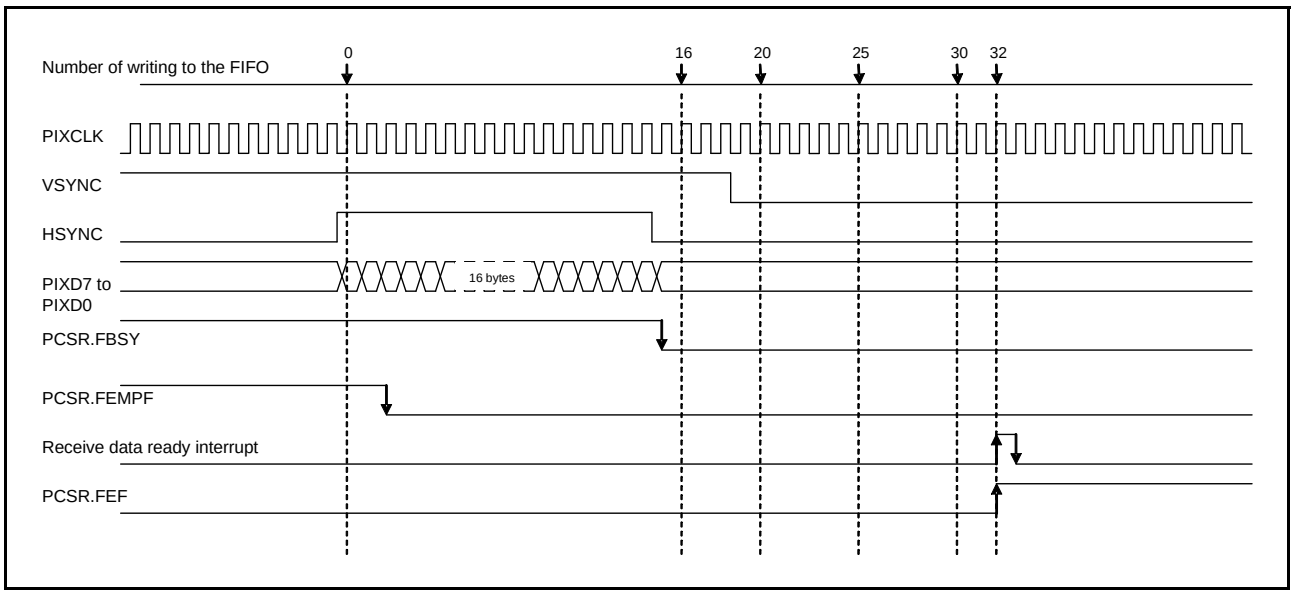

Figure 51.13 Example of Continued Reception at the Time of Frame End

51.3.7 Error Detection

The PDC has functions for error detection so that the software can apply control in response to errors during operations for reception. Table 51.4 summarizes the conditions under which each type of error is detected and the interrupt flags set in response.

Table 51.4 Error Detection

Error Factor	Conditions of Error Detection	Interrupt Flag	Example of Operation
Overrun	Data for reception arriving while the FIFO is full.*1	PCSR.OVRF	Figure 51.14
Underrun	The PCDR register being read while the FIFO is empty.	PCSR.UDRF	Figure 51.15
Vertical line number setting error	Negation of the VSYNC signal when the number of captured lines is less than the value set in the VCR register.	PCSR.VERF	Figure 51.16
Horizontal byte number setting error	Negation of the HSYNC signal when the number of bytes captured in a line is less than the value set in the HCR register.	PCSR.HERF	Figure 51.17

Note 1. This includes data reception during operations for continued reception.

When an error is detected, the PDC sets the corresponding interrupt flag to 1 to stop operations for reception. While the interrupt flag is set to 1, the PDC does not detect effective edges of the VSYNC signal and does not start operations for reception. Clear all error source interrupt flags to 0 to start operations for reception.
In addition, when an error occurs, data stored in the FIFO is disabled.

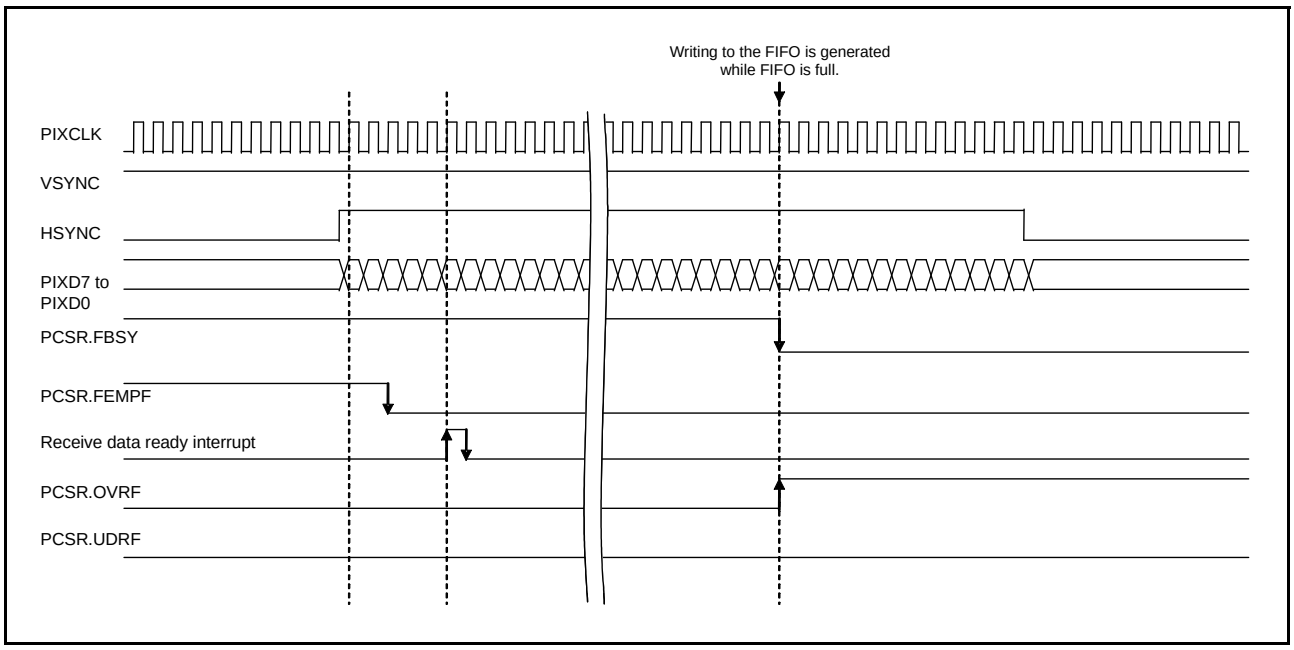

Figure 51.14 Overrun Detected

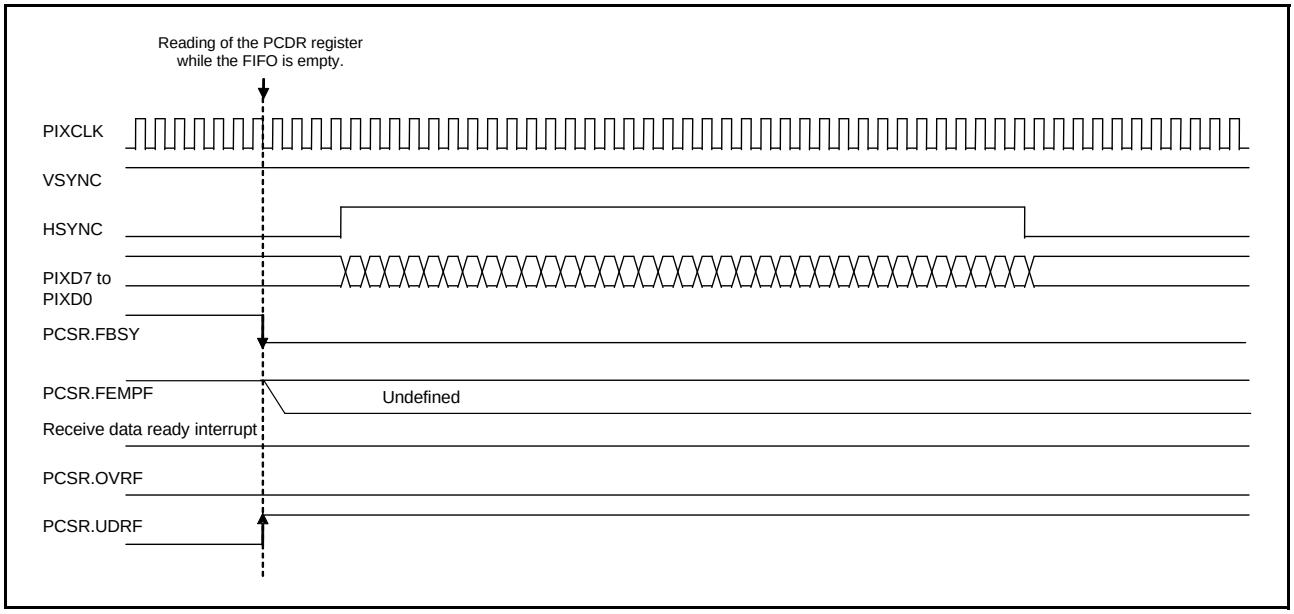

Figure 51.15 Underrun Detected

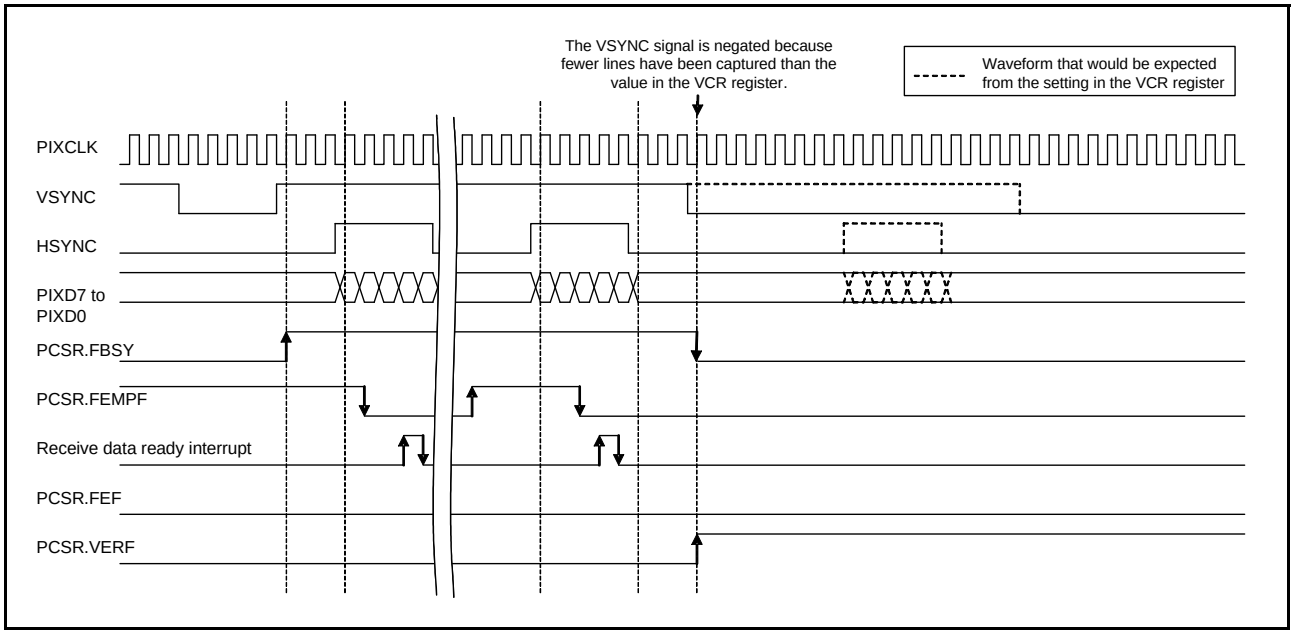

Figure 51.16 Vertical Line Number Setting Error Detected

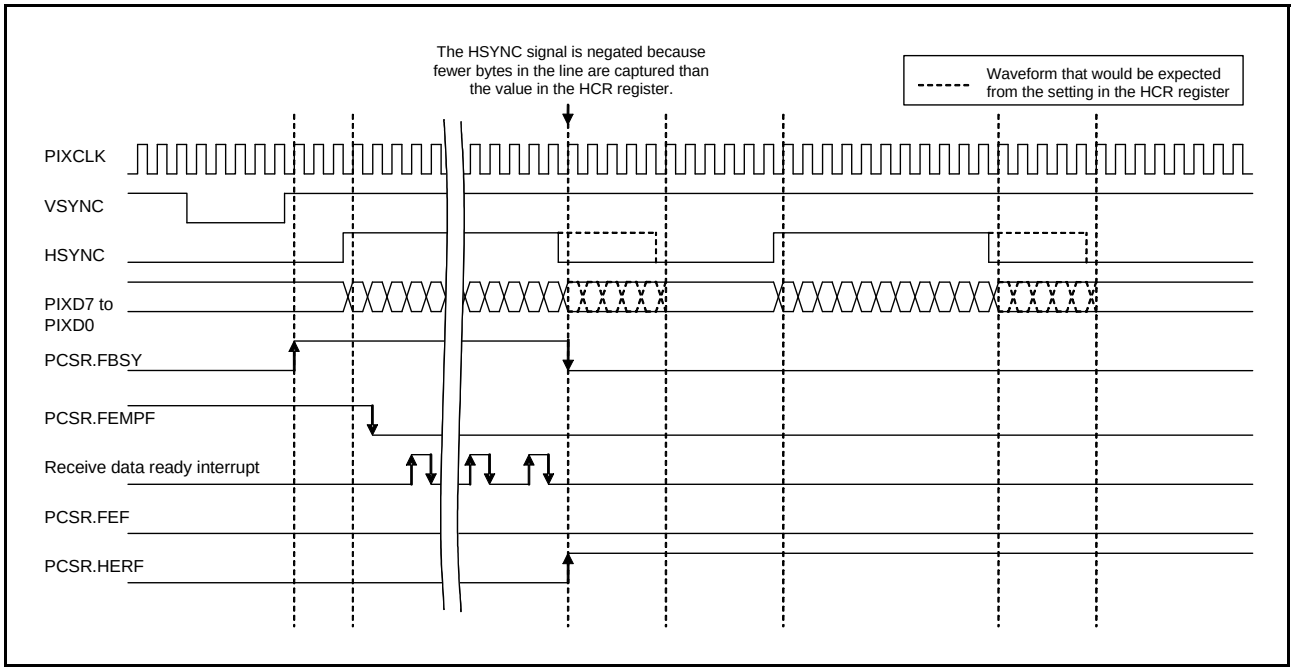

Figure 51.17 Horizontal Byte Number Setting Error Detected

51.3.8 Initial Settings

Figure 51.18 is a sample flowchart for initial settings. For a description of how to set up the input and output ports and the interrupt controller, see the descriptions given in the sections on the relevant blocks.

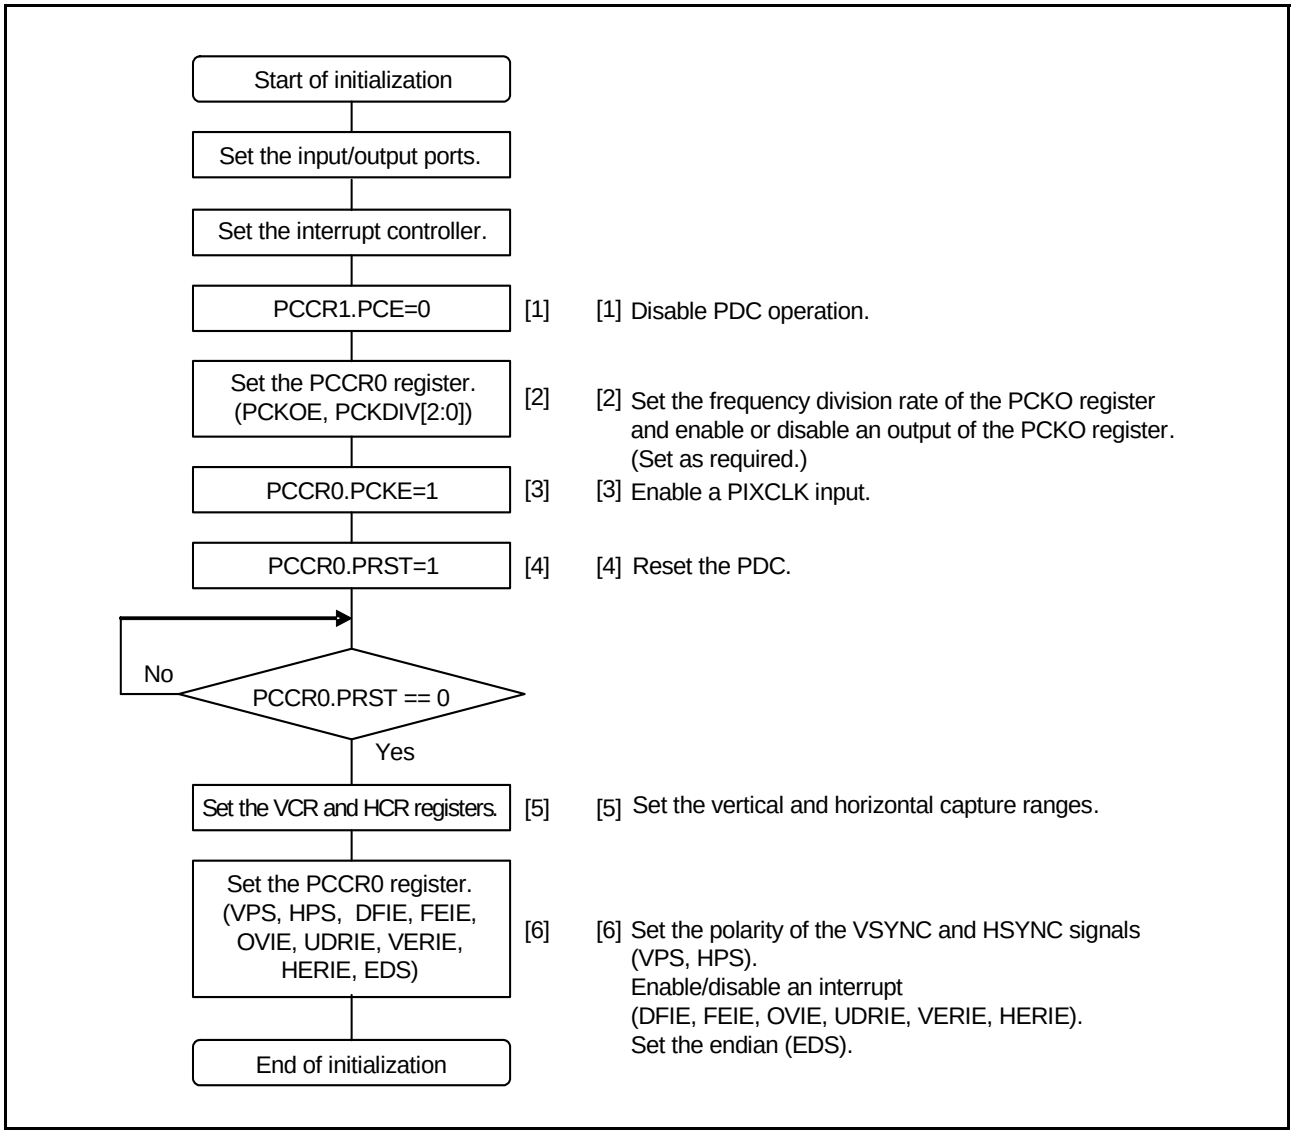

Figure 51.18 Sample Flowchart for Initial Setting of the PDC

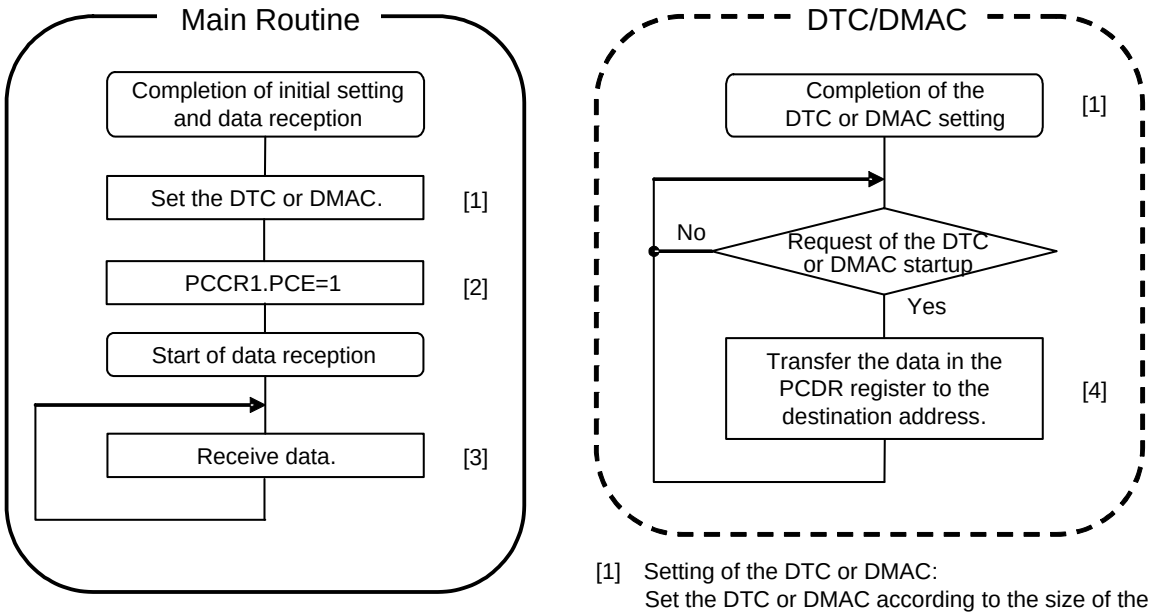
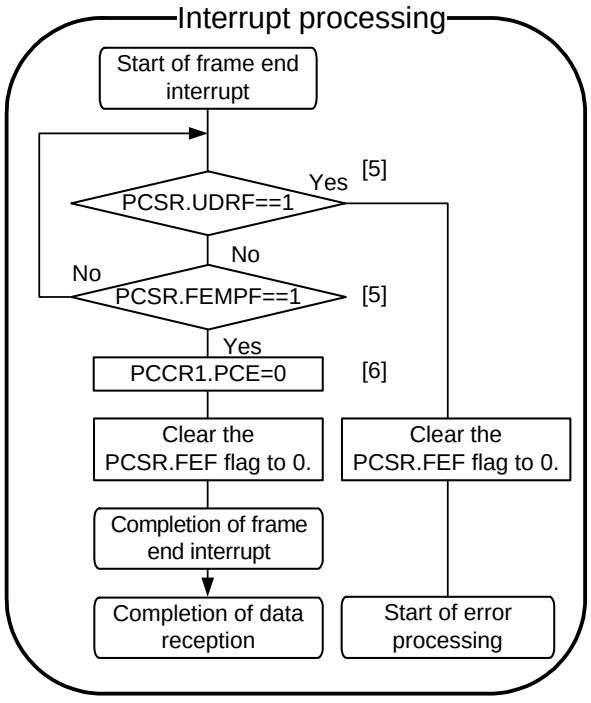
51.3.9 Flows of Operations

Figure 51.19 shows an example of the flows of operations when the receive data ready interrupt (to start up the DTC or DMAC) and frame end interrupt are in use. For a description of how to set up the DTC or DMAC, see section 18, DMA Controller (DMACAa) and section 20, Data Transfer Controller (DTCa).





[1] Setting of the DTC or DMAC:
Set the DTC or DMAC according to the size of the captured image.

[2] Enabling of PDC operation:
Set the PCE bit in the PCCR1 register to 1 to enable PDC operation.

[3] Data reception:
Receive the data from the external I/O and wait for generation of a receive data ready interrupt (DTC/DMAC startup) or a frame end interrupt.

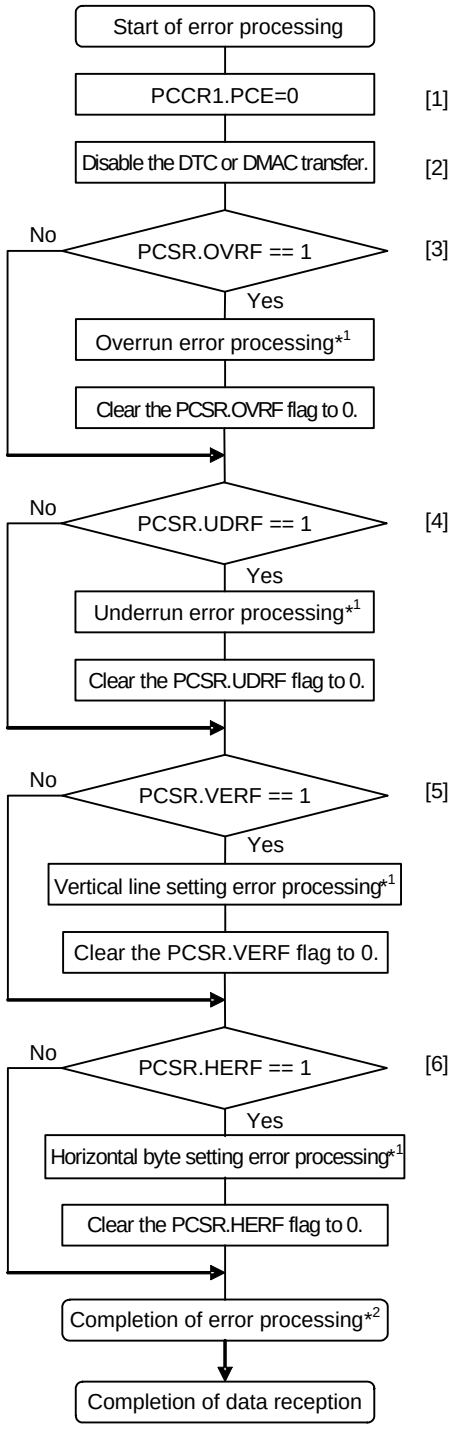
[4] Transfer by the DTC or DMAC:
Transfer the data in the PCDR register to the destination address in response to a receive data ready interrupt (DTC/DMAC startup).
Read the PCDR register in longword access and transfer 32 bytes of data per receive data ready interrupt.

[5] Frame end interrupt:
Read the FEMPF flag in the PCSR register and verify completion of the DTC or DMAC transfer.
If an underrun occurs during DTC or DMAC transfer, setting of the FEMPF flag may not proceed. When an underrun occurs, clear the FEF flag to 0 and branch to the appropriate error processing routine.

[6] Completion of data reception:
After completion of the transfer, clear the PCE bit in the PCCR1 register to 0, and then clear the FEF flag in the PCSR register to 0. This completes handling of the frame end interrupt and data reception.

Figure 51.19 Example of Flows of Operations

Figure 51.20 shows an example of the flow of operations in response to an error interrupt.



[1] Disabling of PDC operation:
Clear the PCE bit in the PCCR1 register to 0 to disable PDC operation.

[2] Disabling of the DTC or DMAC transfer:
Disable the transfer of the DTC or DMAC.

[3] Checking the overrun flag:
Read the PCSR register to check the state of The OVRF flag. If the flag is set, processing to handle the overrun error proceeds and the flag is then cleared.

[4] Checking the underrun flag:
Read the PCSR register to check the state of The UDRF flag. If the flag is set, processing to handle the underrun error proceeds and the flag is then cleared.

[5] Checking the vertical line setting error flag:
Read the PCSR register to check the state of The VERF flag. If the flag is set, processing to handle the vertical line setting error proceeds and the flag is then cleared.

[6] Checking the horizontal byte setting error flag:
Read the PCSR register to check the status of The HERF flag. If the flag is set, processing to handle the horizontal byte setting error proceeds and the flag is then cleared.

Note 1. Processing for each type of error is defined by the user, so the user needs to prepare error processing for each.

Note 2. If the CPU, DTC, or DMAC reads the PCDR register after an error interrupt has occurred in response to an interrupt source other than an underrun, an underrun may occur. If an underrun occurs on completion of error processing, run the error processing again and clear the UDRF flag.
Since an underrun after error processing still requires detection, do not prohibit the underrun interrupt before the error processing.

Figure 51.20 Example of Error Processing Flow

51.3.10 Interrupt Source

The interrupt sources of the PDC are receive data ready, frame end, overrun, underrun, vertical line number setting error, and horizontal byte number setting error. The PDC can start up the DTC or DMAC in response to a receive data ready interrupt request for the transfer of data.

Table 51.5 summarizes the interrupt sources of the PDC. When an interrupt condition listed in Table 51.5 is satisfied, the corresponding interrupt is generated. In the case of receive data ready, the interrupt source flag is cleared by reading of the PCDR register. For the interrupt source flag for frame end, the FEF flag in the PCSR register is cleared. For an overrun, underrun, vertical line number setting error, or a horizontal byte number setting error, the flags must be checked to identify the error source flag because their interrupt vectors are allocated to the same address by the PCERI. Once identified, the corresponding error interrupt source flag (the OVRF, UDRF, VERF, or HERF flag) in the PCSR register should be cleared.

When the DTC or DMAC is to handle data transfer, whichever is selected should be set up first. After enabling the block to handle transfer, set up the PDC. For descriptions of how to set up the DTC and DMAC, see section 18, DMA Controller (DMACAa) and section 20, Data Transfer Controller (DTCa).

In addition, for receive data ready, if the ICU.IRn.IR flag is 1, the interrupt request signal is retained internally but an interrupt request is not output to the ICU, even if the interrupt condition is satisfied. In this case, however, only one interrupt request signal can be retained internally. If the ICU.IRn.IR flag is 0, the retained interrupt request signal is output to the ICU. After completion of output, the request flag is automatically cleared. An interrupt request signal retained internally can also be cleared by setting the corresponding interrupt enable bit (the DFIE bit in the PCCR0 register) to 0.

When the receive data ready interrupt is disabled from the enabled state, set the ICU.IRn.IR flag to 0 according to the following procedure.

1. Set the IERn.IENj bit to the value that disables interrupt requests.
2. Set the receive data ready interrupt enable bit (the DFIE bit) to “disabled” and read out the register after writing to verify that the bit has the new value.
3. Set the ICU.IRn.IR flag to 0.

Table 51.5 PDC Interrupt Source

Interrupt Source	Abbre -viation	Interrupt Conditions	DTC/DMAC Startup
Receive Data Ready	PCDFI	Receive data ready occurring while the DFIE bit in the PCCR0 register is 1.	Possible
Frame End	PCFEI	Frame end occurring while the FEIE bit in the PCCR0 register is 1.	Impossible
Errors	PCERI	An overrun occurring while the OVIE bit in the PCCR0 register is 1. An underrun occurring while the UDRIE bit in the PCCR0 register is 1. A vertical line number setting error occurring while the VERIE bit in the PCCR0 register is 1. A horizontal byte number setting error occurring while the HERIE bit in the PCCR0 register is 1.	Impossible

51.3.11 Reset State

Resetting of the PDC is divided into two types, PDC reset and other reset. Other resets include RES# pin reset, power-on reset, voltage monitoring reset 0, voltage monitoring reset 1, voltage monitoring reset 2, deep software standby reset, independent watchdog timer reset, watchdog timer reset, and software reset. Table 51.6 shows the range and states following the two types of reset.

Table 51.6 Reset State

	PDC Reset	Other reset
PCCR0	Retained	Reset
PCCR1	Retained	Reset
PCSR	Reset	Reset
PCMONR	Retained	Reset
PCDR	Retained	Reset
VCR	Retained	Reset
HCR	Retained	Reset

51.4 Usage Notes

51.4.1 Setting of the Module Stop Function

The module stop control register B (MSTPCRB) enables or disables operation of the PDC. Operation of the PDC is stopped when the value is that following a reset. The register becomes accessible following release from the module stop state. For details, see section 11, Low Power Consumption.

51.4.2 Notes on the Power Consumption Reduction Function

When power consumption by the PDC is to be reduced by using the power consumption reduction function, set the PCE bit in the PCCR1 register to 0 to disable operations for reception, and set the PCKE bit in the PCCR0 register to 0 to disable input through the PIXCLK pin. After that, use the power consumption reduction function.
If the setting of the PCKOE bit in the PCCR0 register is 1, it should be set to 0 to stop output of the PCKO signal, and input through the PIXCLK pin should be disabled in the way described above. After that, use the power consumption reduction function.
On return from the low power consumption state, set the PCKE bit to 1, and after enabling input through the PIXCLK pin, use the PRST bit to initialize the PDC.

51.4.3 Notes on Error Interrupts

When an error interrupt occurs, there is a possibility that the DTC or DMAC might be transmitting parallel data depending on their operation state. Therefore, transmitting executed by the DTC or DMAC should be prohibited after the PDC operation is prohibited at the top of the error interrupt processing routine (PCCR1.PCE = 0).

51.4.4 Notes on Use of the DTC

When the DTC is used with the receive data ready interrupt, set the DISEL bit in the MRB register to 0 and the SZ bit in the MRA register to 10b.
The maximum number of blocks the DTC can transfer in block transfer mode is 65536. If 32 bytes are transferred per block transfer, this represents a total of up to 2097152 bytes. If more data are to be transferred, set up the DTC again during the horizontal blanking period.

51.4.5 Notes on Use of the DMAC

When the DMAC is used with the receive data ready interrupt, set the DISEL bit in the DMCSL register to 0, set the SZ bit in the DMTMD register to 10b, and set the IPRn.IPR[3:0] bit responding to an ICU receive data ready interrupt to level 0 (the interrupt is prohibited).
The maximum number of blocks the DMAC can transfer in block transfer mode is 65536. If 32 bytes are transferred per block transfer, this represents a total of up to 2097152 bytes. If more data are to be transferred, set up the DMAC again during the horizontal blanking period.

51.4.6 Notes on Start of Transfer

When transfer starts while the ICU.IRn.IR flag is 1, an interrupt request signal is internally retained after the start of transfer. This may cause the ICU.IRn.IR flag to behave in an unexpected way.
In such cases, therefore, clear the interrupt request flag by following the procedures below before enabling operations (i.e. before setting the PCE bit in the PCCR1 to 1).

(1) Ensure that transfer is stopped (the PCE bit in the PCCR1 is 0).
(2) Set the corresponding interrupt enable bit (the DFIE bit in the PCCR0 register) to 0.
(3) Read out the corresponding interrupt enable bit (the DFIE bit in the PCCR0 register) to ensure that it is 0.
(4) Set the ICU.IRn.IR flag to 0.

52. Boundary Scan

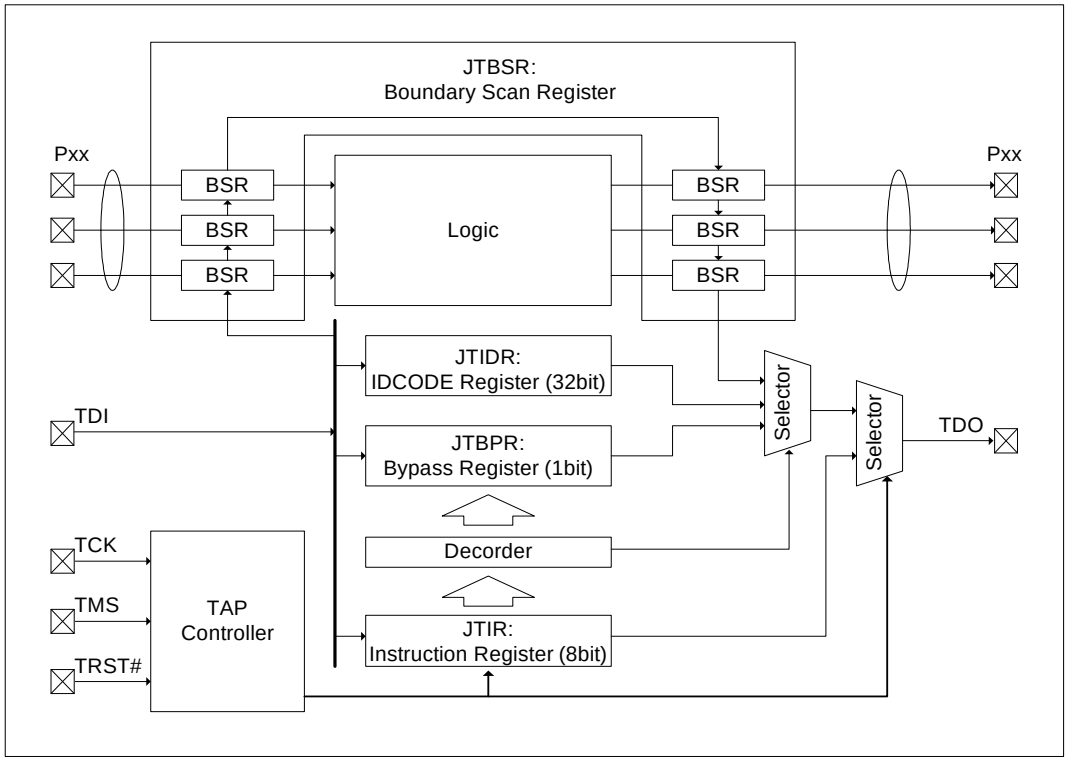
This MCU has boundary scan function.
The boundary scan is a serial I/O interface based on the JTAG (Joint Test Action Group, IEEE Std.1149.1 and IEEE Standard Test Access Port and Boundary-Scan Architecture).

52.1 Overview

Table 52.1 lists the specifications of boundary scan.
Figure 52.1 shows a block diagram of the boundary scan function.

Table 52.1 Specifications of Boundary Scan

Item	Description
Boundary scan enabled/disabled	Boundary scan is enabled when the RES# pin and the BSCANP pin are driven high and the EMLE pin is driven low.
Dedicated boundary scan pins	The following pins are dedicated for the JTAG, when boundary scan function is enabled (TDO/TCK/TDI/TMS/TRST#). 177-pin TFLGA/176-pin LFBGA: PF0/PF1/PF2/PF3/PF4 145-pin TFLGA: P26/P27/P30/P31/P34
Six test modes	• BYPASS mode • EXTEST mode • SAMPLE/PRELOAD mode • CLAMP mode • HIGHZ mode • IDCODE mode



JTBPR: Bypass register
JTBSR: Boundary scan register
JTIR: Instruction register
JTIDR: ID code register

Figure 52.1 Block Diagram of JTAG

Table 52.2 shows the I/O pins used in the boundary scan function.

Table 52.2 Pin Configuration

Pin Name	I/O	Description
TCK	Input	Test clock input pin Clock signal for boundary scan. Input the clock the duty cycle of which is 50 percent when boundary scan function is used.
TMS	Input	Test mode select pin
TDI	Input	Test data input pin
TDO	Output	Test data output pin
TRST#	Input	Test reset input pin

52.2 Register Descriptions

Table 52.3 lists the boundary scan registers.

Table 52.3 List of Boundary Scan Registers

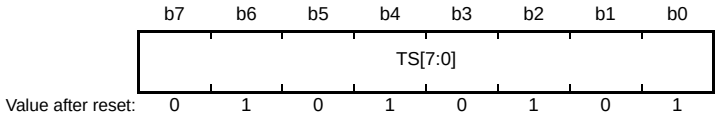
Register Name	Symbol	Value after Reset
Instruction register	JTIR	55h
ID code register	JTIDR	0819 3447h
Bypass register	JTBPR	Undefined
Boundary scan register	JTBSR	Undefined

Instructions can be input to the JTIR register via the TDI pin by serial transfer.
The JTBPR register, which is a 1-bit register, is connected between the TDI and TDO pins in BYPASS mode.
The JTBSR register, which is configured according to Table 52.6 and Table 52.7, is connected between the TDI and TDO pins when test data are being shifted in.
None of the registers is accessible from the CPU.
Table 52.4 shows the availability of serial transfer for the registers.

Table 52.4 Serial Transfer for the Registers

Register Name	Serial Input	Serial Output
Instruction register (JTIR)	Available	Available
ID code register (JTIDR)	Available	Available
Bypass register (JTBPR)	Available	Available
Boundary scan register (JTBSR)	Available	Available

52.2.1 Instruction Register (JTIR)



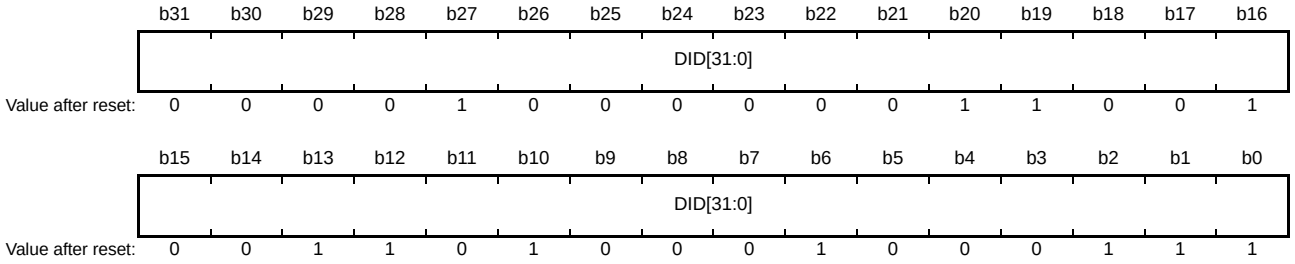
Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TS[7:0]	Test Bit Set	The command configuration is as shown in Table 52.5.	—

Table 52.5 Command Configuration

TS7	TS6	TS5	TS4	TS3	TS2	TS1	TS0	Instruction
0	0	0	0	0	0	0	0	EXTEST
0	1	0	0	0	0	0	0	SAMPLE/PRELOAD
0	1	0	1	0	1	0	1	IDCODE (initial value)
1	1	0	1	0	0	0	0	CLAMP
1	0	0	0	0	0	0	0	HIGHZ
1	1	1	1	1	1	1	1	BYPASS
Other than above								Reserved

JTAG instructions can be transferred to the JTIR register by serial input from the TDI pin.
The JTIR register is initialized when the TRST# pin is driven low, or when the TAP controller is in the Test-Logic-Reset state.

52.2.2 ID Code Register (JTIDR)



Bit	Symbol	Bit Name	Description	R/W
b31 to b0	DID[31:0]	Reserved	JTIDR is a register with the fixed value that indicates the device IDCODE.	—

JTIDR data is output from the TDO pin when the IDCODE instruction has been executed.

52.2.3 Bypass Register (JTBPR)

The JTBPR register is a 1-bit register and is connected between the TDI and TDO pins when the JTIR register is set to BYPASS mode.
The JTBPR register cannot be read from or written to by the CPU.

52.2.4 Boundary Scan Register (JTBSR)

The JTBSR register is a shift register to control the external input and output pins of this LSI and is distributed across the pads.
The EXTEST, SAMPLE/PRELOAD, CLAMP, and HIGHZ instructions are issued to apply the JTBSR register in boundary-scan testing.
Table 52.6 and Table 52.7 show the correspondence between the JTBSR bits and the pins of this LSI.
The value after reset is undefined.

52.3 Operations

The boundary scan functionality is valid when the RES# pin is driven high, the EMLE pin is driven low, and the BSCANP pin is driven high.

52.3.1 TAP Controller

Figure 52.2 shows the state transition diagram of the TAP controller.

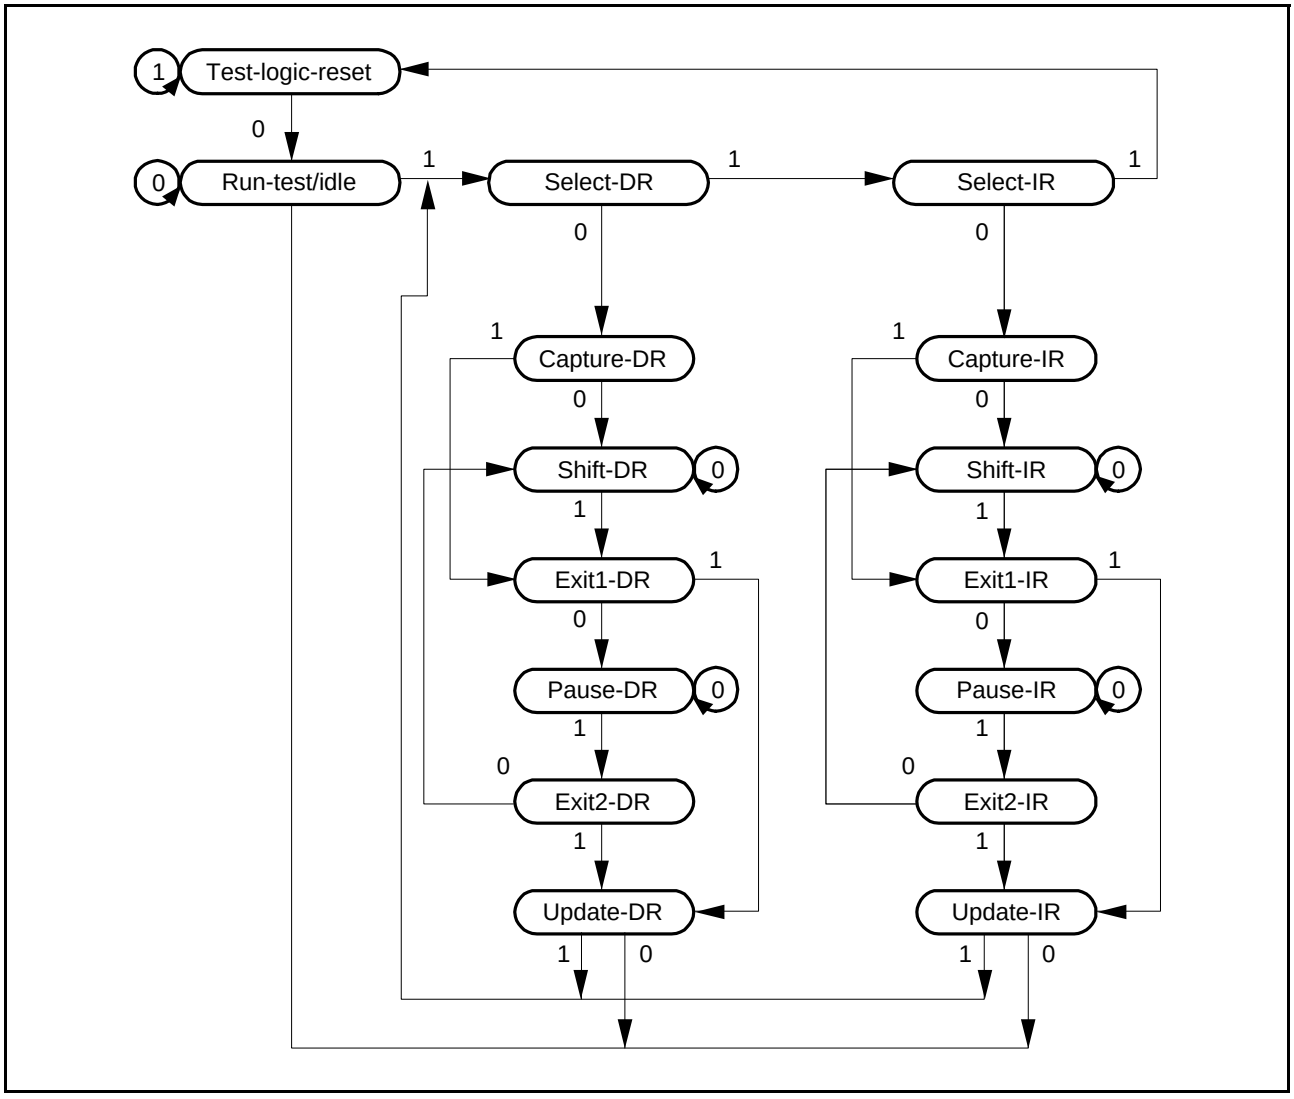

Figure 52.2 State Transition Diagram of TAP Controller

52.3.2 List of Commands

(1) BYPASS [Instruction Code: 1111 1111b]

The BYPASS instruction is an instruction that drives the bypass register (JTBPR). This instruction shortens the shift path, facilitating the transfer of serial data to other LSIs on a printed-circuit board at higher speeds. While this instruction is being executed, the test circuit has no effect on the system circuits.
The bypass register (JTBPR) is connected between the TDI and TDO pins. Bypass operation is initiated from shift-DR operation. The TDO is low in the first clock cycle in the shift-DR state; in the subsequent clock cycles, the TDI signal is output on the TDO pin.

(2) EXTEST [Instruction Code: 0000 0000b]

The EXTEST instruction is used to test external circuits when this LSI is installed on the printed circuit board. If this instruction is executed, output pins are used to output test data (specified by the SAMPLE/PRELOAD instruction) from the boundary scan register to the print circuit board, and input pins are used to input test result.

(3) SAMPLE/PRELOAD [Instruction Code: 0100 0000b]

The SAMPLE/PRELOAD instruction is used to input data from the LSI internal circuits to the boundary scan register, output data from scan path, and reload the data to the scan path. While this instruction is executed, input signals are directly input to the LSI and output signals are also directly output to the external circuits. The LSI system circuit is not affected by this instruction.
In SAMPLE operation, the boundary scan register latches the snap shot of data transferred from input pins to internal circuit or data transferred from internal circuit to output pins. The latched data is read from the scan path. The scan register latches the snap data at the rising edge of the TCK in Capture-DR state. The scan register latches snap shot without affecting the LSI normal operation.
In PRELOAD operation, initial value is written from the scan path to the parallel output latch of the boundary scan register prior to the EXTEST instruction execution. If the EXTEST is executed without executing this PRELOAD operation, undefined values are output from the beginning to the end (transfer to the output latch) of the EXTEST sequence. (In EXTEST instruction, output parallel latches are always output to the output pins.)

(4) IDCODE [Instruction Code: 0101 0101b]

When the IDCODE instruction is selected, IDCODE register value is output to the TDO in Shift-DR state of the TAP controller. In this case, IDCODE register value is output from the LSB. During this instruction execution, test circuit does not affect the system circuit. JTIR is initialized by the IDCODE instruction in Test-Logic-Reset state of the TAP controller.

(5) CLAMP [Instruction Code: 1101 0000b]

When the CLAMP instruction is selected, output pins output the boundary scan register value which was specified by the SAMPLE/PRELOAD instruction in advance. While the CLAMP instruction is selected, the status of boundary scan register is maintained regardless of the TAP controller state.
BYPASS is connected between TDI and TDO, the same operation as BYPASS instruction can be achieved.

(6) HIGHZ [Instruction Code: 1000 0000b]

When the HIGHZ instruction is selected, all output pins enter high-impedance state. While the HIGHZ instruction is selected, the status of boundary scan register is maintained regardless of the state of the TAP controller.
BYPASS is connected between TDI and TDO pins, leading to the same operation as when the BYPASS instruction has been selected.

52.4 Usage Notes

(1) Pin serial transfer, data are input or output in LSB order (see Figure 52.3).

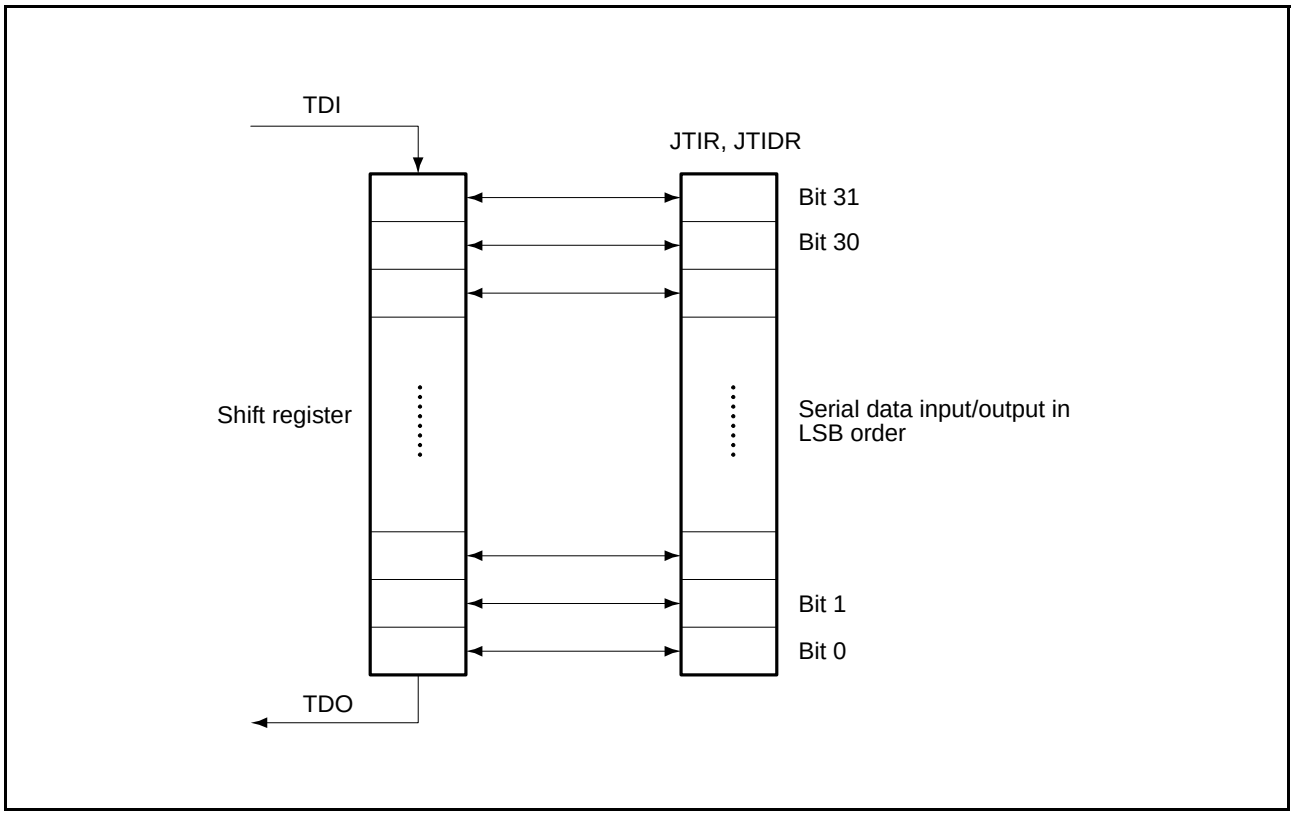

Figure 52.3 Serial Data Input/Output

(2) Pins of the boundary scan (TCK, TDI, TMS, and TRST#) have to be pulled up by pull-up resistors.
However, handle the #TRST pin in the way described in the manual for the given on-chip emulator if an on-chip emulator is in use.
If the #TRST pin is pulled down but a boundary scan is to proceed, ensure that the #TRST pin is also controllable.

(3) Power supply pins (VCC, VCL, VSS, AVCC0, AVCC1, AVSS0, AVSS1, VCC_USB, VSS_USB, AVCC_USBA, AVSS_USBA, PVSS_USBA, VCC_USBA VSS1_USBA, and VSS2_USBA) cannot be boundary-scanned.

(4) Analog reference pins (VREFH0, VREFL0, VBATT, USBA_RREF) cannot be boundary-scanned.

(5) Clock pins (EXTAL, XTAL, XCIN, and XCOUT) cannot be boundary-scanned.

(6) Reset signal (RES#) cannot be boundary-scanned.

(7) USB dedicated pins (USB0_DP, USB0_DM, USBA_DP, USBA_DM) cannot be boundary-scanned.

(8) The on-chip emulator enable pin (EMLE) cannot be boundary-scanned.

(9) The boundary-scan pin (BSCANP) cannot be boundary-scanned.

(10) The boundary-scan pins (TCK, TMS, TRST#, TDI, and TDO) cannot be boundary-scanned.

(11) The boundary-scan facility is not available when the chip is in the states below.

- Reset state
- Software standby or deep software standby

(12) For a pin that incorporates open-drain functionality and for which the open-drain function is enabled, if the boundary-scan function sets the corresponding bit in the output scan register and output enable register to 1, executing an EXTEST, CLAMP, or SAMPLE/PRELOAD instruction makes the pin output the high level rather than placing it in the high-impedance state.

(13) Be sure to satisfy the standards for the boundary scan function when multiplex ports are used. Figure 52.4 (1) shows the pin configuration of the multiplex port pins in combination with the RIIC pins (P12, P13, P16, and P17).

When the boundary scan function is used with pins P12, P13, P16, and P17 to be used as RIIC pins (SCL0[FM+], SCL2, SDA0[FM+], and SDA2), the conflict with open-drain output or sneak current might be generated.

(14) Figure 52.4 (2) shows the pin configuration of the pins P00 to P02, P40 to P47, P90 to P93, PD0 to PD7, and PE0 to PE7. When the boundary scan function is used with pins P00 to P02, P40 to P47, P90 to P93, PD0 to PD7, and PE0 to PE7 to be used as AD input pins (AN000 to AN007, ANEX0, ANEX1, and AN100 to AN120), the conflict with open-drain output or sneak current might be generated.

(15) Figure 52.4 (3) shows the pin configuration of pins P03 and P05. When the boundary scan function is used with pins P03 and P05 to be used as DA output pins (DA0 and DA1), the conflict with the DA output or sneak current might be generated.

57. 12-Bit A/D Converter (S12ADC)

57.1 Overview

This MCU incorporates two units of a 12-bit successive approximation A/D converter. In unit 0, up to eight analog input channels are selectable. In unit 1, up to 21 analog input channels, temperature sensor output, and internal reference voltage are selectable for conversion.

The 12-bit A/D converter converts a maximum of 8 and 21 analog input channels (unit 0 and 1, respectively), temperature sensor output, and internal reference voltage, which have been selected, into a 12-bit digital value through successive approximation.

The A/D converter has three operating modes: single scan mode in which the analog inputs of up to 8 (unit 0) and 21 (unit 1) channels arbitrarily selected are converted for only once in ascending channel order; continuous scan mode in which the analog inputs of up to 8 (unit 0) and 21 (unit 1) channels arbitrarily selected are continuously converted in ascending channel order; and group scan mode in which up to 8 (unit 0) and 21 (unit 1) channels of the analog inputs are arbitrarily divided into two groups (group A and group B) and converted in ascending channel order in each group.

In group scan mode, the conditions for scanning start of group A and group B (synchronous trigger) can be independently selected, thus allowing A/D conversion of group A and group B to be started independently. When group A priority control is selected along with operation as described above, if a request to start scanning for group A (a synchronous or asynchronous trigger) is received during A/D conversion for group B, the conversion operation for group B is discontinued and the conversion for group A starts, which is given priority.

In double trigger mode, one analog input channel arbitrarily selected is converted in single scan mode or group scan mode (group A), and the resulting data of A/D conversion started by the first and second synchronous triggers are stored into different registers (duplication of A/D conversion data).

Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages internally generated in the 12-bit A/D converter is converted.

The temperature sensor output and internal reference voltage can be selected at the same time as the analog input of channels, and A/D conversion of the analog input of channels, the temperature sensor output, and the internal reference voltage is performed in that order.

A/D conversion of the extended analog input is independently performed.

Table 57.1 lists the specifications of the 12-bit A/D converter and Table 57.2 indicates the functions of the 12-bit A/D converter. Figure 57.1 shows a block diagram of the 12-bit A/D converter (unit 0) and Figure 57.2 shows a block diagram of the 12-bit A/D converter (unit 1).

Table 57.1 Specifications of 12-Bit A/D Converter (1/2)

Item	Specifications
Number of units	Two units
Input channels	Unit 0: Up to eight channels Unit 1: Up to 21 channels + one extended
Extended analog function	Temperature sensor output, internal reference voltage
A/D conversion method	Successive approximation method
Resolution	12 bits
Conversion time	0.48 µs per channel (for 12-bit conversion) 0.45 µs per channel (for 10-bit conversion) 0.42 µs per channel (for 8-bit conversion) (when A/D conversion clock ADCLK = 60 MHz)
A/D conversion clock	Peripheral module clock PCLKB*1 and A/D conversion clock ADCLK*1 can be set so that the frequency division ratio should be one of the following. PCLKB to ADCLK frequency division ratio = 1:1, 1:2, 1:4, 1:8 ADCLK is set using the clock generation circuit (CPG).
Data registers	• 29 registers for analog input (8 for unit 0 and 21 for unit 1), 1 for A/D-converted data duplication in double trigger mode in each unit, and 2 for A/D-converted data duplication during extended operation in double trigger mode in each unit • One register for temperature sensor output (in unit 1 only) • One register for internal reference voltage (in unit 1 only) • The results of A/D conversion are stored in 12-bit A/D data registers. • 8-, 10-, and 12-bit accuracy output for the results of A/D conversion • The value obtained by adding up A/D-converted results is stored as a value in the number of bit for conversion accuracy + 2 bits in the A/D data registers in A/D-converted value addition mode. • Double trigger mode (selectable in single scan and group scan modes): The first piece of A/D-converted analog-input data on one selected channel is stored in the data register for the channel, and the second piece is stored in the duplication register. • Extended operation in double trigger mode (available for specific triggers): A/D-converted analog-input data on one selected channel is stored in the duplication register that is prepared for each type of trigger.
Operating modes	• Single scan mode: A/D conversion is performed only once on the analog inputs of up to 8 (unit 0) and 21 (unit 1) channels arbitrarily selected, on the temperature sensor output (in unit 1 only), and on the internal reference voltage (in unit 1 only). A/D conversion is performed only once on the extended analog input (in unit 1 only). • Continuous scan mode: A/D conversion is performed repeatedly on the analog inputs of up to 8 (unit 0) and 21 (unit 1) channels arbitrarily selected, on the temperature sensor output (in unit 1 only), and on the internal reference voltage (in unit 1 only). A/D conversion is performed repeatedly on the extended analog input (in unit 1 only). • Group scan mode: Analog inputs of up to 8 (unit 0) and 21 (unit 1) channels arbitrarily selected, the temperature sensor output (in unit 1 only), and the internal reference voltage (in unit 1 only) are divided into group A and group B, and A/D conversion of the analog input selected on a group basis is performed only once. The conditions for scanning start of group A and group B (synchronous trigger) can be independently selected, thus allowing A/D conversion of group A and group B to be started independently. • Group scan mode (when group A is given priority): If a group A trigger (synchronous or asynchronous) is input during A/D conversion on group B, the A/D conversion on group B is stopped and A/D conversion is performed on group A. Restart (rescan) of A/D conversion on group B after completion of A/D conversion on group A can be set.
Conditions for A/D conversion start	• Software trigger • Synchronous trigger Trigger by the multi-function timer pulse unit (MTU), the general-purpose PWM timer (GPT), the event link controller (ELC), 8-bit timer (TMR), and 16-bit timer pulse unit (TPU). • Asynchronous trigger A/D conversion can be triggered by the external trigger pins, ADTRG0# (unit 0) and ADTRG1# (unit 1).

Table 57.1 Specifications of 12-Bit A/D Converter (2/2)

Item	Specifications
Function	• Sample-and-hold function • Channel-dedicated sample-and-hold function (3 channels for unit 0 only; continuous sampling can be set) • Variable sampling state count • Self-diagnosis of 12-bit A/D converter • Selectable A/D-converted value addition mode or average mode • Analog input disconnection detection function (Discharge function/precharge function) • Double trigger mode (duplication of A/D conversion data) • Switching function of 8-, 10-, and 12-bit conversion*2 • Automatic clear function of A/D data registers • Extended analog input function • Digital comparison (window function can be selected)
Interrupt source	• In the modes except double trigger mode and group scan mode, A/D scan end interrupt (S12ADI) request can be generated on completion of single scan. • In double trigger mode, A/D scan end interrupt (S12ADI) request can be generated on completion of double scan. • In group scan mode, an A/D scan end interrupt (S12ADI) request can be generated on completion of group A scan, whereas an A/D scan end interrupt for group B (S12GBADI) request can be generated on completion of group B scan. • When double trigger mode is selected in group scan mode, A/D scan end interrupt (S12ADI) request can be generated on completion of double scan of group A, whereas A/D scan end interrupt specially for group B (S12GBADI) request can be generated on completion of group B scan. • A compare interrupt (S12CMPI) can be generated in response to matches with a condition for comparison by digital comparison. • The S12ADI and S12GBADI interrupts can activate the DMA controller (DMAC) and the data transfer controller (DTC).
Event link function	• An ELC event is generated on completion of scans other than group B scan in group scan mode. • Scan can be started by a trigger output by ELC.
Low power consumption function	• Module stop state can be specified.*3

Note 1. Peripheral module clock PCLKB is set according to the setting of the SCKCR.PCKB[3:0] bits and A/D conversion clock ADCLK is set according to the setting of the SCKCR.PCKC[3:0] bits and the SCKCR.PCKD[3:0] bits in unit 0 and unit 1, respectively.
Note 2. When A/D conversion accuracy is modified, A/D conversion time is also changed. See section 57.3.7, Analog Input Sampling and Scan Conversion Time for details.
Note 3. See section 11, Low Power Consumption for details.

Table 57.2 Functions of 12-Bit A/D Converter (1/2)

Item			Unit 0 (S12AD)	Unit 1 (S12AD1)
Analog input channel			AN000 to AN007	AN100 to AN120 Internal reference voltage Temperature sensor output Extended input
Conditions for A/D conversion start	Software	Software trigger	Enabled	Enabled
	External trigger	Trigger input pin	ADTRG0#	ADTRG1#
	Synchronous trigger (trigger from MTU)	Compare match with or input capture to MTU0.TGRA	TRGA0N	TRGA0N
		Compare match with or input capture to MTU1.TGRA	TRGA1N	TRGA1N
		Compare match with or input capture to MTU2.TGRA	TRGA2N	TRGA2N
		Compare match with or input capture to MTU3.TGRA	TRGA3N	TRGA3N
		Compare match with or input capture to MTU4.TGRA or underflow (trough) of MTU4.TCNT in complementary PWM mode	TRGA4N	TRGA4N
		Compare match with or input capture to MTU6.TGRA	TRGA6N	TRGA6N
		Compare match with or input capture to MTU7.TGRA or underflow (trough) of MTU7.TCNT in complementary PWM mode	TRGA7N	TRGA7N
		Compare match with MTU0.TGRE	TRG0N	TRG0N
		Compare match between MTU4.TADCORA and MTU4.TCNT	TRG4AN	TRG4AN
		Compare match between MTU4.TADCORB and MTU4.TCNT	TRG4BN	TRG4BN
		Compare match between MTU4.TADCORA and MTU4.TCNT or compare match between MTU4.TADCORB and MTU4.TCNT	TRG4AN or TRG4BN	TRG4AN or TRG4BN
		Compare match between MTU4.TADCORA and MTU4.TCNT and compare match between MTU4.TADCORB and MTU4.TCNT (when interrupt skipping function 2 is used)	TRG4ABN	TRG4ABN
		Compare match between MTU7.TADCORA and MTU7.TCNT	TRG7AN	TRG7AN
		Compare match between MTU7.TADCORB and MTU7.TCNT	TRG7BN	TRG7BN
		Compare match between MTU7.TADCORA and MTU7.TCNT or compare match between MTU7.TADCORB and MTU7.TCNT	TRG7AN or TRG7BN	TRG7AN or TRG7BN
		Compare match between MTU7.TADCORA and MTU7.TCNT and compare match between MTU7.TADCORB and MTU7.TCNT (when interrupt skipping function 2 is used)	TRG7ABN	TRG7ABN
	Synchronous trigger (trigger from GPT)	Compare match with GTP0.GTADTRA	GTADTRA0N	GTADTRA0N
		Compare match with GPT0.GTADTRB	GTADTRB0N	GTADTRB0N
		Compare match with GPT1.GTADTRA	GTADTRA1N	GTADTRA1N
		Compare match with GPT1.GTADTRB	GTADTRB1N	GTADTRB1N
		Compare match with GPT2.GTADTRA	GTADTRA2N	GTADTRA2N
		Compare match with GPT2.GTADTRB	GTADTRB2N	GTADTRB2N
		Compare match with GPT3.GTADTRA	GTADTRA3N	GTADTRA3N
		Compare match with GPT3.GTADTRB	GTADTRB3N	GTADTRB3N
		Compare match with GTP0.GTADTRA or compare match with GTP0.GTADTRB	GTADTRA0N or GTADTRB0N	GTADTRA0N or GTADTRB0N
		Compare match with GTP1.GTADTRA or compare match with GTP1.GTADTRB	GTADTRA1N or GTADTRB1N	GTADTRA1N or GTADTRB1N
		Compare match with GTP2.GTADTRA or compare match with GTP2.GTADTRB	GTADTRA2N or GTADTRB2N	GTADTRA2N or GTADTRB2N
		Compare match with GTP3.GTADTRA or compare match with GTP3.GTADTRB	GTADTRA3N or GTADTRB3N	GTADTRA3N or GTADTRB3N
	Synchronous trigger (trigger from TMR)*1	Compare match between TMR0.TCORA and TMR0.TCNT	TMTRG0AN_0	TMTRG0AN_0
		Compare match between TMR2.TCORA and TMR2.TCNT	TMTRG0AN_1	TMTRG0AN_1
	Synchronous trigger (trigger from TPU)*1	Compare match with or input capture to TPU0.TGRA, compare match with or input capture to TPU1.TGRA, compare match with or input capture to TPU2.TGRA, compare match with or input capture to TPU3.TGRA, or compare match with or input capture to TPU4.TGRA	TPTRGAN_0	TPTRGAN_0
		Compare match with or input capture to TPU0.TGRA0	TPTRG0AN_0	TPTRG0AN_0

Table 57.2 Functions of 12-Bit A/D Converter (2/2)

Item			Unit 0 (S12AD)	Unit 1 (S12AD1)
Conditions for A/D conversion start	Synchronous trigger (trigger from ELC)	ELC trigger	ELCTRG0	ELCTRG1
Channel-dedicated sample-and-hold function	Target channel		AN000 to AN002	—
Interrupt			S12ADI S12GBADI S12CMPI	S12ADI1 S12GBADI1 S12CMPI1
Setting of module stop function*2			MSTPCRA.MSTPA17 bit	MSTPCRA.MSTPA16 bit

Note 1. “0” and “1” added to synchronous triggers indicate the number of unit. For the settings to output synchronous triggers, see the sections related to A/D converter startup of the responding modules.

Note 2. See section 11, Low Power Consumption for details.

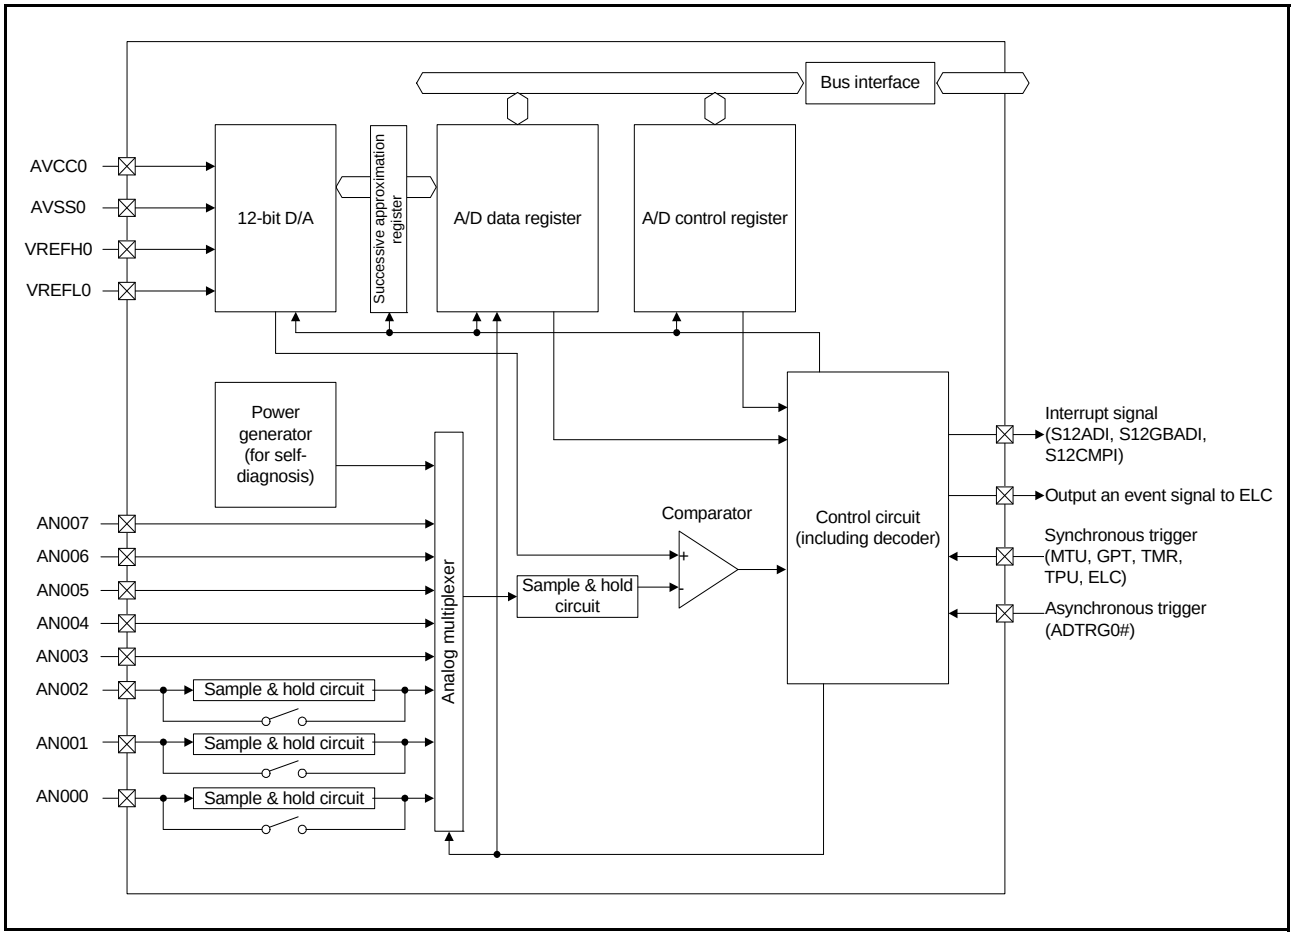

Figure 57.1 Block Diagram of 12-Bit A/D Converter (Unit 0)

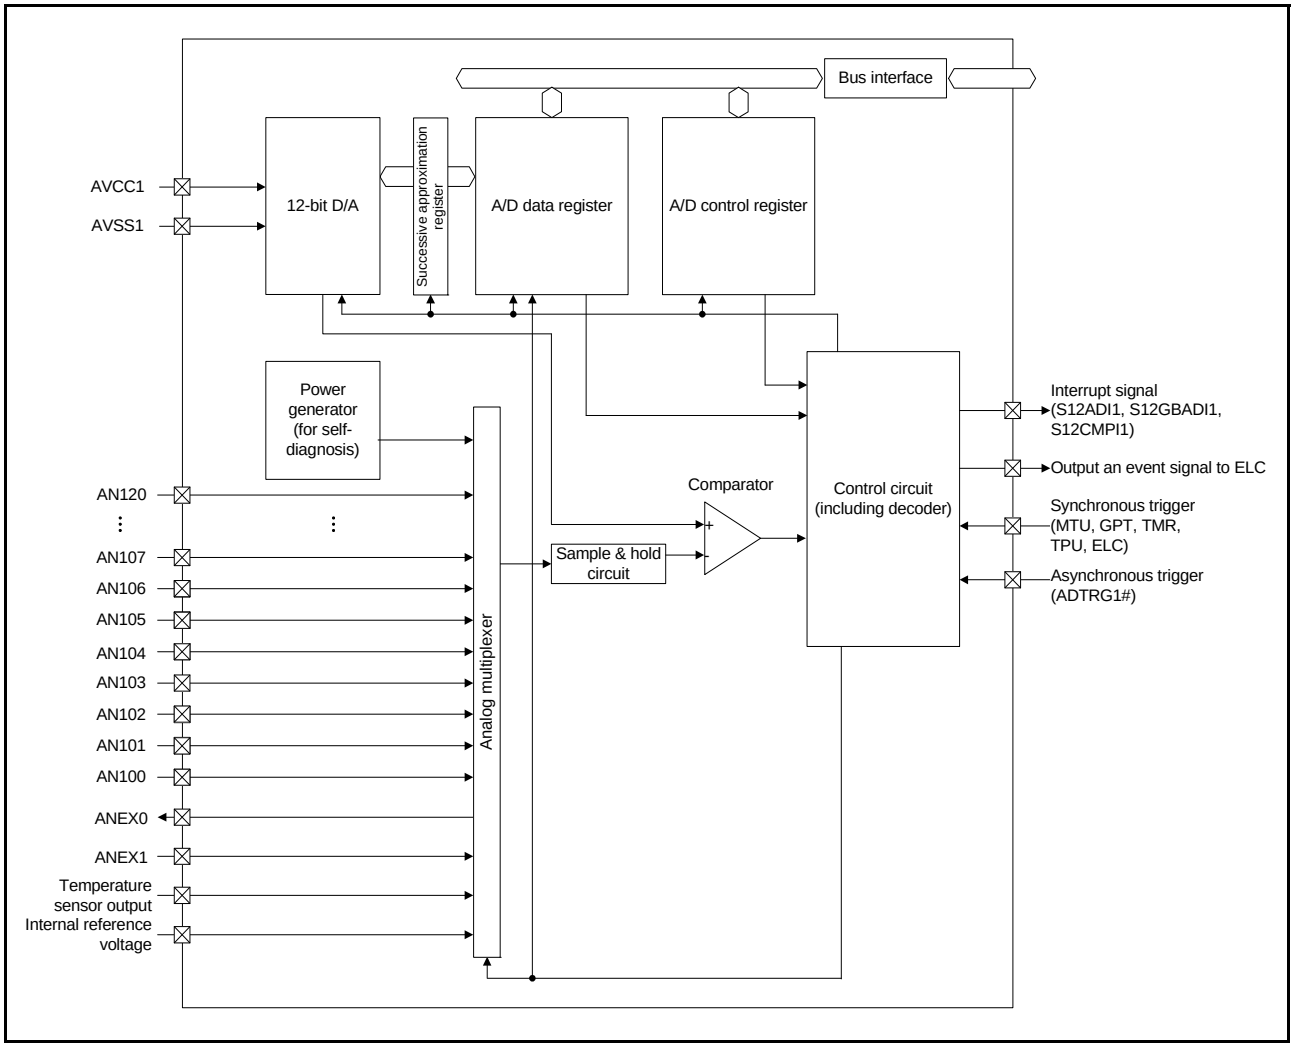

Figure 57.2 Block Diagram of 12-Bit A/D Converter (Unit 1)

Table 57.3 lists the I/O pins of the 12-bit A/D converter.

Table 57.3 I/O Pins of 12-Bit A/D Converter

Unit	Pin Name	I/O	Function
Unit 0	AVCC0	Input	Analog block power supply pin
	AVSS0	Input	Analog block ground pin
	VREFH0	Input	Reference power supply pin
	VREFL0	Input	Reference power supply ground pin
	AN000 to AN007	Input	Analog input pin 0 to 7
	ADTRG0#	Input	External trigger input pin for starting A/D conversion
Unit 1	AVCC1	Input	Multiplexed analog block power supply and reference power supply pin functions
	AVSS1	Input	Multiplexed analog block ground and reference power supply ground pin functions
	AN100 to AN120	Input	Analog input pin 8 to 28
	ANEX0	Output	Extended analog output pin
	ANEX1	Input	Extended analog input pin
	ADTRG1#	Input	External trigger input pin for starting A/D conversion

57.2 Register Descriptions

57.2.1 A/D Data Registers y (ADDRy), A/D Data Duplication Register (ADDBLDR), A/D Data Duplication Register A (ADDBLDRA), A/D Data Duplication Register B (ADDBLDRB), A/D Temperature Sensor Data Register (ADTSDR), A/D Internal Reference Voltage Data Register (ADOCDR)

ADDRy registers (y = 0 to 7 in unit 0; y = 0 to 20 in unit 1) are 16-bit read-only registers for storing the result of A/D conversion. The ADDBLDR register is a 16-bit read-only register for storing the result of A/D conversion in response to the second trigger in double trigger mode. The ADDBLDRA and ADDBLDRB are 16-bit read-only registers for storing the result of A/D conversion in response to the respective triggers during extended operation in double trigger mode. Register ADTSDR is a 16-bit read-only register for storing the A/D conversion result of temperature sensor output. Register ADOCDR is a 16-bit read-only register for storing the A/D result of internal reference voltage.
The formats for data in the ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, and ADOCDR registers vary according to the following conditions.

- The setting of the A/D data register format select bit (ADCER.ADRFT) (determining whether the data are flush-left or flush-right in the registers)
- The setting of the A/D data register bit-accuracy specification bits (ADCER.ADPRC[1:0]) (8-, 10-, or 12-bit is selectable.)
- The setting of the addition frequency select bits (ADADC.ADC[1:0]) (once, twice, or three times is selectable.)
- The setting of the average mode enable bit (ADADC.AVEE) (Addition or average is selectable.)

The data formats for each given condition are shown below.

(1) When A/D-converted value addition/average mode is not selected

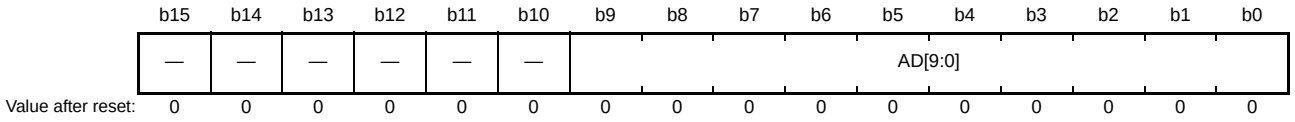
- The settings for flush-right data with 12-bit accuracy

Address(es): S12AD.ADDR0 0008 9020h to S12AD.ADDR7 0008 902Eh,
S12AD.ADDBLDR 0008 9018h, S12AD.ADDBLDRA 0008 9084h, S12AD.ADDBLDRB 0008 9086h,
S12AD1.ADDR0 0008 9120h to S12AD1.ADDR20 0008 9148h,
S12AD1.ADDBLDR 0008 9118h, S12AD1.ADDBLDRA 0008 9184h, S12AD1.ADDBLDRB 0008 9186h,
S12AD1.ADTSDR 0008 911Ah, S12AD1.ADOCDR 0008 911Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	AD[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

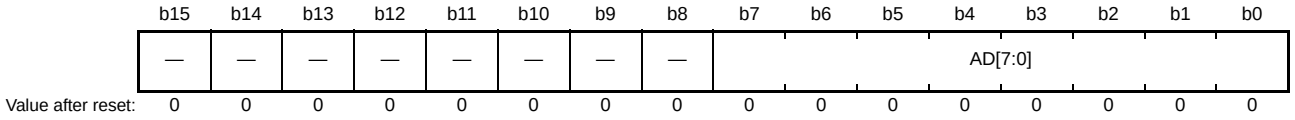
Bit	Symbol	Bit Name	Description	R/W
b11 to b0	AD[11:0]	Converted Value 11 to 0	12-bit A/D-converted value	R
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

- The settings for flush-right data with 10-bit accuracy



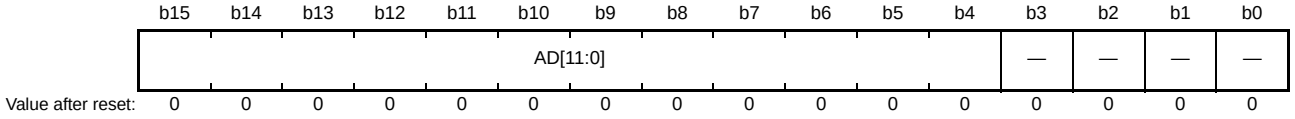
Bit	Symbol	Bit Name	Description	R/W
b9 to b0	AD[9:0]	Converted Value 9 to 0	10-bit A/D-converted value	R
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

- The settings for flush-right data with 8-bit accuracy



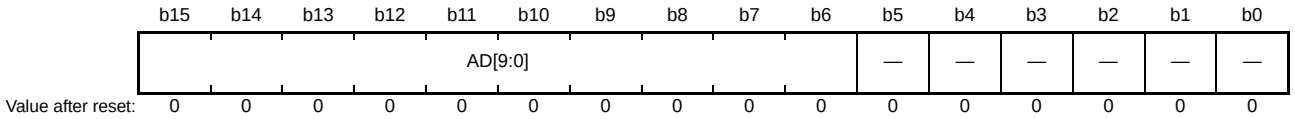
Bit	Symbol	Bit Name	Description	R/W
b7 to b0	AD[7:0]	Converted Value 7 to 0	8-bit A/D-converted value	R
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

- The settings for flush-left data with 12-bit accuracy



Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b4	AD[11:0]	Converted Value 11 to 0	12-bit A/D-converted value	R

- The settings for flush-left data with 10-bit accuracy



Bit	Symbol	Bit Name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b6	AD[9:0]	Converted Value 9 to 0	10-bit A/D-converted value	R

- The settings for flush-left data with 8-bit accuracy

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	AD[7:0]								—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	AD[7:0]	Converted Value 7 to 0	8-bit A/D-converted value	R

(2) When A/D-converted value average mode is selected

When A/D-converted value average mode is selected, the AD[11:0] bits indicate the mean of A/D-converted values on a specific channel. Even if A/D-converted value average mode is selected, the value is stored in the A/D data register according to the settings of the A/D data register format select bit in the same way as normal A/D conversion.

(3) When A/D-converted value addition mode is selected

When A/D-converted value addition mode is selected, the AD[13:0] bits indicate the value that is obtained by adding up A/D-converted values on a specific channel. In A/D-converted value addition mode, the value obtained by adding up of A/D conversion results is retained in the A/D data register as a 2-bit-extended value of the conversion accuracy specified. Even if A/D-converted value addition mode is selected, the value is stored in the A/D data register according to the settings of the A/D data register format select bits.
The data formats for each given condition are shown below.

- The settings for flush-right data with 12-bit accuracy
  (when A/D-converted value addition mode is selected)

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	AD[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

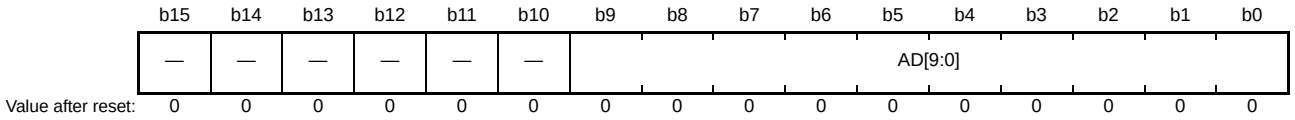
Bit	Symbol	Bit Name	Description	R/W
b13 to b0	AD[13:0]	Added Value 13 to 0	14-bit value obtained by adding up of A/D conversion results	R
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

- The settings for flush-right data with 10-bit accuracy
  (when A/D-converted value addition mode is selected)

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	AD[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	AD[11:0]	Added Value 11 to 0	12-bit value obtained by adding up of A/D conversion results	R
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

- The settings for flush-right data with 8-bit accuracy
  (when A/D-converted value addition mode is selected)

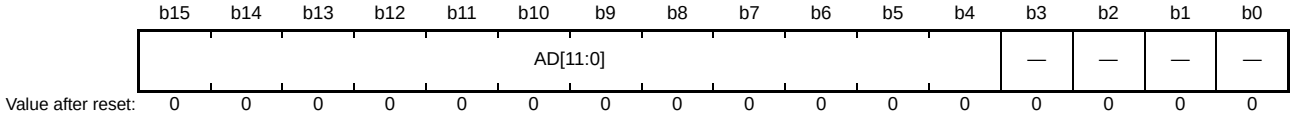


Bit	Symbol	Bit Name	Description	R/W
b9 to b0	AD[9:0]	Added Value 9 to 0	10-bit value obtained by adding up of A/D conversion results	R
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

- The settings for flush-left data with 12-bit accuracy
  (when A/D-converted value addition mode is selected)

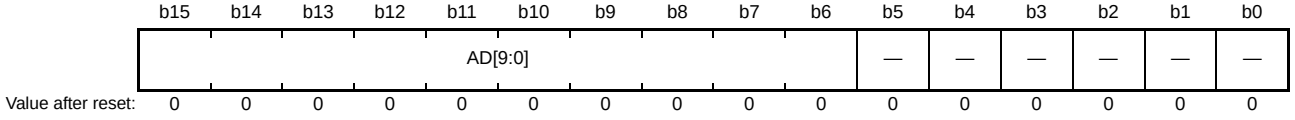
Bit	Symbol	Bit Name	Description	R/W
b1, b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b2	AD[13:0]	Added Value 13 to 0	14-bit value obtained by adding up of A/D conversion results	R

- The settings for flush-left data with 10-bit accuracy
  (when A/D-converted value addition mode is selected)



Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b4	AD[11:0]	Added Value 11 to 0	12-bit value obtained by adding up of A/D conversion results	R

- The settings for flush-left data with 8-bit accuracy
  (when A/D-converted value addition mode is selected)



Bit	Symbol	Bit Name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b6	AD[9:0]	Added Value 9 to 0	10-bit value obtained by adding up of A/D conversion results	R

57.2.2 A/D Self-Diagnosis Data Register (ADRD)

ADRD is a 16-bit read-only register that holds the A/D conversion results based on the 12-bit A/D converter's self-diagnosis. In addition to the AD bit indicating A/D-converted value, the self-diagnosis status bit (DIAGST[1:0]) is included in. In the ADRD register, the following different formats are used depending on the conditions below.

- The setting of the A/D data register format select bit (ADCER.ADRFT) (determining whether the data are flush-left or flush-right in the registers)
- The setting of the A/D data register bit-accuracy specify bits (ADCER.ADPRC[1:0]) (8-, 10-, or 12-bit is selectable.)

The A/D-converted value addition mode and A/D-converted value average mode cannot be applied to the A/D self-diagnosis function. For details of self-diagnosis, see section 57.2.11, A/D Control Extended Register (ADCER). The data formats for each given condition are shown below.

- The settings for flush-right data with 12-bit accuracy

Address(es): S12AD.ADRD 0008 901Eh, S12AD1.ADRD 0008 911Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DIAGST[1:0]		—	—	AD[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	AD[11:0]	Converted Value 11 to 0	12-bit A/D-converted value	R
b13, b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15, b14	DIAGST[1:0]	Self-Diagnosis Status	b15 b14 0 0: Self-diagnosis has never been executed since power-on. 0 1: Self-diagnosis using the voltage of 0 V has been executed. 1 0: Self-diagnosis using the voltage of reference power supply*1 × 1/2 has been executed. 1 1: Self-diagnosis using the voltage of reference power supply*1 has been executed. For details of self-diagnosis, see section 57.2.11, A/D Control Extended Register (ADCER).	R

Note 1. "Reference voltage" refers to VREFH0 for unit 0 and to AVCC1 for unit 1.

- The settings for flush-right data with 10-bit accuracy

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DIAGST[1:0]		—	—	—	—	AD[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	AD[9:0]	Converted Value 9 to 0	10-bit A/D-converted value	R
b13 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15, b14	DIAGST[1:0]	Self-Diagnosis Status	b15 b14 0 0: Self-diagnosis has never been executed since power-on. 0 1: Self-diagnosis using the voltage of 0 V has been executed. 1 0: Self-diagnosis using the voltage of reference power supply*1 × 1/2 has been executed. 1 1: Self-diagnosis using the voltage of reference power supply*1 has been executed. For details of self-diagnosis, see section 57.2.11, A/D Control Extended Register (ADCER).	R

Note 1. “Reference voltage” refers to VREFH0 for unit 0 and to AVCC1 for unit 1.

- The settings for flush-right data with 8-bit accuracy

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DIAGST[1:0]		—	—	—	—	—	—	AD[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	AD[7:0]	Converted Value 7 to 0	8-bit A/D-converted value	R
b13 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15, b14	DIAGST[1:0]	Self-Diagnosis Status	b15 b14 0 0: Self-diagnosis has never been executed since power-on. 0 1: Self-diagnosis using the voltage of 0 V has been executed. 1 0: Self-diagnosis using the voltage of reference power supply*1 × 1/2 has been executed. 1 1: Self-diagnosis using the voltage of reference power supply*1 has been executed. For details of self-diagnosis, see section 57.2.11, A/D Control Extended Register (ADCER).	R

Note 1. “Reference voltage” refers to VREFH0 for unit 0 and to AVCC1 for unit 1.

- The settings for flush-left data with 12-bit accuracy

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	AD[11:0]												—	—	DIAGST[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	DIAGST[1:0]	Self-Diagnosis Status	b1 b0 0 0: Self-diagnosis has never been executed since power-on. 0 1: Self-diagnosis using the voltage of 0 V has been executed. 1 0: Self-diagnosis using the voltage of reference power supply*1 × 1/2 has been executed. 1 1: Self-diagnosis using the voltage of reference power supply*1 has been executed. For details of self-diagnosis, see section 57.2.11, A/D Control Extended Register (ADCER).	R
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b4	AD[11:0]	Converted Value 11 to 0	12-bit A/D-converted value	R

Note 1. “Reference voltage” refers to VREFH0 for unit 0 and to AVCC1 for unit 1.

- The settings for flush-left data with 10-bit accuracy

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	DBLANS[4:0]	Double Trigger Channel Select	These bits select one analog input channel for double triggered operation. The setting is only effective while double trigger mode is selected.	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	GBADIE	Group B Scan End Interrupt Enable	0: Disables S12GBADI interrupt generation upon group B scan completion. 1: Enables S12GBADI interrupt generation upon group B scan completion.	R/W
b7	DBLE	Double Trigger Mode Select	0: Deselects double trigger mode. 1: Selects double trigger mode.	R/W
b8	EXTRG	Trigger Select*1	0: A/D conversion is started by a synchronous trigger (MTU, GPT, TPU, TMR, ELC). 1: A/D conversion is started by the asynchronous trigger (ADTRG0# in unit 0; ADTRG1# in unit 1).	R/W
b9	TRGE	Trigger Start Enable	0: Disables A/D conversion to be started by the synchronous or asynchronous trigger. 1: Enables A/D conversion to be started by the synchronous or asynchronous trigger.	R/W
b11, b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	ADIE	Scan End Interrupt Enable	0: Disables S12ADI interrupt generation upon scan completion. 1: Enables S12ADI interrupt generation upon scan completion.	R/W
b14, b13	ADCS[1:0]	Scan Mode Select	b14 b13 0 0: Single scan mode 0 1: Group scan mode 1 0: Continuous scan mode 1 1: Setting prohibited	R/W
b15	ADST	A/D Conversion Start	0: Stops A/D conversion process. 1: Starts A/D conversion process.	R/W

Note 1. Starting A/D conversion using an external pin (asynchronous trigger)
After a high-level signal is input to the external pin (ADTRG0# in unit 0; ADTRG1# in unit 1), write 1 to both the TRGE and EXTRG bits in ADCSR register and change the signals of ADTRG0# in unit 0 and ADTRG1# in unit 1 to Low. Thus the falling edge of ADTRG0# in unit 0 and ADTRG1# in unit 1 are detected and the scan conversion process is started. In this case, the pulse width of the low-level input must be at least 1.5 clock cycles of PCLKB.

ADCSR sets double trigger mode, A/D conversion start trigger; enables/disables scan end interrupt; selects the scan mode; and starts or stops A/D conversion.

DBLANS[4:0] Bits (Double Trigger Channel Select)

The DBLANS[4:0] bits select one of the channels for A/D conversion data duplication in double trigger mode. The A/D conversion results of the analog input of the channel selected by the DBLANS[4:0] bits are stored into the A/D data register y when conversion is started by the first trigger, and into the A/D data duplication register when started by the second trigger. Table 57.4 shows selection of the channel for double triggered operation.
When double trigger mode is selected, the channels selected by ADANSA0 and ADANSA1 registers are invalid, and the channel selected by the DBLANS[4:0] bits is subjected to A/D conversion instead.
When double trigger mode is used, do not select A/D conversion for the self-diagnosis function, temperature sensor output, and internal reference voltage (temperature sensor output and internal reference voltage can be selected for A/D

conversion for group B in group scan mode). The DBLANS[4:0] bits should be set while the ADCSR.ADST bit is 0. (They should not be set simultaneously when 1 is written to the ADCSR.ADST bit.)
To enter A/D-converted value addition/average mode while double trigger mode is set, the channel selected by the DBLANS[4:0] bits should be selected in the ADANSA0 and ADANSA1 registers.

Table 57.4 Relationship between DBLANS[4:0] Bits Settings and Double Trigger Enabled Channels

Unit 0		Unit 1					
DBLANS[4:0]	Duplication channel	DBLANS[4:0]	Duplication channel	DBLANS[4:0]	Duplication channel	DBLANS[4:0]	Duplication channel
00000	AN000	00000	AN100	01000	AN108	10000	AN116
00001	AN001	00001	AN101	01001	AN109	10001	AN117
00010	AN002	00010	AN102	01010	AN110	10010	AN118
00011	AN003	00011	AN103	01011	AN111	10011	AN119
00100	AN004	00100	AN104	01100	AN112	10100	AN120
00101	AN005	00101	AN105	01101	AN113		
00110	AN006	00110	AN106	01110	AN114		
00111	AN007	00111	AN107	01111	AN115		

Note: A/D-converted data of the self-diagnosis function, temperature sensor output, and internal reference voltage cannot be used in double trigger mode.

GBADIE Bit (Group B Scan End Interrupt Enable)

The GBADIE bit enables or disables group B scan end interrupt (S12GBADI) in group scan mode.

DBLE Bit (Double Trigger Mode Select)

Double trigger mode has a function to store the resulting data of A/D conversion started by the first and second synchronous triggers into separate registers.
When double trigger mode is selected, the channels specified in the ADANS0 and ADANS1 registers are invalid and the channel selected by the DBLANS[4:0] bits is effective instead. Double trigger mode can be only operated by the synchronous trigger (MTU, ELC, GPT, TMR, TPU) selected by the ADSTRGR.TRSA[5:0] bits; it cannot be operated by the asynchronous or software trigger. The A/D conversion results started by the first trigger are stored into the A/D data register y and those started by the second trigger are stored into the A/D data duplication register. In this case, if the ADIE bit is set to 1, the interrupt is output not upon completion of the first conversion but upon completion of the second conversion.
In continuous scan mode, double trigger mode should not be selected. Also do not select double trigger mode for conversion of the self-diagnosis function, temperature sensor output, and internal reference voltage.
The DBLE bit should be set after the ADCSR.ADST bit has been set to 0.

EXTRG Bit (Trigger Select)

The EXTRG bit selects the synchronous trigger or the asynchronous trigger as the trigger for starting A/D conversion.

TRGE Bit (Trigger Start Enable)

The TRGE bit enables or disables A/D conversion by the synchronous trigger and the asynchronous trigger.
This bit should be set to 1 in group scan mode.

ADIE Bit (Scan End Interrupt Enable)

The ADIE bit enables or disables the A/D scan end interrupt (S12ADI) in scans except for group B scan in group scan mode.
With double trigger mode deselected, the S12ADI interrupt is generated after the first scan is completed if the ADIE bit is set to 1.

With the extended analog input selected, the S12ADI interrupt is generated after A/D conversion is completed if the ADIE bit is set to 1.
With double trigger mode selected, the S12ADI interrupt is generated after the second scan is completed if the ADIE bit is set to 1 as long as the scan is started by the synchronous trigger (MTU, ELC, GPT, TMR, TPU) selected by the ADSTRGR.TRSA[5:0] bits.
When a scan is started by a software trigger, even if double trigger mode is selected, the S12ADI interrupt is generated after the scan is completed as long as the ADIE bit is set to 1.

ADCS[1:0] Bits (Scan Mode Select)

The ADCS bit select the scan mode.
In single scan mode, A/D conversion is performed for the analog inputs of a maximum of eight channels in unit 0 and 21 channels in unit 1 selected with the ADANSA0 and ADANSA1 registers in the ascending order of the channel number, and when one cycle of A/D conversion is completed for all the selected channels, the scan conversion is stopped.*1
In continuous scan mode, while the ADST bit in ADCSR register is 1, A/D conversion is performed for the analog inputs of a maximum of eight channels in unit 0 and 21 channels in unit 1 selected with the ADANSA0 and ADANSA1 registers in the ascending order of the channel number, and when one cycle of A/D conversion is completed for all the selected channels, A/D conversion is repeated from the first channel. If the ADST bit in ADCSR register is set to 0 during continuous scan, A/D conversion is stopped even if scanning is in progress.*1
In group scan mode, A/D conversion is performed for the analog inputs (group A) of a maximum of eight channels in unit 0 and 21 channels in unit 1 selected with the ADANSA0 and ADANSA1 registers in the ascending order of the channel number after scanning is started by the synchronous trigger (MTU, ELC, GPT, TMR, TPU) selected by the TRSA[5:0] bits in ADSTRGR register, and when one cycle of A/D conversion is completed for all the selected channels, A/D conversion is stopped.*1 A/D conversion is also performed for the analog inputs (group B) of a maximum of eight channels in unit 0 and 21 channels in unit 1 selected with the ADANSB0 and ADANSB1 registers in the ascending order of the channel number after scanning is started by the synchronous trigger (MTU, ELC, GPT, TMR, TPU) selected by the TRSB[5:0] bits in ADSTRGR register, and when one cycle of A/D conversion is completed for all the selected channels, A/D conversion is stopped.*1 If the conversion processes in group A and B occur at the same time, those conversion cannot be controlled separately. In this case, set the group A priority control setting bit (ADGSPCR.PGS) in the A/D group scan priority control register (ADGSPCR) to 1 in order to assign a priority to conversion of group A.*1
In group scan mode, different channels and triggers should be selected for group A and group B.
When the extended analog input is selected, single scan mode or continuous scan mode should be selected.
The ADCS[1:0] bits should be set while the ADCSR.ADST bit is 0 (it should not be set simultaneously when 1 is written to the ADCSR.ADST bit.)

Note 1. When the temperature sensor output or internal reference voltage is selected, A/D conversion of the designated analog input channels is followed by A/D conversion of the temperature sensor output and the internal reference voltage in that order.

Table 57.5 shows the selectable targets for A/D conversion depending on the settings of scan mode and double trigger mode.

Table 57.5 Selectable Targets for A/D Conversion Depending on the Settings of Scan Mode and Double Trigger Mode

Scan mode setting	Double Trigger Mode Setting	Targets for A/D conversion					
		Self-diagnosis	Analog input (including group A)	Analog input (group B)	Temperature sensor output	Internal reference voltage	Extended analog input
Single scan	DBLE = 0	○	○	×	○	○	○
	DBLE = 1	○	○ (1ch only)	×	×	×	×
Continuous scan	DBLE = 0	○	○	×	○	○	○
	DBLE = 1	×	×	×	×	×	×
Group scan	DBLE = 0	○	○	○	○	○	×
	DBLE = 1	○	○ (1ch only)	○	○ (group B only)	○ (group B only)	×

Note: ○: Selectable; ×: Not selectable
Note: When the extended analog input is selected as a target for A/D conversion, other A/D conversion targets should not be selected.

ADST Bit (A/D Conversion Start)

The ADST bit starts or stops A/D conversion process.
Before the ADST bit is set to 1, set the A/D conversion clock, the conversion mode, and conversion target analog input.
[Setting conditions]

- 1 is written by software.
- The synchronous trigger (MTU, ELC, GPT, TMR, TPU) selected by the ADSTRGR.TRSA[5:0] bits is detected with ADCSR.EXTRG and ADCSR.TRGE bits being set to 0 and 1, respectively.
- The synchronous trigger (MTU, ELC, GPT, TMR, TPU) selected by the ADSTRGR.TRSB[5:0] bits is detected with the ADCSR.TRGE bit being set to 1 in group scan mode.
- The asynchronous trigger is detected with the ADCSR.TRGE and ADCSR.EXTRG bits being set to 1 and the ADSTRGR.TRSA[5:0] bits being set to 000000b.
- With group-A priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), a group B trigger is detected and A/D conversion of group B is started.
- With group-A priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADGSPCR.GBRSCN bit is set to 1 and A/D conversion of group B is restarted.
- With group-A priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADGSPCR.GBRP bit is set to 1 and A/D conversion of group B is started.

[Clearing conditions]

- 0 is written by software.
- The A/D conversion of all the selected channels, the temperature sensor output or the internal reference voltage is completed in single scan mode.
- The A/D conversion of the extended analog input is completed in single scan mode.
- Group A scan is completed in group scan mode.
- Group B scan is completed in group scan mode.
- With group-A priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), a group A trigger is detected during group B A/D conversion and the scanning of group B is stopped.
- With group-A priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADGSPCR.GBRP bit is set to 1 and the scanning of group B started by a resumption trigger is completed.
- With group-A priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1) the ADGSPCR.GBRSCN bit is set to 1 and the scanning of group B by a trigger is completed.

Note: When group-A priority control operation mode has been enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), do not set the ADST bit to 1.
Note: When group-A priority control operation mode has been enabled (ADCSR.ADCS[1:0] bits = 01b and

ADGSPCR.PGS bit = 1) and ADGSPCR.GBRP = 1, do not set the ADST bit to 0. When forcibly terminating A/D conversion, follow the procedure for clearing the ADST bit.

57.2.4 A/D Channel Select Register A0 (ADANSA0)

Address(es): S12AD.ADANSA0 0008 9004h, S12AD1.ADANSA0 0008 9104h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ANSA0[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	ANSA0[15:0]	A/D Conversion Channels Select	0: AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) are not subjected to conversion. 1: AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) are subjected to conversion.	R/W

ADANSA0 selects analog input channels for A/D conversion among AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1). In group scan mode, this register selects group A channels.

ANSA0[15:0] Bits (A/D Conversion Channels Select)

The ANSA0[15:0] bits select analog input channels for A/D conversion among AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1). The channels to be selected and the number of channels can be arbitrarily set. In unit 0, the ANSA0[0] bit corresponds to AN000 and the ANSA0[7] bit corresponds to AN007. In unit 1, the ANSA0[0] bit corresponds to AN100 and the ANSA0[15] bit corresponds to AN115.

When double trigger mode is selected, the channel selected by the ANSA0[15:0] bits is invalid, and the channel selected by the ADCSR.DBLANS[4:0] bits is selected in group A instead.

When group scan mode is selected, do not select the channels specified in the A/D channel select register B0 (ADANSB0) and the A/D channel select register B1 (ADANSB1).

The ANSA0[15:0] bits should be set while the ADCSR.ADST bit is 0.

57.2.5 A/D Channel Select Register A1 (ADANSA1)

Address(es): S12AD1.ADANSA1 0008 9106h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	ANSA1[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	ANSA1[4:0]	A/D Conversion Channels Select	0: AN116 to AN120 (unit 1) are not subjected to conversion. 1: AN116 to AN120 (unit 1) are subjected to conversion.	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ADANSA1 selects analog input channels for A/D conversion among AN116 to AN120 (unit 1). In group scan mode, group A channels are to be selected. There is no register dedicated to unit 0.

ANSA1[4:0] Bits (A/D Conversion Channels Select)

The ANSA1[4:0] bits select analog input channels for A/D conversion among AN116 to AN120 (unit 1). The channels to be selected and the number of channels can be arbitrarily set. The ANSA1[0] bit corresponds to AN116 and the ANSA1[4] bit corresponds to AN120.

When double trigger mode is selected, the channel selected by the ANSA1[4:0] bits is invalid, and the channel selected by the ADCSR.DBLANS[4:0] bits is selected in group A instead.

When group scan mode is selected, do not select the channels specified in the A/D channel select register B0 (ADANSB0) and the A/D channel select register B1 (ADANSB1).

The ANSA1[4:0] bits should be set while the ADCSR.ADST bit is 0.

57.2.6 A/D Channel Select Register B0 (ADANSB0)

Address(es): S12AD.ADANSB0 0008 9014h, S12AD1.ADANSB0 0008 9114h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ANSB0[15:0]

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	ANSB0[15:0]	A/D Conversion Channels Select	0: AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) are not subjected to conversion. 1: AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) are subjected to conversion.	R/W

ADANSB0 selects analog input channels for A/D conversion among AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) in group B when group scan mode is selected. The ADANSB0 register is not used in any scan mode other than group scan mode.

ANSB0[15:0] Bits (A/D Conversion Channels Select)

The ANSB0[15:0] bits select analog input channels for A/D conversion among AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) in group B when group scan mode is selected. The ADANSB0 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the channels corresponding to group A, selected with the ADANSA0 and ADANSA1 registers and the ADCSR.DBLANS[4:0] bits in double trigger mode) should be excluded as the channels to be selected and the number of channels to be set.

In unit 0, the ANSB0[0] bit corresponds to AN000 and the ANSB0[7] bit corresponds to AN007. In unit 1, the ANSB0[0] bit corresponds to AN100 and the ANSB0[15] bit corresponds to AN115.

The ANSB0[15:0] bits should be set while the ADCSR.ADST bit is 0.

57.2.7 A/D Channel Select Register B1 (ADANSB1)

Address(es): S12AD1.ADANSB1 0008 9116h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	ANSB1[4:0]	A/D Conversion Channels Select	0: AN116 to AN120 (unit 1) are not subjected to conversion. 1: AN116 to AN120 (unit 1) are subjected to conversion.	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ADANSB1 selects analog input channels for A/D conversion among AN116 to AN120 (unit 1) in group B when group scan mode is selected. The ADANSB1 register is not used in any scan mode other than group scan mode. There is no register dedicated to unit 0.

ANSB1[4:0] Bits (A/D Conversion Channels Select)

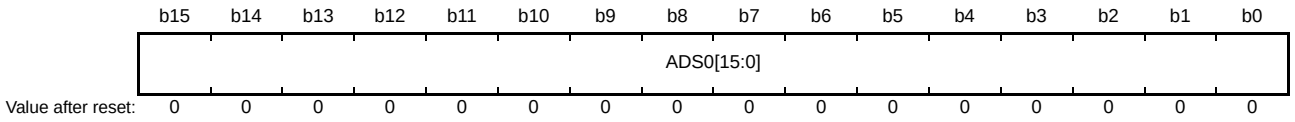
The ANSB1[4:0] bits select analog input channels for A/D conversion among AN116 to AN120 (unit 1) in group B when group scan mode is selected. The ADANSB1 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the channels corresponding to group A, selected with the ADANSA0 and ADANSA1 registers and the ADCSR.DBLANS[4:0] bits in double trigger mode) should be excluded as the channels to be selected and the number of channels to be set.

The ANSB1[0] bit corresponds to AN116 and the ANSB1[4] bit corresponds to AN120.

The ANSB1[4:0] bits should be set while the ADCSR.ADST bit is 0.

57.2.8 A/D-Converted Value Addition/Average Mode Select Register 0 (ADADS0)

Address(es): S12AD.ADADS0 0008 9008h, S12AD1.ADADS0 0008 9108h



Bit	Symbol	Bit Name	Description	R/W
b15 to b0	ADS0[15:0]	A/D-Converted Value Addition/ Average Channel Select	0: A/D-converted value addition/average mode for AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) is not selected. 1: A/D-converted value addition/average mode for AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) is selected.	R/W

ADADS0 selects the channels 0 to 15 on which A/D conversion is performed successively 2 to 4 times and then converted values are added (integrated) or averaged.

ADS0[15:0] Bits (A/D-Converted Value Addition/Average Channel Select)

When the ADS0[n] bit of the number that is the same as that of A/D-converted channel selected by the ANSA0[n] bits (n = 0 to 15) in ADANSA0 register or DBLANS[4:0] bits in ADCSR register and ANSB0[n] bits (n = 0 to 15) in ADANSB0 register is set to 1, A/D conversion of analog input of the selected channels is performed successively 2 to 4 times that is set with the ADC[1:0] bits in ADADC register. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition (integration) is stored in the A/D data register. As for the channel on which the A/D conversion is performed and addition/average mode is not selected, a normal one-time conversion is executed and the conversion result is stored to the A/D data register.

The ADS0[15:0] bits should be set while the ADCSR.ADST bit is 0.

57.2.9 A/D-Converted Value Addition/Average Mode Select Register 1 (ADADS1)

Address(es): S12AD1.ADADS1 0008 910Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	ADS1[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	ADS1[4:0]	A/D-Converted Value Addition/ Average Channel Select	0: A/D-converted value addition/average mode for AN116 to AN120 (unit 1) is not selected. 1: A/D-converted value addition/average mode for AN116 to AN120 (unit 1) is selected.	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ADADS1 selects the channels 16 to 20 on which A/D conversion is performed successively 2 to 4 times and then converted values are added (integrated) or averaged.

ADS1[4:0] Bits (A/D-Converted Value Addition/Average Channel Select)

When the ADS1[n] bit of the number that is the same as that of A/D-converted channel selected by the ANSA1[n] bits (n = 16 to 20) in ADANSA1 register or DBLANS[4:0] bits in ADCSR register and ANSB1[n] bits (n = 16 to 20) in ADANSB1 register is set to 1, A/D conversion of analog input of the selected channels is performed successively 2 to 4 times that is set with the ADC[1:0] bits in ADADC register. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition (integration) is stored in the A/D data register. As for the channel on which the A/D conversion is performed and addition/average mode is not selected, a normal one-time conversion is executed and the conversion result is stored to the A/D data register.
The ADS1[4:0] bits should be set while the ADCSR.ADST bit is 0.

Figure 57.3 shows a scanning operation sequence in which both the ADS[2] and ADS[6] bits are set to 1.
It is assumed that addition mode is selected (ADADS.AVEE = 0), the addition count is set to 4 (ADADC.ADC[1:0] = 11b), and the channels AN000 to AN007 are selected (ADANSA0.ANSA0[15:0] = 00FFh) in continuous scan mode (ADCSR.ADCS[1:0] = 10b). The conversion process begins with AN000. The AN002 conversion is performed successively 4 times, and the added (integrated) value is returned to the A/ D data register 2. After that the AN003 conversion process is started. The AN006 conversion is performed successively 4 times and the added (integrated) value is returned to the A/D data register 6. After conversion of AN007, the conversion operation is once again performed in the same sequence from AN000.

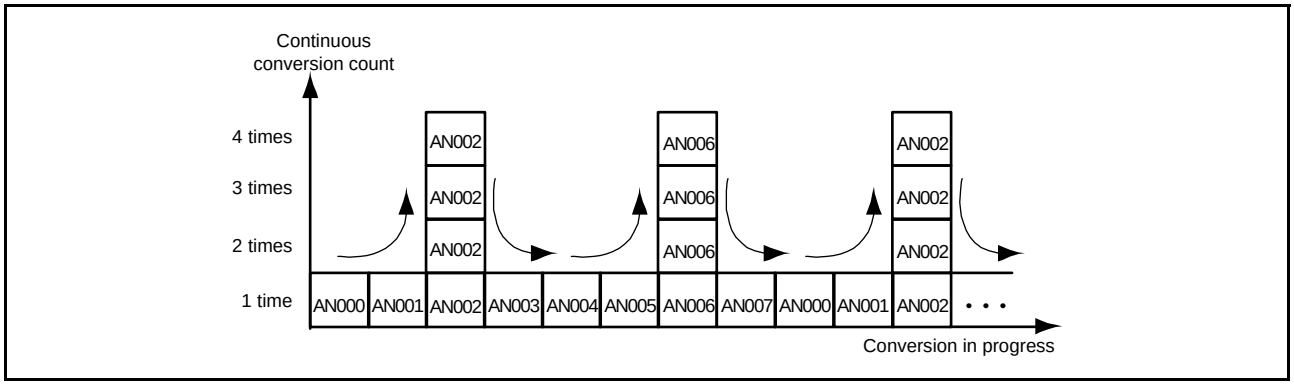


Figure 57.3 Scan Conversion Sequence with ADADC.ADC[1:0] = 11b, ADS[2] = 1, and ADS[6] = 1

57.2.10 A/D-Converted Value Addition/Average Count Select Register (ADADC)

b1, b0	ADC[1:0]	Addition Count Select	b1 b0 0 0: 1-time conversion (no addition; same as normal conversion) 0 1: 2-time conversion (addition once) 1 0: 3-time conversion (addition twice)*1 1 1: 4-time conversion (addition three times)	R/W
b6 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	AVEE	Average Mode Enable	0: Addition mode is selected. 1: Average mode is selected.	R/W

Note 1. When average mode is selected by setting the ADADC.AVEE bit to 1, do not set the addition count to three times (ADADC.ADC[1:0] = 10b)

ADADC sets the addition count for A/D conversion of the channel, temperature sensor output, and internal reference voltage for which A/D-converted value addition/average mode is selected, and selects either addition or average mode.

ADC[1:0] Bits (Addition Count Select)

The ADC[1:0] bits set the addition count common to the channels for which A/D conversion and A/D-converted value addition/average mode is selected, including the channels selected in double trigger mode (by ADCSR.DBLANS[4:0] bits), and to A/D conversion of temperature sensor output and internal reference voltage.
When average mode is selected by setting the ADADC.AVEE bit to 1, do not set the addition count to three times (ADADC.ADC[1:0] = 10b).
The ADC[1:0] bits should be set while the ADCSR.ADST bit is 0. When self-diagnosis is executed (ADCER.DIAGM = 1), do not set the ADC[1:0] bits to any value other than 00b.

AVEE Bit (Average Mode Enable)

The AVEE bit selects addition or average mode for A/D conversion of the channel for which A/D conversion and A/D-converted value addition/average mode is selected, including the channels selected in double trigger mode (by ADCSR.DBLANS[4:0] bits), temperature sensor output, and internal reference voltage.
When average mode is selected by setting the ADADC.AVEE bit to 1, do not set the addition count to three times (ADADC.ADC[1:0] = 10b).
The AVEE bits should be set while the ADCSR.ADST bit is 0.

57.2.11 A/D Control Extended Register (ADCER)

Address(es): S12AD.ADCER 0008 900Eh, S12AD1.ADCER 0008 910Eh

b14 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	ADRFMT	A/D Data Register Format Select	0: Right-alignment is selected for the A/D data register format. 1: Left-alignment is selected for the A/D data register format.	R/W

Note 1. “Reference voltage” refers to VREFH0 for unit 0 and to AVCC1 for unit 1.

ADCER sets self-diagnosis mode, format of the A/D data registers y (ADDRy), and automatic clearing of A/D data registers.

ADPRC[1:0] Bits (A/D Conversion Accuracy Specify)

These bits select the A/D conversion accuracy among 8-, 10-, or 12-bit accuracy. When the A/D conversion accuracy is changed, the bit width of effective data stored in the result register and A/D conversion time are also changed. See section 57.3.7, Analog Input Sampling and Scan Conversion Time for details. The ADPRC[1:0] bits should be set while the ADCSR.ADST bit is 0.

ACE Bit (A/D Data Register Automatic Clearing Enable)

The ACE bit enables or disables automatic clearing (all “0”) of ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, or ADOCDR registers after any of these registers have been read by the CPU, DTC, or DMACA. Automatic clearing of the A/D data register enables a failure which has not been updated in the A/D data register to be detected.

DIAGVAL[1:0] Bits (Self-Diagnosis Conversion Voltage Select)

These bits select the voltage value used in self-diagnosis voltage fixed mode. For details, refer to the descriptions of the ADCER.DIAGLD bit.

Self-diagnosis should not be executed by setting the ADCER.DIAGLD bit to 1 when the ADCER.DIAGVAL[1:0] bits are set to 00b.

DIAGLD Bit (Self-Diagnosis Mode Select)

The DIAGLD bit selects whether the three voltage values are rotated or the fixed voltage is used in self-diagnosis. Setting this bit (ADCER.DIAGLD) to 0 allows conversion of the voltages in rotation mode where 0, the reference power supply × 1/2, and the reference power supply are converted in this order. When self-diagnosis rotation mode is selected after a reset, self-diagnosis is performed from 0 V. When self-diagnosis voltage fixed mode is selected, the fixed voltage specified by the ADCER.DIAGVAL[1:0] bits is converted. In self-diagnosis voltage rotation mode, the self-diagnosis voltage value does not return to 0 when scan conversion is completed. When scan conversion is restarted, therefore, rotation starts at the voltage value following the previous value. If fixed mode is switched to rotation mode, rotation starts at the fixed voltage value.

The DIAGLD bit should be set while the ADCSR.ADST bit is 0.

DIAGM Bit (Self-Diagnosis Enable)

The DIAGM bit enables or disables self-diagnosis.

Self-diagnosis is used to detect a failure of the 12-bit A/D converter. Specifically, one of the internally generated voltage values 0, the reference power supply × 1/2, and the reference power supply is converted. When conversion is completed, information on the converted voltage and the conversion result is stored into the self-diagnosis data register (ADRD). ADRD can then be read out by software to determine whether the conversion result falls within the normal range (normal) or not (abnormal). Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages is converted. The execution time of self-diagnosis differs from the A/D conversion time of one channel.

When self-diagnosis is selected in double trigger mode, self-diagnosis is executed only for the first scan conversion by a synchronous trigger (MTU, ELC, GPT, TMR, TPU), not executed in the second scan. When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed in group A and B.

The DIAGM bit should be set while the ADCSR.ADST bit is 0.

ADRFMT Bit (A/D Data Register Format Select)

The ADRFMT bit specifies right-alignment or left-alignment for the data to be stored in ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADRD, or ADCMPDR registers.

For details on the format of each data register, see section 57.2.1, A/D Data Registers y (ADDRy), A/D Data Duplication Register (ADDBLDR), A/D Data Duplication Register A (ADDBLDRA), A/D Data Duplication Register B (ADDBLDRB), A/D Temperature Sensor Data Register (ADTSDR), A/D Internal Reference Voltage Data Register (ADOCDR), section 57.2.2, A/D Self-Diagnosis Data Register (ADRD), and section 57.2.26, A/D Compare Data Register y (ADCMPDRy) (y = 0, 1).

57.2.12 A/D Start Trigger Select Register (ADSTRGR)

Address(es): S12AD.ADSTRGR 0008 9010h, S12AD1.ADSTRG 0008 9110h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	TRSA[5:0]						—	—	TRSB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	TRSB[5:0]	A/D Conversion Start Trigger Select for Group B	Select the A/D conversion start trigger for group B in group scan mode.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13 to b8	TRSA[5:0]	A/D Conversion Start Trigger Select	Select the A/D conversion start trigger in single scan mode and continuous mode. In group scan mode, the A/D conversion start trigger for group A is selected.	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ADSTRGR selects the A/D conversion start trigger.

TRSB[5:0] Bits (A/D Conversion Start Trigger Select for Group B)

The TRSB[5:0] bits select the trigger to start scanning of the analog input selected in group B. The TRSB[5:0] bits require to be set only in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for group B, setting a software trigger or an asynchronous trigger is prohibited. Therefore, the TRSB[5:0] bits should be set to the value other than 000000b and the ADCSR.TRGE bit should be set to 1 in group scan mode.

When group A is given priority in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows group B to continuously operate in single scan mode. When setting the ADGSPCR.GBRP bit to 1, set the TRSB[5:0] bits to 3Fh.

Note that the issuance period of trigger for A/D conversion must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by the trigger may have no effect.

When the trigger from the module operated in 120 MHz (MTU/GPT) is selected as an A/D conversion start trigger, a delay of the period for synchronization processing occurs. See section 57.3.7, Analog Input Sampling and Scan Conversion Time for details.

Table 57.6 lists the A/D conversion startup sources selected by the TRSB[5:0] bits.

TRSA[5:0] Bits (A/D Conversion Start Trigger Select)

The TRSA[5:0] bits select the trigger to start A/D conversion in single scan mode and continuous scan mode. In group scan mode, the trigger to start scanning of the analog input selected in group A is selected. When scanning is executed in group scan mode or double trigger mode, set the TRGE bit in ADCSR register to 1.

- When using the A/D conversion startup source of a synchronous trigger (MTU, ELC, GPT, TMR, TPU), set the TRGE bit in ADCSR register to 1.
- When using the asynchronous trigger (ADTRGn#), set the TRGE bit in ADCSR register to 1 and set the EXTRG bit in ADCSR register to 1.
- Software trigger (ADCSR.ADST) is enabled regardless of the settings of the ADCSR.TRGE bit, the ADCSR.EXTRG bit, and the TRSA[5:0] bits. Note that the issuance period of trigger for A/D conversion must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by a trigger may have no effect. When the trigger from the module operated in 120 MHz (MTU/GPT) is selected as an A/D conversion start trigger, a delay of the period for synchronization processing occurs. See section 57.3.7, Analog Input Sampling and Scan Conversion Time for details.

Table 57.7 lists the selection of A/D conversion start sources selected by the TRSA[5:0] bits.

TSSAD Bit (Temperature Sensor Output A/D-Converted Value Addition/Average Mode Select)

When the TSSAD bit is set to 1, A/D conversion of the temperature sensor output is selected and performed successively 2 to 4 times that is set with the ADC[1:0] bits in ADADC register. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D temperature sensor data register (ADTSDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADTSDR.

The TSSAD bit should be set while the ADCSR.ADST bit is 0.

OCSAD Bit (Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select)

When the OCSAD bit is set to 1, A/D conversion of the internal reference voltage is selected and performed successively 2 to 4 times that is set with the ADC[1:0] bits in ADADC register. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D internal reference voltage data register (ADOCDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADOCDR.
The OCSAD bit should be set while the ADCSR.ADST bit is 0.

TSSA Bit (Temperature Sensor Output A/D Conversion Select)

This bit selects A/D conversion of the temperature sensor output for group A in single scan mode, continuous scan mode or group scan mode. When A/D conversion of the temperature sensor output is selected and performed, set the ADCSR.DBLE bit to 0.
The TSSA bit should be set while the ADCSR.ADST bit is 0.

OCSA Bit (Internal Reference Voltage A/D Conversion Select)

This bit selects A/D conversion of the internal reference voltage for group A in single scan mode, continuous scan mode or group scan mode. When A/D conversion of the internal reference voltage is selected and performed, set the ADCSR.DBLE bit to 0.
The OCSA bit should be set while the ADCSR.ADST bit is 0. After the OCSA bit has been set to 1, wait for at least 400 ns to start A/D conversion.

TSSB Bit (Temperature Sensor Output A/D Conversion Select)

This bit selects A/D conversion of the temperature sensor output for group B in group scan mode.
The TSSB bit should be set while the ADCSR.ADST bit is 0. Do not set the TSSB bit to 1 while the TSSA bit is 1.

OCSB Bit (Internal Reference Voltage A/D Conversion Select)

This bit selects A/D conversion of the internal reference voltage for group B in group scan mode.
The OCSB bit should be set while the ADCSR.ADST bit is 0. Do not set the OCSB bit to 1 while the OCSA bit is 1. After the OCSB bit has been set to 1, wait for at least 400 ns to start A/D conversion.

EXSEL[1:0] Bits (Extended Analog Input Select)

These bits select the extended analog input (ANEX1) instead of the analog input channels (ANn).
When ANEX1 is selected, ANEX0 should be input to ANEX1 via the external operational amplifier. In this case, only select AN100 to AN107; do not select AN108 to AN120. For details, see section 57.3.5.1, Usage of ANEX1.

EXOEN Bit (Extended Analog Output Control)

This bit controls the extended analog output (ANEX0). When the output is enabled, the multiplexed value of AN100 to AN107 among analog input channels in unit 1 is output to ANEX0. Do not enable an output when the EXSEL[1:0] bits are 00b.

57.2.14 A/D Sampling State Register n (ADSSTRn) (n = 0 to 7, L, T, O)

Address(es): S12AD.ADSSTR0 0008 9060h, S12AD.ADSSTR1 0008 9073h, S12AD.ADSSTR2 0008 9074h, S12AD.ADSSTR3 0008 9075h, S12AD.ADSSTR4 0008 9076h, S12AD.ADSSTR5 0008 9077h, S12AD.ADSSTR6 0008 9078h, S12AD.ADSSTR7 0008 9079h, S12AD1.ADSSTR0 0008 9160h, S12AD1.ADSSTR1 0008 9173h, S12AD1.ADSSTR2 0008 9174h, S12AD1.ADSSTR3 0008 9175h, S12AD1.ADSSTR4 0008 9176h, S12AD1.ADSSTR5 0008 9177h, S12AD1.ADSSTR6 0008 9178h, S12AD1.ADSSTR7 0008 9179h, S12AD1.ADSSTRL 0008 9161h, S12AD1.ADSSTRT 0008 9170h, S12AD1.ADSSTRO 0008 9171h

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	SST[7:0]	Sampling Time Setting	These bits set the sampling time in the range from 5 to 255 states.	R/W

ADSSTRn sets the sampling time for analog input.
If one state is one ADCLK (A/D conversion clock) cycle and the ADCLK clock is 60 MHz, one state is 16.7 ns. The initial value is 11 states. If the impedance of analog input signal source is too high to secure sufficient sampling time or if the ADCLK clock is slow, the sampling time can be adjusted. The SST[7:0] bits should be set while the ADCSR.ADST bit is 0. The sampling time must be set to a value that is 5 states or more and is 255 or less. Table 57.8 shows the relationship between the A/D sampling state register and the relevant channels.
For details, refer to section 57.3.7, Analog Input Sampling and Scan Conversion Time.

Table 57.8 Relationship between A/D Sampling State Register and Relevant Channels

	Corresponding Channels	
Bit Name	**Unit 0**	**Unit 1**
ADSSTR0.SST[7:0] bits*1	AN000	AN100
ADSSTR1.SST[7:0] bits	AN001	AN101
ADSSTR2.SST[7:0] bits	AN002	AN102
ADSSTR3.SST[7:0] bits	AN003	AN103
ADSSTR4.SST[7:0] bits	AN004	AN104
ADSSTR5.SST[7:0] bits	AN005	AN105
ADSSTR6.SST[7:0] bits	AN006	AN106
ADSSTR7.SST[7:0] bits	AN007	AN107
ADSSTRL.SST[7:0] bits	—	AN108 to AN120
ADSSTRT.SST[7:0] bits	—	Temperature sensor output (in unit 1 only)
ADSSTRO.SST[7:0] bits	—	Internal reference voltage (in unit 1 only)

Note 1. When self-diagnosis function is selected, the sampling time set by the ADSSTR0.SST[7:0] bits is applied to it.

57.2.15 A/D Sample-and-Hold Circuit Control Register (ADSHCR)

Address(es): S12AD.ADSHCR 0008 9066h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SHANS[2:0]			SSTSH[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	SSTSH[7:0]	Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting	Set the sampling time (4 to 255 states).	R/W
b10 to b8	SHANS[2:0]	Channel-Dedicated Sample-and-Hold Circuit Bypass Select	Select whether to use or not use (bypass) AN000 to AN002 channel-dedicated sample-and-hold circuits. 0: Bypass the channel-dedicated sample-and-hold circuits. 1: Use the channel-dedicated sample-and-hold circuits.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ADSHCR sets the parameters related to channel-dedicated sample-and-hold circuits.

SSTSH[7:0] Bits (Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting)

The SSTSH[7:0] bits set the sampling time for the channel-dedicated sample-and-hold circuits when the ADSHMSR.SHMD bit is 0. If one state is one ADCLK (A/D conversion clock) cycle and the ADCLK clock is 60 MHz, one state is 16.7 ns. The initial value is 24 states. If the impedance of analog input signal source is too high to secure sufficient sampling time or if the ADCLK clock is slow, the sampling time can be adjusted. The SSTSH[7:0] bits should be set while the ADCSR.ADST bit is 0. The sampling time must be set to a value that is 4 states or more and is 255 or less.

SHANS[2:0] Bits (Channel-Dedicated Sample-and-Hold Circuit Bypass Select)

The SHANS[2:0] bits select whether to use or not use (bypass) AN000 to AN002 channel-dedicated sample-and-hold circuits. The SHANS[0] bit selects AN000, SHANS[1] bit selects AN001, and SHANS[2] bit selects AN002. The SHANS[2:0] bits should be set while the ADCSR.ADST and ADSHMSR.SHMD bits are 0.

If any channel from among AN000 to AN002 is selected for group B while operation is in group scan mode under group A priority control, make the setting to bypass the channel's dedicated sample-and-hold circuit.

The channels in unit 1 do not include channel-dedicated sample-and-hold circuits.

57.2.16 A/D Sample-and-Hold Circuit Operating Mode Select Register (ADSHMSR)

Address(es): S12AD.ADSHMSR 0008 907Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SHMD
Value after reset:	0	0	0	0	1	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SHMD	Channel-Dedicated Sample-and-Hold Circuit Operating Mode Select	0: Continuous sampling by the channel-dedicated sample-and-hold circuits is disabled. 1: Continuous sampling by the channel-dedicated sample-and-hold circuits is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ADSHMSR enables or disables continuous sampling by the channel-dedicated sample-and-hold circuits.

SHMD Bit (Channel-Dedicated Sample-and-Hold Circuit Operating Mode Select)

Setting the SHMD bit to 1 enables continuous sampling by the channel-dedicated sample-and-hold circuits selected by the ADSHCR.SHANS[2:0] bits. The SHMD bit should be set while the ADCSR.ADST bit is 0.

When continuous sampling is enabled, continuous sampling proceeds while the 12-bit A/D converter is in a waiting state and holding proceeds during A/D conversion.

57.2.17 A/D Disconnection Detection Control Register (ADDISCR)

Address(es): S12AD.ADDISCR 0008 907Ah, S12AD1.ADDISCR 0008 917Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	ADNDIS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	ADNDIS[4:0]	Disconnection Detection Assist Setting	Disconnection detection assist function is set.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ADDISCR sets the disconnection detection assist function.

ADNDIS[4:0] Bits (Disconnection Detection Assist Setting)

These bits selects either precharge or discharge and the period of precharge/discharge for the A/D disconnection detection assist function. Setting the ADNDIS[4] bit = 1 allows to select precharge and setting the ADNDIS[4] bit = 0 allows to select discharge. The period of precharge/discharge can be set with the ADNDIS[3:0] bits. When the ADNDIS[3:0] bits = 0000b, the disconnection detection assist function is not effective. Setting of the ADNDIS[3:0] bits to 0001b is prohibited. Except for the case of the ADNDIS[3:0] = 0000b or 0001b, the specified value indicates the number of states for the period of precharge/discharge. When the temperature sensor output or internal reference voltage is converted or self-diagnosis is used, the disconnection detection assistance cannot be used. In that case, the ADNDIS[3:0] bits should be set to 0000b. When the ADNDIS[3:0] bits are set to any values other than 0000b or 0001b, and the disconnection detection assistance is enabled, the disconnection detection assistance for the channel-dedicated sample-and-hold circuit used for analog inputs are also enabled.

57.2.18 A/D Group Scan Priority Control Register (ADGSPCR)

Address(es): S12AD.ADGSPCR 0008 9080h, S12AD1.ADGSPCR 0008 9180h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	GBRP	—	—	—	—	—	—	—	—	—	—	—	—	—	GBRSCN	PGS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PGS	Group-A Priority Control Setting*1	0: Operation is without group A priority control 1: Operation is with group A priority control	R/W
b1	GBRSCN	Group B Restart Setting*2	(Enabled only when PGS = 1. Reserved when PGS = 0.) 0: Scanning for group B is not restarted after having been discontinued due to group A priority control. 1: Scanning for group B is restarted after having been discontinued due to group A priority control.	R/W
b14 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	GBRP	Group B Single Scan Continuous Start*3	(Enabled only when PGS = 1. Reserved when PGS = 0.) 0: Single scan for group B is not continuously activated. 1: Single scan for group B is continuously activated.	R/W

Note 1. When the PGS bit is to be set to 1, the ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode). If the bits are set to any other values, proper operation is not guaranteed.
Note 2. When the GBRSCN bit is set to 1, clock frequency ratio of PCLKB to ADCLK should be 1:1.
Note 3. When the GBRP bit has been set to 1, single scan is performed continuously for group B regardless of the setting of the GBRSCN bit.

ADGSPCR sets priority control of A/D conversion for group A in group scan mode.

PGS Bit (Group-A Priority Control Setting)

This bit sets the priority of operation on group A. Set this bit to 1 when giving priority to operation on group A.
When the PGS bit is to be set to 1, the ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode). If the bits are set to any other values, proper operation is not guaranteed.
When the PGS bit has been set to 0, clear operation must be performed by software according to section 57.5.2, Notes on Stopping A/D Conversion. When the PGS bit has been set to 1, make settings according to section 57.3.4.3, Operation under Group-A Priority Control.

GBRSCN Bit (Group B Restart Setting)

This bit controls the restarting of scan operation on group B when operation on group A is given priority.
If a scan operation on group B has been stopped by a group A trigger input with the GBRSCN bit set to 1, the scan operation is restarted on completion of the A/D conversion on group A. Also, if a group B trigger is input during A/D conversion on group A, the scan operation on group B is restarted on completion of the A/D conversion on group A.
If the GBRSCN bit has been set to 0, triggers that are input during A/D conversion are ignored. Also, the ADCSR.ADST bit must be 0 when the GBRSCN bit is to be set.
The setting of the GBRSCN bit has an effect when the PGS bit is set to 1.

GBRP Bit (Group B Single Scan Continuous Start)

This bit is set when a single scan operation is to be performed continuously on group B.
Setting the GBRP bit to 1 starts a single scan on group B. On completion of the scan, another single scan on group B is automatically started. If an A/D conversion on group B has been stopped due to an operation on group A that takes priority, single scan on group B is automatically restarted on completion of the A/D conversion on group A.
Disable group B trigger input before setting the GBRP bit to 1. Setting the GBRP bit to 1 invalidates the setting of the

GBRSCN bit. The ADCSR.ADST bit must be 0 when the GBRP bit is to be set.
The setting of the GBRP bit is valid when the PGS bit is 1.

57.2.19 A/D Compare Control Register (ADCMPCR)

Address(es): S12AD.ADCMPCR 0008 9090h, S12AD1.ADCMPCR 0008 9190h

	b7	b6	b5	b4	b3	b2	b1	b0
	CMPIE	WCMPE	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	WCMPE	Window Function	0: Window function disabled 1: Window function enabled	R/W
b7	CMPIE	Compare Interrupt Enable	0: Generation of an S12CMPI interrupt in response to matches with a condition for comparison is disabled. 1: Generation of an S12CMPI interrupt in response to matches with a condition for comparison is enabled.	R/W

ADCMPCR sets the compare function.

WCMPE Bit (Window Function)

The WCMPE bit selects enabling or disabling of Window function. This bit should be set while the ADCSR.ADST bit is 0.

CMPIE Bit (Compare Interrupt Enable)

The CMPIE bit enables or disables generation of a compare interrupt (S12CMPI) in response to matches with a condition for comparison.

57.2.20 A/D Compare Channel Select Register 0 (ADCMPANSR0)

Address(es): S12AD.ADCMPANSR0 0008 9094h, S12AD1.ADCMPANSR0 0008 9194h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CMPS0[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	CMPS0[15:0]	Compare Channel Select	0: The corresponding channel from among AN000 to AN007 and AN100 to AN115 is not a target for comparison. 1: The corresponding channel from among AN000 to AN007 and AN100 to AN115 is a target for comparison.	R/W

ADCMPANSR0 selects analog input channels for comparison from among AN000 to AN007 and AN100 to AN115.

CMPS0[15:0] Bits (Compare Channel Select)

Setting the CMPS0[n] bit which has the same number as the A/D channel selected by the ADANSA0.ANSA0[n] (n = 0 to 7 for unit 0, n = 0 to 15 for unit 1) or ADANSB0.ANSB0[n] (n = 0 to 7 for unit 0, n = 0 to 15 for unit 1) bits to 1 enables comparison with that channel.

Set the CMPS0[15:0] bits while ADCSR.ADST bit is 0.

The CMPS0[15:8] bits of the unit 0 are reserved bits. Reading to these bits returns 0. Writing value should be 0.

57.2.21 A/D Compare Channel Select Register1 (ADCMPANSR1)

Address(es): S12AD1.ADCMPANSR1 0008 9196h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	CMPS1[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	CMPS1[4:0]	Compare Channel Select	0: The corresponding channel from among AN116 to AN120 is not a target for comparison. 1: The corresponding channel from among AN116 to AN120 is a target for comparison.	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ADCMPANSR1 selects analog input channels for comparison from among AN116 to AN120.

CMPS1[4:0] Bits (Compare Channel Select)

Setting the CMPS1[n] which has the same number as the A/D channel selected by the ADANSB1.ANSB1[n] (n = 0 to 4) bits to 1 enables comparison with that channel.

Set the CMPS1[4:0] bits while ADCSR.ADST bit is 0.

57.2.22 A/D Compare Channel Select Extended Register (ADCMPANSER)

Address(es): S12AD1.ADCMPANSER 0008 9192h

	b7	b6	b5	b4	b3	b2	b1	b0
			—	—	—	—	CMPSOC	CMPSTS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPSTS	Temperature Sensor Output Compare Select	0: Temperature sensor output is not a target for comparison. 1: Temperature sensor output is a target for comparison.	R/W
b1	CMPSOC	Internal Reference Voltage Compare Select	0: Internal reference voltage is not a target for comparison. 1: Internal reference voltage is a target for comparison.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

CMPSTS Bit (Temperature Sensor Output Compare Select)

Setting the CMPSTS bit to 1 while ADEXICR.TSSA or ADEXICR.TSSB = 1 enables comparison. This bit should be set while the ADCSR.ADST bit is 0.

CMPSOC Bit (Internal Reference Voltage Compare Select)

Setting the CMPSOC bit to 1 while ADEXICR.OCSA or ADEXICR.OCSB = 1 enables comparison. This bit should be set while the ADCSR.ADST bit is 0.

57.2.23 A/D Compare Level Register 0 (ADCMPLR0)

Address(es): S12AD.ADCMPLR0 0008 9098h, S12AD1.ADCMPLR0 0008 9198h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CMPL0[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	CMPL0[15:0]	Compare Level Select	Set the condition for comparison with the selected channels from among AN000 to AN007 and AN100 to AN115. When Window function is disabled (ADCMPCR.WCMPE bit = 0): 0: ADCMPDR0 register value > A/D-converted value 1: ADCMPDR0 register value < A/D-converted value When Window function is enabled (ADCMPCR.WCMPE bit = 1): 0: AD-converted value < ADCMPDR0 register value or A/D-converted value > ADCMPDR1 register value 1: ADCMPDR0 register value < A/D-converted value < ADCMPDR1 register value	R/W

ADCMPLR0 sets the condition for use in comparing the values of the ADCMPDR0 and ADCMPDR1 registers with results of A/D conversion.
Set the ADCMPLR0 register while ADCSR.ADST is 0.

CMPL0[15:0] Bits (Compare Level Select)

The CMPL0[15:0] bits set the condition for use in comparison with the selected channel from among AN000 to AN007 and AN100 to AN115. A condition can be set for individual comparison of each analog input.
The CMPL0[0] bit is used for AN000 (unit0) and AN100 (unit 1), the CMPL0[7] bit is used for AN007 (unit 0) and AN107 (unit 1), and the CMPL0[15] bit is used for AN115 (unit 1).
When the result of comparison matches the set condition, ADCMPSR0.CMPF0n is set to 1 and a compare interrupt (S12CMPI) is generated.
The CMPL0[15:8] bits of the unit 0 are reserved. Reading to these bits return 0. Writing value should be 0.

57.2.24 A/D Compare Level Register1 (ADCMPLR1)

Address(es): S12AD1.ADCMPLR1 0008 919Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	CMPL1[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	CMPL1[4:0]	Compare Level Select	Set the condition for comparison with the selected channels from among AN116 to AN120. When Window function is disabled (ADCMPCR.WCMPE bit = 0): 0: ADCMPDR0 register value > A/D-converted value 1: ADCMPDR0 register value < A/D-converted value When Window function is enabled (ADCMPCR.WCMPE bit = 1): 0: AD-converted value < ADCMPDR0 register value or A/D-converted value > ADCMPDR1 register value 1: ADCMPDR0 register value < A/D-converted value < ADCMPDR1 register value	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ADCMPLR1 sets the condition for use in comparing the values of the ADCMPDR0 and ADCMPDR1 registers with results of A/D conversion.
Set the ADCMPLR1 register while ADCSR.ADST is 0.

CMPL1[4:0] Bits (Compare Level Select)

The CMPL1[4:0] bits set the condition for use in comparison with the selected channel from among AN116 to AN120. A condition can be set for individual comparison of each analog input.
The CMPL1[0] bit is used for AN116 and the CMPL1[4] bit is used for AN120.
When the result of comparison matches the set condition, ADCMPSR1.CMPF1n is set to 1 and a compare interrupt (S12CMPI) is generated.

57.2.25 A/D Compare Level Extended Register (ADCMPLER)

Address(es): S12AD1.ADCMPLER 0008 9193h

	b7	b6	b5	b4	b3	b2	b1	b0
			—	—	—	—	CMPLOC	CMPLTS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPLTS	Temperature Sensor Output Compare Level Select	When Window function is disabled (ADCMPCR.WCMPE bit = 0): 0: ADCMPDR0 register value > A/D-converted value 1: ADCMPDR0 register value < A/D-converted value When Window function is enabled (ADCMPCR.WCMPE bit = 1): 0: AD-converted value < ADCMPDR0 register value or A/D-converted value > ADCMPDR1 register value 1: ADCMPDR0 register value < A/D-converted value < ADCMPDR1 register value	R/W
b1	CMPLOC	Internal Reference Voltage Compare Level Select	When Window function is disabled (ADCMPCR.WCMPE bit = 0): 0: ADCMPDR0 register value > A/D-converted value 1: ADCMPDR0 register value < A/D-converted value When Window function is enabled (ADCMPCR.WCMPE bit = 1): 0: AD-converted value < ADCMPDR0 register value or A/D-converted value > ADCMPDR1 register value 1: ADCMPDR0 register value < A/D-converted value < ADCMPDR1 register value	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ADCMPLER sets the condition for use in comparing the values of ADCMPDR0 and ADCMPDR1 registers with results of A/D conversion.

Set the ADCMPLER register while ADCSR.ADST is 0.

CMPLTS Bit (Temperature Sensor Output Compare Level Select)

This bit sets the condition for use in comparison with temperature sensor output.

When the result of comparison matches the set condition, ADCMPSER.CMPFTS is set to 1 and a compare interrupt (S12CMPI) is generated.

CMPLOC Bit (Internal Reference Voltage Compare Level Select)

This bit sets conditions for use in comparison with internal reference voltage.

When the result of comparison matches the set condition, ADCMPSER.CMPFOC is set to 1 and a compare interrupt (S12CMPI) is generated.

57.2.26 A/D Compare Data Register y (ADCMPDRy) (y = 0, 1)

Set the reference data for comparison with the selected channels.
This register is accessible even during A/D conversion which allows dynamic changing of the reference data. The ADCMPDR1 register is not used when the Window function is disabled.
The ADCMPDRy register uses different formats depending on the following conditions.

- The value of A/D data register format select bit (flush-right or flush-left)
- The value of A/D-conversion accuracy specification bit (12 bits, 10 bits, 8 bits)
- The value of A/D-converted value addition/average mode select register (A/D-converted value addition mode selected or not selected)

(1) When A/D-Converted Value Addition Mode is Not Selected

- Flush-right format with 12-bit precision

Address(es): S12AD.ADCMPDR0 0008 909Ch, S12AD.ADCMPDR1 0008 909Eh, S12AD1.ADCMPDR0 0008 919Ch, S12AD1.ADCMPDR1 0008 919Eh

57.2.27 A/D Compare Status Register0 (ADCMPSR0)

Address(es): S12AD.ADCMPSR0 0008 90A0h, S12AD1.ADCMPSR0 0008 91A0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CMPF0[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	CMPF0[15:0]	Compare Flag	Indicates compare results of AN000 to AN007 and AN100 to AN115. 0: Condition for comparison was not met. 1: Condition for comparison was met.	R/W

Compare results using compare function are stored in the ADCMPSR0 register.

CMPF0[15:0] Bits (Compare Flag)

These bits are status flags to indicate the results of comparison with the selected analog inputs from among AN000 to AN007 and AN100 to AN115. When the result of comparison on completion of A/D conversion matches the condition set in ADCMPLR0.CMPL0n, the corresponding flags are set to 1.

When the ADCMPCR.CMPIE bit is 1, a compare interrupt (S12CMPI) request is generated when the setting of the flag becomes 1.

The CMPF0[0] bit is used for AN000 (unit 0)/AN100 (unit 1), the CMPF0[7] bit is used for AN007 (unit 0)/AN107 (unit 1), and the CMPF0[15] bit is used for AN115 (unit 1).

The value 1 cannot be written to the CMPF0n bit.

The CMPF0[15:8] bits of the unit 0 are reserved. Reading to these bits return 0. Writing value should be 0.

[Setting condition]

- The condition set in ADCMPLR0.CMPL0n is met.

[Clearing condition]

- 0 is written after reading 1.

57.2.28 A/D Compare Status Register1 (ADCMPSR1)

Address(es): S12AD1.ADCMPSR1 0008 91A2h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	CMPF1[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	CMPF1[4:0]	Compare Flag	Indicates compare results of AN116 to AN120. 0: Condition for comparison was not met. 1: Condition for comparison was met.	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Compare results using compare function are stored in the ADCMPSR1 register.

CMPF1[4:0] Bits (Compare Flag)

These bits are status flags to indicate the results of comparison with the selected analog inputs from among AN116 to AN120. When the result of comparison on completion of A/D conversion matches the condition set in ADCMPLR1.CMPL1n, the corresponding flags are set to 1.

When the ADCMPCR.CMPIE bit is 1, a compare interrupt (S12CMPI) request is generated when the setting of the flag becomes 1.

The CMPF1[0] bit is used for AN116 and the CMPF1[4] bit is used for AN120.

The value 1 cannot be written to the CMPF1n bit.

[Setting condition]

- The condition set in ADCMPLR1.CMPL1n is met.

[Clearing condition]

- 0 is written after reading 1.

57.2.29 A/D Compare Status Extended Register (ADCMPSER)

Address(es): S12AD1.ADCMPSER 0008 91A4h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	CMPFOC	CMPFTS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPFTS	Temperature Sensor Output Compare Flag	0: Condition for comparison was not met. 1: Condition for comparison was met.	R/W
b1	CMPFOC	Internal Reference Voltage Compare Flag	0: Condition for comparison was not met. 1: Condition for comparison was met.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Compare results using compare function are stored in the ADCMPSER register.

CMPFTS Bit (Temperature Sensor Output Compare Flag)

This bit is a status flag to indicate the result of comparison with temperature sensor output. When the result of comparison on completion of A/D conversion matches the condition set in ADCMPLER.CMPLTS bit, this flag is set to 1. When the ADCMPCR.CMPIE bit is 1, a compare interrupt (S12CMPI) request is generated when the setting of the flag becomes 1.

The value 1 cannot be written to the CMPFTS bit.

[Setting condition]

- The condition set in ADCMPLER.CMPLTS bit is met.

[Clearing condition]

- 0 is written after reading 1.

CMPFOC Bit (Internal Reference Voltage Compare Flag)

This bit is a status flag to indicate the result of comparison with internal reference voltage. When the result of comparison on completion of A/D conversion matches the condition set in ADCMPLER.CMPLOC bit, this flag is set to 1. When the ADCMPCR.CMPIE bit is 1, a compare interrupt (S12CMPI) request is generated when the setting of the flag becomes 1.

The value 1 cannot be written to the CMPFOC bit.

[Setting condition]

- The condition set in ADCMPLER.CMPLOC bit is met.

[Clearing condition]

- 0 is written after reading 1.

57.3 Operation

57.3.1 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.
A scan conversion is performed in three operating modes: single scan mode, continuous scan mode, and group scan mode. In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until the ADST bit in ADCSR register is cleared to 0 from 1 by software. In group scan mode, the selected channels of group A and the selected channels of group B are scanned once after starting to be scanned according to the respective synchronous triggers (MTU, ELC, GPT, TMR, TPU).
In single scan mode and continuous scan mode, A/D conversion is performed for ANn channels selected by the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n. In group scan mode, A/D conversion is performed for ANn channels of group A selected by the ADANSA0 and ADANSA1 registers first, and then performed for ANn channels of group B selected by the ADANSB0 and ADANSB1 registers, respectively, starting from the channel with the smallest number n.
When self-diagnosis is selected, it is executed once at the beginning of each scan and one of the three voltages internally generated in the 12-bit A/D converter is converted.
The temperature sensor output and internal reference voltage can be selected at the same time as the analog input of channels and A/D conversion of the analog input of channels, the temperature sensor output, and the internal reference voltage is performed in that order.
When the extended analog input is selected, A/D conversion should be performed in single scan mode or continuous scan mode.
Double trigger mode is to be used with single scan mode or group scan mode. With double trigger mode being enabled, A/D conversion data of a channel selected by the DBLANS[4:0] bits in ADCSR register is duplicated only if the conversion is started by any of the synchronous triggers (MTU, ELC, GPT, TMR, TPU) selected by the TRSA[5:0] bits in ADSTRGR register.
When any of AN000 to AN002 channels is set as a channel-dedicated sample-and-hold circuit by the SHANS[2:0] bits in ADSHCR register, the target analog input specified is sampled and held before the first A/D conversion of each scan.

57.3.2 Single Scan Mode

57.3.2.1 Basic Operation (Without Channel-Dedicated Sample-and-Hold Circuits)

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as below.

(1) When the ADST bit in ADCSR register is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (MTU, ELC, GPT, TMR, TPU), or input of an asynchronous trigger. A/D conversion is performed for ANn channels selected by the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
(2) Each time A/D conversion of a single channel is completed, the result of A/D conversion is stored in the corresponding A/D data register (ADDRy).
(3) When A/D conversion of all the selected channels is completed, an S12ADI interrupt request is generated if the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).
(4) The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a waiting state.

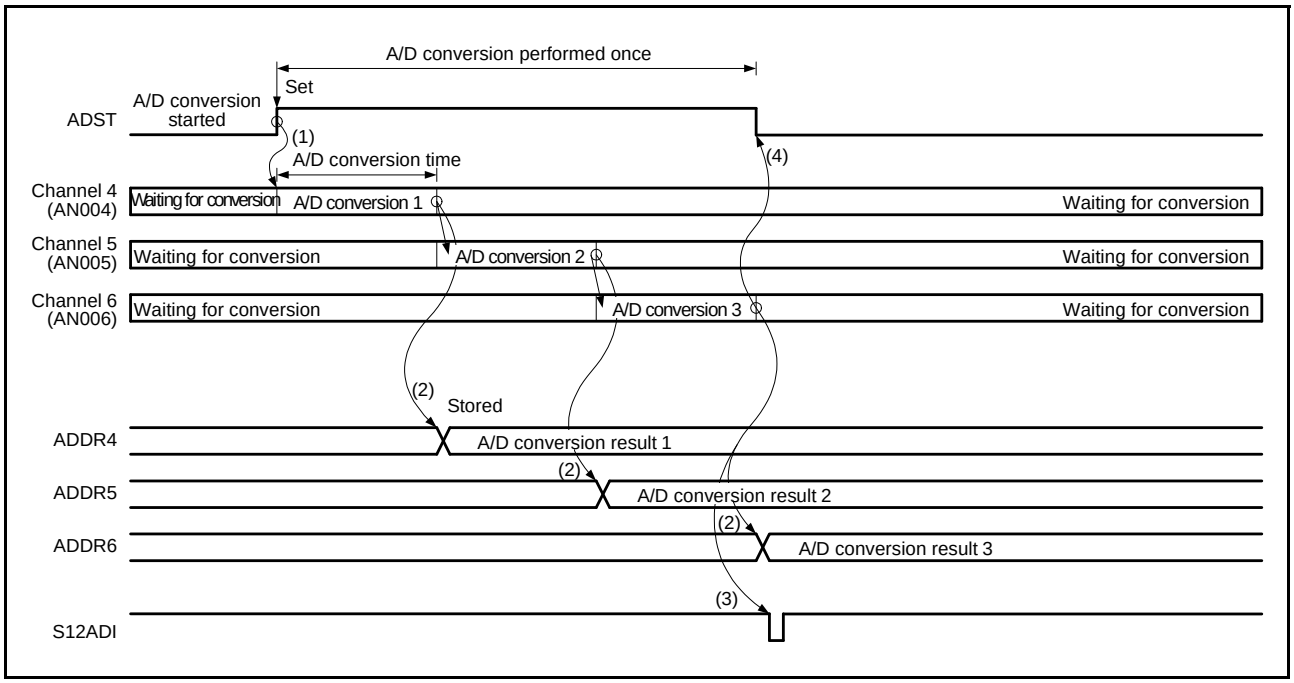

Figure 57.4 Example of Operation in Single Scan Mode (Basic Operation: AN004 to AN006 Selected)

57.3.2.2 Basic Operation (With Channel-Dedicated Sample-and-Hold Circuits, Continuous Sampling Disabled)

When a channel-dedicated sample-and-hold circuit is used while continuous sampling is disabled, sample-and-hold operations are performed first, and this is followed by A/D conversion once of the analog inputs on all selected channels. The ADSHCR.SHANS[2:0] bits are used to select the channels for which the channel-dedicated sample-and-hold circuits are to be used.

(1) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (MTU, ELC, GPT, TMR, TPU), or input of an asynchronous trigger.
(2) After sample-and-hold operation, A/D conversion is performed for ANn channels selected by the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
(3) Each time A/D conversion of a single channel is completed, the result of A/D conversion is stored in the corresponding A/D data register (ADDRy).
(4) When A/D conversion of all the selected channels is completed, an S12ADI interrupt request is generated if the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).
(5) The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a waiting state.

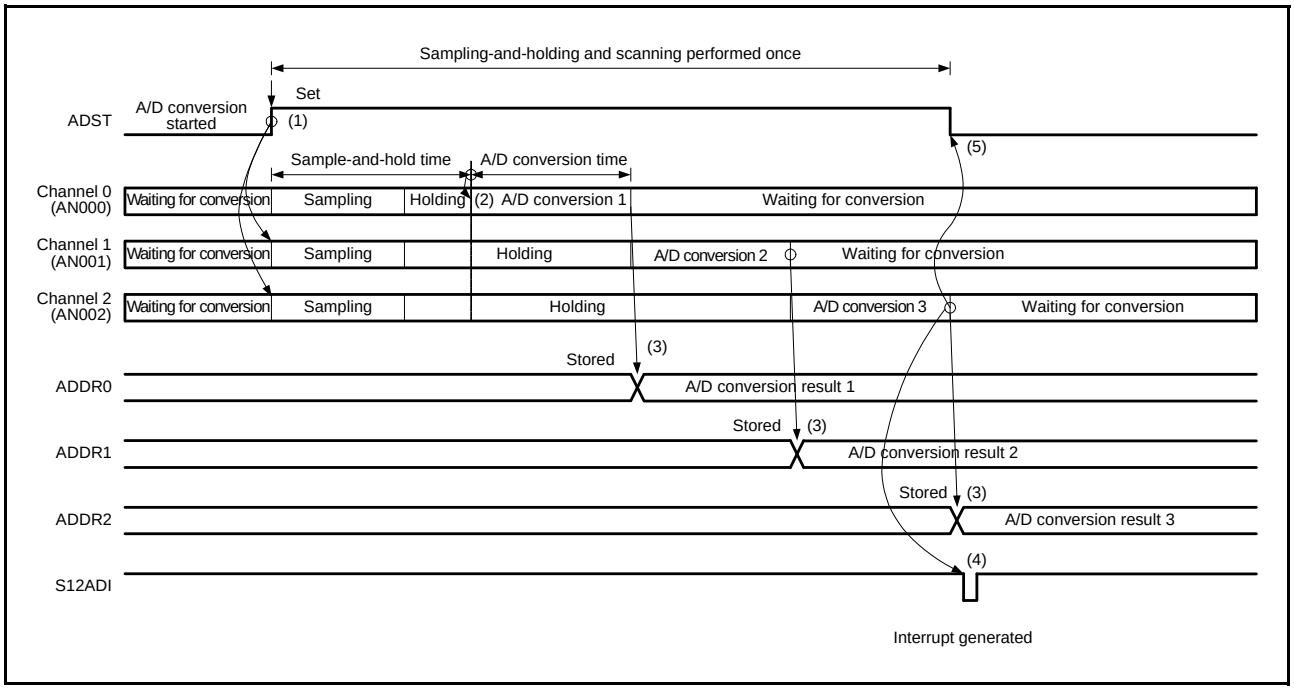

Figure 57.5 Example of Operation in Single Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000 to AN002 Selected; Continuous Sampling Disabled)

57.3.2.3 Basic Operation (With Channel-Dedicated Sample-and-Hold Circuits, Continuous Sampling Enabled)

When a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, and this is followed by A/D conversion once of the analog inputs on all selected channels. The ADSHCR.SHANS[2:0] bits are used to select the channels for which the channel-dedicated sample-and-hold circuits are to be used.

(1) When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected by the ADSHCR.SHANS[2:0] bits start continuous sampling.
(2) Analog input holding of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (MTU, GPT, TMR, TPU, ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 kΩ) has elapsed since the ADSHMSR.SHMD bit was set to 1.
(3) After the stabilization time of the sample-and-hold circuits has elapsed, A/D conversion is performed for ANn channels selected by the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
(4) Each time A/D conversion of a single channel is completed, the result of A/D conversion is stored in the corresponding A/D data register (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
(5) When A/D conversion of all the selected channels is completed, an S12ADI interrupt request is generated if the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion enabled).
(6) The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a waiting state. If this is followed by single scanning, set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).
(7) When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits are stopped.

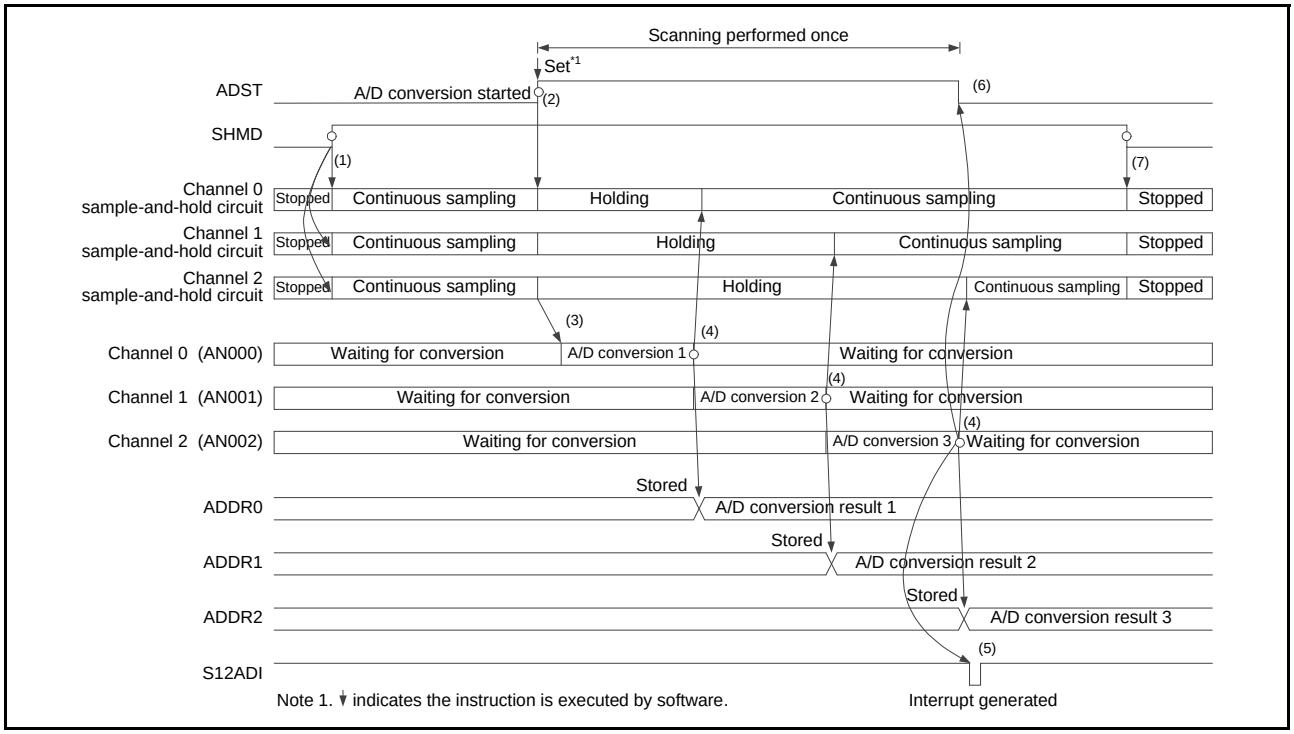

Figure 57.6 Example of Operation in Single Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000 to AN002 Selected; Continuous Sampling Enabled)

57.3.2.4 Channel Selection and Self-Diagnosis (Without Channel-Dedicated Sample-and-Hold Circuits)

When channels and self-diagnosis are selected, A/D conversion is first performed for the reference voltage VREFH0 (unit 0) or AVCC1 (unit 1) (×0, ×1/2, or ×1) supplied to the 12-bit A/D converter, and then A/D conversion is performed once on the analog input of the selected channels as below.

(1) A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (MTU, ELC, GPT, TMR, TPU), or input of an asynchronous trigger.
(2) When A/D conversion for self-diagnosis is completed, the result of A/D conversion is stored in the A/D self-diagnosis data register (ADRD). A/D conversion is then performed for ANn channels selected by the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
(3) Each time A/D conversion of a single channel is completed, the result of A/D conversion is stored in the corresponding A/D data register (ADDRy).
(4) When A/D conversion of all the selected channels is completed, an S12ADI interrupt request is generated if the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion enabled).
(5) The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a waiting state.

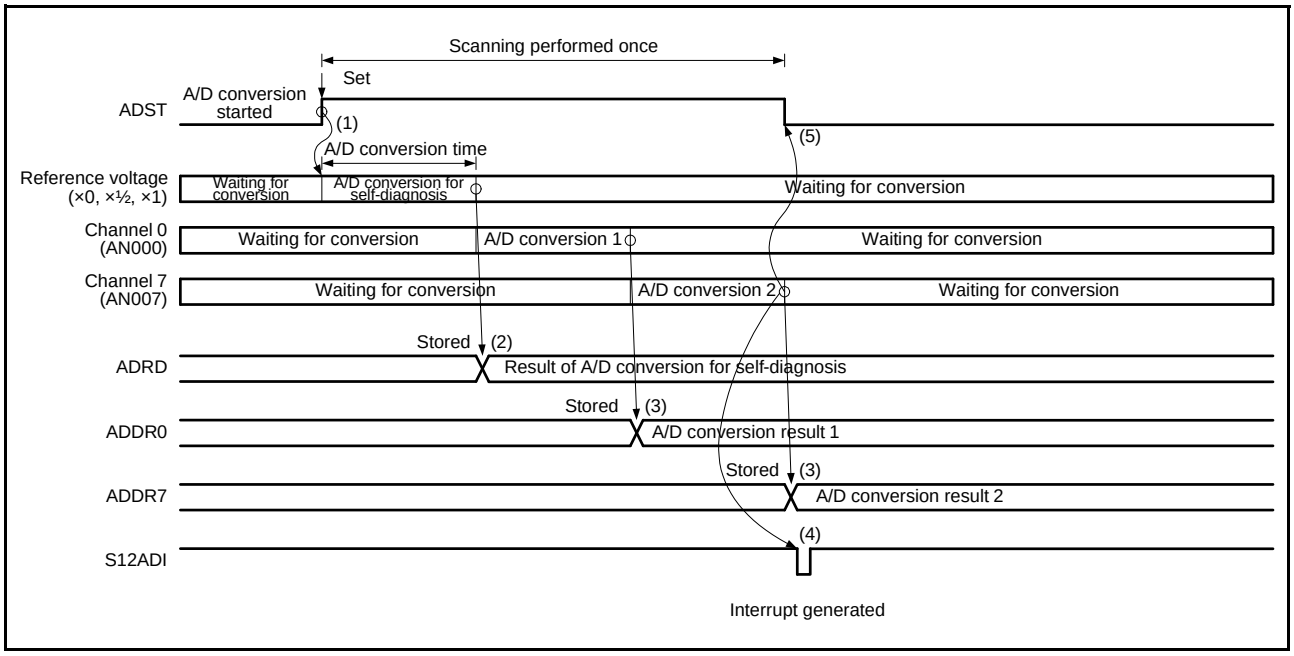

Figure 57.7 Example of Operation in Single Scan Mode (Basic Operation: AN000 and AN007 Selected + Self-Diagnosis)

57.3.2.5 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and-Hold Circuits, Continuous Sampling Disabled)

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is disabled, sample-and-hold operations are performed first, and this is followed by A/D conversion of the reference voltage VREFH0 (unit 0) or AVCC1 (unit 1) (×0, ×1/2, or ×1) supplied to the 12-bit A/D converter as below. After that, A/D conversion is performed only once on the analog input of the selected channels.

(1) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (MTU, ELC, GPT, TMR, TPU), or input of an asynchronous trigger.
(2) After sample-and-hold operation, A/D conversion for self-diagnosis is started.
(3) When A/D conversion for self-diagnosis is completed, the result of A/D conversion is stored in the A/D self-diagnosis data register (ADRD). A/D conversion is then performed for ANn channels selected by the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
(4) Each time A/D conversion of a single channel is completed, the result of A/D conversion is stored in the corresponding A/D data register (ADDRy).
(5) When A/D conversion of all the selected channels is completed, an S12ADI interrupt request is generated if the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion enabled).
(6) The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a waiting state.

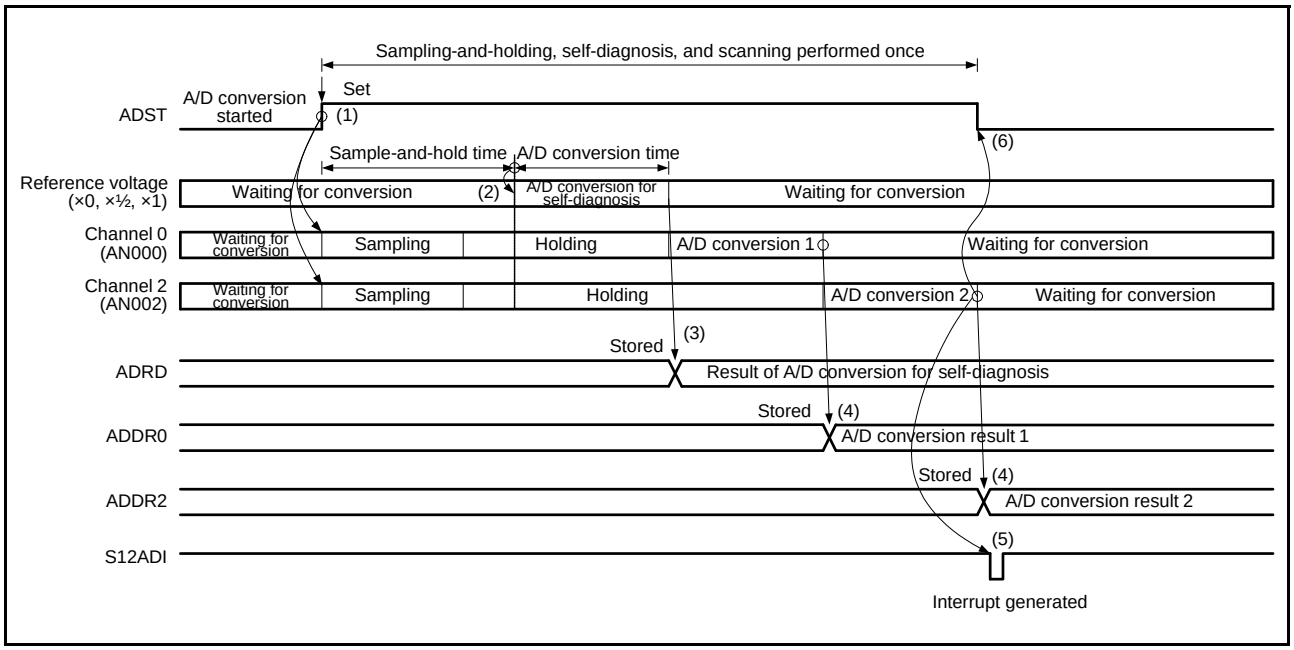

Figure 57.8 Example of Operation in Single Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000 and AN002 Selected + Self-Diagnosis; Continuous Sampling Disabled)

57.3.2.6 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and-Hold Circuits; Continuous Sampling Enabled)

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, and this is followed by A/D conversion of the reference voltage VREFH0 (unit 0) or AVCC1 (unit 1) (×0, ×1/2, or ×1) supplied to the 12-bit A/D converter as below. After that, A/D conversion is performed only once on the analog input of the selected channels.

(1) When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected by the ADSHCR.SHANS[2:0] bits start continuous sampling.

(2) Analog input holding of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (MTU, GPT, TMR, TPU, ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 kΩ) has elapsed since the ADSHMSR.SHMD bit was set to 1.

(3) After the stabilization time of the sample-and-hold circuits has elapsed, A/D conversion for self-diagnosis is started.

(4) When A/D conversion for self-diagnosis is completed, the result of A/D conversion is stored in the A/D self-diagnosis data register (ADRD). A/D conversion is then performed for ANn channels selected by the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.

(5) Each time A/D conversion of a single channel is completed, the result of A/D conversion is stored in the corresponding A/D data register (ADDRy), and the sample-and-hold circuit restarts continuous sampling.

(6) When A/D conversion of all the selected channels is completed, an S12ADI interrupt request is generated if the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion enabled).

(7) The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a waiting state. If this is followed by single scanning, set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).

(8) When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits are stopped.

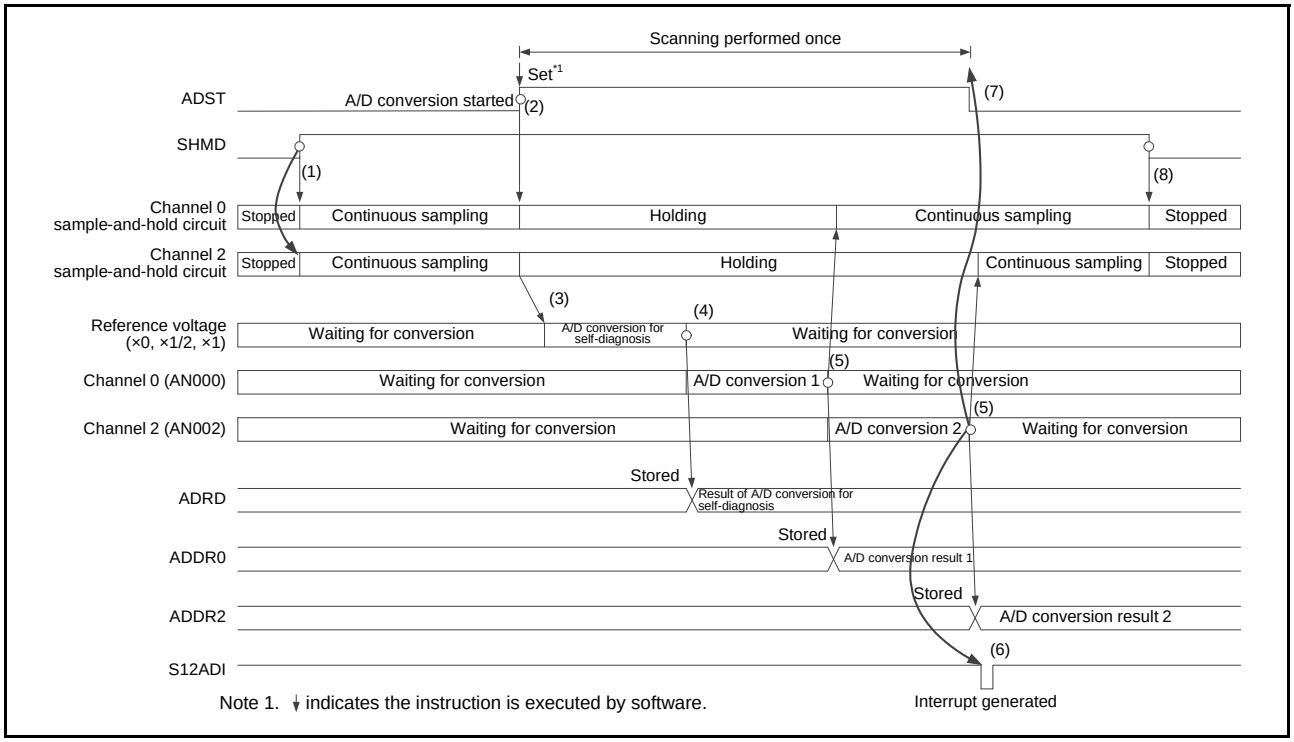

Figure 57.9 Example of Operation in Single Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000 to AN002 Selected + Self-Diagnosis; Continuous Sampling Enabled)

57.3.2.7 A/D Conversion of Temperature Sensor Output/Internal Reference Voltage

When the channels and temperature sensor output or internal reference voltage are selected at the same time, A/D conversion is first performed on the analog input of the selected channels, and then A/D conversion is performed once on the temperature sensor output or the internal reference voltage as below. When both temperature sensor output and internal reference voltage are selected, A/D conversion of the temperature sensor output and internal reference voltage is performed in that order.
With the channels deselected, selecting only the temperature sensor output or internal reference voltage is also possible.

(1) When software, synchronous trigger (MTU, ELC, GPT, TMR or TPU), or asynchronous trigger sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers starts in order from the channel with the lowest number n.
(2) On completion of A/D conversion on the channel, the result is stored in the corresponding A/D data register (ADDRy), and then A/D conversion of temperature sensor output starts.
(3) On completion of A/D conversion of temperature sensor output, the result is stored in the corresponding A/D temperature sensor data register (ADTRDR), and then A/D conversion of internal reference voltage starts.
(4) On completion of A/D conversion of internal reference voltage, the result is stored in the corresponding A/D internal reference voltage data register (ADOCDR), and if the ADCSR.ADIE bit is set to 1 (enabling S12ADI interrupt generation upon scan conversion completion), an S12ADI interrupt request is generated.
(5) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 upon completion of A/D conversion. Then the 12-bit A/D converter enters a waiting state.

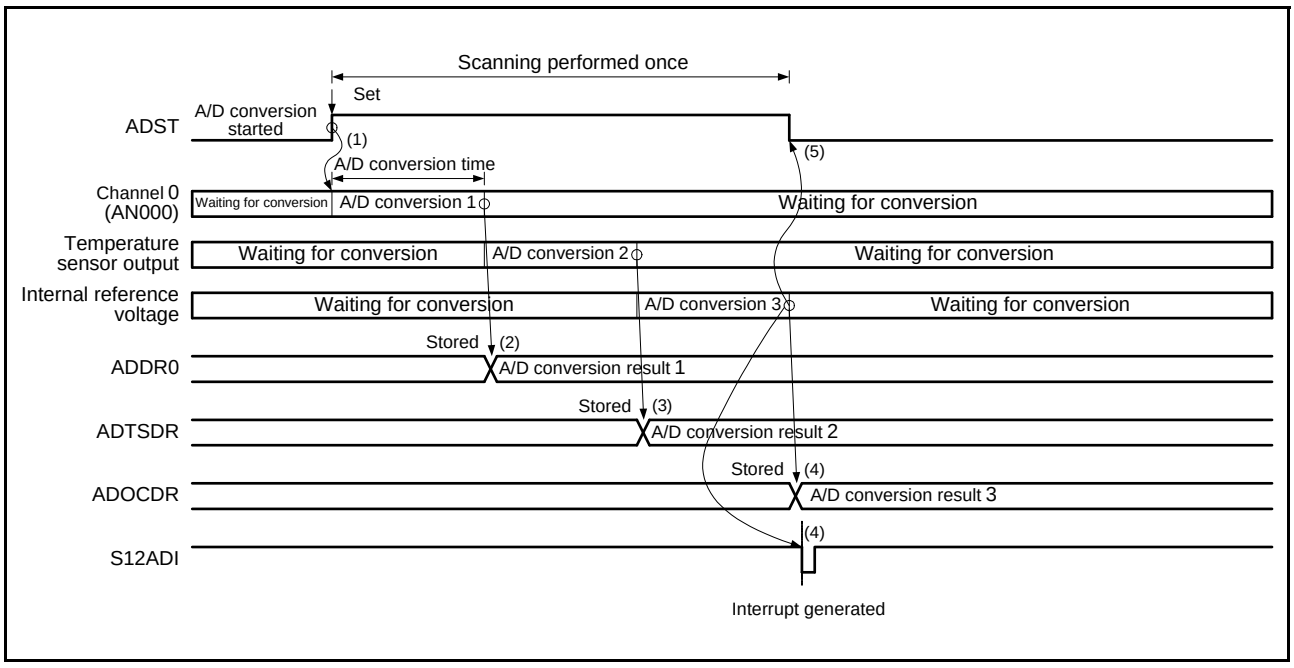

Figure 57.10 Example of Operation in Single Scan Mode (Basic Operation: AN000 and Temperature Sensor Output or Internal Reference Voltage Selected)

57.3.2.8 A/D Conversion in Double Trigger Mode

When double trigger mode is selected in single scan mode, two rounds of single scan operation started by a synchronous trigger (MTU, ELC, GPT, TMR, TPU) are performed as a sequence as shown below.
Self-diagnosis should be deselected, and the temperature sensor output A/D conversion select bits (ADEXICR.TSSA and ADEXICR.TSSB) and the internal reference voltage A/D conversion select bits (ADEXICR.OCSA and ADEXICR.OCSB) should be both set to 0.
Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the DBLANS[4:0] bits in ADCSR register and setting the DBLE bit in ADCSR register to 1. When the DBLE bit in ADCSR register is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid. In double trigger mode, a synchronous trigger (MTU, ELC, GPT, TMR, TPU) should be selected using the TRSA[5:0] bits in ADSTRGR register; the EXTRG bit and TRGE bit in ADCSR register should be set to 0 and 1, respectively. Software trigger should not be used.

(1) When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (MTU, ELC, GPT, TMR, TPU), A/D conversion is started on the single channel selected by the DBLANS[4:0] bits in ADCSR register.
(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(3) The ADCSR.ADST bit is automatically cleared to 0 and the 12-bit A/D converter enters a waiting state. Here, an S12ADI interrupt request is not generated irrespective of the ADIE (S12ADI interrupt upon scanning completion enabled) bit setting in ADCSR register.
(4) When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger input, A/D conversion is started on the single channel selected by the DBLANS[4:0] bits in ADCSR register.
(5) When A/D conversion is completed, the A/D conversion result is stored into the A/D data duplication register (ADDBLDR), which is exclusively used in double trigger mode.
(6) If the ADIE bit in ADCSR register is 1 (S12ADI interrupt upon scanning completion enabled), an S12ADI interrupt request is generated.
(7) The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion is completed. Then the 12-bit A/D converter enters a waiting state.

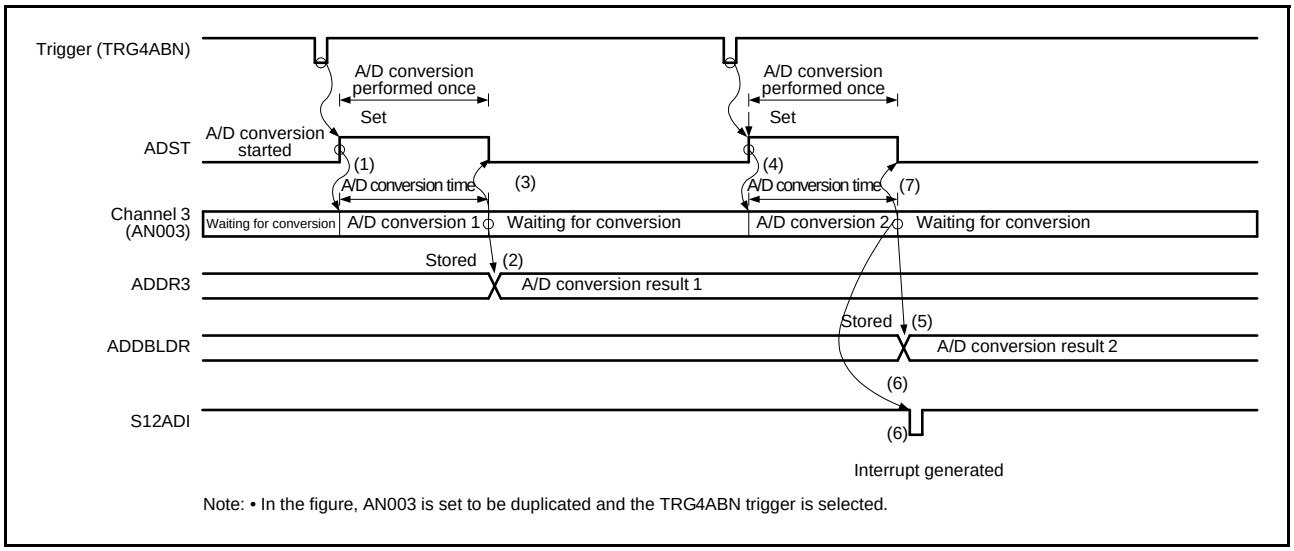

Figure 57.11 Example of Operation in Single Scan Mode (Double Trigger Mode Selected; AN003 Duplicated)

57.3.2.9 Extended Operations When Double Trigger Mode is Selected

When double trigger mode is selected in single scan mode, and a synchronous trigger TRGnAN or TRGnBN (n = 4, 7) is selected as the trigger for the start of A/D conversion (the ADSTRGR.TRSA[5:0] bits are set to 0Bh or 0Fh), or GTADTRAmN or GTADTRBmN (m = 0 to 3) is selected (the ADSTRGR.TRSA[5:0] bits are set to 19h, 1Ah, 1Bh, or 1Ch), the following operations are included with the operations described when double trigger mode is selected.
When A/D conversion is started by a synchronous trigger A (TRGnAN; n = 4, 7, or GTADTRAmN; m = 0 to 3), the results of A/D conversion are stored in A/D data duplication register A (ADDBLDRA). Furthermore, when A/D conversion is started by a synchronous trigger B (TRGnBN; n = 4, 7) or GTADTRBmN (m = 0 to 3), the results of A/D conversion are stored in A/D data duplication register B (ADDBLDRB). With the correspondence between synchronous trigger sources and registers for data storage determined in this way, the target register for storing the results of A/D conversion does not depend on the order of trigger input. Results of A/D conversion are also stored in the A/D data register (ADDRy) and the A/D data duplication register (ADDBLDR) at the same time, and this depends on the order of trigger input.
In extended double trigger mode, if two types of triggers have occurred simultaneously with TRGnAN or TRGnBN (n = 4, 7) or GTADTRAmN or GTADTRBmN (m = 0 to 3) selected, results are not sorted by the trigger sources and are stored in A/D data duplication register B (ADDBLDRB).
Note that if a new trigger source is input during A/D conversion caused by another trigger source, the former new trigger source is ignored and sorting is performed by the latter trigger source.

The extended operations in double trigger mode when the first trigger is TRG4AN with the synchronous trigger TRG4AN or TRG4BN selected as the trigger for the start of A/D conversion are performed as follows.

(1) A/D conversion for the single channel selected by the ADCSR.DBLANS[4:0] bits starts when the TRG4AN input sets the ADCSR.ADST bit to 1 (starting A/D conversion).
(2) The result is stored in A/D data-duplication register A (ADDBLDRA) and in the corresponding A/D data register (ADDRy) on completion of the A/D conversion for the channel.
(3) The ADCSR.ADST bit is automatically cleared and the 12-bit A/D converter enters the waiting state. An S12ADI interrupt is not output at this time, regardless of the setting of the ADCSR.ADIE bit (i.e. whether or not this is set to enable S12ADI interrupts in response to scan completion).
(4) When the TRG4BN input sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the single channel selected by the ADCSR.DBLANS[4:0] bits starts.
(5) The result is stored in A/D data-duplication register B (ADDBLDRB) and in the A/D data-duplication register (ADDBLDR) on completion of A/D conversion.
(6) An S12ADI interrupt request is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion enabled).
(7) The ADCSR.ADST bit retains the value 1 (starting A/D conversion) during A/D conversion and is automatically cleared on completion of conversion, after which the 12-bit A/D converter enters the waiting state.

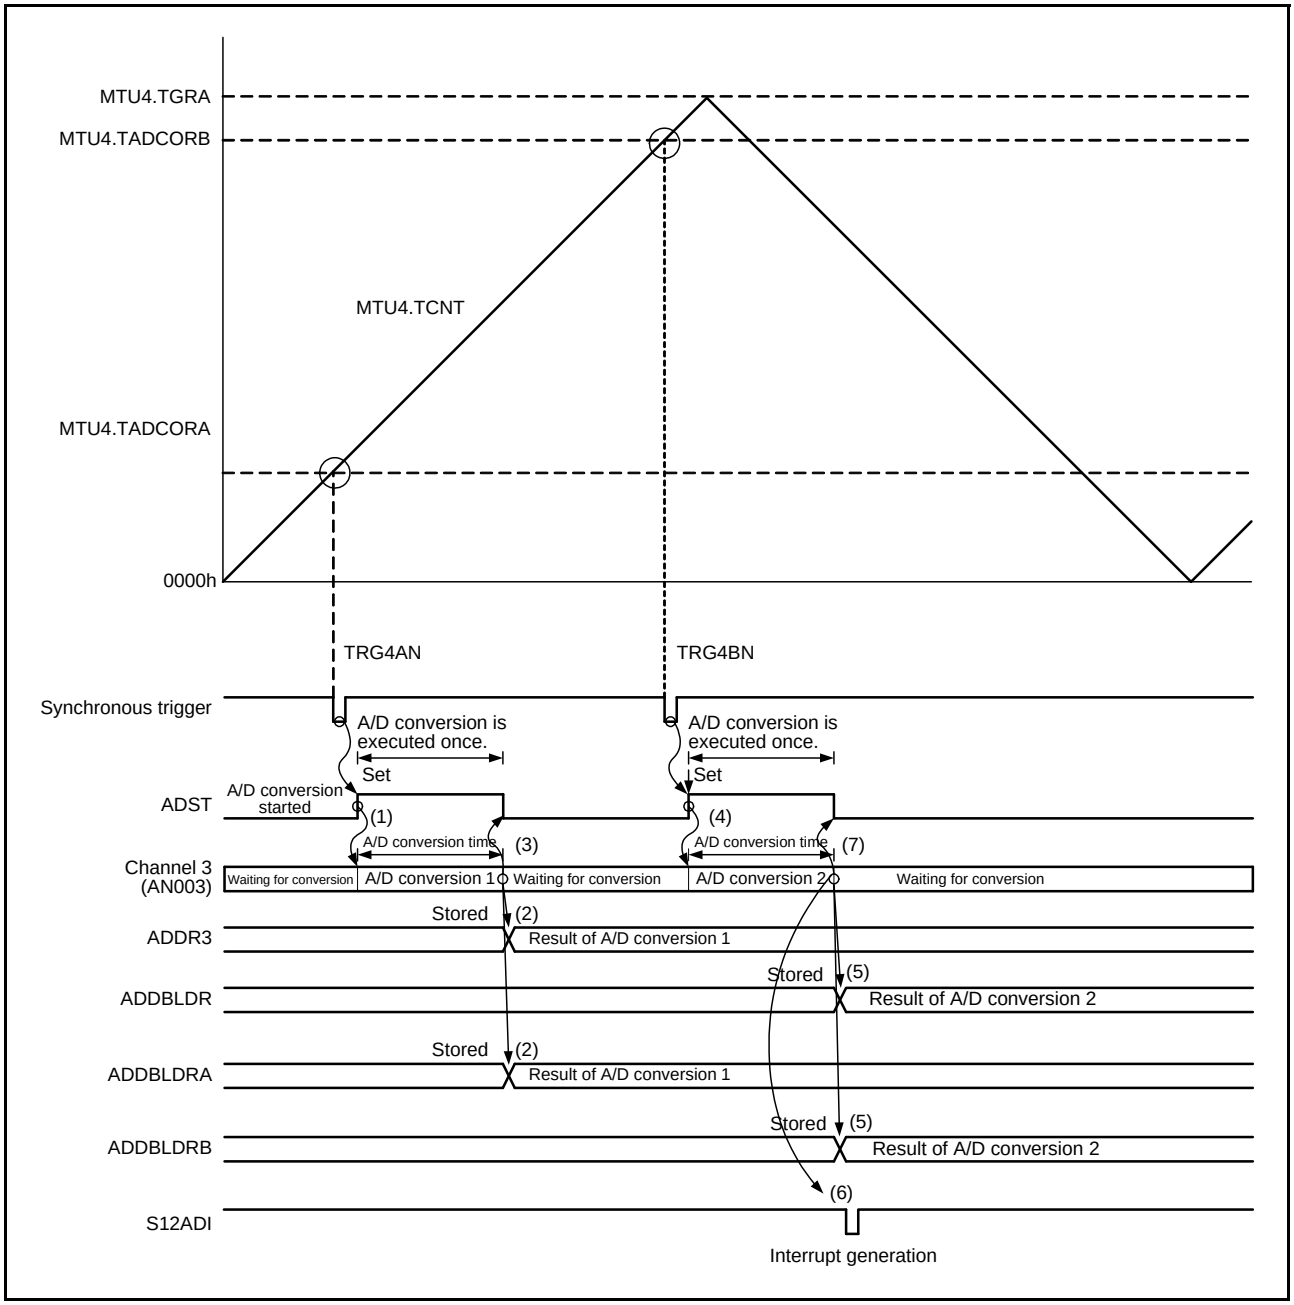

Figure 57.12 Example of Extended Operation in Double Trigger Mode (1)
(Duplication Selected for AN003, TRG4AN or TRG4BN Selected, First Trigger is TRG4AN)

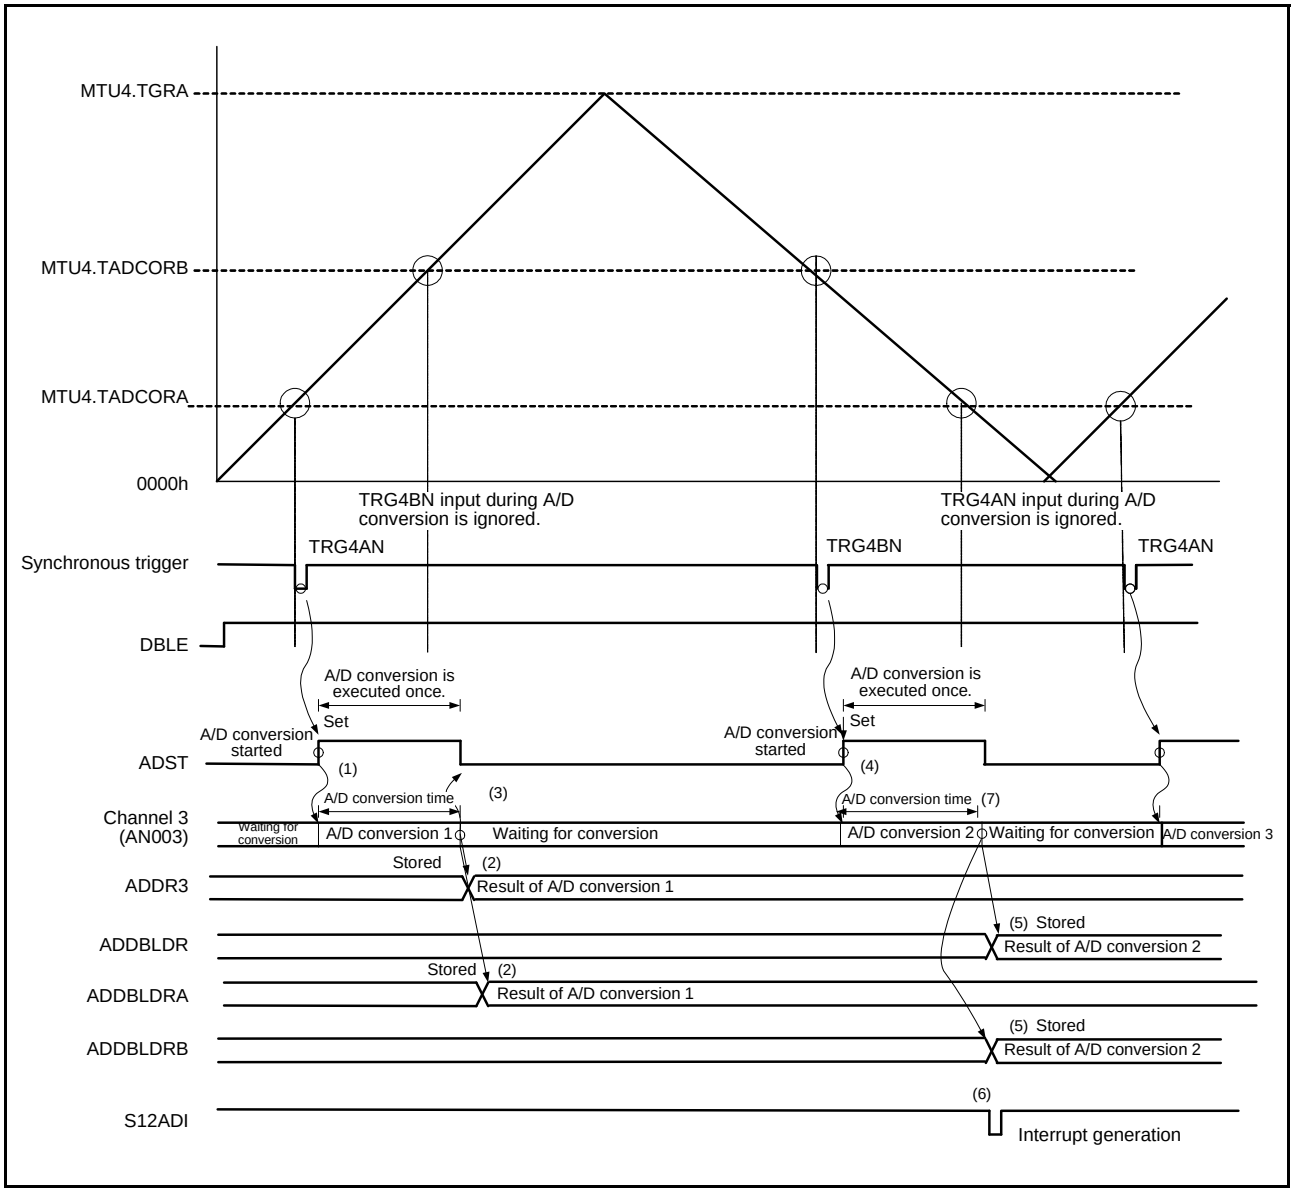

Figure 57.13 Example of Extended Operation in Double Trigger Mode (2)
(Duplication Selected for AN003, TRG4AN and TRG4BN Selected, First Trigger is TRG4AN)

The following describes the extended operations in double trigger mode in response to TRG4BN as the first trigger, again in the case where TRG4AN or TRG4BN is selected as the synchronous trigger for the start of A/D conversion.

(1) When the TRG4BN input sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the single channel selected by the ADCSR.DBLANS[4:0] bits starts.
(2) On completion of A/D conversion, the result is stored in A/D data duplication register B (ADDBLDRB) and in the corresponding A/D data register (ADDRy).
(3) The ADCSR.ADST bit is automatically cleared and the 12-bit A/D converter enters the waiting state. An S12ADI interrupt is not generated at this time, regardless of the setting of the ADCSR.ADIE bit (i.e. whether or not this is set to enable S12ADI interrupts in response to scan completion).
(4) When the TRG4AN input sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the single channel selected by the ADCSR.DBLANS[4:0] bits starts.
(5) On completion of A/D conversion, the result is stored in A/D data duplication register A (ADDBLDRA) and in the A/ D data duplication register (ADDBLDR).
(6) An S12ADI interrupt request is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).
(7) The ADCSR.ADST bit retains the value 1 (starting A/D conversion) during A/D conversion and is cleared on completion of conversion, after which the 12-bit A/D converter enters the waiting state.

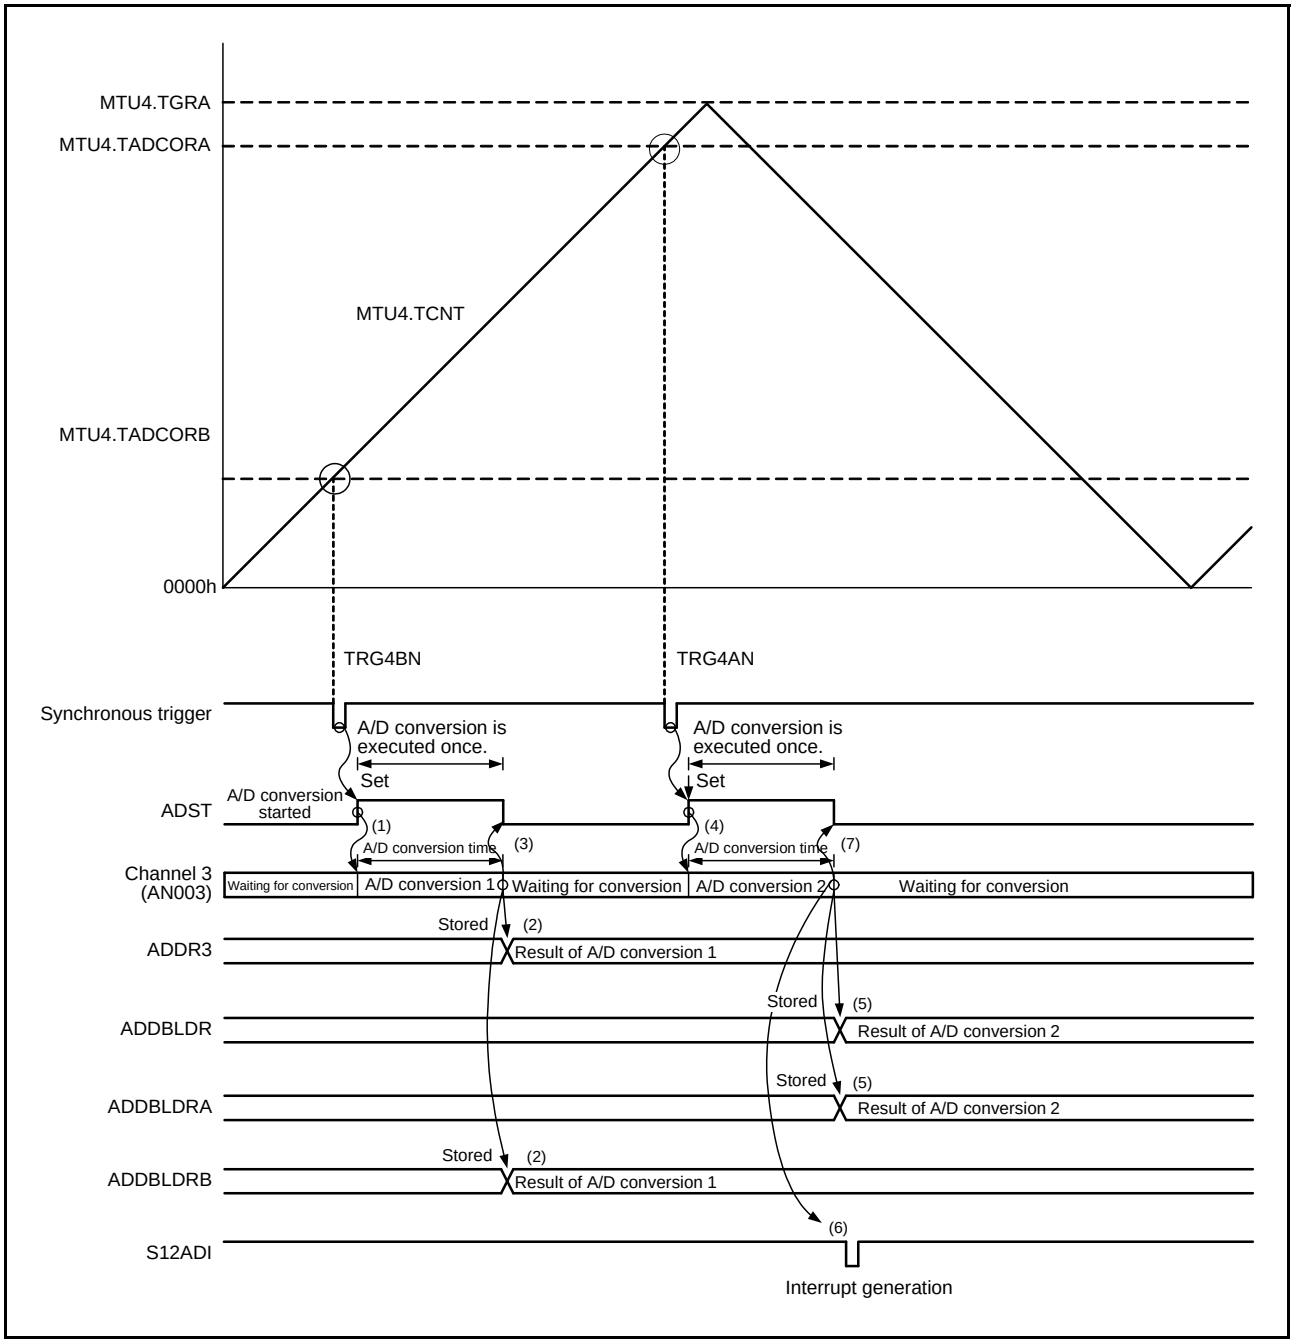

Figure 57.14 Example of Extended Operation in Double Trigger Mode (1)
(Duplication Selected for AN003, TRG4AN and TRG4BN Selected, First Trigger is TRG4BN)

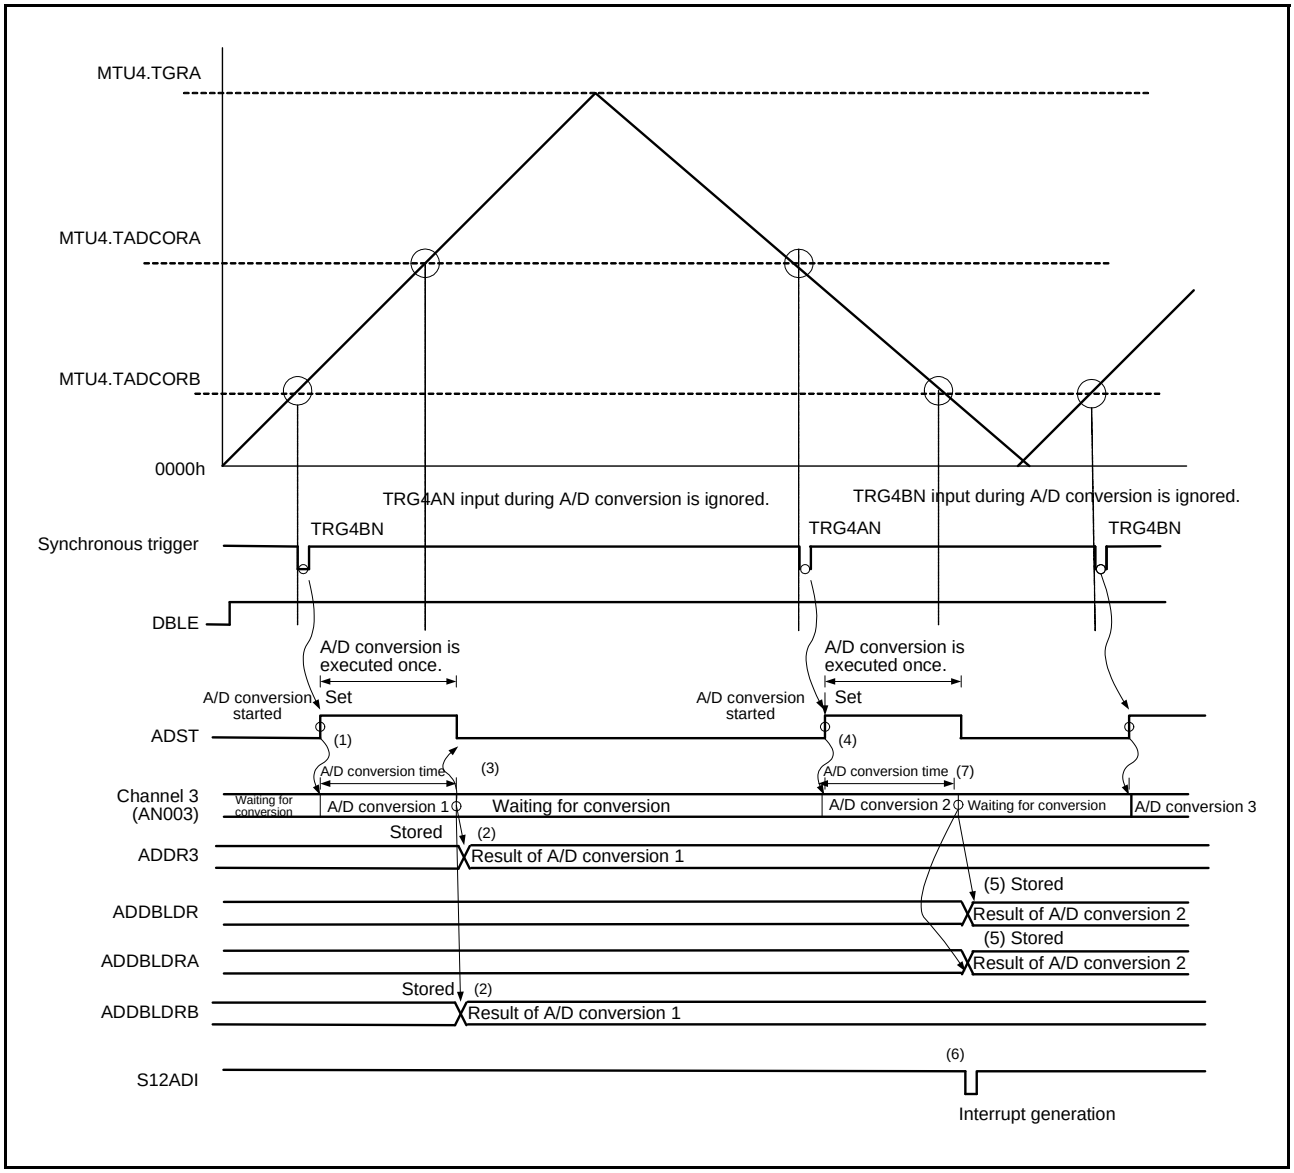

Figure 57.15 Example of Extended Operation in Double Trigger Mode (2)
(Duplication Selected for AN003, TRG4AN and TRG4BN Selected, First Trigger is TRG4BN)

The followings are the extended operations in double trigger mode performed when two types of trigger sources simultaneously occur with the synchronous trigger GTADTRA0N or GTADTRB0N selected as an A/D conversion start trigger.

(1) The first A/D conversion on the single channel selected by the ADCSR.DBLANS[4:0] bits starts when the first simultaneous input of the two trigger sources GTADTRA0N and GTADTRB0N sets the ADCSR.ADST bit to 1 (starting A/D conversion).
(2) The result is stored in A/D data duplication register B (ADDBLDRB) and in the corresponding A/D data register (ADDRy) on completion of the A/D conversion on the channel.
(3) The ADCSR.ADST bit is automatically cleared and the 12-bit A/D converter enters the waiting state. An S12ADI interrupt is not generated at this time, regardless of the setting of the ADCSR.ADIE bit (i.e. whether or not this is set to enable S12ADI interrupts in response to scan completion).
(4) The second A/D conversion on the single channel selected by the ADCSR.DBLANS[4:0] bits starts when the second simultaneous input of the two trigger sources GTADTRA0N and GTADTRB0N sets the ADCSR.ADST bit to 1 (starting A/D conversion).
(5) The result is stored in A/D data duplication register B (ADDBLDRB) and in A/D data duplication register (ADDBLDR) on completion of the A/D conversion.
(6) An S12ADI interrupt request is generated if the setting of the ADCSR.ADIE bit is 1 (enabling S12ADI interrupt).
(7) The ADCSR.ADST bit retains the value 1 (starting A/D conversion) during A/D conversion and is cleared on completion of conversion, after which the 12-bit A/D converter enters the waiting state.

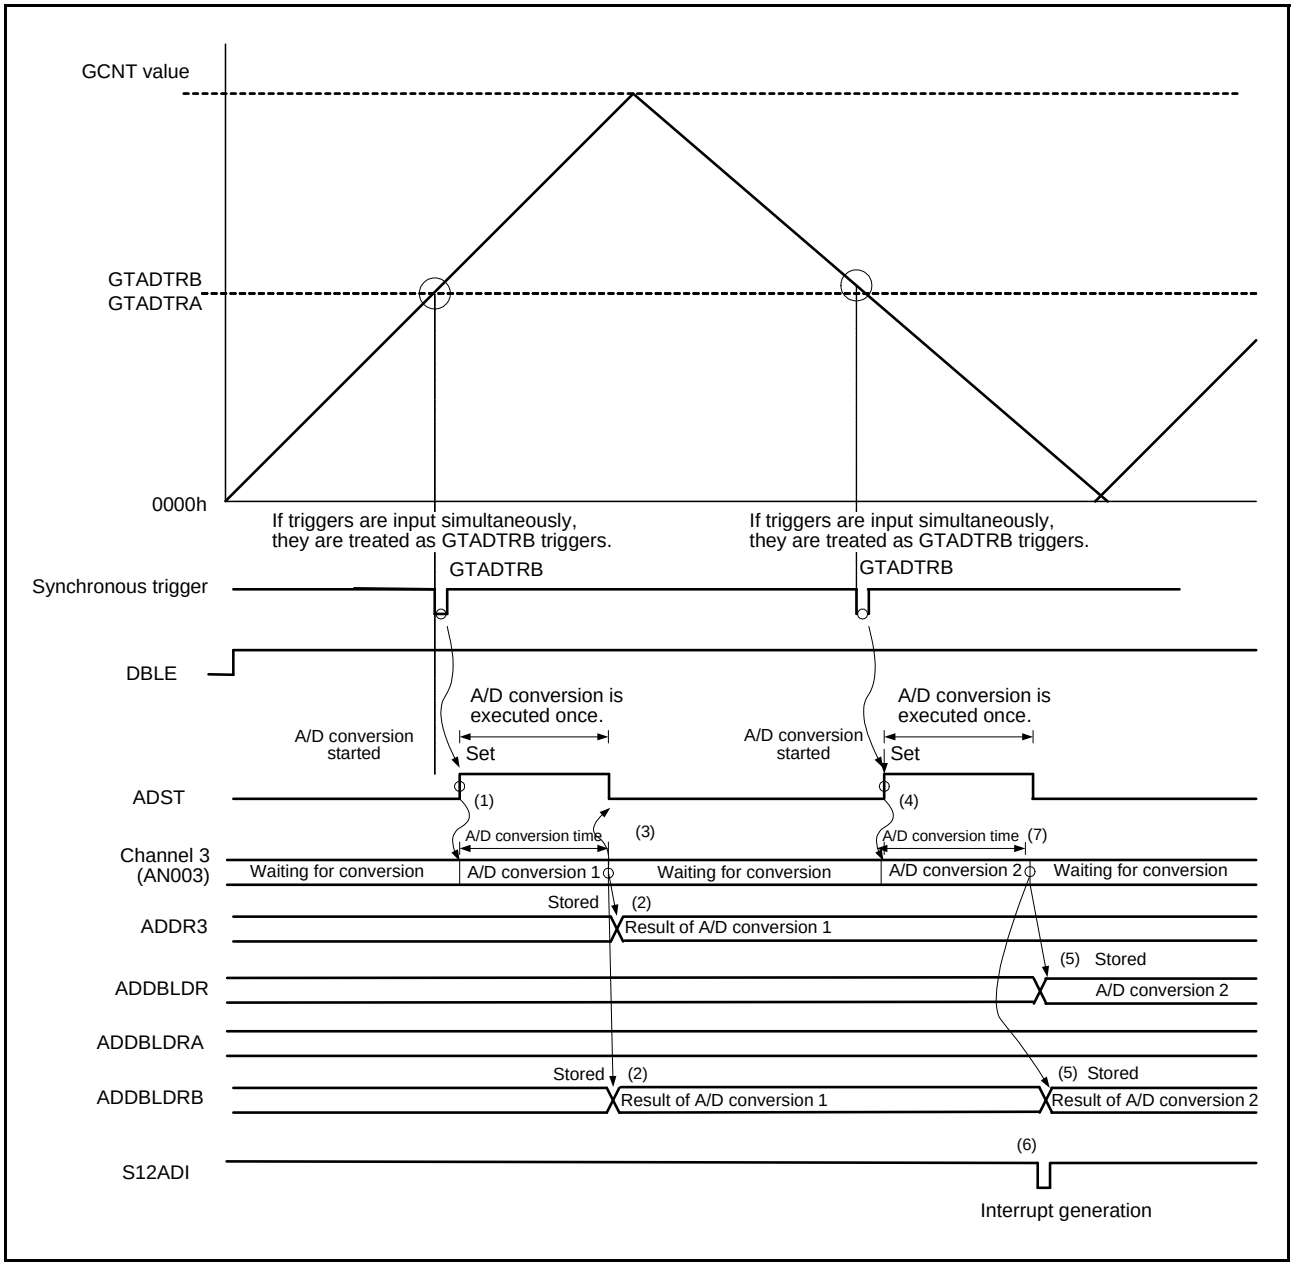

Figure 57.16 Example of Extended Operation in Double Trigger Mode (Duplication Selected for AN003, GTADTRA0N and GTADTRB0N Selected, Two Trigger Sources Simultaneously Occurred)

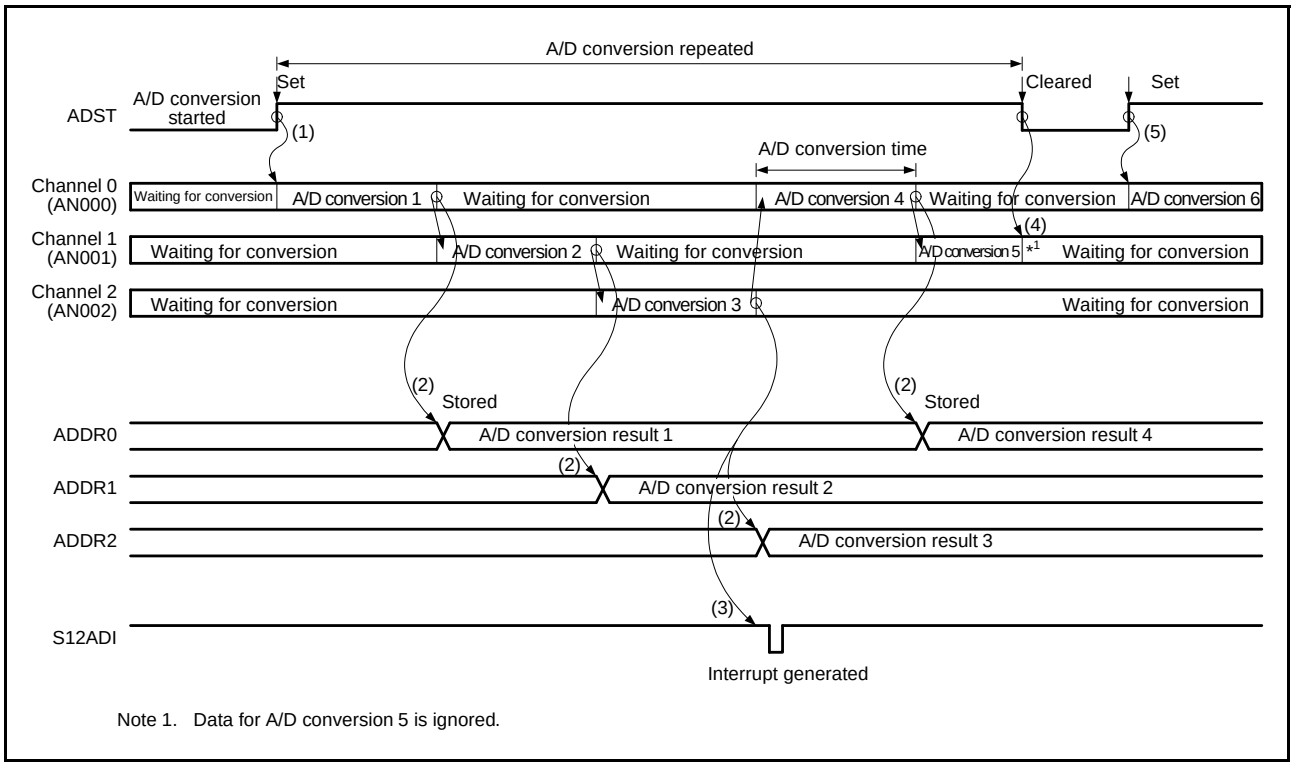
57.3.3 Continuous Scan Mode

57.3.3.1 Basic Operation (Without Channel-Dedicated Sample-and-Hold Circuits)

In basic operation of continuous scan mode, A/D conversion is performed repeatedly on the analog input of the specified channels as below.

(1) When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (MTU, ELC, GPT, TMR, TPU), or an asynchronous trigger input, A/D conversion is performed for ANn channels selected by the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(3) When A/D conversion of all the selected channels is completed, an S12ADI interrupt request is generated if the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion enabled).
The 12-bit A/D converter sequentially starts A/D conversion for ANn channels selected by the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
(4) The ADCSR.ADST bit is not automatically cleared and steps 2 and 3 are repeated as long as the bit remains 1 (A/ D conversion start). When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the 12-bit A/D converter enters a waiting state.
(5) When the ADCSR.ADST bit is later set to 1 (A/D conversion start), A/D conversion is started again for ANn channels selected by the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.



Note 1. Data for A/D conversion 5 is ignored.

Figure 57.17 Example of Operation in Continuous Scan Mode (Basic Operation: AN000 to AN002 Selected)

57.3.3.2 Basic Operation (With Channel-Dedicated Sample-and-Hold Circuits, Continuous Sampling Disabled)

When a channel-dedicated sample-and-hold circuit is used while continuous sampling is disabled, sample-and-hold operations are performed first, after which the analog inputs on all selected channels are A/D converted in accord with the description below. The channels for which the channel-dedicated sample-and-hold circuits are to be used can be selected by the ADSHCR.SHANS[2:0] bits.

(1) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (MTU, ELC, GPT, TMR, TPU), or input of an asynchronous trigger.
(2) After sample-and-hold operation, A/D conversion is performed for ANn channels selected by the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
(3) Each time A/D conversion of a single channel is completed, the result of A/D conversion is stored in the corresponding A/D data register (ADDRy).
(4) When A/D conversion of all the selected channels is completed, an S12ADI interrupt request is generated if the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled). At the same time, analog input sampling is started for all the channels for which the channel-dedicated sample-and-hold circuits are to be used.
(5) The ADCSR.ADST bit is not automatically cleared and steps 2 to 4 are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the 12-bit A/D converter enters a waiting state.
(6) When the ADCSR.ADST bit is then set to 1 (A/D conversion start), analog input sampling is started again for all the channels for which the channel-dedicated sample-and-hold circuits are to be used.

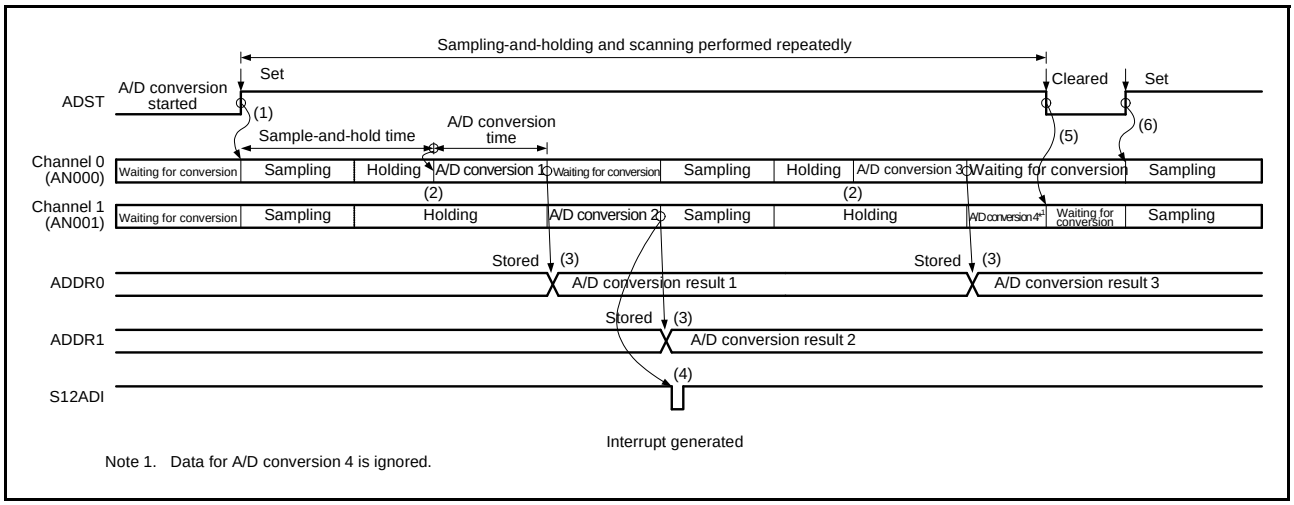


Figure 57.18 Example of Operation in Continuous Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000 and AN001 Selected; Continuous Sampling Disabled)

57.3.3.3 Basic Operation (With Channel-Dedicated Sample-and-Hold Circuits, Continuous Sampling Enabled)

When a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, after which the analog inputs on all selected channels are A/D converted in accord with the description below. The channels for which the channel-dedicated sample-and-hold circuits are to be used can be selected by the ADSHCR.SHANS[2:0] bits.

(1) When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected by the ADSHCR.SHANS[2:0] bits start continuous sampling.
(2) Analog input holding of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (MTU, GPT, TMR, TPU, ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 kΩ) has elapsed since the ADSHMSR.SHMD bit was set to 1.
(3) After the stabilization time of the sample-and-hold circuits has elapsed, A/D conversion is performed for ANn channels selected by the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
(4) Each time A/D conversion of a single channel is completed, the result of A/D conversion is stored in the corresponding A/D data register (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
(5) When A/D conversion of all the selected channels is completed, an S12ADI interrupt request is generated if the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion enabled). Also, analog input holding of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started.
(6) The ADCSR.ADST bit is not automatically cleared and steps 3 to 5 are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the 12-bit A/D converter enters a waiting state.
(7) When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits are stopped.
(8) When the ADSHMSR.SHMD bit is then set to 1, the sample-and-hold circuits selected by the ADSHCR.SHANS[2:0] bits start continuous sampling.
(9) When the ADCSR.ADST bit is then set to 1 (A/D conversion start), analog input holding of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started.

Note: If continuous scanning is performed when only the channels with the sample-and-hold circuits are selected, time for continuous sampling cannot be secured in the second and subsequent continuous scanning. When continuous sampling by the channel-dedicated sample-and-hold circuits is enabled for continuous scanning, select one or more channels among AN003 to AN007 and set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).

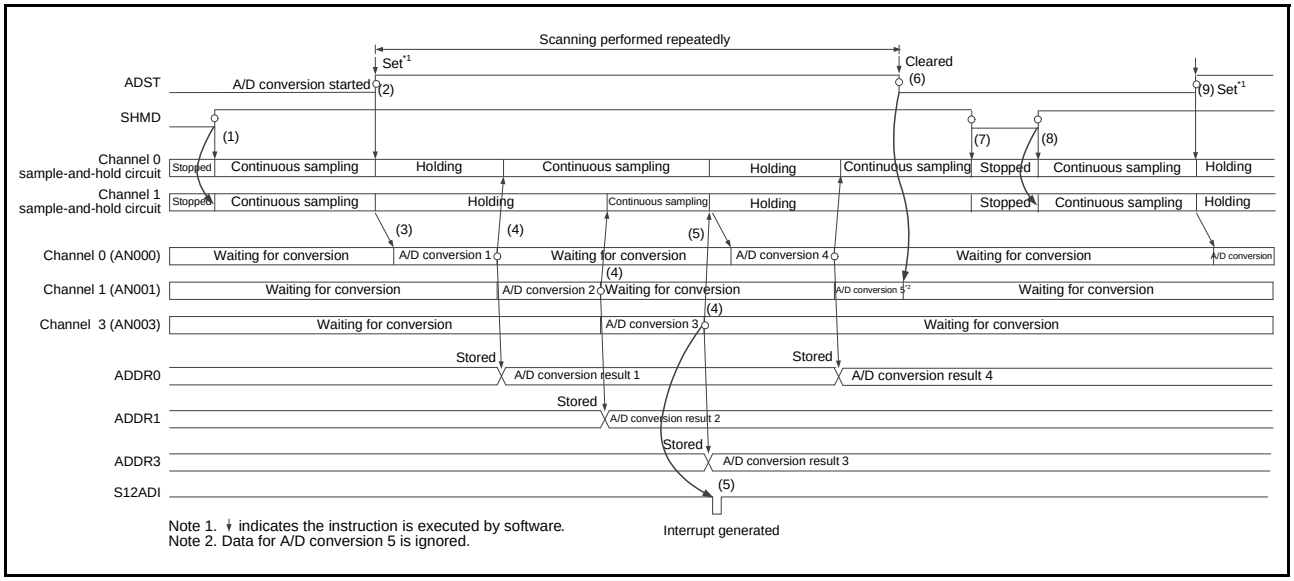

Figure 57.19 Example of Operation in Continuous Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000, AN001, and AN003 Selected; Continuous Sampling Enabled)

57.3.3.4 Channel Selection and Self-Diagnosis (Without Channel-Dedicated Sample-and-Hold Circuits)

When channels and self-diagnosis are selected at the same time, A/D conversion is first performed for the reference voltage VREFH0 (unit 0) or AVCC1 (unit 1) (×0, ×1/2, or ×1) supplied to the 12-bit A/D converter, after which the analog inputs on all selected channels are A/D converted in accord with the description below.

(1) A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (MTU, ELC, GPT, TMR, TPU), or input of an asynchronous trigger.
(2) When A/D conversion for self-diagnosis is completed, the result of A/D conversion is stored in the A/D self-diagnosis data register (ADRD). A/D conversion is then performed for ANn channels selected by the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
(3) Each time A/D conversion of a single channel is completed, the result of A/D conversion is stored in the corresponding A/D data register (ADDRy).
(4) When A/D conversion of all the selected channels is completed, an S12ADI interrupt request is generated if the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled). At the same time, the 12-bit A/D converter starts A/D conversion for self-diagnosis and then starts A/D conversion on ANn channels selected by the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
(5) The ADCSR.ADST bit is not automatically cleared and steps 2 to 4 are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the 12-bit A/D converter enters a waiting state.
(6) When the ADCSR.ADST bit is later set to 1 (A/D conversion start), the A/D conversion for self-diagnosis is started again.

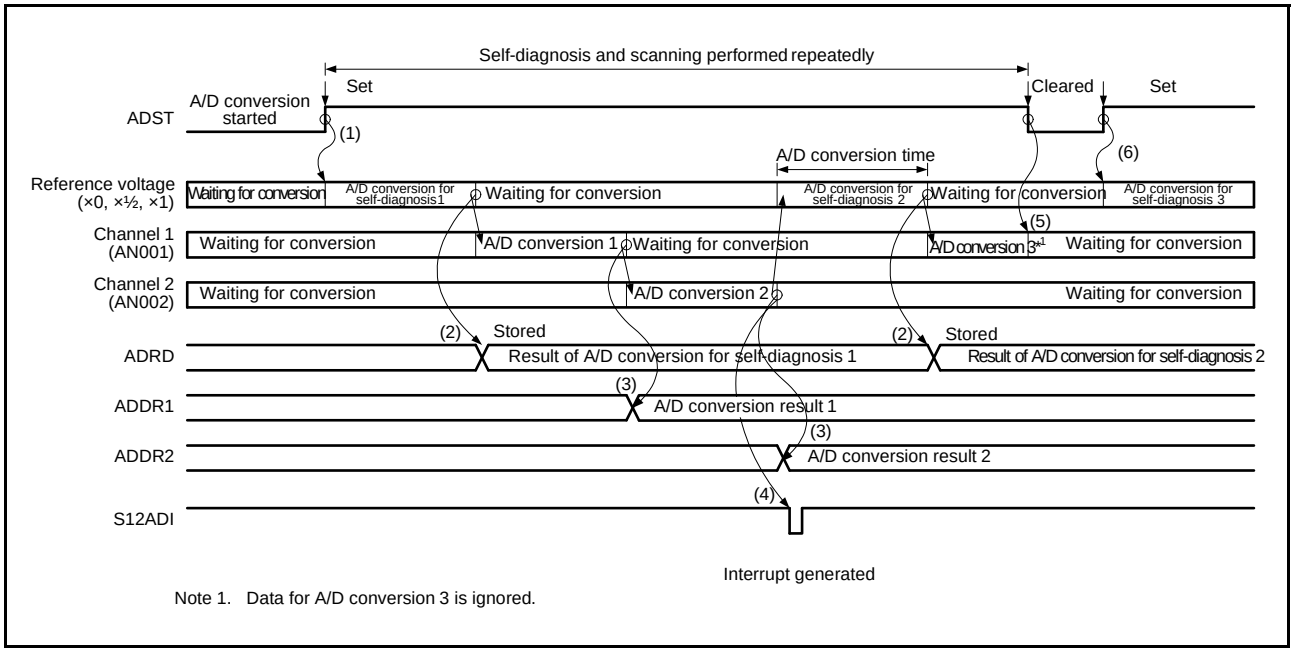

Figure 57.20 Example of Operation in Continuous Scan Mode (Basic Operation; AN001 and AN002 Selected + Self-Diagnosis)

57.3.3.5 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and-Hold Circuits, Continuous Sampling Disabled)

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is disabled, sample-and-hold operations are performed first, and this is followed by A/D conversion of the reference voltage VREFH0 (unit 0) or AVCC1 (unit 1) (×0, ×1/2, or ×1) supplied to the 12-bit A/D converter. After that, A/D conversion is performed on the analog input of the selected channels, which sequence is repeated as below.

(1) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (MTU, ELC, GPT, TMR, TPU), or input of an asynchronous trigger.
(2) After sample-and-hold operation, A/D conversion for self-diagnosis is started.
(3) When A/D conversion for self-diagnosis is completed, the result of A/D conversion is stored in the A/D self-diagnosis data register (ADRD). A/D conversion is then performed for ANn channels selected by the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
(4) Each time A/D conversion of a single channel is completed, the result of A/D conversion is stored in the corresponding A/D data register (ADDRy).
(5) When A/D conversion of all the selected channels is completed, an S12ADI interrupt request is generated if the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion enabled). At the same time, analog input sampling is started for all the channels for which the channel-dedicated sample-and-hold circuits are to be used.
(6) The ADCSR.ADST bit is not automatically cleared and steps 2 to 5 are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the 12-bit A/D converter enters a waiting state.
(7) When the ADCSR.ADST bit is then set to 1 (A/D conversion start), analog input sampling is started again for all the channels for which the channel-dedicated sample-and-hold circuits are be used.

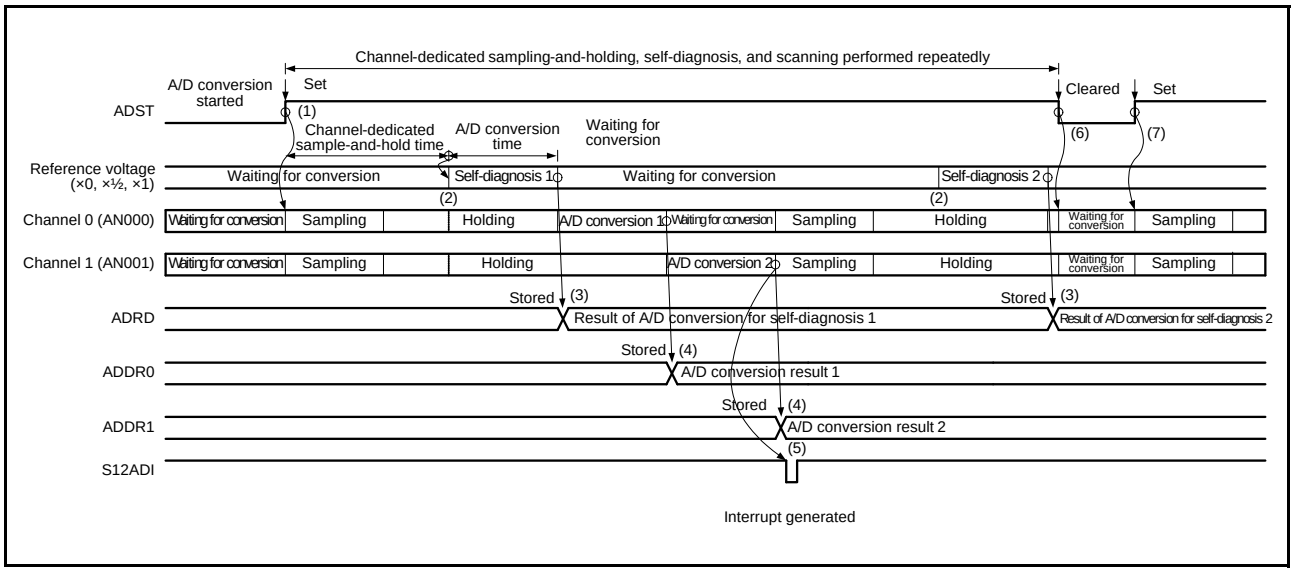

Figure 57.21 Example of Operation in Continuous Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000 and AN001 Selected + Self-Diagnosis; Continuous Sampling Disabled)

57.3.3.6 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and-Hold Circuits, Continuous Sampling Enabled)

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operation is first performed, and this is followed by A/D conversion of the reference voltage VREFH0 (unit 0) or AVCC1 (unit 1) (×0, ×1/2, or ×1) supplied to the 12-bit A/D converter. After that, A/D conversion is performed on the analog input of the selected channels, which sequence is repeated as below.

(1) When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected by the ADSHCR.SHANS[2:0] bits start continuous sampling.
(2) Analog input holding of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (MTU, GPT, TMR, TPU, ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 kΩ) has elapsed since the ADSHMSR.SHMD bit was set to 1.
(3) After the stabilization time of the sample-and-hold circuits has elapsed, A/D conversion for self-diagnosis is started.
(4) When A/D conversion for self-diagnosis is completed, the result of A/D conversion is stored in the A/D self-diagnosis data register (ADRD). A/D conversion is then performed for ANn channels selected by the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
(5) Each time A/D conversion of a single channel is completed, the result of A/D conversion is stored in the corresponding A/D data register (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
(6) When A/D conversion of all the selected channels is completed, an S12ADI interrupt request is generated if the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion enabled). Also, analog input holding of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started.
(7) The ADCSR.ADST bit is not automatically cleared and steps 3 to 6 are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the 12-bit A/D converter enters a waiting state.
(8) When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits are stopped.
(9) When the ADSHMSR.SHMD bit is then set to 1, the sample-and-hold circuits selected by the ADSHCR.SHANS[2:0] bits start continuous sampling.
(10) When the ADCSR.ADST bit is then set to 1 (A/D conversion start), analog input holding of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started.

Note: If continuous scanning is performed when only the channels with the sample-and-hold circuits are selected, time for continuous sampling cannot be secured in the second and subsequent continuous scanning. When continuous sampling by the channel-dedicated sample-and-hold circuits is enabled for continuous scanning, select one or more channels among AN003 to AN007 and set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).

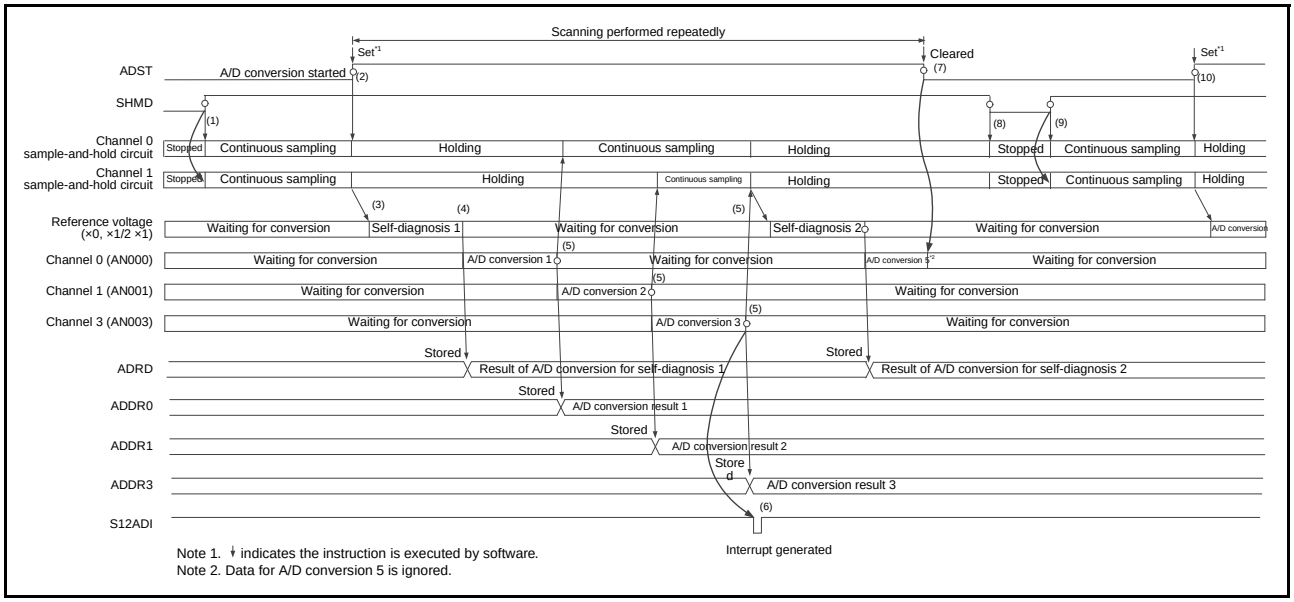

Figure 57.22 Example of Operation in Continuous Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000, AN001, and AN003 Selected + Self-Diagnosis; Continuous Sampling Enabled)

57.3.3.7 A/D Conversion of Temperature Sensor Output/Internal Reference Voltage

When the channels and temperature sensor output or internal reference voltage are selected at the same time, the analog inputs on all selected channels are A/D converted, after which the temperature sensor output and internal reference voltage are A/D converted in accord with the description below. When both temperature sensor output and internal reference voltage are selected, the temperature sensor output and internal reference voltage are A/D converted in that order.

With the channels deselected, selecting only the temperature sensor output or internal reference voltage is also possible.

(1) When software, synchronous trigger (MTU, ELC, GPT, TMR or TPU), or asynchronous trigger sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers starts in order from the channel with the lowest number n.

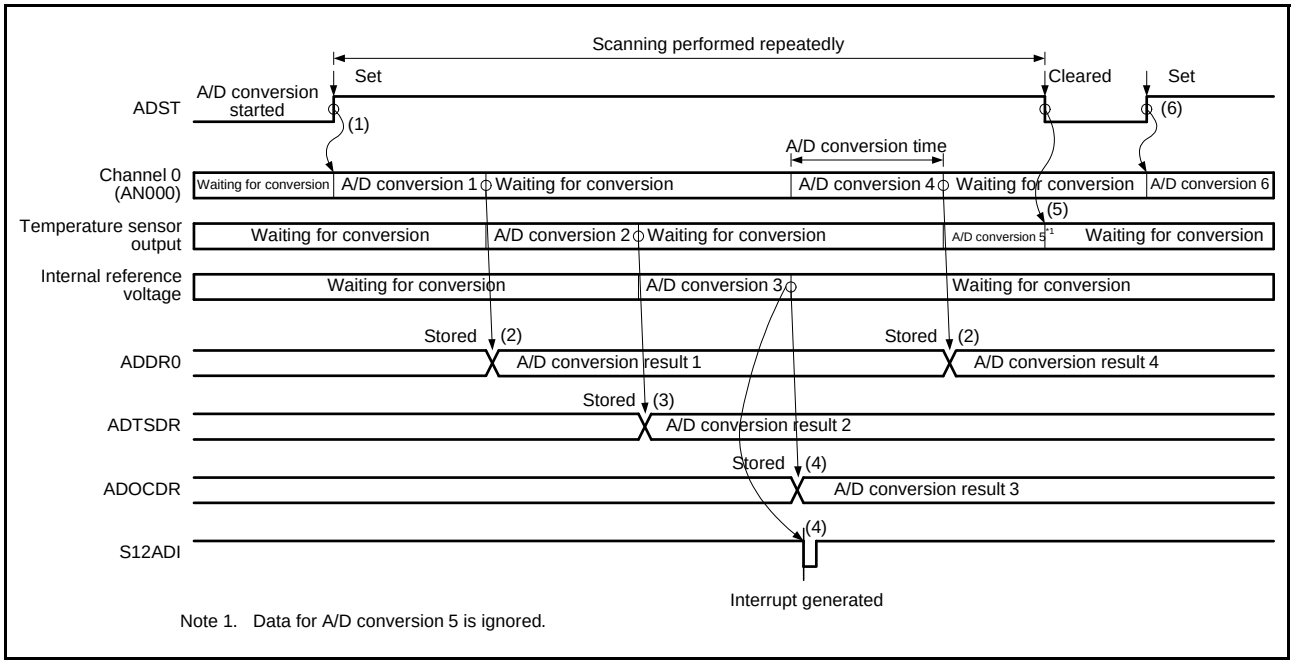
(2) On completion of A/D conversion on the channel, the result is stored in the corresponding A/D data register (ADDRy), and then A/D conversion of temperature sensor output starts.

(3) On completion of A/D conversion of temperature sensor output, the result is stored in the corresponding A/D temperature sensor data register (ADTRDR), and then A/D conversion of internal reference voltage starts.

(4) On completion of A/D conversion of internal reference voltage, the result is stored in the corresponding A/D internal reference voltage data register (ADOCDR), and if the ADCSR.ADIE bit is set to 1 (enabling S12ADI interrupt generation upon scan conversion completion), an S12ADI interrupt request is generated. Furthermore, the 12-bit A/D converter continuously starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers in order from the channel with the lowest number n.

(5) The ADCSR.ADST bit is not cleared automatically, and steps 2 to 4 are repeated as long as this bit remains set to 1. When the ADCSR.ADST bit is set to 0 (stopping A/D conversion), A/D conversion stops and the 12-bit A/D converter enters a wait state.

(6) If the ADCSR.ADST bit is later set to 1 (starting A/D conversion), A/D conversion starts again for ANn channels selected by the ADANSA0 and ADANSA1 registers in order from the channel with the lowest number n.



Note 1. Data for A/D conversion 5 is ignored.

Figure 57.23 Example of Operation in Continuous Scan Mode (Basic Operation: AN000 and Temperature Sensor Output or Internal Reference Voltage Selected)

57.3.4 Group Scan Mode

57.3.4.1 Basic Operation

In basic operation of group scan mode, A/D conversion is performed once on the analog inputs of all the specified channels in group A and group B after scanning is started by a synchronous trigger (MTU, ELC, GPT, TMR, TPU) as below. Scan operation of each group is similar to the scan operation in single scan mode.
The synchronous triggers of group A and B can be selected using the TRSA[5:0] and TRSB[5:0] bits in ADSTRGR register, respectively. The different triggers should be used for group A and group B to prevent simultaneous A/D conversion of group A and group B. Software trigger should not be used.
The group A channels to be A/D-converted are selected using the ADANSA0 and ADANSA1 registers and the ADEXICR.TSSA and OCSA bits, while the group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers and the ADEXICR.TSSB and OCSB bits. Group A and group B cannot use the same channels.
When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed for group A and group B.
The following describes operation in group scan mode using a trigger from the MTU. Specifically, the TRG4AN and TRG4BN triggers from the MTU are assumed to be used to start conversion of group A and group B, respectively.

(1) Scanning of group A is started by the TRG4AN trigger from the MTU.
(2) When group A scanning is completed, an S12ADI interrupt is output if the ADIE bit in ADCSR register is 1 (S12ADI interrupt upon scanning completion is enabled).
(3) Scanning of group B is started by the TRG4BN trigger from the MTU.
(4) When group B scanning is completed, a S12GBADI interrupt is output if the GBADIE bit in ADCSR is 1 (S12GBADI interrupt upon scanning completion is enabled).

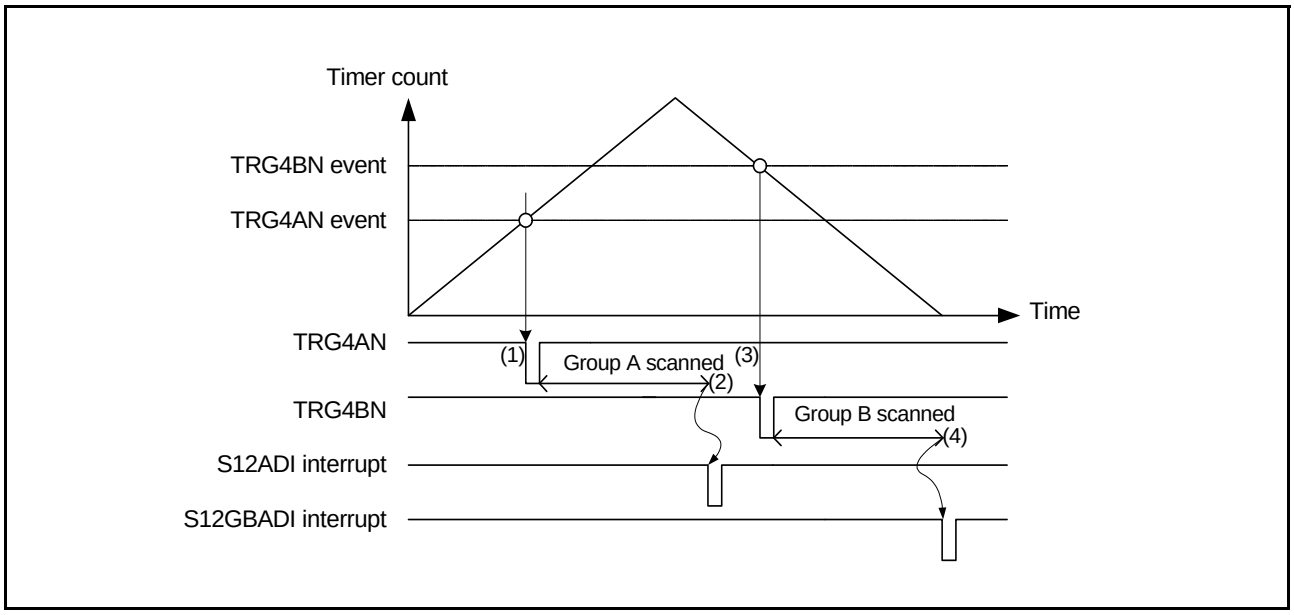


Figure 57.24 Example of Operation in Group Scan Mode (Basic Operation: Triggers from MTU Used)

57.3.4.2 A/D Conversion in Double Trigger Mode

When double trigger mode is selected in group scan mode, two rounds of single scan operation started by a synchronous trigger (MTU, ELC, GPT, TMR, TPU) are performed as a sequence for group A. For group B, single scan operation started by a synchronous trigger (MTU, ELC, GPT, TMR, TPU) is performed once.
In group scan mode, the synchronous triggers of group A and B can be selected using the TRSA[5:0] and TRSB[5:0] bits in ADSTRGR register, respectively. The different triggers should be used for group A and group B to prevent simultaneous A/D conversion of group A and group B. Software trigger, or asynchronous trigger (ADTRGn#) should not be used.
When a synchronous trigger TRGnAN or TRGnBN (n = 4, 7) is selected as the trigger for the start of A/D conversion (the ADSTRGR.TRSA[5:0] bits are set to 0Bh or 0Fh), or GTADTRAmN or GTADTRBmN (m = 0 to 3) is selected (the ADSTRGR.TRSA[5:0] bits are set to 19h, 1Ah, 1Bh, or 1Ch), operation proceeds in extended double trigger mode.
The group A and group B channels to be A/D-converted are selected using the DBLANS[4:0] bits in the ADCSR register and the ADANSB0 and ADANSB1 registers, respectively. The same channels cannot be selected for both groups.
When double trigger mode is selected in group scan mode, the temperature sensor output A/D conversion select bits (ADEXICR.TSSA) and the internal reference voltage A/D conversion select bits (ADEXICR.OCSA) should both be set to 0 (deselected).
When double trigger mode is selected in group scan mode, self-diagnosis cannot be selected.
Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the DBLANS[4:0] bits in ADCSR and setting the DBLE bit in ADCSR to 1.
The following describes operation in group scan mode with double trigger mode using a trigger from the MTU. Specifically, the TRG4ABN and TRG0AN triggers from the MTU are assumed to be used to start conversion of group A and group B, respectively.

(1) Scanning of group B is started by the TRG0AN trigger from the MTU.
(2) When group B scanning is completed, a S12GBADI interrupt is output if the GBADIE bit in ADCSR is 1 (S12GBADI interrupt upon scanning completion is enabled).
(3) The first scanning of group A is started by the first TRG4ABN trigger from the MTU.
(4) When the first scanning of group A is completed, the conversion result is stored into the corresponding A/D data register (ADDRy); an S12ADI interrupt request is not generated irrespective of the ADIE bit setting in ADCSR.
(5) The second scanning of group A is started by the second TRG4ABN trigger from the MTU.
(6) When the second scanning of group A is completed, the conversion result is stored into the ADDBLDR register. An S12ADI interrupt is generated if the ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).

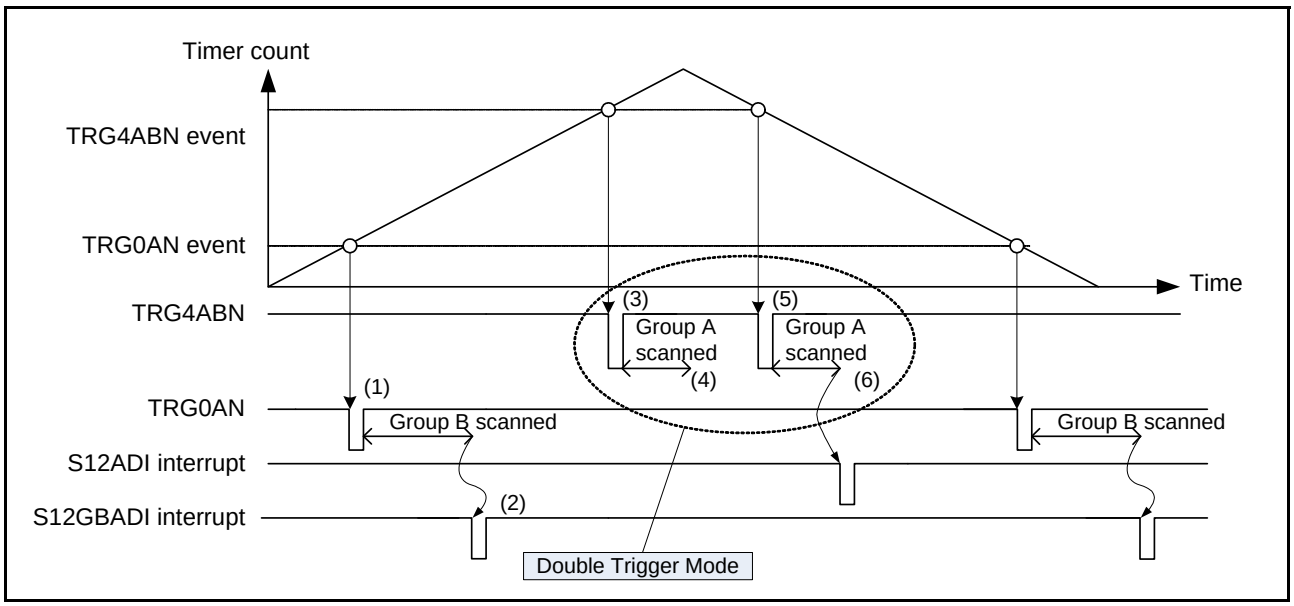

Figure 57.25 Example of Operation in Group Scan Mode with Double Trigger Mode (Basic Operation: Triggers from MTU Used)

57.3.4.3 Operation under Group-A Priority Control

Setting the ADGSPCR.PGS bit to 1 in group scan mode makes operation proceed under group-A priority control. When setting the ADGSPCR.PGS bit to 1, follow the procedure described in Figure 57.26. If the procedure is not followed, A/D conversion operation and stored data are not guaranteed.
In operation in basic group scan mode, input of the trigger for the other group during operation for A/D conversion in group A or group B is ignored. Under group-A priority control, if a group-A trigger is input during A/D conversion for group B, A/D conversion for group B is discontinued and A/D conversion for group A proceeds. If the setting of the ADGSPCR.GBRSCN bit is 0, the converter enters the waiting state on completion of the A/D conversion for group A. If the setting of the ADGSPCR.GBRSCN bit is 1, the converter automatically restarts scanning for group B from the head of the group after completion of the A/D conversion for group A. Table 57.9 summarizes operations in response to the input of a trigger during A/D conversion with the settings of the ADGSPCR.GBRSCN bit.

Scan operations in group A or group B are the same in single scan mode. Furthermore, single scanning continues to proceed if the ADGSPCR.GBRP bit is set to 1 during scanning operations for group B.

For the trigger settings in group scan mode, select a synchronous or asynchronous trigger for group A using the ADSTRGR.TRSA[5:0] bits and select a synchronous trigger different from that of group A for group B using the ADSTRGR.TRSB[5:0] bits. Set the ADSTRGR.TRSB[5:0] bits to 3Fh when setting the ADGSPCR.GBRP bit to 1. Furthermore, as targets for A/D conversion, select channels for group A using the ADANSA0 and ADANSA1 registers and the ADEXICR.TSSA and OCSA bits, and for group B, select channels different from those for group A using the ADANSB0 and ADANSB1 registers and the ADEXICR.TSSB and OCSB bits.

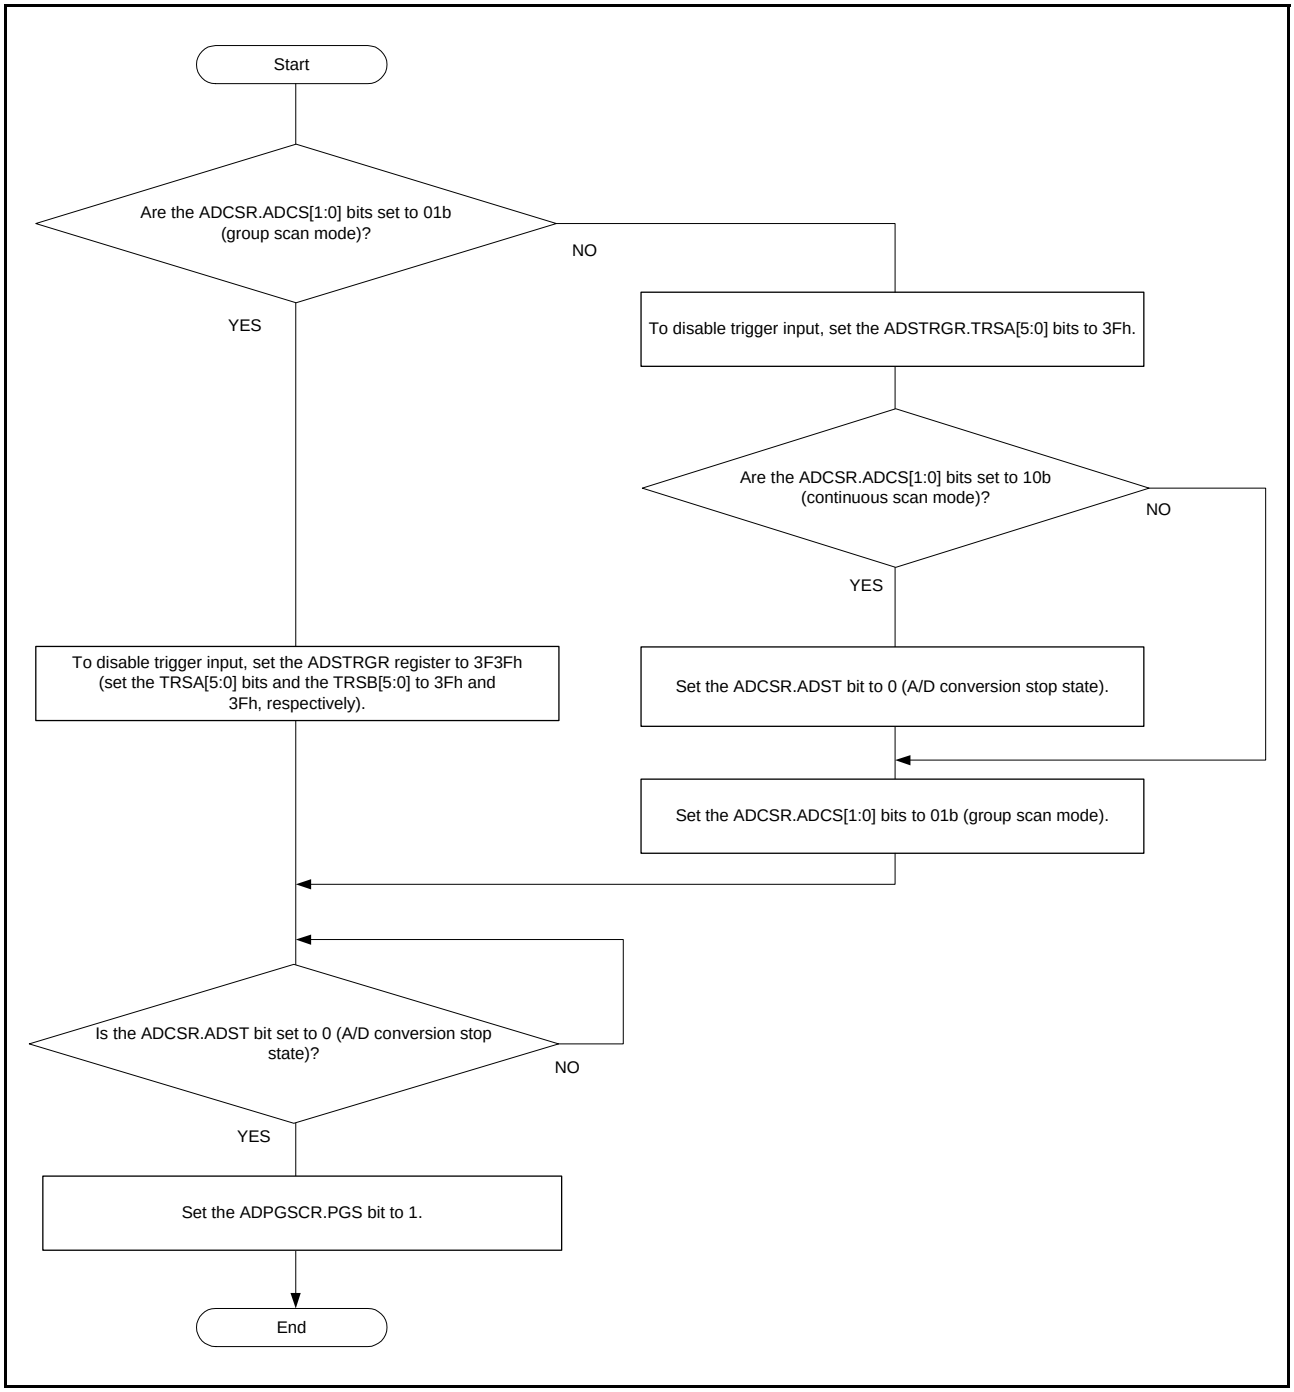

Figure 57.26 Flow of Setting the ADPGSCR.PGS Bit

Table 57.9 Control of A/D Conversion Operations According to the Settings of the ADGSPCR.GBRSCN Bit

A/D Conversion Operation	Trigger Input	ADGSPCR.GBRSCN = 0	ADGSPCR.GBRSCN = 1
When A/D conversion for group A is in progress	Input of trigger for group A	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group B	Trigger input is ineffective.	A/D conversion is performed on group B after A/D conversion on group A is completed.
When A/D conversion for group B is in progress	Input of trigger for group A	Conversion for group B that is in progress is discontinued and conversion for group A starts.	• Conversion in progress for group B is discontinued and conversion for group A starts. • Conversion for group B starts after conversion for group A is completed.
	Input of trigger for group B	Trigger input is ineffective.	Trigger input is ineffective.

The following describes the operations in group scan mode under group-A priority control (i.e. ADGSPCR.GBRSCN = 1 and ADGSPCR.GBRP = 0) when channel 0 is selected for group A and channels 1 to 3 are selected for group B.

(1) When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the ANn channels selected in the ADANSB0 and ADANSB1 registers starts in order from the channel with the lowest number.
(2) On completion of A/D conversion, the result is stored in the corresponding A/D data register (ADDRy).
(3) The ADCSR.ADST bit is cleared on the input of a trigger for group A while operation for A/D conversion in group B is in progress, and the latter is discontinued. After that, the ADCSR.ADST bit is set to 1 (starting A/D conversion), and conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers starts in order from the channel with the lowest number.
(4) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(5) An S12ADI interrupt request is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).
(6) After the ADCSR.ADST bit is automatically cleared, again, the bit is automatically set to 1 (starting A/D conversion) and conversion for the ANn channels of group B selected in the ADANSB0 and ADANSB1 registers starts in order from the channel with the lowest number.
(7) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(8) An S12GBADI interrupt request is generated if the setting of the ADCSR.GBADIE bit is 1 (S12GBADI interrupt upon group B scanning completion enabled).
(9) The ADCSR.ADST bit retains the value 1 (starting A/D conversion) during A/D conversion and is automatically cleared on completion of conversion, after which the A/D converter enters the waiting state.

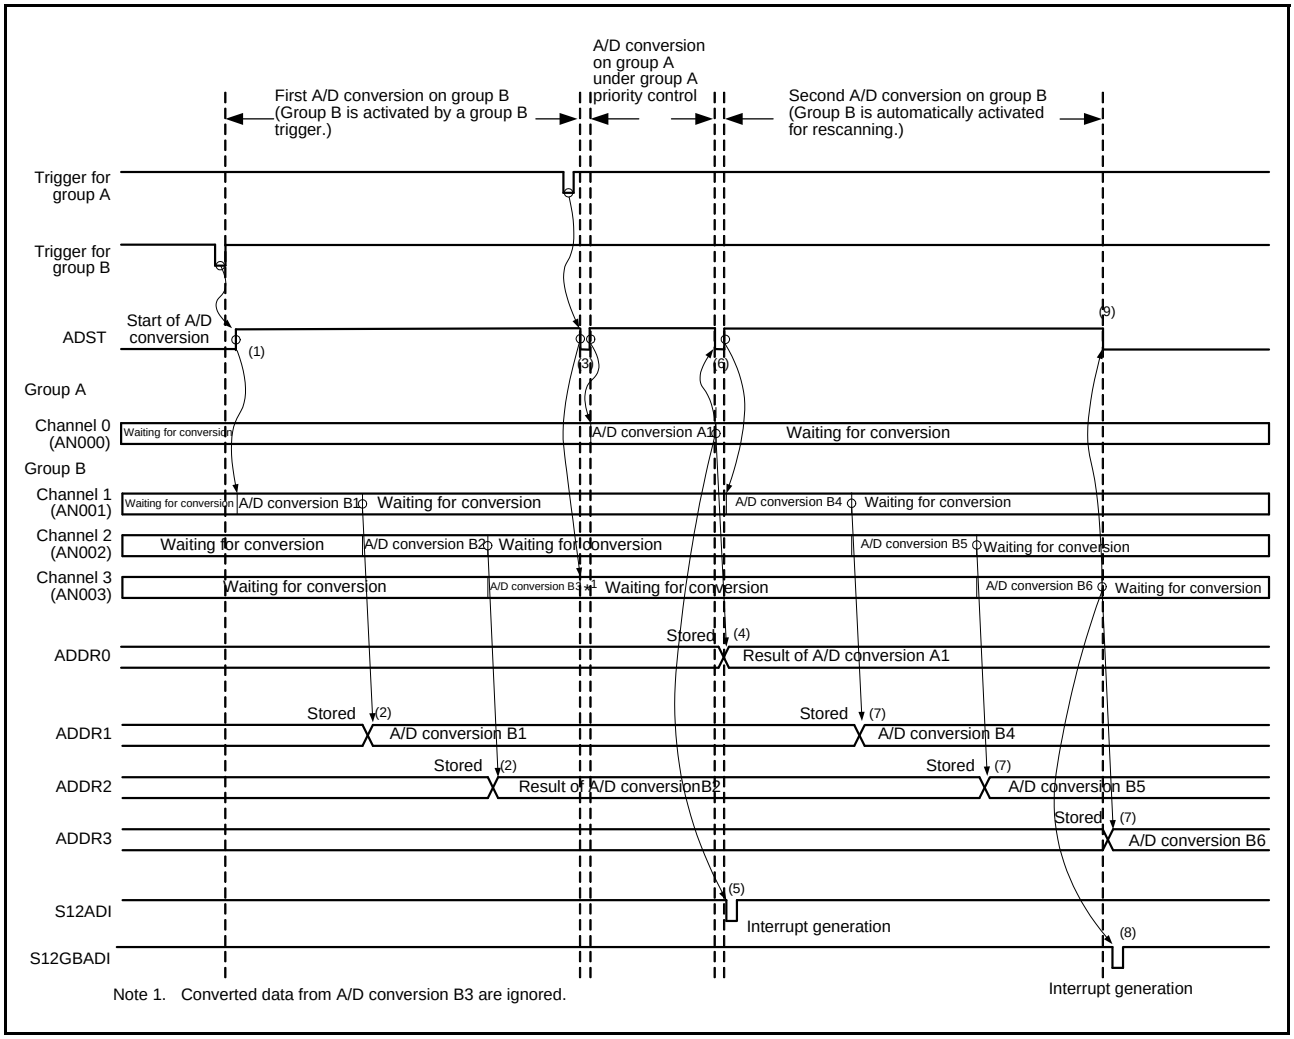

Figure 57.27 Example of Operations under Group-A Priority Control (1) (when ADGSPCR.GBRSCN = 1 and ADGSPCR.GBRP = 0)

The following is an example when a group A trigger is input again during rescanning operation on group B. In this example, channel 0 is selected for group A and channels 1 to 3 are selected for group B when operation on group A is given priority (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0).

(1) When a group B trigger input sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the ANn channels of group B selected in the ADANSB0 and ADANSB1 registers starts in order from the channel with the lowest number n.
(2) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(3) The ADCSR.ADST bit is cleared to 0 (stopping A/D conversion) on the input of a trigger for group A while operation for A/D conversion in group B is in progress, and the latter is discontinued.
(4) After that, the ADCSR.ADST bit is set to 1 automatically and A/D conversion for the ANn group A channels selected in the ADANSA0 and ADANSA1 registers starts in order from the channel with the lowest number n.
(5) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(6) An S12ADI interrupt request is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).
(7) On completion of A/D conversion on the group A, rescanning operation on group B sets the ADCSR.ADST bit to 1 automatically if the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning operation). After that, A/D conversion for the ANn group B channels selected in the ADANSB0 and ADANSB1 registers starts again in order from the channel with the lowest number n.
(8) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(9) If a group A trigger is input during A/D conversion on group B for rescanning, the ADCSR.ADST bit is cleared to 0 (stopping A/D conversion) and the ongoing A/D conversion on group B is stopped.
(10) After that, the ADCSR.ADST bit is set to 1 automatically and A/D conversion for the ANn group A channels selected in the ADANSA0 and ADANSA1 registers starts in order from the channel with the lowest number n.
(11) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(12) An S12ADI interrupt request is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).
(13) On completion of A/D conversion on group A, rescanning operation on group B sets the ADCSR.ADST bit to 1 automatically if the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning operation). After that, A/D conversion for the ANn group B channels selected in the ADANSB0 and ADANSB1 registers starts again in order from the channel with the lowest number n.
(14) If a group A trigger is input during A/D conversion on group B for rescanning, steps 9 to 13 are repeated. If a group A trigger is not input, the ADCSR.ADST bit is cleared automatically on completion of A/D conversion on group B and the 12-bit A/D converter enters a wait state.

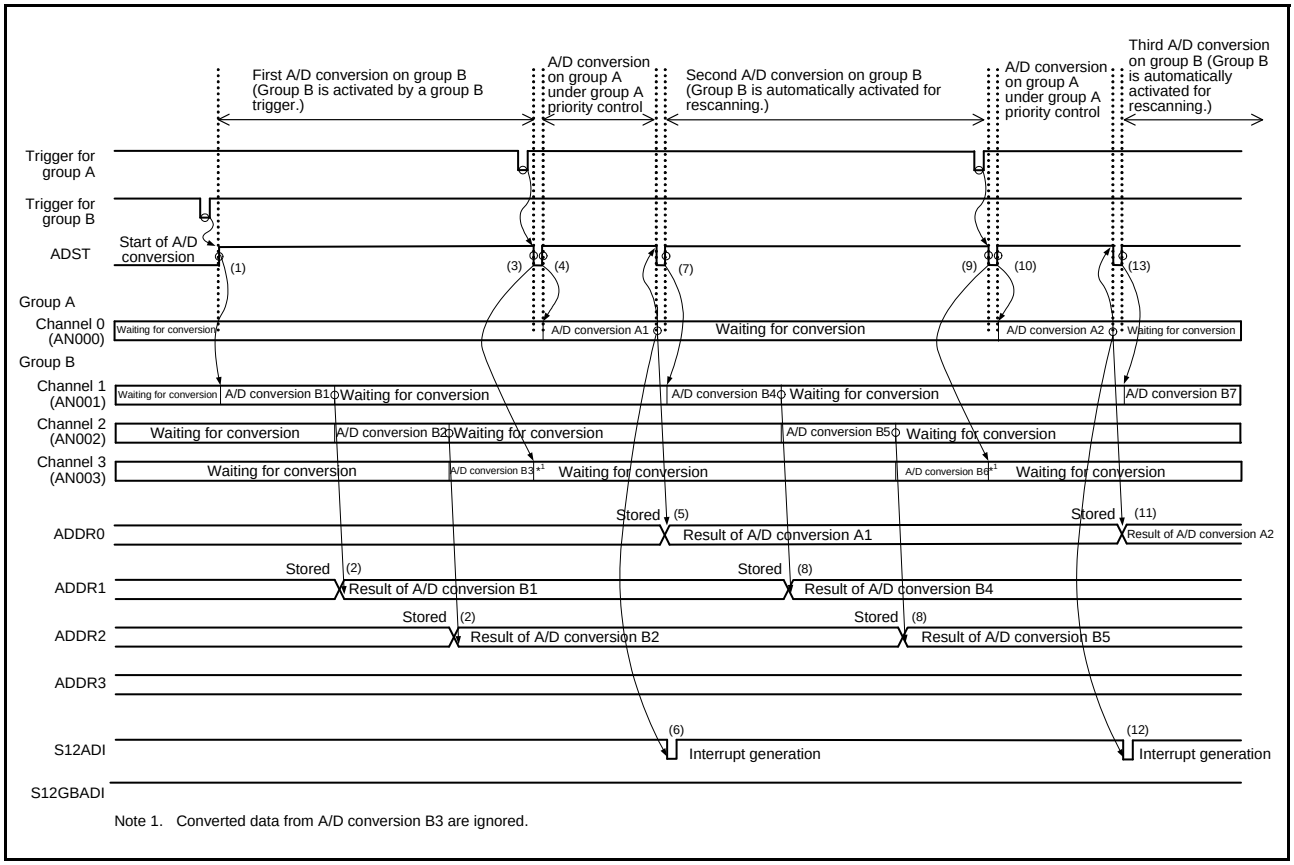

Figure 57.28 Example of Operations under Group-A Priority Control (2) (when ADGSPCR.GBRSCN = 1 and ADGSPCR.GBRP = 0)

The following is an example of a rescanning operation in which a group B trigger is input during A/D conversion on group A. In this example, channels 1 to 3 are selected for group A and channel 0 is selected for group B when operation on group A is given priority (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0).

(1) When input of a trigger for group A sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers starts in order from the channel with the lowest number.

(2) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).

(3) If a group B trigger is input during A/D conversion on group A, A/D conversion on group B can be performed after the A/D conversion on group A is completed. (However, if group A triggers are input continuously, the scan operation on group B is cancelled by group A and is not performed.)

(4) On completion of the A/D conversion on the group A, an S12ADI interrupt request is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).

(5) On completion of the A/D conversion on the group A, activation of group B for rescanning sets the ADCSR.ADST bit to 1 automatically.
After that, conversion for the ANn channels of group B selected in the ADANSB0 and ADANSB1 registers starts in order from the channel with the lowest number.

(6) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).

(7) On completion of the rescanning operation on the group B, an S12GBADI interrupt request is generated if the setting of the ADCSR.GBADIE bit is 1 (S12GBADI interrupt upon scanning completion is enabled).

(8) The ADCSR.ADST bit retains the value 1 (starting A/D conversion) during A/D conversion and is automatically cleared on completion of conversion, after which the A/D converter enters a waiting state.

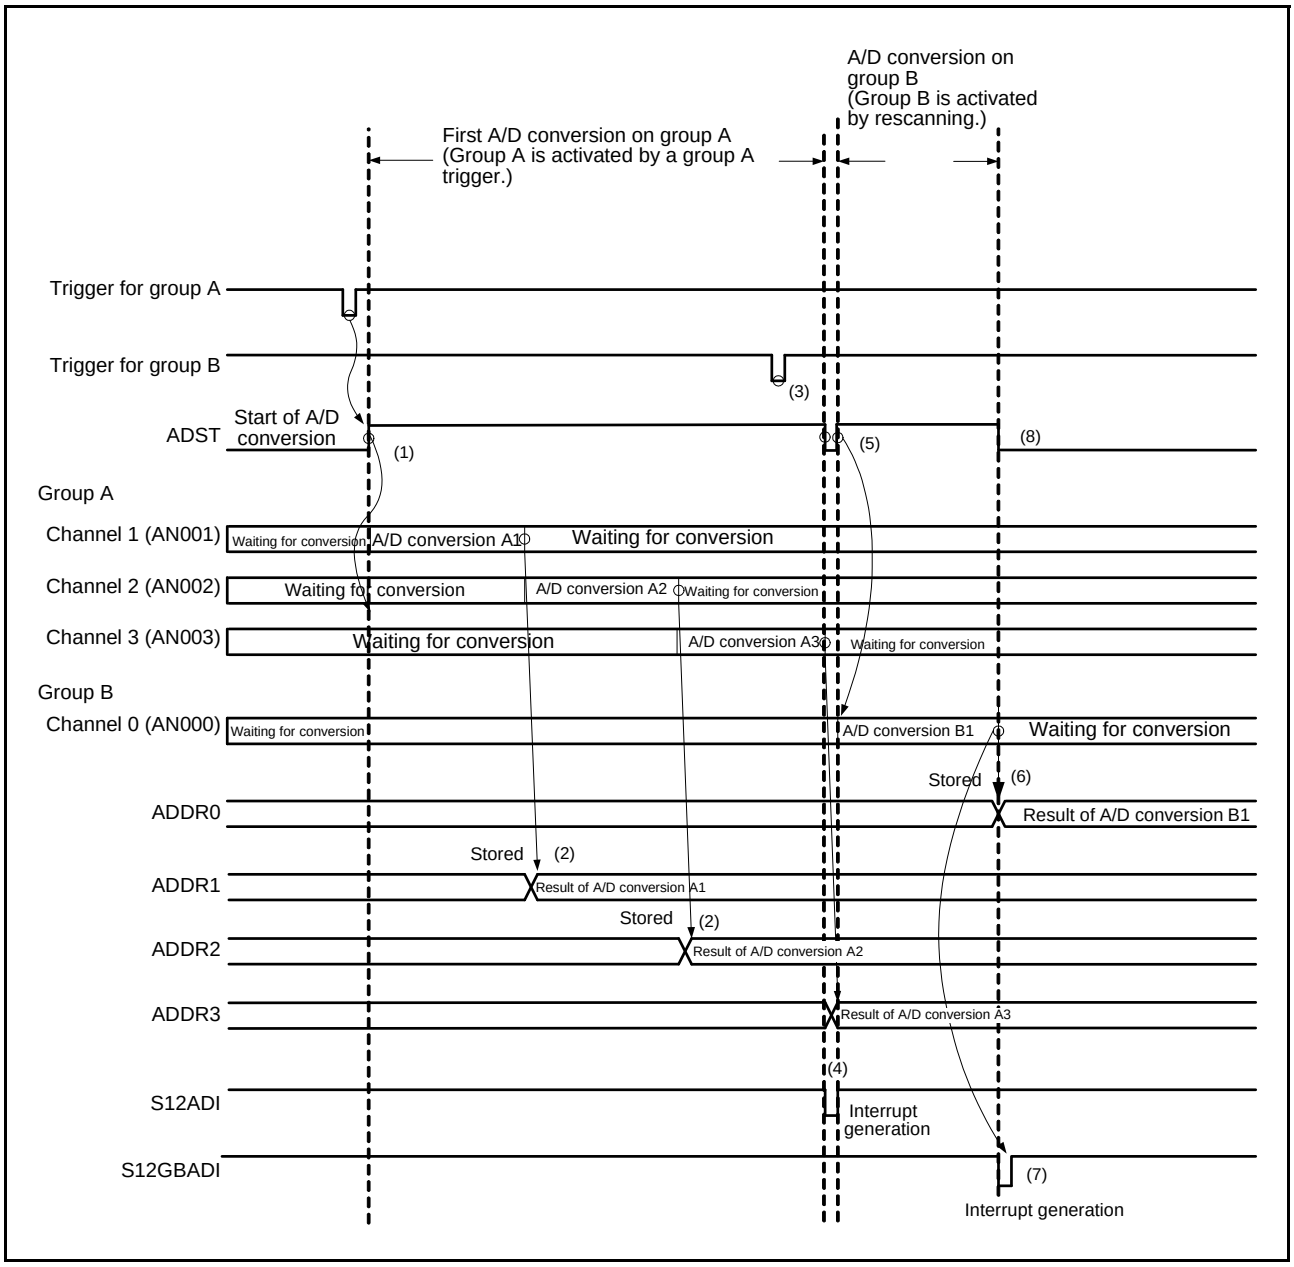

Figure 57.29 Example of Operations under Group-A Priority Control (3) (when ADGSPCR.GBRSCN = 1 and ADGSPCR.GBRP = 0)

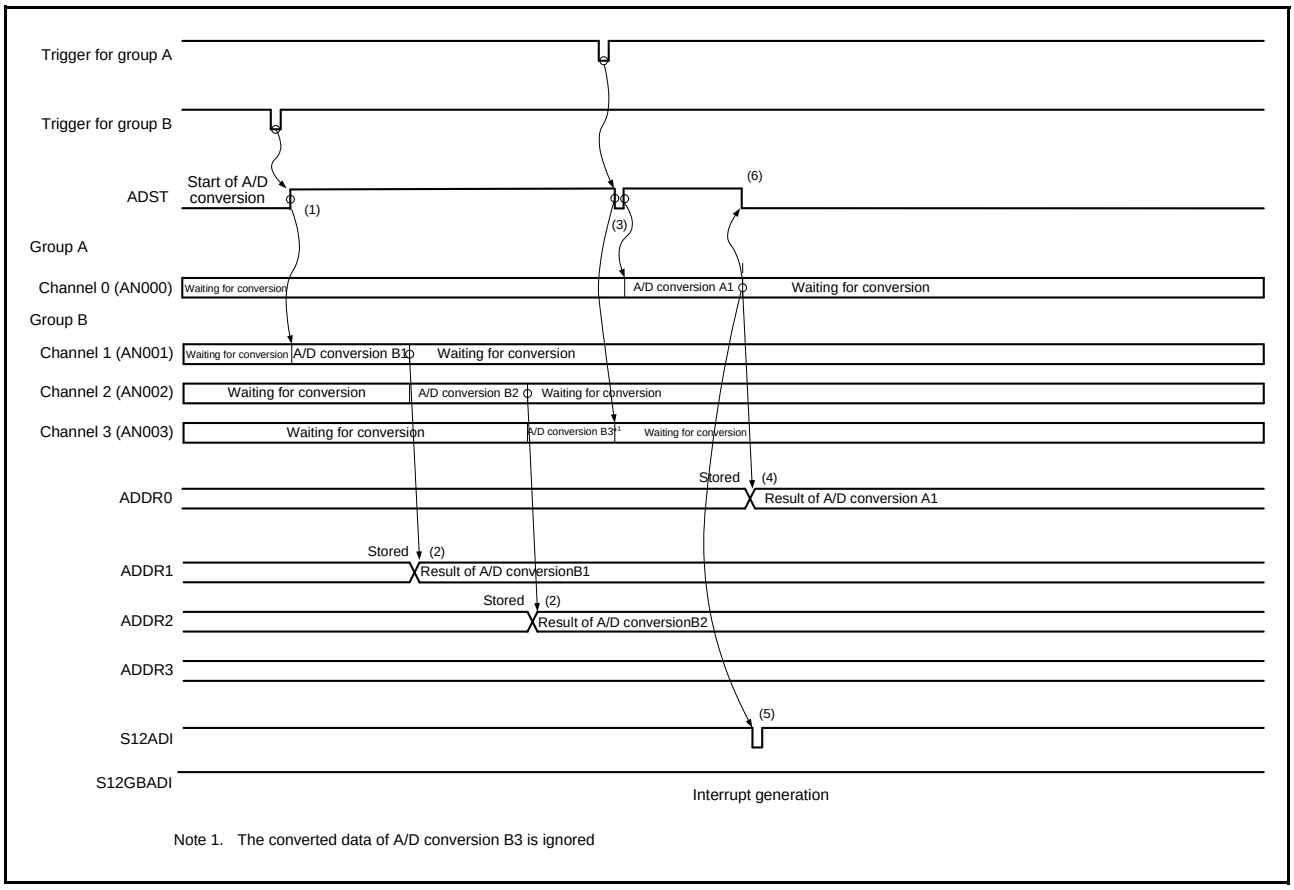
The following is an example of operation under group-A priority control in which channel 0 is selected for group A and channels 1 to 3 are selected for group B (ADGSCR.GBRSCN = 0, ADGSCR.GBRP = 0).

(1) When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the ANn channels selected in the ADANSB0 and ADANSB1 registers starts in order from the channel with the lowest number.
(2) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(3) If a group A trigger is input during A/D conversion on group B, the ADCSR.ADST bit is cleared to 0 and the ongoing A/D conversion on group B is stopped. After that, the ADCSR.ADST bit is set to 1 (starting A/D conversion) and conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers starts in order from the channel with the lowest number.
(4) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(5) An S12ADI interrupt request is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).
(6) The ADCSR.ADST bit retains the value 1 (starting A/D conversion) during A/D conversion and is cleared on completion of conversion, after which the A/D converter enters the waiting state.

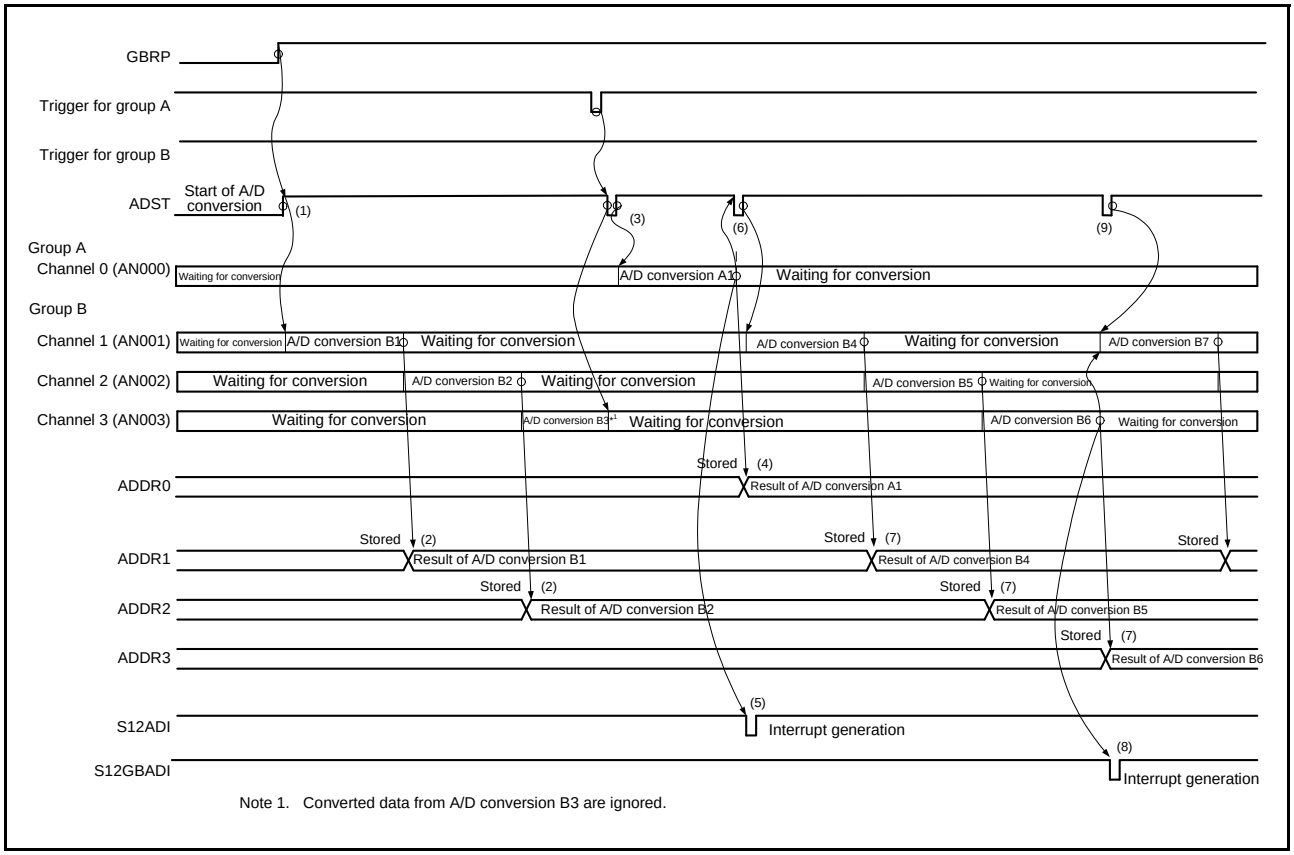


Note 1. The converted data of A/D conversion B3 is ignored

Figure 57.30 Example of Operation under Group-A Priority Control (4) (when ADGSPCR.GBRSCN = 0 and ADGSPCR.GBRP = 0)

The following is an example of operation under group A priority control in which channel 0 is selected for group A and channels 1 to 3 are selected for group B (ADGSCR.GBRP = 1).

(1) The ADCSR.ADST bit is set to 1 (starting A/D conversion) when ADGSPCR.GBRP is set to 1, and conversion for the ANn channels selected in the ADANSB0 and ADANSB1 registers starts in order from the channel with the lowest number.
(2) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(3) If a group A trigger is input during A/D conversion on group B, the ADCSR.ADST bit is cleared to 0 and the ongoing A/D conversion on group B is stopped. After that, the ADCSR.ADST bit is set to 1 (starting A/D conversion) and conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers starts in order from the channel with the lowest number.
(4) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(5) An S12ADI interrupt request is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).
(6) After the ADCSR.ADST bit is automatically cleared, again, the ADCSR.ADST bit is automatically set to 1 (starting A/D conversion) and conversion for the ANn channels selected in the ADANSB0 and ADANSB1 registers starts in order from the channel with the lowest number.
(7) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(8) An S12GBADI interrupt request is generated if the setting of the ADCSR. GBADIE bit is 1.
(9) After the ADCSR.ADST bit is automatically cleared, again, the bit is automatically set to 1 (starting A/D conversion) and conversion for the ANn channels selected in the ADANSB0 and ADANSB1 registers starts in order from the channel with the lowest number. Steps 6 to 9 are repeated as long as the ADGSPCR.GBRP bit remains 1.
Clearing of the ADCSR.ADST bit to 0 is prohibited while the ADGSPCR.GBRP bit is set to 1.
Follow the procedure for clear operation by software through the ADCSR.ADST bit, shown in Figure 57.41, if you wish to forcibly stop A/D conversion while ADGSPCR.GBRP = 1.



Note 1. Converted data from A/D conversion B3 are ignored.

Figure 57.31 Example of Operation under Group-A Priority Control (5) (when ADGSPCR.GBRP = 1)

57.3.5 Extended Analog Input

The extended analog input ANEX1 is used when an external operational amplifier is connected to the LSI to perform A/D conversion for the multiple analog values. When the extended analog input is selected, AN100 to AN107 can only be selected. Do not select AN108 to AN120, the temperature sensor output, or internal reference voltage. When the extended analog input is selected, self-diagnosis and disconnection detection assistance cannot be used.

57.3.5.1 Usage of ANEX1

To perform A/D conversion of the multiple analog values via the operational amplifier, the analog values are input using the analog input channels of the LSI (AN100 to AN107). Then the time-divided analog values are taken from the extended analog output (ANEX0), and the operational amplifier is connected between ANEX0 and ANEX1.
To select ANEX1, set the ADEXICR.EXSEL[1:0] bits to 01b. To enable ANEX0 output, set the ADEXICR.EXOEN bit to 1. Also select single scan mode or continuous scan mode. Do not select group scan mode. Figure 57.32 shows an example of the extended analog input circuit configuration. Figure 57.33 shows the operation when three channels (AN100, AN101, and AN102) and single scan mode are selected.

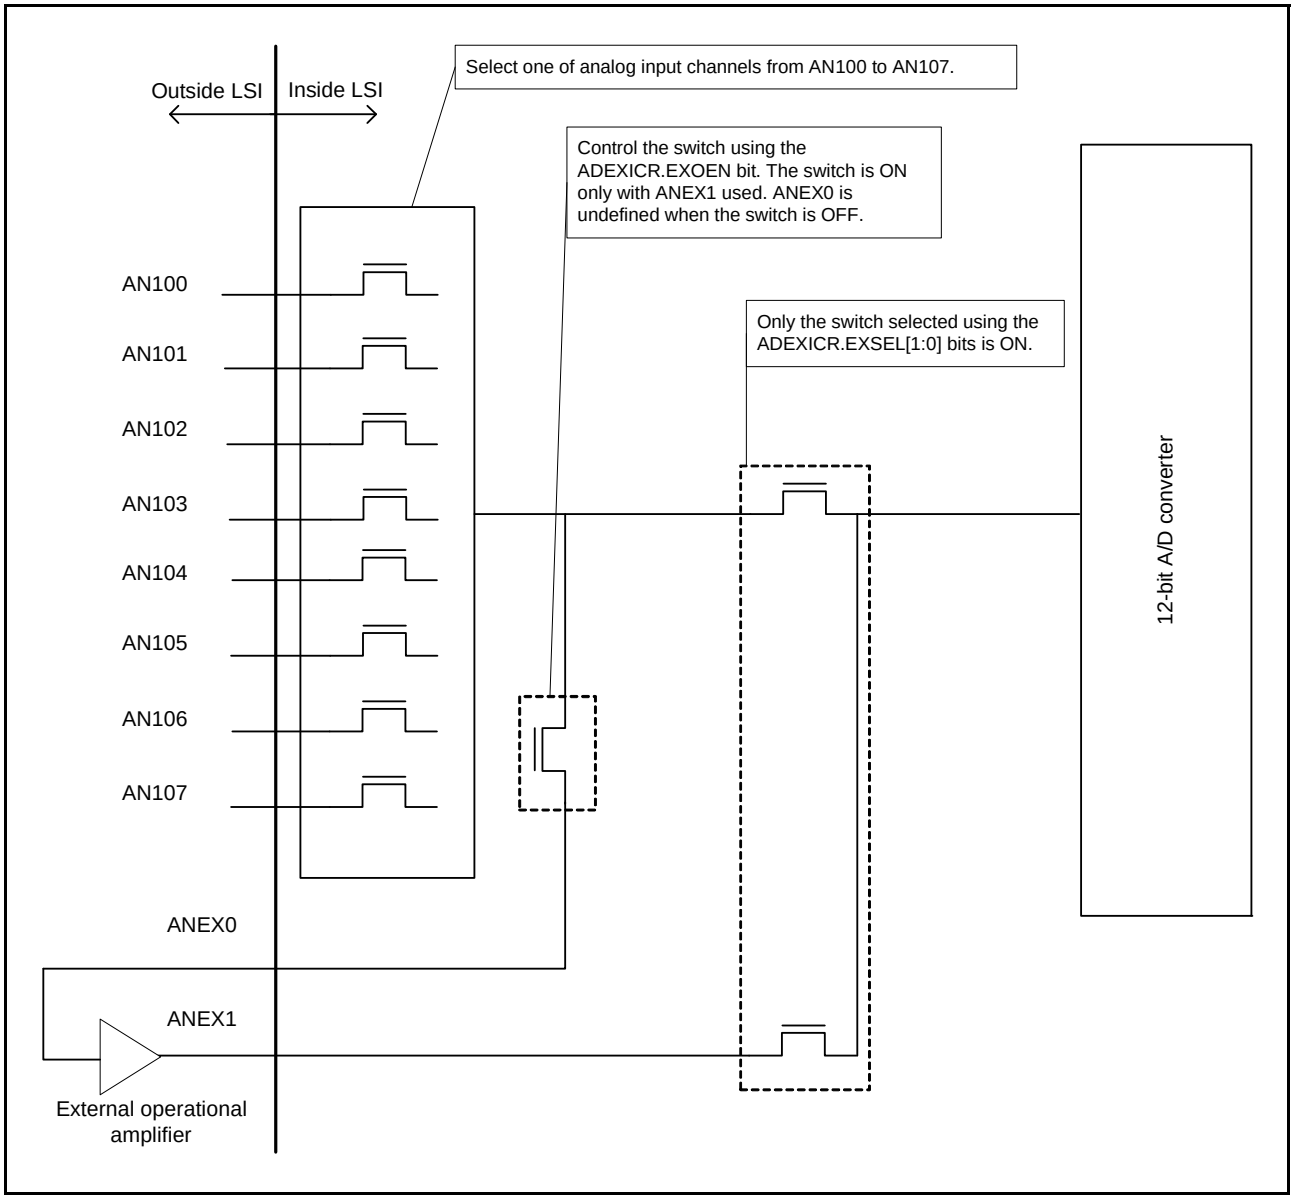


Figure 57.32 Configuration Example of Extended Analog Input Circuit

(1) When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (MTU, ELC, GPT, TMR, TPU), or an asynchronous trigger input, A/D conversion is performed for the selected channels, starting from the channel with the smallest number.

(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).

(3) When A/D conversion of all the selected channels is completed, an S12ADI interrupt request is generated if the ADIE bit in ADCSR register is 1 (S12ADI interrupt upon scanning completion is enabled).

(4) The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a waiting state.

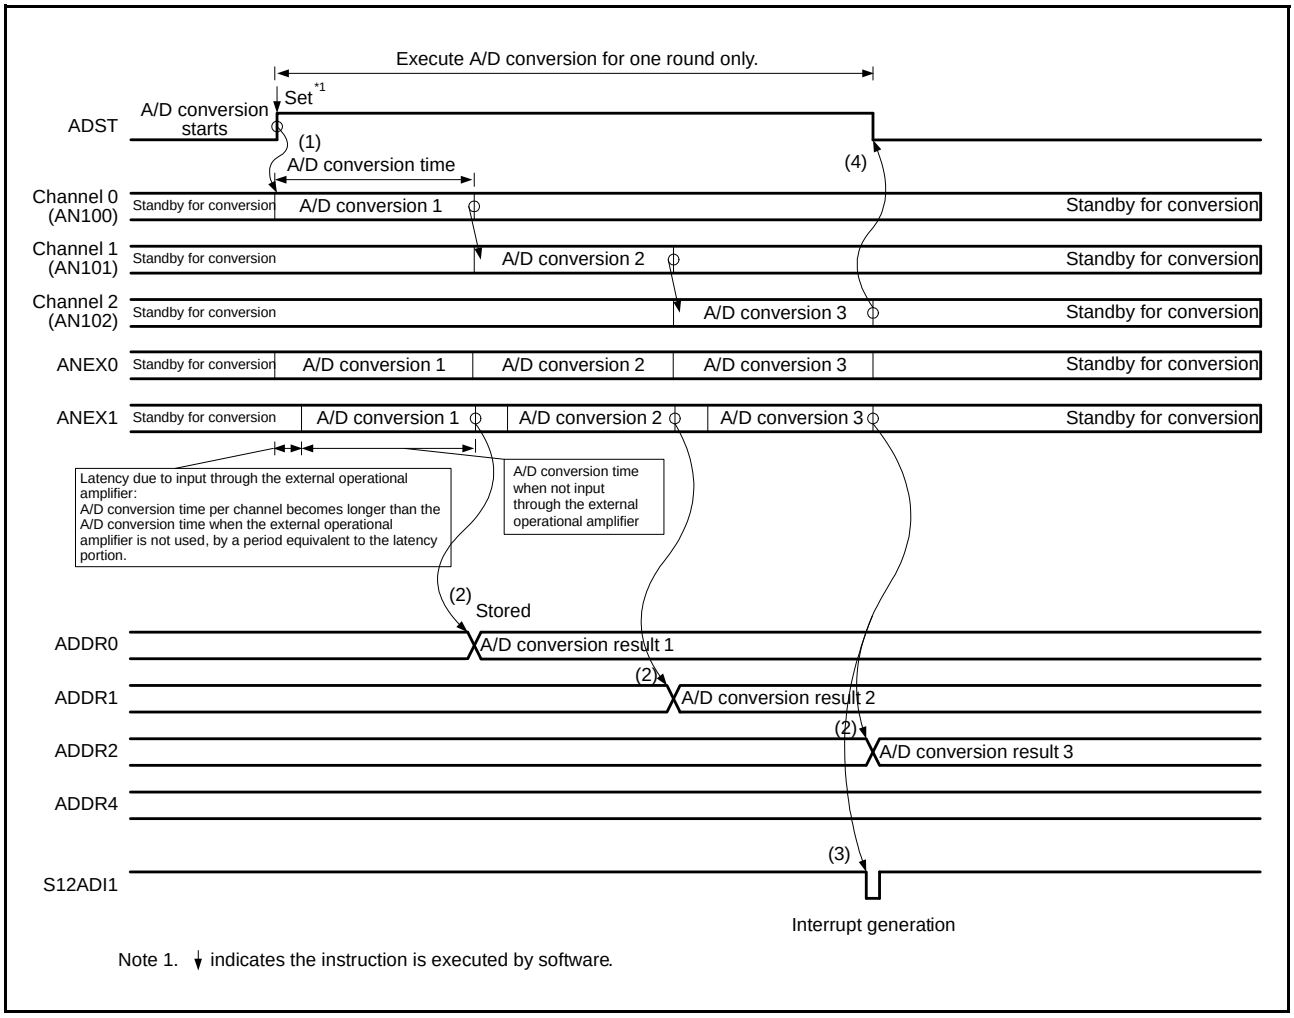

Figure 57.33 ANEX1 Input Operation Example (Single Scan Mode)

When the extended analog input is selected, the individual A/D conversion time becomes longer due to the latency of the operational amplifier, compared to the A/D conversion that is directly performed for the analog input channels.

57.3.6 Comparison

Comparison is of a reference value set in a register with the result of A/D conversion on selected channels. Self-diagnosis function and double-triggered mode are not available while comparison is in use.

Operation using comparison in combination with continuous scan mode is described below.

(1) A/D conversion is started in the order of the selected channels, the temperature sensor output, and the internal reference voltage when the ADCSR.ADST bit is set to 1 (to start A/D conversion) by software, or in response to a synchronous trigger (MTU, GPT, TMR, TPU, ELC) or asynchronous trigger.

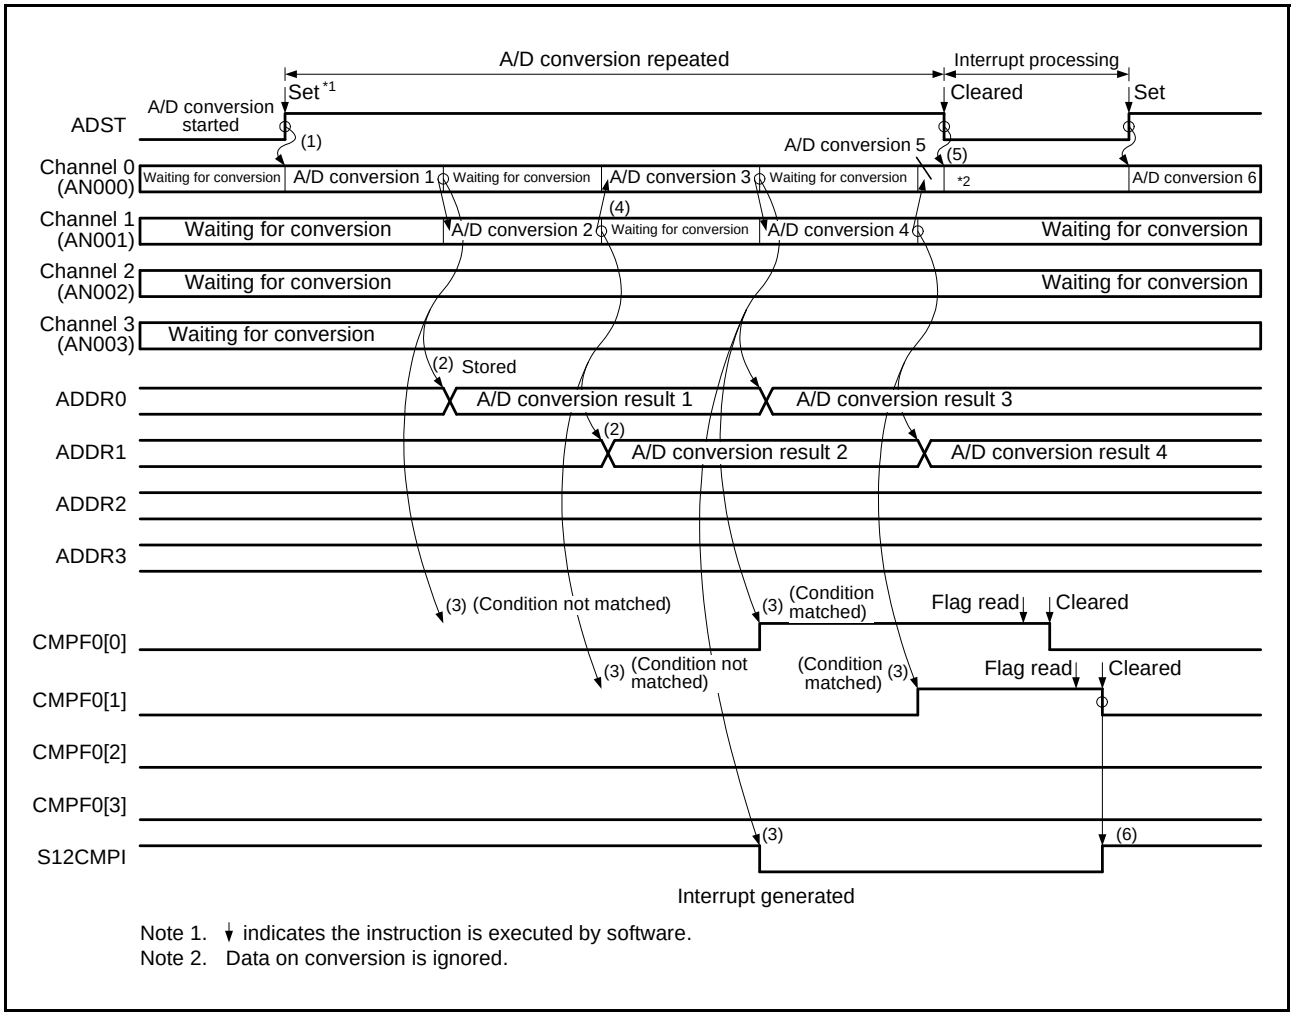
(2) When A/D conversion is completed, the result is stored in the corresponding A/D data register (ADDRy, ADTSDR, ADOCDR). If the register is selected for comparison by the settings of the ADCMPANSRy and ADCMPANSER registers, its value is then compared with that of the ADCMPDR0/1 registers.

(3) If the result of comparison meets the condition set in the ADCMPCR.WCMPE bit, the ADCMPLR0/1 register, and the ADCMPLER register, the bits ADCMPSR0.CMPF0n, ADCMPSR1.CMPF1n, ADCMPSER.CMPFTS, and ADCMPSER.CMPOC are set to 1. If the setting of the ADCMPCR.CMPIE bit is 1 at this time, an S12CMPI interrupt request is also generated.

(4) When A/D conversion is completed for all selected channels, A/D conversion is started again.

(5) If the setting of the ADCSR.ADST bit is 0 (A/D conversion stop) after the S12CMPI interrupt is accepted, processing proceeds for channels that have the compare flag.

(6) The S12CMPI interrupt signal is deasserted when all of the compare flags have been cleared. To start further comparison, start A/D conversion again.



Note 1. ↓ indicates the instruction is executed by software.
Note 2. Data on conversion is ignored.

Figure 57.34 Operation Example of Comparison (AN000 to AN003 Comparison Targets)

57.3.7 Analog Input Sampling and Scan Conversion Time

Scan conversion can be activated either by a software trigger; a synchronous trigger (MTU, ELC, GPT, TMR, TPU); or an asynchronous trigger (ADTRGn#). After the start-of-scanning-delay time (t_D) has elapsed, processing by the channel-dedicated sample-and-hold circuits, processing for disconnection detection assistance, and processing of conversion for self-diagnosis proceed, and this is followed by processing for A/D conversion.

Figure 57.35 shows the scan conversion timing in single scan mode, in which scan conversion is activated by a software trigger or a synchronous trigger (MTU, ELC, GPT, TMR, TPU). Figure 57.36 shows the scan conversion timing in single scan mode, in which scan conversion is activated by an asynchronous trigger ADTRGn#. The scan conversion time (t_{SCAN}) includes the start-of-scanning-delay time (t_D), channel-dedicated sample-and-hold circuit processing time (t_{SPLSH})*1, disconnection detection assistance processing time (t_{DIS})*2, self-diagnosis A/D conversion processing time (t_{DIAG})*3, A/D conversion processing time (t_{CONV}), channel-dedicated sample-and-hold circuit end time (t_{SHED})*4, and end-of-scanning-delay time (t_{ED}).

The A/D conversion processing time (t_{CONV}) consists of input sampling time (t_{SPL}) and time for conversion by successive approximation (t_{SAM}). The sampling time (t_{SPL}) is used to charge sample-and-hold circuits in the A/D converter. If there is not sufficient sampling time due to the high impedance of an analog input signal source, or if the A/D conversion clock (ADCLK) is slow, sampling time can be adjusted using the ADSSTR register.

The time for conversion by successive approximation (t_{SAM}) is at 13 ADCLK states with 12-bit accuracy selected, 11 ADCLK states with 10-bit accuracy selected, and 9 ADCLK states with 8-bit accuracy selected. Table 57.11 shows the scan conversion time.

The scan conversion time (t_{SCAN}) in single scan mode for which the number of selected channels is n can be determined as follows:

$$t_{SCAN} = t_D + t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + (t_{CONV} \times n) + t_{ED}$$

The scan conversion time for the first cycle in continuous scan mode is t_{SCAN} for single scan minus t_{ED} plus t_{SHED}. The scan conversion time for the second and subsequent cycles in continuous scan mode is fixed to $t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + (t_{CONV} \times n) + t_{SHED}$.

Note 1. When no channel-dedicated sample-and-hold circuits are used, $t_{SH} = 0$.
Note 2. When disconnection detection assistance is not selected, $t_{DIS} = 0$.
Note 3. When the self-diagnosis function is not used, $t_{DIAG} = 0$.
Note 4. When no channel-dedicated sample-and-hold circuits are used, $t_{SHED} = 0$. Here, continuous scan mode is assumed. In single scan mode and group scan mode, t_{SHED} is included in the end-of-scanning-delay time (t_{ED}).

Table 57.10 Example of Setting the ADSSTR Register

Use	Setting Range	Sampling Time*1
Standard (initial value)	0Bh	0.18 µs (For PCLKB = ADCLK = 60 MHz)
Use this range if there is not sufficient sampling time due to the high impedance of an analog input signal source.	0Ch to FFh	Example: FFh 4.3 µs (For PCLKB = ADCLK = 60 MHz)
Use this range if ADCLK is less than 60 MHz and the sampling time needs to be less than the initial value.	05h to 0Ah	Example: 0Ah 0.67 µs (For PCLKB = ADCLK = 15 MHz)

Note 1. The sampling time setting should satisfy the electrical characteristics. The sampling time is determined by the following formula.

$$\text{Sampling time (µs)} = \frac{\text{ADSSTR register setting}}{\text{ADCLK (MHz)}}$$

Table 57.11 Times for Conversion during Scanning (in Numbers of Cycles of the ADCLK and PCLKB)

Item			Symbol		Type/Conditions: Synchronous Trigger: MTU, GPT	Type/Conditions: Synchronous Trigger: TMR, TPU, ELC	Type/Conditions: Asynchronous Trigger	Type/Conditions: Software Trigger	Unit
Scan start processing time*1, *2	A/D conversion on group A under group A priority control.	Group B is to be stopped. (Group A is activated after group B is stopped due to an A/D conversion source of group A.)	t_D		4 PCLKB + 6 ADCLK	3 PCLKB + 6 ADCLK	5 PCLKB + 6 ADCLK	—	Cycle
		Group B is not to be stopped. (Activation by an A/D conversion source of group A.)			3 PCLKB + 4 ADCLK	2 PCLKB + 4 ADCLK	4 PCLKB + 4 ADCLK	—	
	A/D conversion when self-diagnosis is enabled	A/D conversion for self-diagnosis is to be started.			3 PCLKB + 6 ADCLK	2 PCLKB + 6 ADCLK	4 PCLKB + 6 ADCLK	6 ADCLK	
		Normal A/D conversion is to be started after completion of self-diagnosis conversion.			2 ADCLK	2 ADCLK	2 ADCLK	2 ADCLK	
		A/D conversion for self-diagnosis is to be started after completion of conversion for continuous scan on the last channel specified.			2 ADCLK	2 ADCLK	2 ADCLK	2 ADCLK	
	Other than above				3 PCLKB + 4 ADCLK	2 PCLKB + 4 ADCLK	4 PCLKB + 4 ADCLK	4 ADCLK	
Channel-dedicated sample-and-hold processing time*1	Sampling time		t_{SPLSH}	t_{SH}	The setting of ADSHCR.SSTSH[7:0] (initial value = 18h) × ADCLKK (continuous sampling disabled) 0 (continuous sampling enabled)				
	Wait time between sampling and A/D Conversion			t_W	12 ADCLK				
Disconnection detection assistance processing time			t_{DIS}		The setting of ADNDIS[3:0] (initial value = 00h) × ADCLK				
Self-diagnosis conversion processing time*1	Sampling time		t_{DIAG}	t_{SPL}	The setting of ADSSTR0 (initial value = 0Bh) × ADCLK				
	Time for conversion by successive approximation	12-bit conversion accuracy		t_{SAM}	15 ADCLK				
		10-bit conversion accuracy			13 ADCLK				
		8-bit conversion accuracy			11 ADCLK				
A/D conversion processing time*1	Sampling time		t_{CONV}	t_{SPL}	The setting of ADSSTRn (n = 0 to 7, L, T, O) (initial value = 0Bh) × ADCLK				
	Time for conversion by successive approximation	12-bit conversion accuracy		t_{SAM}	13 ADCLK				
		10-bit conversion accuracy			11 ADCLK				
		8-bit conversion accuracy			9 ADCLK				
Channel-dedicated sample-and-hold end processing time			t_{SHED}		2 ADCLK				
Scan end processing time*1			t_{ED}		1 PCLKB + 3 ADCLK				

Note 1. Refer to Figure 57.35 and Figure 57.36 for illustration of times t_D, t_{SPLSH}, t_{DIAG}, t_{CONV}, and t_{ED}.
Note 2. This is the maximum time required from software writing or trigger input to A/D conversion start.

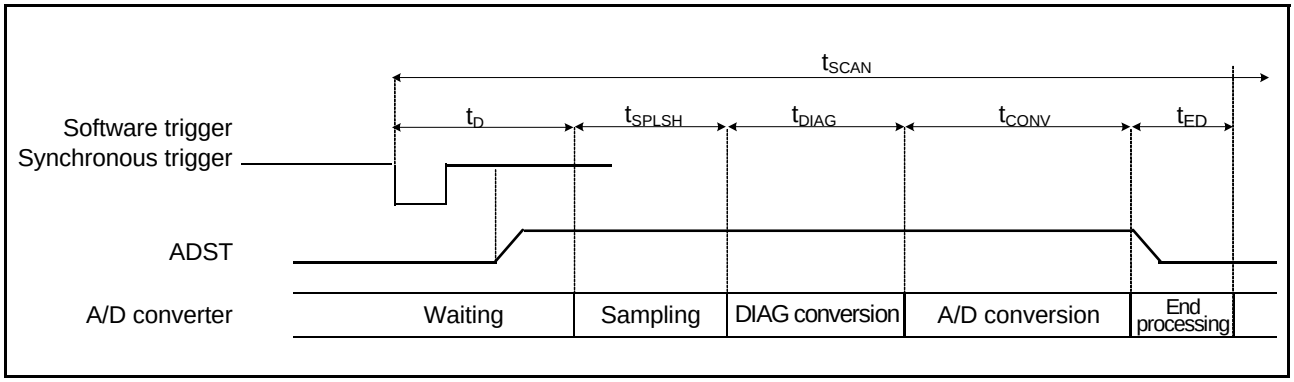


Figure 57.35 Scan Conversion Timing (Activated by Software or Synchronous Trigger Input (MTU, ELC, GPT, TMR, TPU))

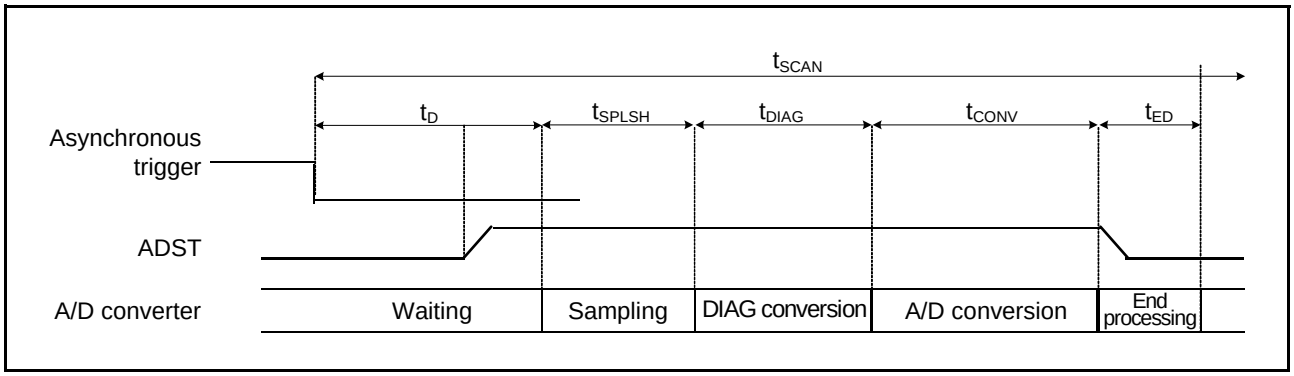

Figure 57.36 Scan Conversion Timing (Activated by Asynchronous Trigger Input (ADTRGn#))

57.3.8 Usage Example of A/D Data Register Automatic Clearing Function

A/D-converted value addition/average mode can be used when A/D conversion of the analog input of the selected channels, A/D conversion of the temperature sensor output, or A/D conversion of the internal reference voltage is selected.

Setting the ACE bit in ADCER register to 1 automatically clears the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR) to 0000h when the A/D data registers are read by the CPU, DTC, or DMACA.

This function enables detection of update failures of the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR). The following describes the examples in which the function to automatically clear the ADDRy register is enabled and disabled.

In a case where the ACE bit in ADCER register is 0 (automatic clearing is disabled), if the A/D conversion result (0222h) is not written to the ADDRy register for some reason, the old data (0111h) will be the ADDRy value. Furthermore, if this ADDRy value is read into a general register using an A/D scan end interrupt, the old data (0111h) can be saved in the general register. When checking whether there is an update failure, it is necessary to frequently save the old data in the RAM or a general register.

In a case where the ACE bit in ADCER register is 1 (automatic clearing is enabled), when ADDRy = 0111h is read by the CPU, DTC, or DMACA, ADDRy is automatically cleared to 0000h. After that, if the A/D conversion result 0222h cannot be transferred to ADDRy for some reason, the cleared data (0000h) remains as the ADDRy value. If this ADDRy value is read into a general register using an A/D scan end interrupt at this point, 0000h will be saved in the general register. Occurrence of an ADDRy update failure can be determined by simply checking that the read data value is 0000h.

57.3.9 A/D-Converted Value Addition/Average Mode

In A/D-converted value addition mode, the same channel is A/D-converted two to four consecutive times and the sum of the converted values is stored in the data register. In A/D-converted value average mode, the same channel is A/D-converted two to four consecutive times and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that are present. This function, however, cannot always guarantee an improvement in A/D conversion accuracy.
The A/D-converted value addition/average mode can be specified when A/D conversion of the channel select analog input, temperature sensor output, or internal reference voltage is selected.

57.3.10 Disconnection Detection Assist Function

This converter incorporates the function to fix the charge for sampling capacitance to the specified state (VREFH0 or VREFL0 for unit 0; AVCC1 or AVSS1 for unit 1) before start of A/D conversion. This function enables disconnection detection in wiring of analog inputs.

Figure 57.37 illustrates the A/D conversion operation when the disconnection detection assist function is used. Figure 57.38 shows an example of disconnection detection when precharge is selected. Figure 57.39 shows an example of disconnection detection when discharge is selected.

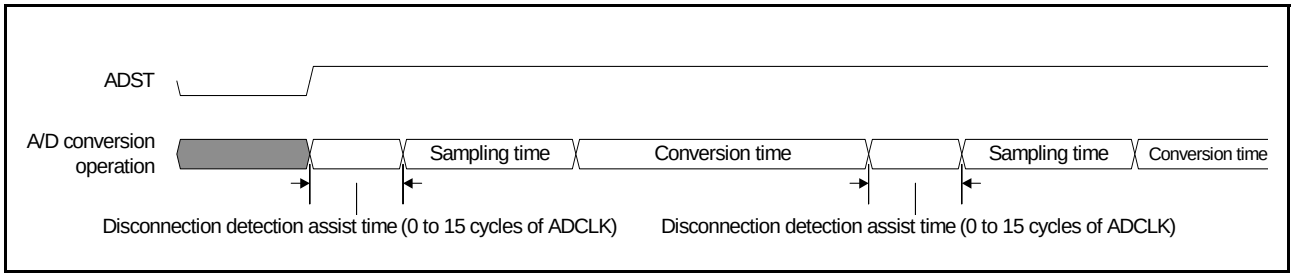

Figure 57.37 Operation of A/D Conversion when the Disconnection Detection Assist Function is Used

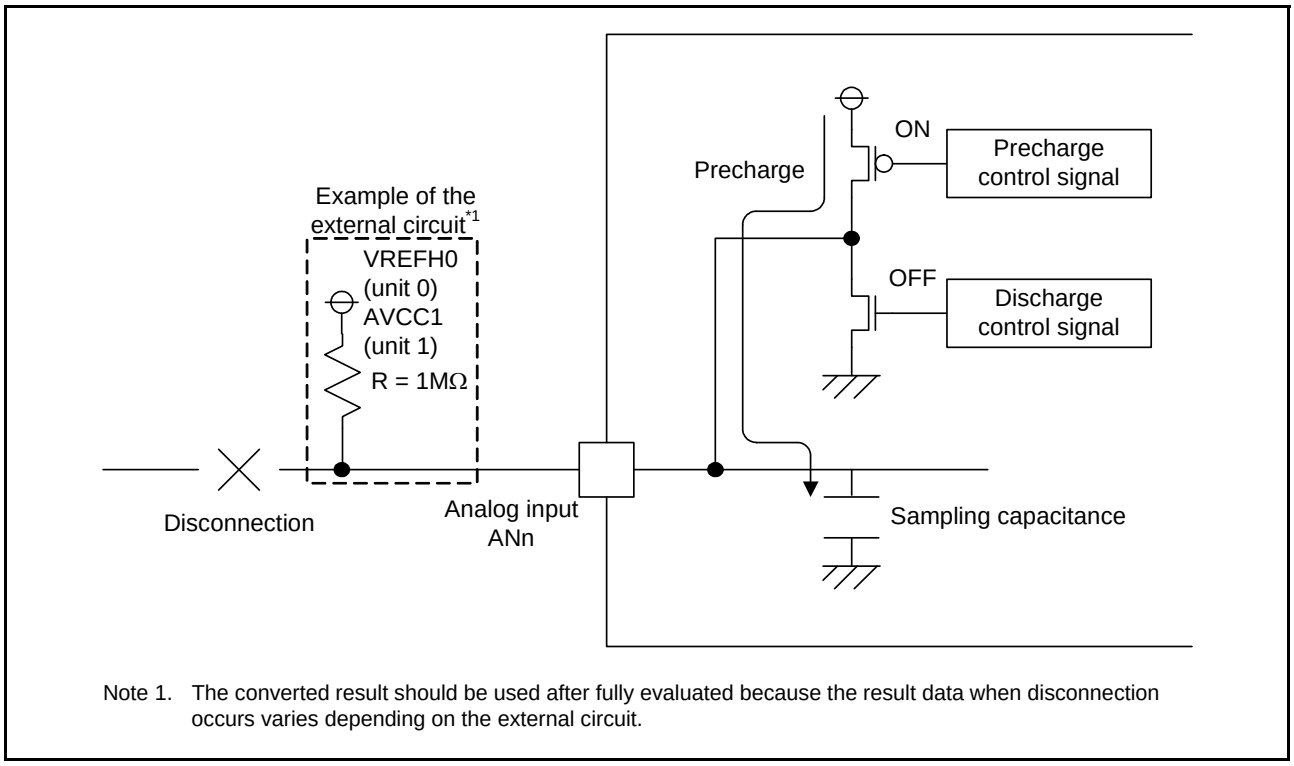
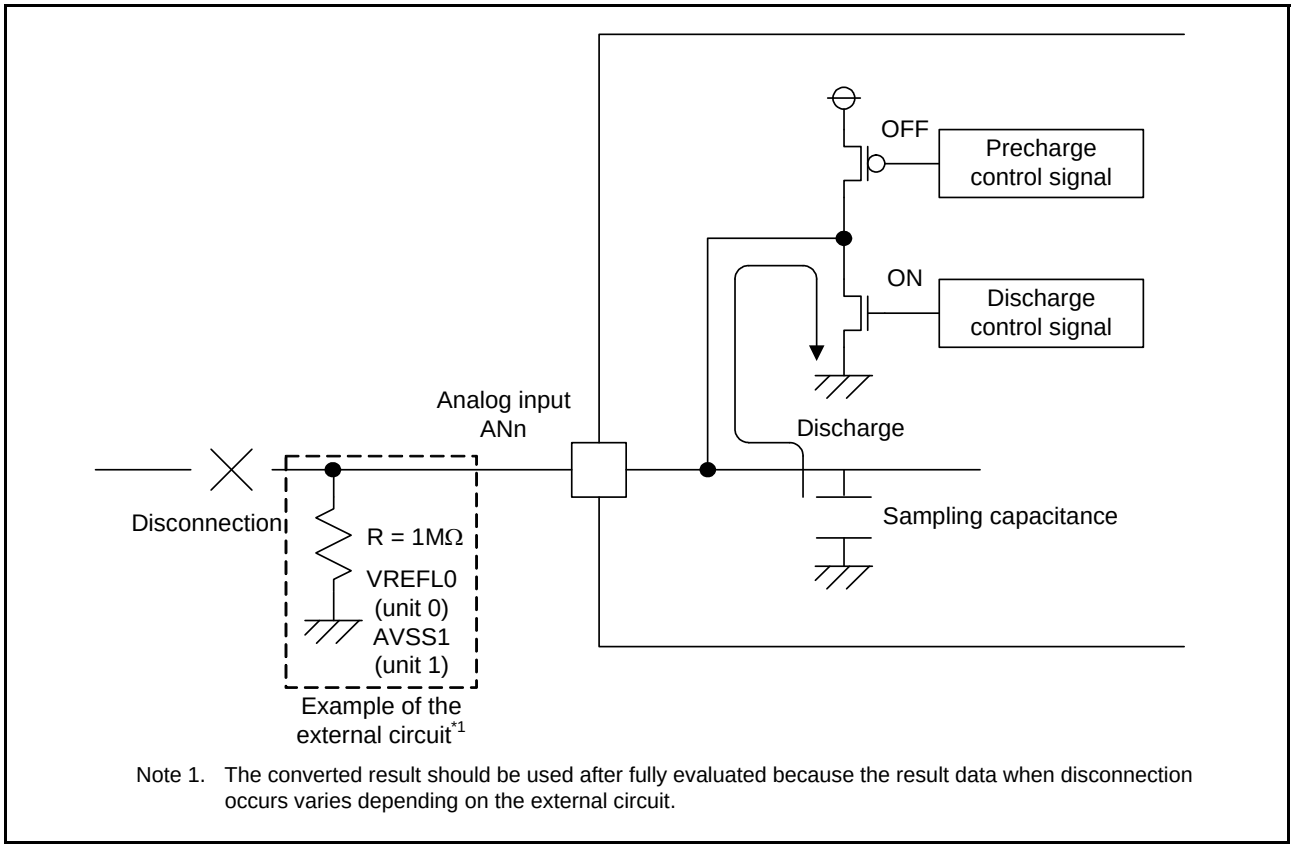


Note 1. The converted result should be used after fully evaluated because the result data when disconnection occurs varies depending on the external circuit.

Figure 57.38 Example of Disconnection Detection when Precharge is Selected



Note 1. The converted result should be used after fully evaluated because the result data when disconnection occurs varies depending on the external circuit.

Figure 57.39 Example of Disconnection Detection when Discharge is Selected

57.3.11 Starting A/D Conversion with Asynchronous Trigger

The A/D conversion can be started by the input of an asynchronous trigger. To start up the A/D converter by an asynchronous trigger, the A/D conversion start trigger select bits (ADSTRGR.TRSA[5:0]) should be set to 000000b and a high-level signal should be input to the asynchronous trigger (ADTRGn# pin). Both the ADCSR.TRGE and ADCSR.EXTRG bits then should be set to 1. Figure 57.40 shows a timing of the asynchronous trigger input.
For the time between setting the ADCSR.ADST bit to 1 and starting A/D conversion, refer to section 57.5.3, A/D Conversion Restarting Timing and Termination Timing.

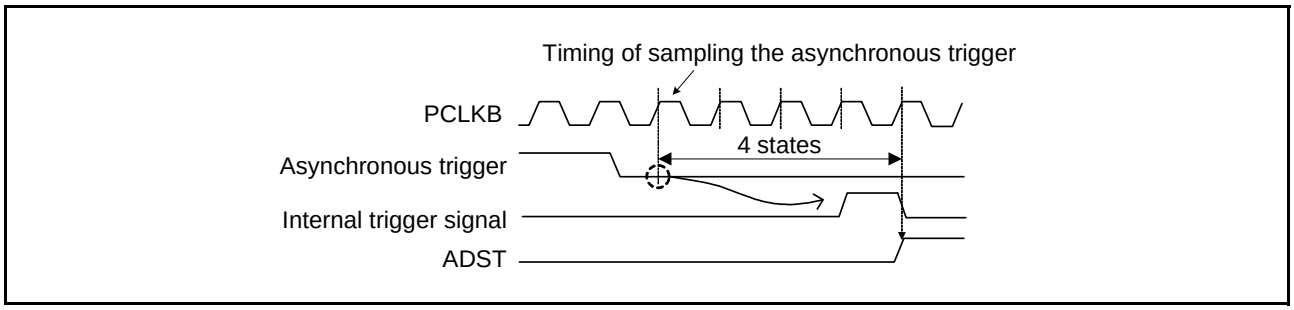


Figure 57.40 Asynchronous Trigger Input Timing

57.3.12 Starting A/D Conversion with Synchronous Trigger from Peripheral Module

The A/D conversion can be started by a synchronous trigger (MTU, ELC, GPT, TMR, TPU). To start the A/D conversion by a synchronous trigger, the ADCSR.TRGE bit should be set to 1, the ADCSR.EXTRG bit should be cleared to 0, and the relevant sources should be selected by the ADSTRGR.TRSA[5:0] and ADSTRGR.TRSB[5:0] bits.

57.4 Interrupt Sources and DTC/DMAC Transfer Requests

57.4.1 Interrupt Requests

The 12-bit A/D converter can send scan end interrupt requests S12ADI and S12GBADI to the CPU. The module also generates the S12CMPI interrupt for the CPU in response to matches with a condition for comparison.
Setting the ADCSR.ADIE bit to 1 and 0 enables and disables an S12ADI interrupt, respectively; similarly, setting the ADCSR.GBADIE bit to 1 and 0 enables and disables a S12GBADI interrupt, respectively. Setting the ADCMPCR.CMPIE bit to 1 and 0 enables and disables an S12CMPI interrupt, respectively.
In addition, the DTC or DMACA can be started up when an S12ADI or an S12GBADI interrupt is generated. Using an S12ADI or an S12GBADI interrupt to allow the DTC or DMACA to read the converted data enables continuous conversion without burden on software.
For details on DTC settings, see section 20, Data Transfer Controller (DTCa), and for details on DMACA settings, see section 18, DMA Controller (DMACAa).
The ADI and GBADI interrupts are output according to the settings of scan mode and double trigger mode as shown in Table 57.12.

Table 57.12 Relationship between Mode Setting and ADI Interrupt Output

Scan mode	Double trigger mode (DBLE)	Trigger	ADI interrupt (ADIE = 1)	GBADI interrupt (GBADIE = 1)
Single scan mode	DBLE = 0	Software trigger	Output on completion of each scan	Not output (group B scan is disabled)
		Synchronous trigger	Output on completion of each scan	Not output (group B scan is disabled)
		Asynchronous trigger	Output on completion of each scan	Not output (group B scan is disabled)
	DBLE = 1	Software trigger	Output on completion of each scan	Not output (group B scan is disabled)
		Synchronous trigger	Output on completion of each even-order scan	Not output (group B scan is disabled)
Continuous scan mode	Setting prohibited	Software trigger	Output on completion of each scan	Not output (group B scan is disabled)
		Synchronous trigger	Output on completion of each scan	Not output (group B scan is disabled)
		Asynchronous trigger	Output on completion of each scan	Not output (group B scan is disabled)
Group scan mode	DBLE = 0	Software trigger	Output on completion of each scan (performed for group A only)	Not output (group B scan is disabled)
		Synchronous trigger	Output on completion of each scan for group A	Output on completion of each scan for group B
	DBLE = 1	Software trigger	Output on completion of each scan (performed for group A only)	Not output (group B scan is disabled)
		Synchronous trigger	Output on completion of each even-order scan for group A	Output on completion of each scan for group B

57.4.2 Scan End Event Output to ELC

The ELC enables a link operation with the modules specified in advance using S12ADI interrupt request signal as an event signal. The S12GBADI and S12CMPI interrupt request signals cannot be used as an event signal. An event signal can be output regardless of the settings of the corresponding interrupt request enable bits. The 12-bit A/D converter outputs an A/D conversion end event.

57.5 Usage Notes

57.5.1 Notes on Reading Data Registers

The A/D data registers, A/D data duplication registers, A/D data duplication register A, A/D data duplication register B, A/D temperature sensor data register, A/D internal reference voltage register, and A/D self-diagnosis data register should be read in word units. If a register is read twice in byte units, that is, the upper byte and lower byte are separately read, the A/D-converted value having been read first may disagree with the A/D-converted value having been read for the second time. To prevent this, the data registers should never be read in byte units.

57.5.2 Notes on Stopping A/D Conversion

To stop A/D conversion when an asynchronous trigger or a synchronous trigger has been selected as the condition for starting A/D conversion, follow the procedure in Figure 57.41.

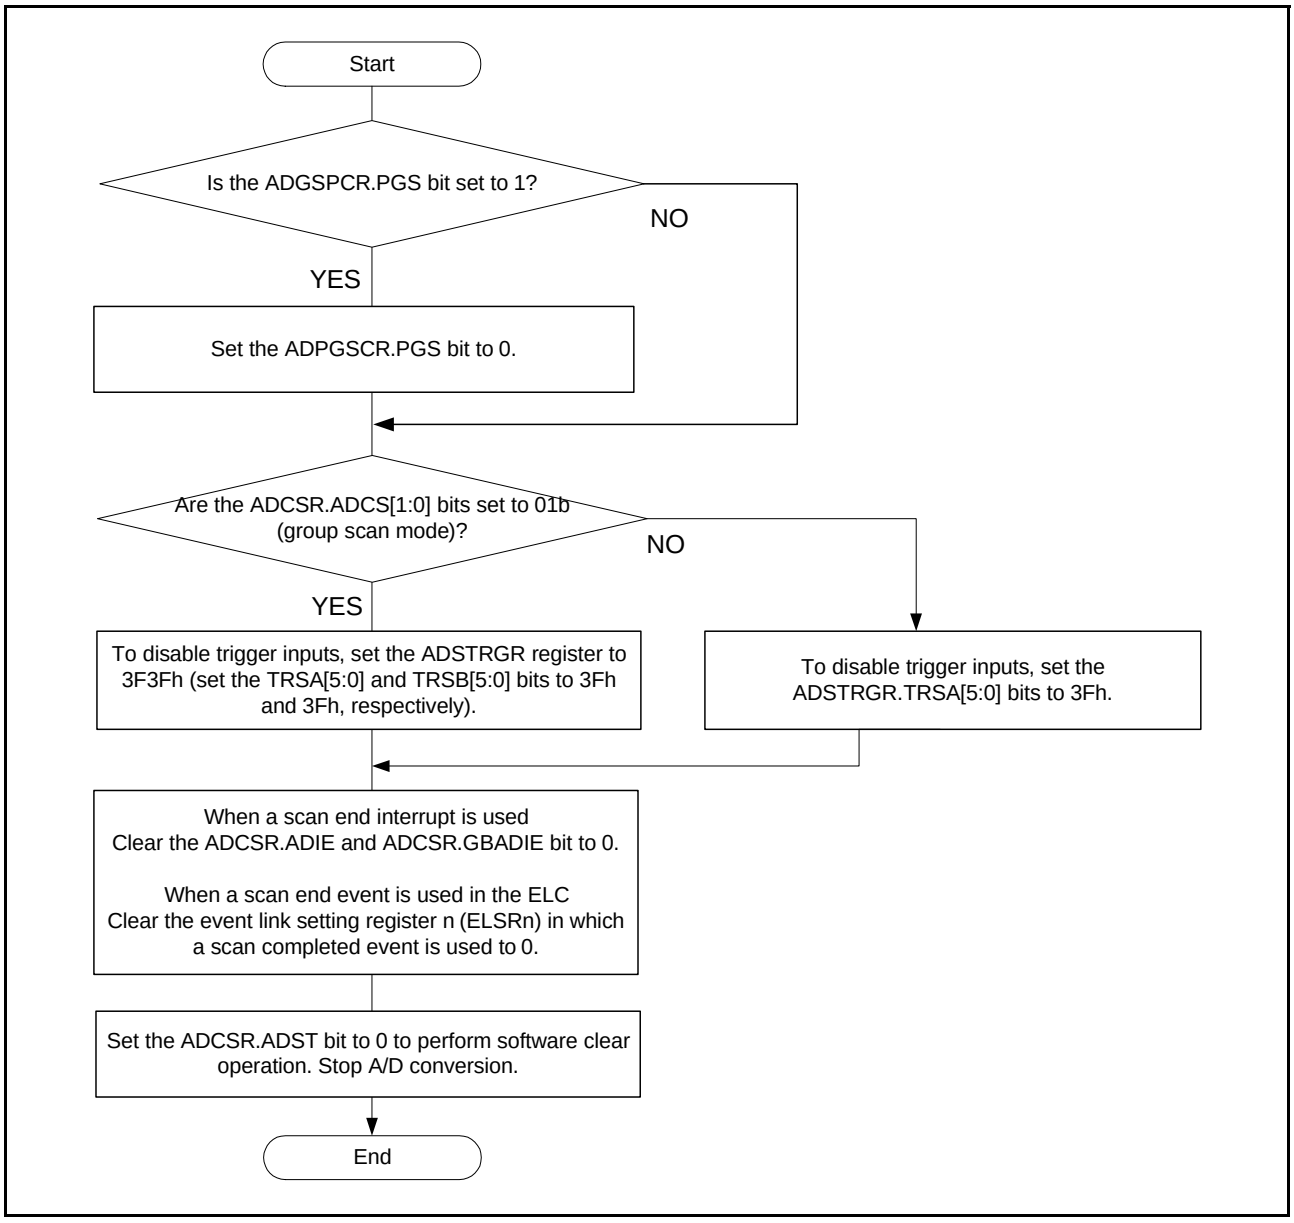

Figure 57.41 Procedures for Clear Operation by Software through the ADCSR.ADST Bit

57.5.3 A/D Conversion Restarting Timing and Termination Timing

It takes a maximum of six ADCLK cycles for the idle analog unit of the 12-bit A/D converter to be restarted by setting the ADST bit in ADCSR register to 1. It takes a maximum of two ADCLK cycles for the operating analog unit of the 12-bit A/D converter to be terminated by setting the ADST bit in ADCSR register to 0.

57.5.4 Notes on Scan End Interrupt Handling

When scanning the same analog input twice using any trigger, the first A/D-converted data is overwritten with the second A/D-converted data in the case that the CPU does not complete reading out the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated.

57.5.5 Module Stop Function Setting

Operation of the 12-bit A/D converter can be disabled or enabled using the module stop control register. The initial setting is for operation of the 12-bit A/D converter to be halted. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Consumption.

57.5.6 Notes on Entering Low Power Consumption States

Before entering the module-stop state or software standby mode, make sure to stop A/D conversion. Here, set the ADST bit in ADCSR register to 0, and secure certain period of time until the analog unit of the 12-bit A/D converter is stopped. Follow the procedure given below to secure this time.
Follow the procedure for clear operation by software through the ADCSR.ADST bit, shown in Figure 57.41. After that, wait for two clock cycles of ADCLK before entering the module-stop state or software standby mode.
To place the 12-bit A/D converter in standby mode, set the MSTPCRA.MSTPA17 bit (unit 0) or the MSTPCRA.MSTPA16 bit (unit 1) to 1.

57.5.7 Port Setting When Using the 12-bit A/D Converter Input

When using the 12-bit A/D converter (unit 0), do not use ports 07, 05, 03 and port 4 as output ports. We also recommend not using ports 02, 01, 00, port 9, port D, and port E as output ports. If ports 02, 01, 00, port 9, port D, and port E are used for output signals, perform A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results.
When using the 12-bit A/D converter (unit 1), we recommend not using ports 02, 01, 00, port 9, port D, and port E as output ports. If ports 02, 01, 00, port 9, port D, and port E are used for output signals, perform A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results.

57.5.8 Caution When Using an External Bus

A/D conversion at the same time as access to an external bus may produce poor results.
Perform conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results.

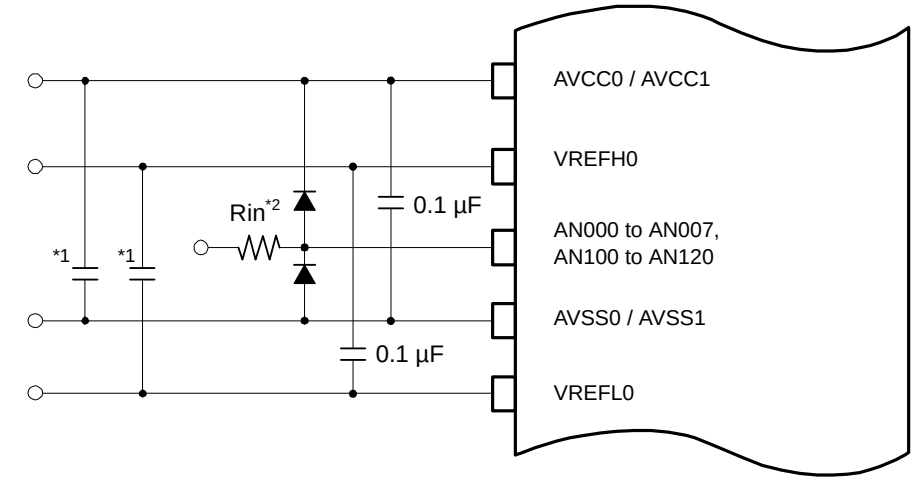
57.5.9 Error in Absolute Accuracy When Disconnection Detection Assistance is in Use

Using disconnection detection assistance leads to an error in absolute accuracy of the A/D converter. This is because an error voltage is input to the analog input pins due to the resistive voltage division between the pull-up or pull-down resistor (Rp) and the resistance of the signal source (Rs). This error in absolute accuracy is calculated from the following formula. Only use disconnection detection assistance after thorough evaluation.

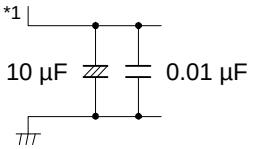
Maximum error in absolute accuracy (LSB) = 4095 × Rs / Rp

57.5.10 Notes on Noise Prevention

To prevent the analog input pins (AN000 to AN007, AN100 to AN120) from being destroyed by abnormal voltage such as excessive surge, a capacitor should be inserted between AVCC0 and AVSS0 and between VREFH0 and VREFL0 and between AVCC1 and AVSS1, and a protection circuit should be connected to protect the analog input pins (AN000 to AN007, AN100 to AN120) as shown Figure 57.42.



Note 1. The values shown here are reference values.



Note 2. Rin: Signal source impedance

Figure 57.42 Sample Protection Circuit for Analog Inputs

57.5.11 Notes on Operating Modes and Status Bits

- When resetting the status of the self-diagnosis voltage, set the ADCER.DIAGLD bit to 1 and set the ADCER.DIAGVAL[1:0] bits to select the voltage value.
- In double trigger mode, when the ADCSR.DBLE bit is modified from 0 to 1, the A/D converter starts from the first scan operation.
- Continuous sampling (the set value of the ADSHMSR.SHMD bit is 1) should be initialized by setting the ADSHMSR.SHMD bit to 0.
  To use continuous sampling again after the function is initialized, wait for at least one ADCLK cycle before setting the ADSHMSR.SHMD bit to 1.

58. 12-Bit D/A Converter (R12DA)

In this section, “PCLK” is used to refer to PCLKB.

58.1 Overview

This MCU includes two channels of 12-bit D/A converter with an output buffer amplifier.
Table 58.1 lists the specifications of the 12-bit D/A converter and Figure 58.1 shows a block diagram of the 12-bit D/A converter.

Table 58.1 Specifications of 12-Bit D/A Converter

Item	Specifications
Resolution	12 bits
Output channels	Two channels
Countermeasure against mutual interference between analog modules	Measure against interference between D/A and A/D conversion D/A converted data update timing is controlled by the 12-bit A/D converter synchronous D/A conversion enable input signal from the 12-bit A/D converter (unit 1). Therefore, the degradation of A/D conversion accuracy due to interference is reduced by controlling the timing in which the 12-bit D/A converter inrush current occurs, with the enable signal.
Low power consumption function	Module stop state can be set.
Event link function (input)	DA0 conversion can be started when an event signal is input.
Output buffer amplifier control function	Buffered output (gain = 1) or unbuffered output can be selected.

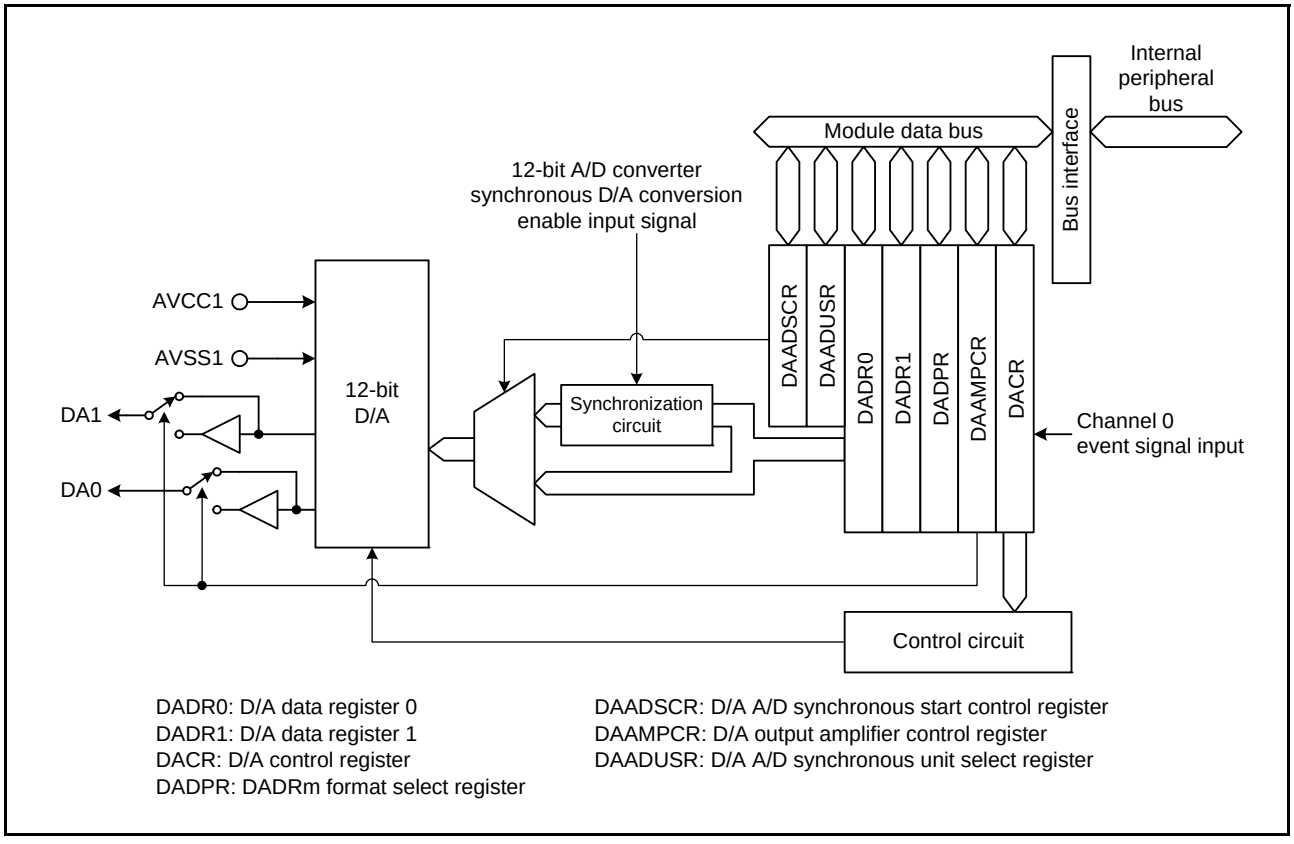


Figure 58.1 Block Diagram of 12-Bit D/A Converter

Table 58.2 lists the pin configuration of the 12-bit D/A converter.

Table 58.2 Pin Configuration of 12-Bit D/A Converter

Pin Name	I/O	Function
AVCC1	Input	Reference voltage input pin for the 12-bit A/D converter (unit 1) and the 12-bit D/A converter: This pin is also used as an analog power supply pin for the modules and temperature sensor. Connect to VCC when the 12-bit A/D converter (unit 1), the 12-bit D/A converter, and the temperature sensor are not used.
AVSS1	Input	Reference voltage input pin for the 12-bit A/D converter (unit 1) and the 12-bit D/A converter: This pin is also used as an analog ground pin for the modules and temperature sensor. Set to the same potential as that of the VSS pin.
DA0	Output	Channel 0 analog output pin
DA1	Output	Channel 1 analog output pin

58.2 Register Descriptions

58.2.1 D/A Data Register m (DADRm) (m = 0, 1)

Address(es): DA.DADR0 0008 8040h, DA.DADR1 0008 8042h

• DADPR.DPSEL bit = 0 (data is flush with the right end of the register)

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

• DADPR.DPSEL bit = 1 (data is flush with the left end of the register)

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
													—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DADRm register is a 16-bit readable/writable register, which stores data to which D/A conversion is to be performed. Whenever an analog output is enabled, the values in DADRm are converted and output to the analog output pins.

12-bit data can be relocated by setting the DADPR.DPSEL bit.

Bits "—" are read as 0. The write value should be 0.

When the output buffer amplifier is used, see section 58.6.5, Initial Setting Procedure when the Output Buffer Amplifier is Used.

58.2.2 D/A Control Register (DACR)

Address(es): DA.DACR 0008 8044h

	b7	b6	b5	b4	b3	b2	b1	b0
	DAOE1	DAOE0	DAE	—	—	—	—	—
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b5	DAE	D/A Enable*1	0: D/A conversion of channels 0 and 1 is controlled individually. 1: D/A conversion of channels 0 and 1 is enabled collectively.	R/W
b6	DAOE0	D/A Output Enable 0	0: Analog output of channel 0 (DA0) is disabled. 1: D/A conversion of channel 0 is enabled. Analog output of channel 0 (DA0) is enabled.	R/W
b7	DAOE1	D/A Output Enable 1	0: Analog output of channel 1 (DA1) is disabled. 1: D/A conversion of channel 1 is enabled. Analog output of channel 1 (DA1) is enabled.	R/W

Note 1. This bit controls D/A conversion in combination with the DAOEm bit (m = 0, 1). The DAOEm bit controls output of the results of conversion. For details, see Table 58.3.

Table 58.3 Controls of D/A Conversion

b5	b7	b6	
DAE	DAOE1	DAOE0	Description
0	0	0	D/A conversion and analog output pins (DA0, DA1) are disabled.*1
		1	D/A conversion of channel 0 is enabled. D/A conversion of channel 1 is disabled. Analog output of channel 0 (DA0) is enabled. Analog output of channel 1 (DA1) is disabled.*1
	1	0	D/A conversion of channel 0 is disabled. D/A conversion of channel 1 is enabled. Analog output of channel 0 (DA0) is disabled.*1 Analog output of channel 1 (DA1) is enabled.
		1	D/A conversion of channels 0 and 1 is enabled. Analog output of channels 0 and 1 (DA0, DA1) is enabled.
1	x	x	D/A conversion of channels 0 and 1 is enabled. Analog output of channels 0 and 1 (DA0, DA1) is enabled collectively.

x: Don't care

Note 1. When analog output is disabled, the analog output signal is placed in the Hi-Z state.

This register should be set when the DAADSCR.DAADST bit is 1 (measure against interference between D/A and A/D conversion is enabled) while the 12-bit A/D converter (unit 1) is halted (the ADCSR.ADST bit is 0). At that time, the software trigger should be selected for the 12-bit A/D converter (unit 1) trigger to securely stop the 12-bit A/D converter (unit 1).

DAE Bit (D/A Enable)

The DAE bit controls D/A conversion, amplifier operation, and analog output in combination with the DAOEm bit (m = 0, 1) and the DAAMPCR.DAAMPm bit. See Table 58.4 for details.

When the countermeasure against an interference between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the DAE bit while the ADCSR.ADST bit in the 12-bit A/D converter (unit 1) is 0. At that time, the software trigger should be selected for the 12-bit A/D converter (unit 1) trigger to securely stop the 12-bit A/D converter (unit 1).

DAOEm Bit (D/A Output Enable m) (m = 0, 1)

The DAOEm bit controls D/A conversion, amplifier operation, and analog output in combination with the DAE bit and DAAMPCR.DAAMPm bit. See Table 58.4 for details.

When both the DAOEm bit and DAE bit are 0, D/A conversion of channel m is not done and no conversion result is output.

When the countermeasure against an interference between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the DAOEi bit while the ADCSR.ADST bit in the 12-bit A/D converter (unit 1) is 0. At that time, the software trigger should be selected for the 12-bit A/D converter (unit 1) trigger to securely stop the 12-bit A/D converter (unit 1).

The event link function can be used to set the DAOE0 bit to 1. The DAOE0 bit becomes 1 when the event specified by setting the ELSR16 register of the ELC occurs, and output of the D/A conversion results starts.

Table 58.4 D/A Conversion and Analog Output Control (m = 0, 1)

DACR		DAAMPCR	D/A Conversion Operation of Channel m	Amplifier Operation of Channel m	Analog Output of Channel m
DAE	DAOEm	DAAMPm			
0	0	0	Disabled	Disabled	Hi-Z
		1	Disabled	Disabled	Hi-Z
	1	0	Enabled	Disabled	Unbuffered output
		1	Enabled	Enabled	Buffered output
1	0	0	Enabled	Disabled	Unbuffered output
		1	Enabled	Enabled	Buffered output
	1	0	Enabled	Disabled	Unbuffered output
		1	Enabled	Enabled	Buffered output

58.2.3 DADRm Format Select Register (DADPR) (m = 0, 1)

Address(es): DA.DADPR 0008 8045h

	b7	b6	b5	b4	b3	b2	b1	b0
	DPSEL	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	DPSEL	DADRm Format Select	0: Data is flush with the right end of the D/A data register. 1: Data is flush with the left end of the D/A data register.	R/W

58.2.4 D/A A/D Synchronous Start Control Register (DAADSCR)

Address(es): DA.DAADSCR 0008 8046h

	b7	b6	b5	b4	b3	b2	b1	b0
	DAADST	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	DAADST	D/A A/D Synchronous Conversion	0: 12-bit D/A converter operation does not synchronize with 12-bit A/D converter (unit 1) operation. (measure against interference between D/A and A/D conversion is disabled) 1: 12-bit D/A converter operation synchronizes with 12-bit A/D converter (unit 1) operation. (measure against interference between D/A and A/D conversion is enabled)	R/W

As a measure against interference between D/A and A/D conversion, the DAADSCR register selects whether or not the timing for starting 12-bit D/A conversion is synchronized with the 12-bit A/D converter synchronous D/A conversion enable input signal from the 12-bit A/D converter (unit 1).
This register should be set while the 12-bit A/D converter (unit 1) is halted (while the ADCSR.ADST bit is 0 after selecting software trigger as the 12-bit A/D converter (unit 1) trigger).
Unit 1 should be selected as the target unit of the 12-bit A/D converter before setting the DAADST bit to 1.
Set the DAADUSR.AMADSEL1 bit to 1 to select unit 1.

DAADST Bit (D/A A/D Synchronous Conversion)

Setting the DAADST bit to 0 allows the DADRm register value (m = 0, 1) to be converted into analog data at any time.
Setting the DAADST bit to 1 allows synchronous D/A conversion with the 12-bit A/D converter synchronous D/A conversion enable input signal from the 12-bit A/D converter (unit 1). Therefore, even if the DADRm register value is modified, D/A conversion does not start until the 12-bit A/D converter (unit 1) completes A/D conversion.
Set this bit while the ADCSR.ADST bit is set to 0. At this time, the software trigger should be selected for the 12-bit A/D converter trigger to securely stop the 12-bit A/D converter (unit 1). Set the DAADUSR.AMADSEL1 bit to 1 before setting the DAADST bit to 1.
The event link function cannot be used when the DAADST bit is set to 1. Stop the event link function by setting the ELSR16 register of the ELC. The setting of the DAADST bit is common to channels 0 and 1 of the 12-bit D/A converter.

58.2.5 D/A Output Amplifier Control Register (DAAMPCR)

Address(es): DA.DAAMPCR 0008 8048h

	b7	b6	b5	b4	b3	b2	b1	b0
	DAAMP1	DAAMP0	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	DAAMP0	Amplifier Control 0	0: Output buffer amplifier of channel 0 is not used. 1: Output buffer amplifier of channel 0 is used.	R/W
b7	DAAMP1	Amplifier Control 1	0: Output buffer amplifier of channel 1 is not used. 1: Output buffer amplifier of channel 1 is used.	R/W

The DAAMPCR register selects D/A converter output with or without using the output buffer amplifier.

DAAMP0 Bit (Amplifier Control 0)

When the DAAMP0 bit is 0, the conversion result for the D/A converter channel 0 is output without using the output buffer amplifier. When the DAAMP0 bit is 1, the conversion result for the D/A converter channel 0 is output via the output buffer amplifier.

When both the DAE and DAOE0 bits are 0, the output buffer amplifier is disabled regardless of the setting of the DAAMP0 bit. See Table 58.4 for details.

DAAMP1 Bit (Amplifier Control 1)

When the DAAMP1 bit is 0, the conversion result for the D/A converter channel 1 is output without using the output buffer amplifier. When the DAAMP1 bit is 1, the conversion result for the D/A converter channel 1 is output via the output buffer amplifier.

When both the DAE and DAOE1 bits are 0, the output buffer amplifier is disabled regardless of the setting of the DAAMP1 bit. See Table 58.4 for details.

58.2.6 D/A A/D Synchronous Unit Select Register (DAADUSR)

Address(es): DA.DAADUSR 0008 C5C0h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	AMADSEL1	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	AMADSEL1	A/D Unit 1 Select	0: Unit 1 is not selected. 1: Unit 1 is selected.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The DAADUSR register is used to select the target unit of the 12-bit A/D converter for D/A and A/D synchronous conversions. When setting the DAADSCR.DAADST bit to 1 for synchronous conversions, the target unit should be selected by this register in advance. Set the AMADSEL1 bit to 1 and select unit 1 as the target synchronous unit. The DAADUSR register should be set when the ADCSR.ADST bit of the 12-bit A/D converter is set to 0 and the DAADSCR.DAADST bit is set to 0.

58.3 Operation

The 12-bit D/A converter includes D/A conversion circuits for two channels, each of which can operate independently. When the DACR.DAOEm bit (m = 0, 1) is set to 1, D/A converter is enabled and the conversion result is output. An operation example of D/A conversion on channel 0 is shown below. Figure 58.2 shows the timing of this operation.

(1) Set the data for D/A conversion in the DADPR.DPSEL bit and the DADR0 register.

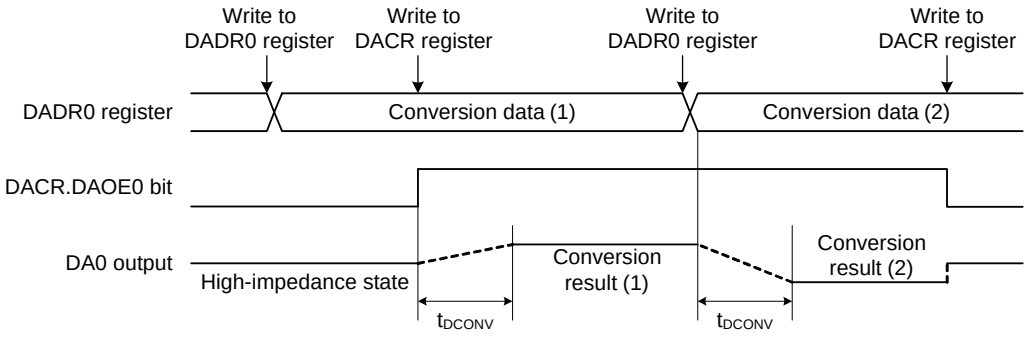
(2) Set the DACR.DAOE0 bit to 1 to start D/A conversion. The conversion result is output from the analog output pin DA0 after the conversion time tDCONV has elapsed. The conversion result continues to be output until the DADR0 register is written to again or the DAOE0 bit is cleared to 0. The output value (reference) is expressed by the following formula:

$$\frac{\text{Value of DADRm register}}{4096} \times \text{AVCC1}$$

When the output buffer amplifier is used, the output voltage does not reach AVSS1 or AVCC1. Refer to section 64, Electrical Characteristics for the output voltage range.

(3) If the DADR0 register is written to again, the conversion is started. The conversion result is output after the conversion time tDCONV has elapsed.
When the DAADSCR.DAADST bit is 1 (measure against interference between D/A and A/D conversion is enabled), it takes a maximum of one A/D conversion time for D/A conversion to start.

(4) If the DAOE0 bit is set to 0, analog output is disabled.



t_{DCONV}: D/A conversion time. Refer to the electric characteristics for the value.

Figure 58.2 Example of 12-Bit D/A Converter Operation

58.3.1 Measure against Interference between D/A and A/D Conversion

When D/A conversion starts, an inrush current occurs to the 12-bit D/A converter. Since the same analog power supply is shared by the 12-bit D/A converter and 12-bit A/D converter (unit 1), the inrush current may interfere with the proper operation of the 12-bit A/D converter (unit 1).
With the DAADSCR.DAADST bit being 1, even if the DADRm register data (m = 0, 1) is modified during 12-bit A/D converter (unit 1) operation, D/A conversion does not start immediately but starts synchronously with A/D conversion completion. It takes a maximum of one A/D conversion time for the DADRm register data update to be reflected as the D/A conversion circuit input. Before reflection, the DADRm register value does not correspond to the analog output value.
When this function is enabled, it is impossible to check by any software means whether the DADRm register value has been D/A converted or not.
Even with the DAADSCR.DAADST bit being 1, when the DADRm register data is modified while the 12-bit A/D converter (unit 1) is halted, D/A conversion starts in one PCLK cycle.
Figure 58.3 shows an example of channel 0 D/A conversion, in which the 12-bit D/A converter operates synchronously with the 12-bit A/D converter (unit 1).

(1) Confirm that the 12-bit A/D converter (unit 1) is halted. Set the DAADUSR.AMADSEL1 bit to 1.
(2) Confirm that the 12-bit A/D converter (unit 1) is halted. Set the DAADSCR.DAADST bit to 1.
(3) Confirm that the 12-bit A/D converter (unit 1) is halted. Set the DACR.DAOE0 bit to 1.
(4) Set the DADR0 register.

- If the 12-bit A/D conversion is halted (ADCSR.ADST bit = 0) when the DADR0 register is modified, D/A conversion starts in one PCLK cycle.
- If the 12-bit A/D conversion is in progress (ADCSR.ADST bit = 1) when the DADR0 register is modified, D/A conversion starts upon A/D conversion completion. If the DADR0 register is modified twice during A/D conversion, the first update may not be converted.

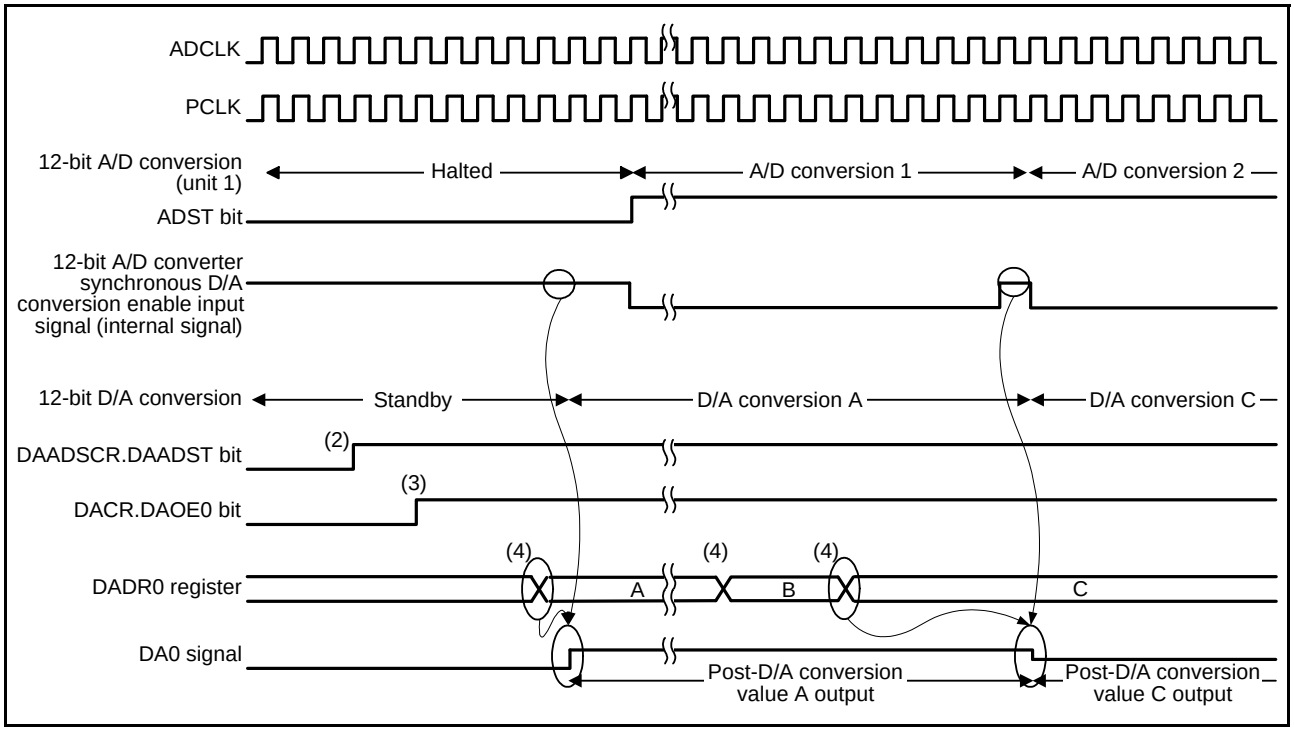


Figure 58.3 Example of Conversion When the 12-Bit D/A Converter is Synchronized with the 12-Bit A/D Converter (Unit 1)

58.4 Event Link Operation Setting Procedure

The event link operation procedure is described below.

(1) Set the DADPR.DPSEL bit and set the data for D/A conversion in the DADR0 register.
(2) Set the bit value of the ELSR16 setting event signal to link the ELSR16 register of the ELC.
(3) Set the ELCR.ELCON bit to 1. This procedure enables event link operation for all modules with the event link function selected.
(4) Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE0 bit becomes 1, and D/A conversion on channel 0 starts.
(5) Set the ELSR16.ELS[7:0] bits to 0000 0000b to stop event link operation of 12-bit D/A converter channel 0. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

58.5 Usage Notes on Event Link Operation

(1) When the event link function is used, do not use the output buffer amplifier.
(2) When the event link function is used, set the DACR.DAE bit to 0.
(3) When the event specified by the ELSR16 register is generated while the write cycle is performed to the DACR.DAOE0 bit, the write cycle is stopped, and the setting to 1 by the generated event takes precedence.
(4) Use of the event link function is prohibited when the DAADSCR.DAADST bit is set to 1 as the countermeasure against an interfere between D/A and A/D conversions.

58.6 Usage Notes

58.6.1 Module Stop Function Setting

Operation of the 12-bit D/A converter can be disabled or enabled using the module stop control register. The initial setting is for operation of the 12-bit D/A converter to be stopped. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

58.6.2 Operation of the D/A Converter in Module Stop State

When the MCU enters the module stop state with D/A conversion enabled, the D/A converter outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current has to be reduced in the module stop state, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

58.6.3 Operation of the D/A Converter in Software Standby Mode

When the MCU enters software standby mode with D/A conversion enabled, the D/A converter outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current has to be reduced in software standby mode, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

58.6.4 Note on Entering Deep Software Standby Mode

When the MCU enters deep software standby mode with D/A conversion enabled, the outputs of the D/A converter are placed in a high impedance state.

58.6.5 Initial Setting Procedure when the Output Buffer Amplifier is Used

When using the output buffer amplifier, enable the amplifier output in the following procedure. An example for channel 0 is described below.

(1) Write 0000h to the DADR0 register.
(2) Set the DAAMPCR.DAAMP0 bit to 1.
(3) Set the DACR.DAE or DACR.DAOE0 bit to 1. The output buffer amplifier starts the operation.
(4) Wait for at least 3 μs and then write a value to be converted in the DADR0 register.

While the output buffer amplifier is operating, setting the DACR.DAE and DACR.DAOE0 bits to 0 disables the output buffer amplifier. Repeat the procedure from (1) to (4) to use the output buffer amplifier again.

58.6.6 Note on Usage When Measure against Interference between D/A and A/D Conversion is Enabled

When the DAADSCR.DAADST bit is 1 (measure against interference between D/A and A/D conversion is enabled), do not place the 12-bit A/D converter (unit 1) in the module stop state. It may halt D/A conversion in addition to A/D conversion.

59. Temperature Sensor (TEMPS)

59.1 Overview

This MCU includes a temperature sensor. The temperature sensor outputs a voltage which varies with the temperature. The 12-bit A/D converter unit 1 can convert the voltage from the sensor into a digital value. The temperature around the MCU can be obtained by converting the value into the temperature.

Table 59.1 lists the specifications of the temperature sensor, and Figure 59.1 shows a block diagram of the temperature sensor.

Table 59.1 Specifications of Temperature Sensor

Item	Description
Temperature sensor voltage output	Temperature sensor outputs a voltage to the 12-bit A/D converter unit 1.
Low-power consumption function	The module-stop state is selectable.
Temperature Sensor Calibration Data	Reference data measured for each chip at factory shipment is stored.

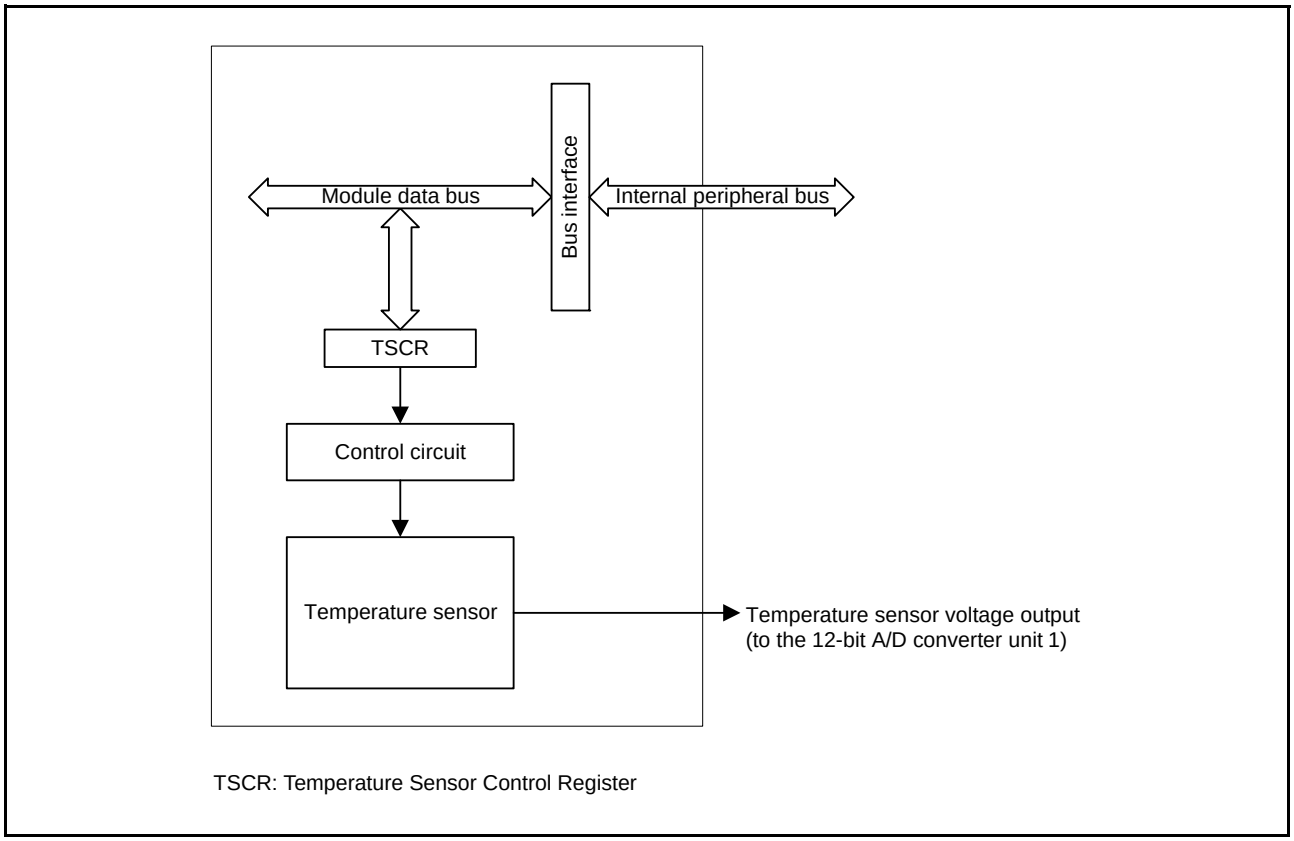

Figure 59.1 Block Diagram of Temperature Sensor

59.2 Register Descriptions

59.2.1 Temperature Sensor Control Register (TSCR)

Address(es): 0008 C500h

	b7	b6	b5	b4	b3	b2	b1	b0
	TSEN	—	—	TSOE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	TSOE	Temperature Sensor Output Enable	0: Disables output from the temperature sensor to the 12-bit A/D converter unit 1. 1: Enables output from the temperature sensor to the 12-bit A/D converter unit 1.	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	TSEN	Temperature Sensor Enable	0: Stops the temperature sensor. 1: Starts the temperature sensor.	R/W

The settings of TSCR register have the timing restrictions shown in Figure 59.4.

59.2.2 Temperature Sensor Calibration Data Register (TSCDR)

Address(es): 007F B17Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—												
Value after reset:	0	0	0	0	Unique value for each chip											

The TSCDR register stores temperature sensor calibration data measured for each chip at factory shipment. Temperature sensor calibration data is a digital value obtained using the 12-bit A/D converter unit 1 to convert the voltage output by the temperature sensor under the condition Ta = Tj = 128°C and AVCC1 = 3.3 V.
The TSCDR register is a 32-bit read-only register and should be read in 32-bit units.

59.3 Using the Temperature Sensor

The temperature sensor outputs a voltage which varies with the temperature.
This voltage is converted to a digital value by the 12-bit A/D converter unit 1. The temperature around the MCU can be obtained by converting the value into the temperature.

59.3.1 Preparation for Using the Temperature Sensor

Perform a calibration of the temperature sensor as shown below. The voltage output by the temperature sensor is proportional to temperature, which can be calculated according to the following formula.

Formula for the temperature characteristic:
T = (Vs – V1)/Slope + T1

T: Measured temperature (°C)
Vs: Voltage output by the temperature sensor when the temperature is measured (V)
T1: Sample temperature measurement at first point (°C)
V1: Voltage output by the temperature sensor when T1 is measured (V)
T2: Sample temperature measurement at second point (°C)
V2: Voltage output by the temperature sensor when T2 is measured (V)
Slope: Temperature slope of the temperature sensor (V/°C); Slope = (V2 – V1)/(T2 – T1)

Characteristics of the temperature sensor vary from MCU to MCU. Therefore, a two-point calibration (the following experimental measurement at two different temperatures) is recommended.
Use the 12-bit A/D converter unit 1 to measure the voltage V1 output by the temperature sensor at temperature T1. Again, using the 12-bit A/D converter unit 1, measure the voltage V2 output by the temperature sensor at a different temperature T2. Obtain the temperature slope (Slope = (V2 – V1)/(T2 – T1)) from these results.
Subsequently, obtain temperatures by substituting the slope into the formula for the temperature characteristic (T = (Vs – V1)/Slope + T1).

If you are using the temperature slope given in Table 64.49 of section 64, Electrical Characteristics, use the 12-bit A/D converter unit 1 to measure the voltage V1 output by the temperature sensor at temperature T1, and then calculate the temperature characteristic by using the formula below.
However, this calibration gives less accurate temperatures than two-point calibration.

T = (Vs – V1)/Slope + T1

T: Measured temperature (°C)
Vs: Voltage output by the temperature sensor when the temperature is measured (V)
T1: Sample temperature measurement at first point (°C)
V1: Voltage output by the temperature sensor when T1 is measured (V)
Slope: Temperature slope given in Table 64.49 ÷ 1000 (V/°C)

In this MCU, the TSCDR register stores the temperature value (CAL_{128}) of the temperature sensor measured under the condition Ta = Tj = 128°C and AVCC1 = 3.3 V. By using this value as the sample measurement result at the first point, preparation before using the temperature sensor can be omitted.
If V1 is calculated from CAL_{128},

$V1 = 3.3 \times CAL_{128}/4096$ [V]
Using this, the measured temperature can be calculated according to the formula below.

T = (Vs - V1)/Slope + 128 [°C]

T: Measured temperature (°C)
Vs: Voltage output by the temperature sensor when the temperature is measured (V)
V1: Voltage output by the temperature sensor when Ta = Tj = 128°C and AVCC1 = 3.3 V (V)
Slope: Temperature slope given in Table 64.49 ÷ 1000 (V/°C)

Error in the measured temperature (variation range is 3σ) is shown in Figure 59.2.

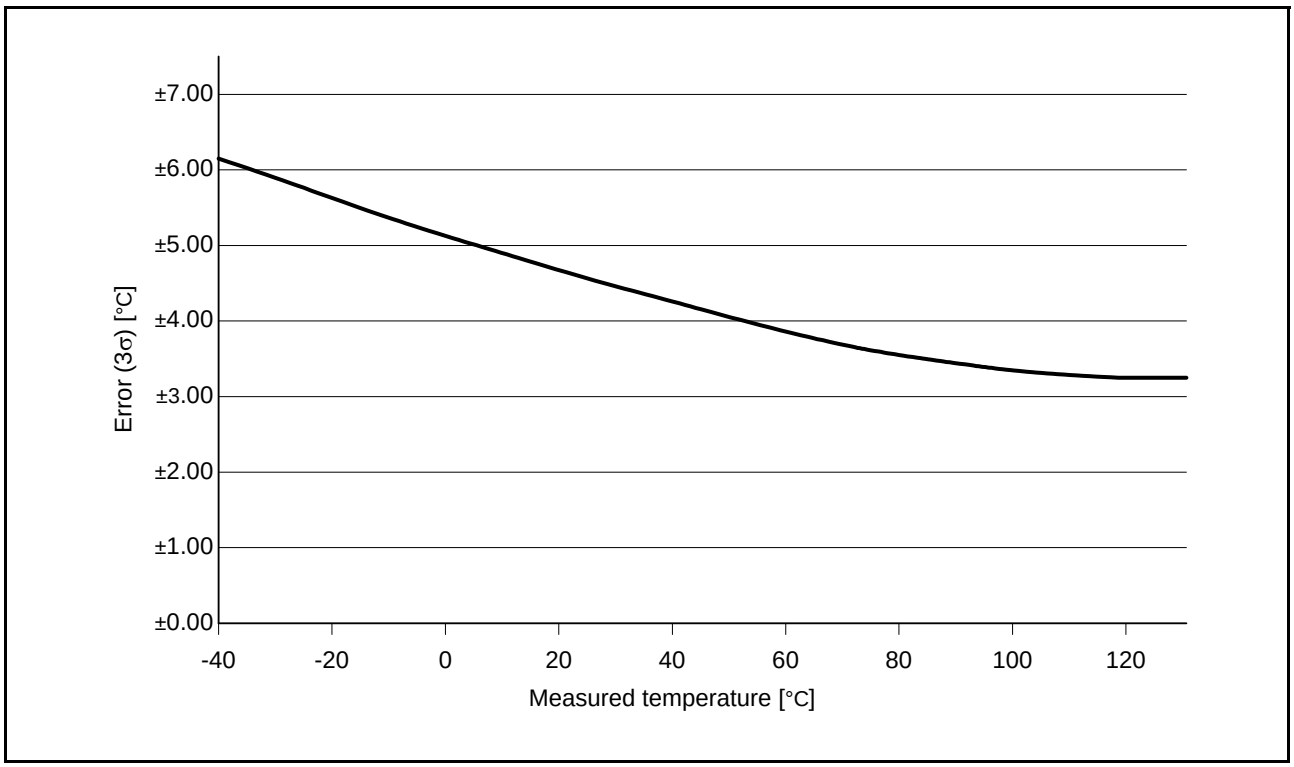

Figure 59.2 Error in the Measured Temperature

59.3.2 Setting of 12-Bit A/D Converter unit 1

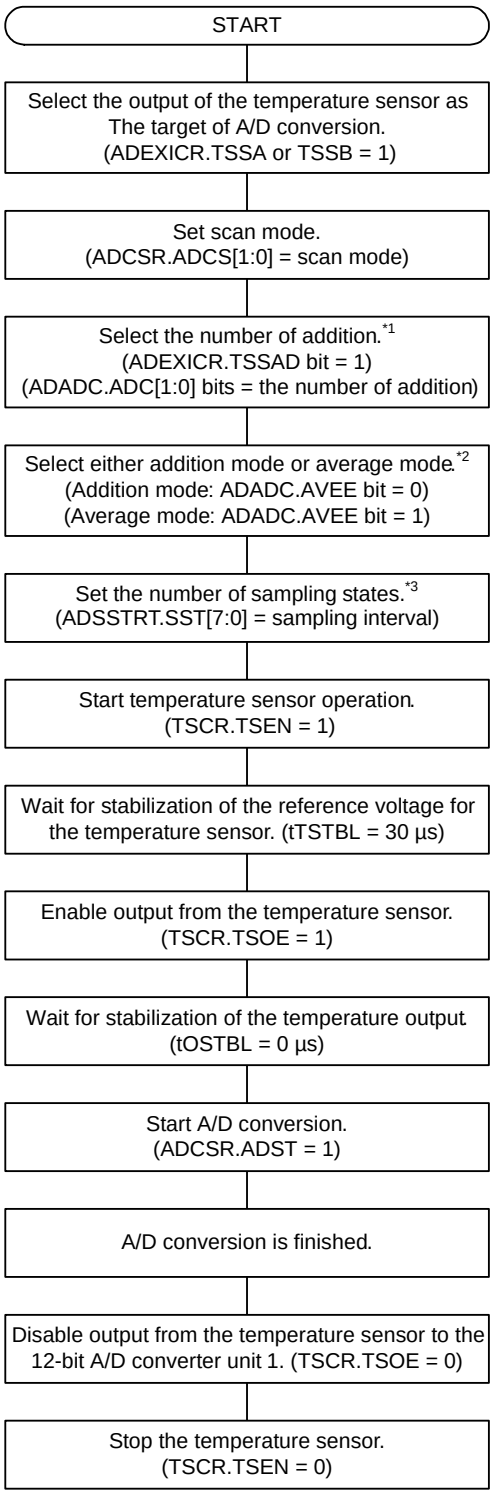
For A/D conversion of temperature sensor output voltages, 12-bit A/D converter unit 1 registers should be set as follows.

- Selecting the Temperature Sensor Voltage as an A/D Conversion Target
  Select A/D conversion of the voltage from the temperature sensor by setting the temperature sensor output A/D conversion select bit in the A/D conversion extended input control register (ADEXICR.TSSA or TSSB) to 1.
- Setting Scan Mode
  Select scan mode by setting the scan mode select bits in the A/D control register (ADCSR.ADCS[1:0]).
- Setting Addition/Average Mode
  For A/D conversion of the temperature sensor output, additional or average mode is selectable. To use either additional or average mode, set the temperature sensor output A/D converted value addition mode select bit in the A/D conversion extended input control register (ADEXICR.TSSAD) to 1, and the addition count select bits in the A/D converted value addition count select register (ADADC.ADC[1:0]) to the desired number of addition. Furthermore, clear the AVEE bit in ADADC to 0 to select addition mode; set the AVEE bit in ADADC to 1 to select average mode. In average mode, however, the ADC[1:0] bits in ADADC should not be set to 10b.
- Setting the Number of Sampling States of the 12-bit A/D converter unit 1
  The number of states for sampling of the output of the temperature sensor for A/D conversion is selectable. The initial setting is for 11 states. To change the number of states for sampling from 11 states, set the sampling time setting bits in A/D sampling state register T (ADSSTRT.SST[7:0]), when the ADST bit in ADCSR is 0.

Setting the A/D conversion start bit in the A/D control register (ADCSR.ADST) to 1 starts A/D conversion, and the result is stored in the A/D temperature sensor data register (ADTSDR). If you will be using A/D conversion of the output from the temperature sensor, do so in accord with section 59.3.3, Procedure for Using the Temperature Sensor.

59.3.3 Procedure for Using the Temperature Sensor

Figure 59.3 shows the procedure for using the temperature sensor.



Note 1. Unless addition/average mode is set, this setting is not required. To select average mode, do not set the ADC[1:0] bits to 10b.
Note 2. Unless addition/average mode is set, this setting is not required.
Note 3. The initial value for the number of states over which sampling proceeds is 11.
If the number of states is not to be changed, this setting is not required.

Figure 59.3 Procedure for Using the Temperature Sensor

59.3.4 Timing of A/D Conversion of Temperature Sensor Output

Figure 59.4 shows the timing from the start of temperature-sensor operation until the completion of A/D conversion when only the output from the temperature sensor is to be A/D converted and conversion is in single-scan mode. The times shown in the figure are described in Table 59.2.

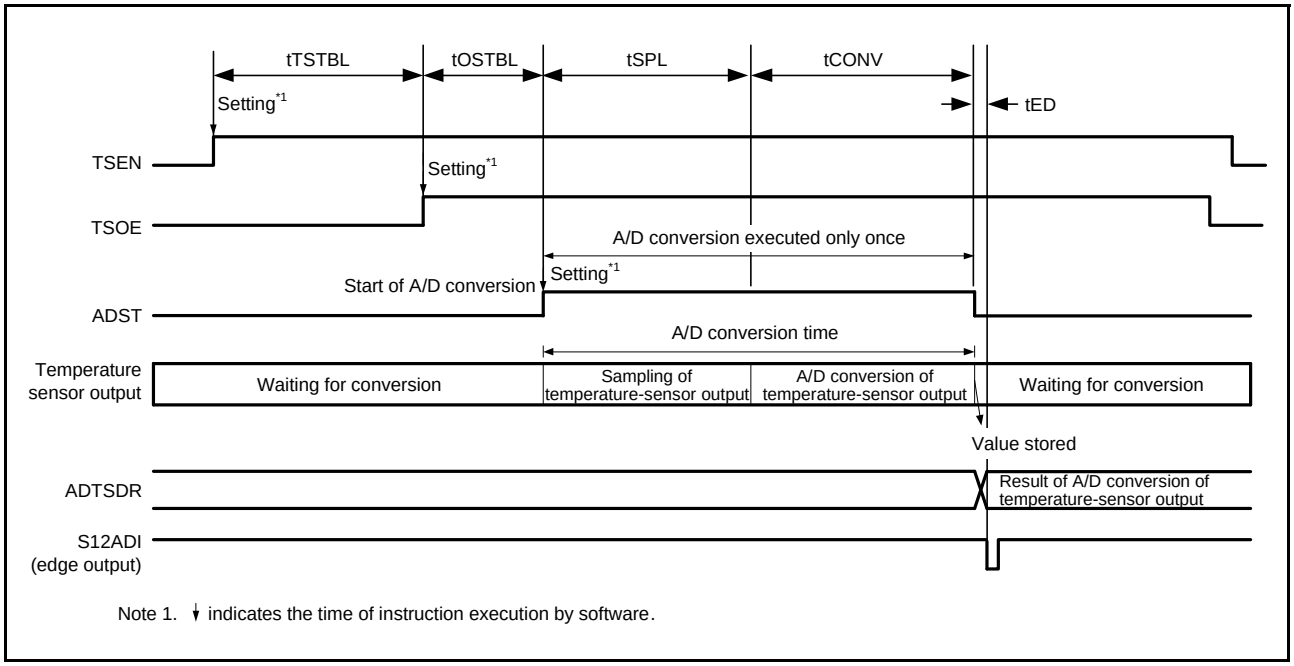


Figure 59.4 Timing from the Start of Temperature-Sensor Operation until Completion of A/D Conversion

Table 59.2 Time until Completion of A/D Conversion after the Start of Temperature-Sensor Operation

Item	Symbol	Time
Temperature-sensor reference-voltage stabilization wait time	tTSTBL	30 µs (min)
Temperature-sensor output stabilization wait time	tOSTBL	0 µs (min)
12-bit A/D converter unit 1 input sampling time	tSPL	ADSSTRT setting × ADCLK cycles
A/D conversion time	tCONV	Refer to Table 57.11, Times for Conversion during Scanning (in Numbers of Cycles of the ADCLK and PCLKB) in section 57.3.7, Analog Input Sampling and Scan Conversion Time.
Scan conversion end delay time	tED	Refer to Table 57.11, Times for Conversion during Scanning (in Numbers of Cycles of the ADCLK and PCLKB) in section 57.3.7, Analog Input Sampling and Scan Conversion Time.

59.4 Usage Note

59.4.1 Module-Stop Function Setting

The corresponding bit in module stop control register B (MSTPCRB) can be used to enable and disable the temperature sensor. The initial setting is for the temperature sensor to be stopped. The register becomes accessible on release from the module-stop state. For details, see section 11, Low Power Consumption.

60. Data Operation Circuit (DOC)

60.1 Overview

The data operation circuit (DOC) is used to compare, add, and subtract 16-bit data.
Table 60.1 lists the data operation circuit specifications and Figure 60.1 shows a block diagram of the data operation circuit.
16-bit data is compared and an interrupt can be generated when a selected condition applies.

Table 60.1 DOC Specifications

Item	Description
Data operation function	16-bit data comparison, addition, and subtraction
Lower power consumption function	Module stop state can be set.
Interrupts	An interrupt occurs at the following timings: • The compared values either match or mismatch • The result of data addition is greater than FFFFh • The result of data subtraction is less than 0000h
Event link function (output)	An interrupt occurs at the following timings: • The compared values either match or mismatch • The result of data addition is greater than FFFFh • The result of data subtraction is less than 0000h

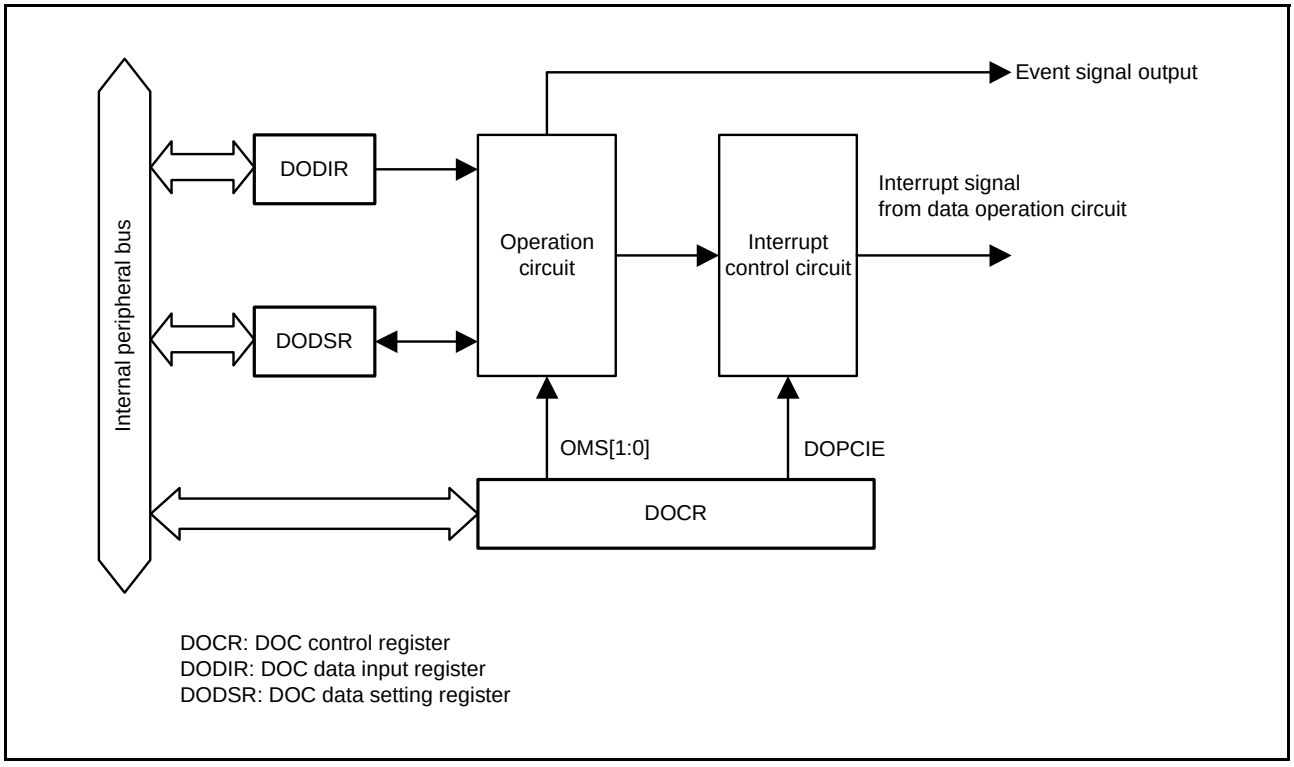

Figure 60.1 DOC Block Diagram

60.2 Register Descriptions

60.2.1 DOC Control Register (DOCR)

Address(es): 0008 B080h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	DOPCFCL	DOPCF	DOPCIE	—	DCSEL	OMS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	OMS[1:0]	Operating Mode Select	b1 b0 0 0: Data comparison mode 0 1: Data addition mode 1 0: Data subtraction mode 1 1: Setting prohibited	R/W
b2	DCSEL*1	Detection Condition Select	Result of data comparison 0: Data mismatch is detected. 1: Data match is detected.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	DOPCIE	Data Operation Circuit Interrupt Enable	0: Disables interrupts from the data operation circuit. 1: Enables interrupts from the data operation circuit.	R/W
b5	DOPCF	Data Operation Circuit Flag	Indicates the result of an operation.	R
b6	DOPCFCL	DOPCF Clear	0: Maintains the DOPCF flag state. 1: Clears the DOPCF flag.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. Valid only when data comparison mode is selected.

OMS[1:0] Bits (Operating Mode Select)

These bits select the operating mode of the data operation circuit.

DCSEL Bit (Detection Condition Select)

This bit is valid only when data comparison mode is selected.

This bit selects the condition for detection in data comparison mode.

DOPCIE Bit (Data Operation Circuit Interrupt Enable)

Setting this bit to 1 enables interrupts from the data operation circuit.

DOPCF Flag (Data Operation Circuit Flag)

[Setting conditions]

- The condition selected by the DCSEL bit is met
- A result of data addition is greater than FFFFh
- A result of data subtraction is less than 0000h

[Clearing condition]

- Writing 1 to the DOPCFCL bit

DOPCFCL Bit (DOPCF Clear)

Setting this bit to 1 clears the DOPCF flag.

This bit is read as 0.

60.2.2 DOC Data Input Register (DODIR)

Address(es): 0008 B082h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DODIR is a 16-bit readable/writable register in which 16-bit data for use in the operations are stored.

60.2.3 DOC Data Setting Register (DODSR)

Address(es): 0008 B084h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DODSR is a 16-bit readable/writable register. This register stores 16-bit data for use as a reference in data comparison mode. This register also stores the results of operations in data addition and data subtraction modes.

60.3 Operation

60.3.1 Data Comparison Mode

Figure 60.2 shows an example of the steps involved in data comparison mode operation by the data operation circuit. The following is an example of operation when DCSEL is set to 0 (data mismatch is detected as a result of data comparison).

(1) Writing 00b to the DOCR.OMS[1:0] bits selects data comparison mode.
(2) The 16-bit reference data is set in DODSR.
(3) 16-bit data for comparison is written to DODIR.
(4) Writing of 16-bit data continues until all data for comparison have been written to DODIR.
(5) If a value written to DODIR does not match that in DODSR*1, the DOCR.DOPCF flag is set to 1. When the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also generated.

Note 1. When DOCR.DCSEL = 0

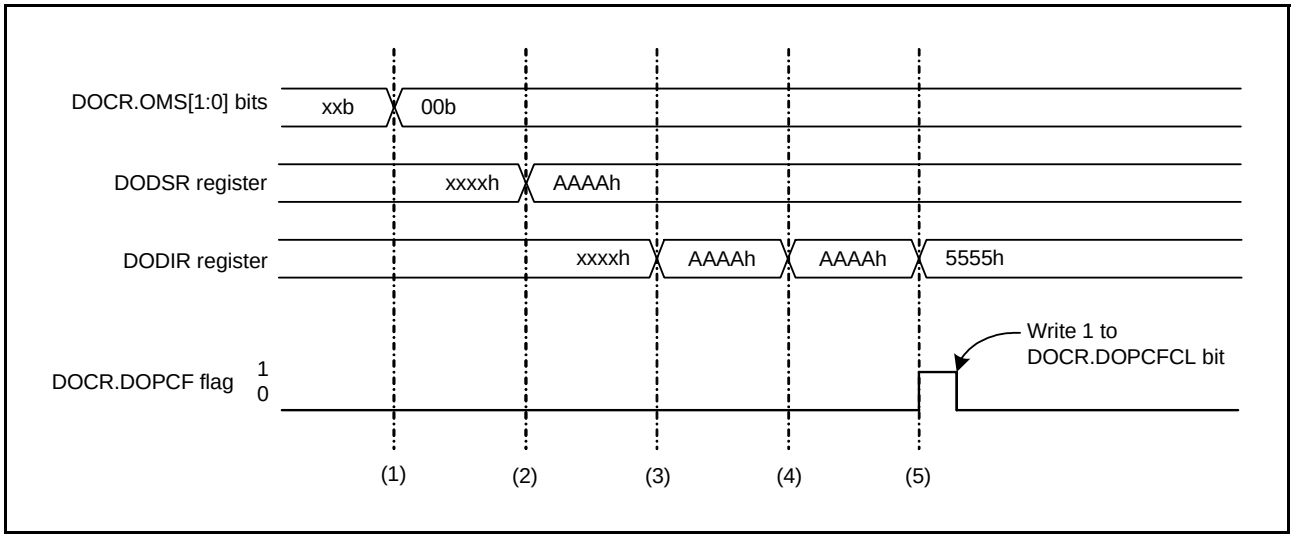

Figure 60.2 Example of Operation in Data Comparison Mode

60.3.2 Data Addition Mode

Figure 60.3 shows an example of the steps involved in data addition mode operation by the data operation circuit.

(1) Writing 01b to the DOCR.OMS[1:0] bits selects data addition mode.
(2) 16-bit data is set in the DODSR register as the initial value.
(3) 16-bit data to be added is written to DODIR. The result of the operation is stored in DODSR.
(4) Writing of 16-bit data continues until all data for addition have been written to DODIR.
(5) If the result of an operation is greater than FFFFh, the DOCR.DOPCF flag is set to 1. When the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also generated.

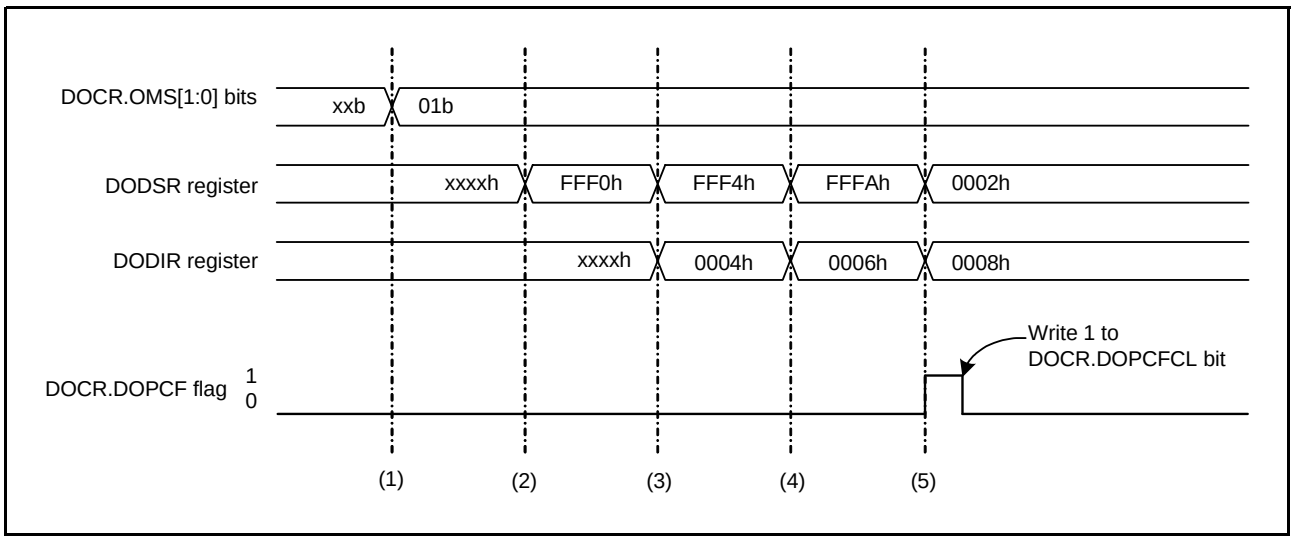

Figure 60.3 Example of Operation in Data Addition Mode

60.3.3 Data Subtraction Mode

Figure 60.4 shows an example of the steps involved in data subtraction mode operation by the data operation circuit.

(1) Writing 10b to the DOCR.OMS[1:0] bits selects data subtraction mode.
(2) 16-bit data is set in the DODSR register as the initial value.
(3) 16-bit data to be subtracted is written to DODIR. The result of the operation is stored in DODSR.
(4) Writing of 16-bit data continues until all data for subtraction have been written to DODIR.
(5) If the result of an operation is less than 0000h, the DOCR.DOPCF flag is set to 1. When the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also generated.

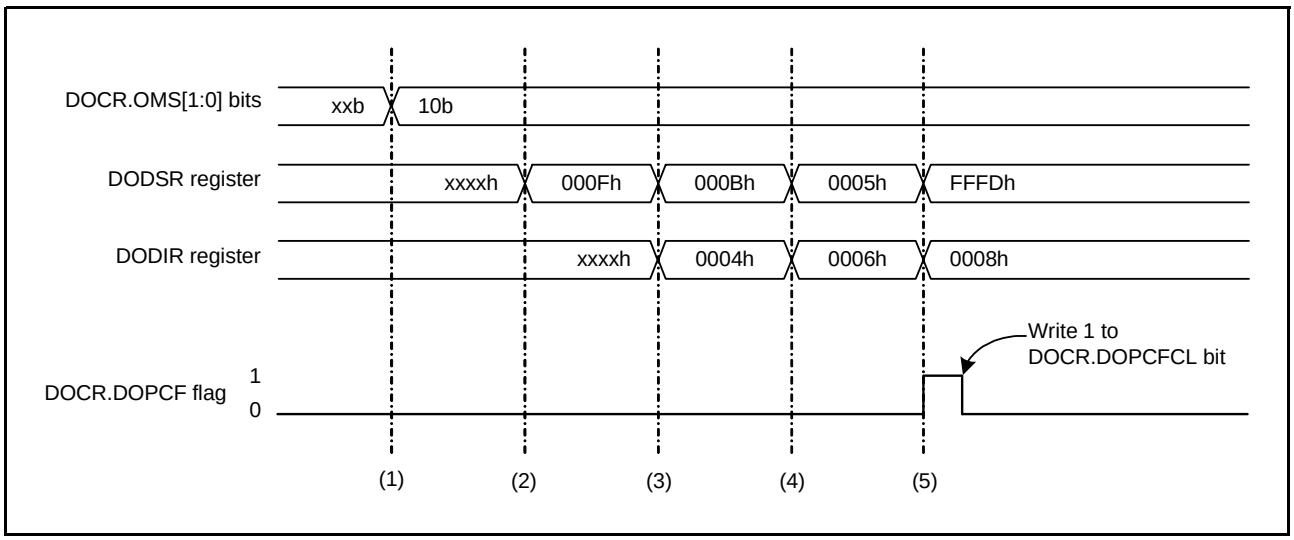

Figure 60.4 Example of Operation in Data Subtraction Mode

60.4 Interrupt Requests

The data operation circuit generates the data operation circuit interrupt as an interrupt request. When an interrupt source is generated, the data operation circuit flag corresponding to the interrupt is set to 1. Table 60.2 describes the interrupt request.

Table 60.2 Interrupt Request from Data Operation Circuit

Interrupt Request	Data Operation Circuit Flag	Interrupt Generation Timing
Data operation circuit interrupt	DOPCF	• The compared values either match or mismatch • The result of data addition is greater than FFFFh • The result of data subtraction is less than 0000h

60.5 Event Link Output

The DOC outputs event signals for the event link controller (ELC) under the following conditions, and these can be used to initiate operations by other modules selected in advance.

- The compared values either match or mismatch
- The result of data addition is greater than FFFFh
- The result of data subtraction is less than 0000h

60.5.1 Interrupt Handling and Event Linking

The DOC has a bit to enable or disable interrupts. An interrupt request signal is output for the CPU when an interrupt source is generated while the corresponding enable bit is enabled.
In contrast, an event link output signal is sent to other modules as an event signal via the ELC when an interrupt source is generated, regardless of the setting of the corresponding interrupt enable bit.

60.6 Usage Note

60.6.1 Module Stop Function Setting

Operation of the data operation circuit can be disabled or enabled using module stop control register B (MSTPCRB). The initial setting is for the data operation circuit to be stopped. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

61. RAM

This MCU has an on-chip high-speed static RAM (without ECC error correction) and on-chip high-speed static RAM (with ECC error correction).

61.1 Overview

Table 61.1 lists the specifications of the RAM.

Table 61.1 Specifications of RAM

Item	Without ECC Error Correction	With ECC Error Correction (ECCRAM)
RAM capacity	512 Kbytes (RAM: 512 Kbytes)	32 Kbytes
RAM address	RAM0: 0000 0000h to 0007 FFFFh	ECCRAM: 00FF 8000h to 00FF FFFFh
Memory bus	Memory bus 1	Memory bus 3 (ECCRAM)
Access	• Single-cycle access is possible for both reading and writing.*1 • Enabling or disabling of the RAM is selectable.*2	• Enabling or disabling of the ECCRAM is selectable.*3 • The ECC function is disabled: Access is done in two cycles for both reading and writing.*1 • The ECC function is enabled (when no error has occurred): Access is done in two cycles for both reading and writing.*1 • The ECC function is enabled (when an error has occurred): Access is done in three cycles for both reading and writing.*1
Data retention function	Not available in deep software standby mode	Not available in deep software standby mode
Low power consumption function	The module-stop state is selectable.	The module-stop state is selectable.
Error checking	• Detection of 1-bit errors • A non-maskable interrupt or interrupt is generated in response to an error.	• ECC Error Correction Correction of 1-bit errors and detection of 2-bit errors • A non-maskable interrupt or interrupt is generated in response to an error.

Note 1. When accessing across the 8-byte boundary, the number of cycles is doubled.
Note 2. Selectable by the RAME bit in SYSCR1. For details on SYSCR1, see section 3.2.4, System Control Register 1 (SYSCR1).
Note 3. Enabling and disabling of the ECCRAM can be selected through the setting of the SYSCR1.ECCRAME bit. For details on SYSCR1, see section 3.2.4, System Control Register 1 (SYSCR1).

61.2 Register Descriptions

61.2.1 ECCRAM Operating Mode Control Register (ECCRAMMODE)

Address(es): 0008 12C0h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	RAMMOD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	RAMMOD[1:0]	RAM Operating Mode Select	b1 b0 0 0: ECCs are disabled. 0 1: Setting prohibited. 1 0: ECCs are enabled without error checking. 1 1: ECCs are enabled with error checking.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ECCRAMMODE register is write-protected by the ECCRAM protection register (ECCRAMPRCR). Before writing to the ECCRAMMODE register, set the corresponding bit in the ECCRAMPRCR register to 1 to enable writing to it. Be sure to read this register immediately after writing to it, and then compare the read and written values. If this operation is not performed, access to the RAM is not guaranteed.
Also, do write to this register while accessing to the RAM.

61.2.2 ECCRAM 2-Bit Error Status Register (ECCRAM2STS)

Address(es): 0008 12C1h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	ECC2ERR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ECC2ERR	2-Bit ECC Error Status Flag	0: A 2-bit ECC error has not occurred. 1: A 2-bit ECC error has occurred.	R/(W)*1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 0 can be written to clear the flag.

When the ECCRAMMODE.RAMMOD[1:0] bits are set to 11b, the ECC2ERR flag is set to 1 if a 2-bit error is found. The RAM error interrupt is also generated at this time. Writing of 0 to the ECC2ERR flag leads to clearing of the RAM error interrupt having the 2-bit ECC error as its source.

61.2.3 ECCRAM 1-Bit Error Information Update Enable Register (ECCRAM1STSEN)

Address(es): 0008 12C2h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	ECC1STSEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ECC1STSEN	1-Bit ECC Error Information Update Enable	0: Disables updating of the 1-bit ECC error information. 1: Enables updating of the 1-bit ECC error information.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ECCRAM1STSEN register enables or disables updating of the ECCRAM 1-bit error status register (ECCRAM1STS) in response to a 1-bit error in the ECCRAM.
The ECCRAMPRCR register can protect this register against writing. Accordingly, change the effective bit in the ECCRAMPRCR register to the enabled setting before attempting to write to the ECCRAM1STSEN register.
Always be sure to read this register immediately after writing to it, and then compare the read and written values. Do not attempt access to the RAM during this process. Also, do not write to this register while accessing to the RAM.

61.2.4 ECCRAM 1-Bit Error Status Register (ECCRAM1STS)

Address(es): 0008 12C3h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	ECC1ERR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ECC1ERR	1-Bit ECC Error Status	0: A 1-bit ECC error has not occurred. 1: A 1-bit ECC error has occurred.	R/(W)*1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 0 can be written to clear the bit.

When ECCs are enabled, error checking is selected, and updating of the 1-bit error information is enabled, the ECC1ERR bit is set to 1 if a 1-bit error is found. The RAM error interrupt is also generated at this time. Writing of 0 to the ECC1ERR bit leads to clearing of the RAM error interrupt having the 1-bit ECC error as its source.

61.2.5 ECCRAM Protection Register (ECCRAMPRCR)

Address(es): 0008 12C4h

	b7	b6	b5	b4	b3	b2	b1	b0
	KW[6:0]							PRCR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PRCR	ECCRAMMODE and ECCRAM1STSEN Registers Write Control	0: Disables writing to the ECCRAMMODE and ECCRAM1STSEN registers. 1: Enables writing to the ECCRAMMODE and ECCRAM1STSEN registers.	R/W
b7 to b1	KW[6:0]	Write Key Word	Enables or disables the rewriting of the ECCRAMPRCR register. When rewriting the ECCRAMPRCR register, write 1111000b to the KW[6:0] bits.	R/W

Writing 1 to the PRCR bit is possible when KW[6:0] = 1111000b.
Otherwise writing to PRCR clears the bit to 0. KW[6:0] is read as 0000000b.
The targets for write protection by the ECCRAMPRCR register are the ECCRAMMODE and ECCRAM1STSEN registers. Once the PRCR bit is set to 1, writing to ECCRAMMODE and ECCRAM1STSEN registers is enabled until the PRCR bit is cleared to 0. Clear the PRCR bit to 0 after writing to ECCRAMMODE and ECCRAM1STSEN registers.

61.2.6 ECCRAM 2-Bit Error Address Capture Register (ECCRAM2ECAD)

Address(es): 0008 12C8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	ECC2EAD												—	—	—
Value after reset:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	—	Reserved	These bits are read as 0.	R
b14 to b3	ECC2EAD	2-Bit ECC Error Address	The address where a 2-bit ECC error was found is read.	R
b23 to b15	—	Reserved	These bits are read as 1.	R
b31 to b24	—	Reserved	These bits are read as 0.	R

When the ECCRAMMODE.RAMMOD[1:0] bits are set to 11b, this register will hold the address where a 2-bit ECC error was found. Specifically, the address of the 8-byte boundary below the location where the error was found is written to the ECC2EAD bits of this register at the same time as the ECCRAM2STS.ECC2ERR flag is set. The address is not updated whenever the ECC2ERR flag is set to 1 to indicate an error. Its value does not change if ECCs are disabled. The value is initialized by a reset, and this is the only condition that leads to clearing of the register.

61.2.7 ECCRAM 1-Bit Error Address Capture Register (ECCRAM1ECAD)

Address(es): 0008 12CCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	ECC1EAD												—	—	—
Value after reset:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	—	Reserved	These bits are read as 0.	R
b14 to b3	ECC1EAD	1-Bit ECC Error Address	The address where a 1-bit ECC error was found is read.	R
b23 to b15	—	Reserved	These bits are read as 1.	R
b31 to b24	—	Reserved	These bits are read as 0.	R

When ECCs are enabled, error checking is selected, and updating of the 1-bit error information is enabled, this register will hold the address where a 1-bit error was found. Specifically, the address of the 8-byte boundary below the location where the error was found is written to the effective bits of this register at the same time as the ECCRAM1STS.ECC1ERR bit is set.

The address is not updated whenever the ECC1ERR bit is set to 1 to indicate an error. Its value does not change if ECCs are disabled. The value is initialized by a reset, and this is the only condition that leads to clearing of the register.

61.2.8 ECCRAM Protection Register 2 (ECCRAMPRCR2)

Address(es): 0008 12D0h

	b7	b6	b5	b4	b3	b2	b1	b0
	KW2[6:0]							PRCR2
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PRCR2	ECCRAMETST Register Write Control	0: Writing to ECCRAMETST is disabled. 1: Writing to ECCRAMETST is enabled.	R/W
b7 to b1	KW2[6:0]	Write Keyword	Enables or disables the rewriting of the ECCRAMPRCR2 register. When rewriting the ECCRAMPRCR2 register, write 1111000b to the KW2[6:0] bits.	R/W

When KW2[6:0] = 1111000b, writing 1 to the PRCR2 bit is enabled.

Otherwise writing to PRCR2 clears the bit to 0. The KW2[6:0] bits are read as 0000000b.

The target for write protection by the PRCR2 bit is the ECCRAM test control register (ECCRAMETST). Once the PRCR2 bit is set to 1, writing to the ECCRAMETST register is enabled until the PRCR2 bit is cleared to 0. After writing to the ECCRAMETST register, clear the PRCR2 bit to 0.

61.2.9 ECCRAM Test Control Register (ECCRAMETST)

Address(es): 0008 12D4h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	TSTBYP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TSTBYP	ECC Bypass Select	0: ECC bypass is disabled. 1: ECC bypass is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The protection register 2 (ECCRAMPRCR2) protects this register against writing. Accordingly, change the effective bit in the ECCRAMPRCR2 register to the enabled setting before attempting to write to the ECCRAMETST register. Do not write to ECCRAMETST while access to RAM is in progress.
Eight of the 72 bits of data in the RAM are used for the ECC. When the TSTBYP bit is set to 1 to select bypassing of the ECC circuit, the 8 bits for the ECC become directly accessible. Setting the TSTBYP bit for bypassing of the ECC is only possible when the ECC is disabled by setting the ECCRAMMODE.RAMMOD[1:0] bit to 00b.

61.2.10 RAM Operating Mode Control Register (RAMMODE)

Address(es): 0008 1200h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	RAMMODE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	RAMMODE[1:0]	RAM Operating Mode Select	b1 b0 0 0: Parity checking is disabled. 0 1: Parity checking is enabled. Settings other than above are prohibited.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The RAMMODE register is write-protected by the RAM protection register (RAMPRCR). Before writing to the RAMMODE register, set the RAMPRCR.RAMPRCR bit to 1 to enable writing to it. Set the RAMMODE register before starting access to the RAM. If this register is modified after accessing to the RAM, RAM operation is not guaranteed.

61.2.11 RAM Error Status Register (RAMSTS)

Address(es): 0008 1201h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	RAMERR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RAMERR	RAM Error Status Flag	0: A parity check error has not occurred. 1: A parity check error has occurred.	R/(W)*1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 0 can be written to clear the flag.

When parity checking is enabled, the RAMERR flag is set to 1 if a parity check error is detected. The RAM error interrupt request is also generated at this time.
When parity checking is disabled, the RAMERR flag is not set to 1 because no parity check error is detected.
Writing 0 to the RAMERR flag clears the RAM error interrupt request corresponding to the parity check error.

61.2.12 RAM Error Address Capture Register (RAMECAD)

Address(es): 0008 1208h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	READ		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

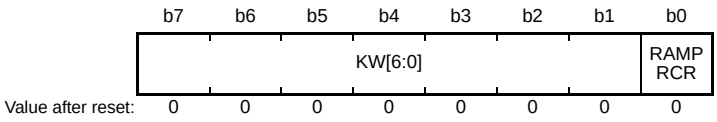
	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	READ													—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	—	Reserved	These bits are read as 0.	R
b18 to b3	READ	Error Address	The address where an error is found is read.	R
b31 to b19	—	Reserved	These bits are read as 0.	R

When parity checking is enabled, this register will hold the address where a parity check error was found.
The address of the 8-byte boundary below the location where the error was found is stored in this register at the same time the RAMSTS.RAMERR flag is set to 1.
The error address is not updated when the RAMERR flag is 1 (error has occurred). Its value does not change when parity checking is disabled because no parity check error is detected.
The RAMECAD register is initialized only by a reset.

61.2.13 RAM Protection Register (RAMPRCR)

Address(es): 0008 1204h



Bit	Symbol	Bit Name	Description	R/W
b0	RAMPRCR	RAMMODE Register Write Control	0: Disables writing to the RAMMODE register. 1: Enables writing to the RAMMODE register.	R/W
b7 to b1	KW[6:0]	Write Key Word	Enables or disables the rewriting of the RAMPRCR register. When rewriting the RAMPRCR register, write 1111000b to the KW[6:0] bits.	R/W

Writing 1 to the RAMPRCR bit is possible when KW[6:0] = 1111000b. Otherwise writing to RAMPRCR clears the bit to 0. The value of KW[6:0] is read as 0000000b.

The targets for write protection by the RAMPRCR register is the RAM operating mode control register (RAMMODE). Once the RAMPRCR bit is set to 1, writing to RAMMODE register is enabled until the RAMPRCR bit is cleared to 0. Clear the RAMPRCR bit to 0 after writing to RAMMODE register.

61.3 Operation

61.3.1 Low Power Consumption Function

Power consumption can be reduced by setting module stop control register C (MSTPCRC) to stop supply of the clock signal to RAM.
When the MSTPC0 bit in MSTPCRC is set to 1, supply of the clock signal to RAM0 is stopped. When the MSTPC6 bit in MSTPCRC is set to 1, supply of the clock signal to the ECCRAM is stopped.
The RAM is thus placed in the module-stop state by stopping supply of the clock signals. The RAM operates after a reset.
RAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to RAM is in progress.
Access to the RAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.
For details on the MSTPCRC register, see section 11, Low Power Consumption.

61.3.2 Correction of ECC Errors

Enabling and disabling of ECC error correction can be selected through the register setting. In the initial state, ECC error correction is disabled. The ECC used in this device is SEC-DED (Single-Error Correction and Double-Error Detection Code).
When ECCs are enabled, an 8-bit ECC code is appended to 64-bit data for writing. For reading, 72-bit (data: 64 bits, ECC code: 8 bits) data is read out from the RAM.
When ECCs are enabled and error checking is selected, error correction is done if a 1-bit error occurs and the ECCRAM1STS.ECC1ERR bit is set to 1 if the ECCRAM1STSEN.ECC1STSEN bit is 1. When an error is detected, the address of the 8-byte boundary including the location where the error was found is set to the ECCRAM1ECAD register.
If a 2-bit error occurs, error detection is done and the ECCRAM2STS.ECC2ERR flag is set to 1, though error correction is not performed. When an error is detected, the address of the 8-byte boundary including the location where the error was found is set to the ECCRAM2ECAD register. In addition, there is no way to confirm the location where the error was found within the 8-byte boundary. Therefore, when the correct data is written after the occurrence of an error, update all the data in the 8-byte boundary.
When ECCs are enabled but error checking is not selected, error correction is done if a 1-bit error occurs when reading; however, the corrected data is not written back to the RAM, and ECC codes are neither generated nor written back. In writing, write data is replaced and ECC codes are generated then written back.
Since the RAM data is undefined after power on and release from deep software standby mode, accessing the RAM when ECCs are enabled and error checking is selected causes an ECC error to occur. Therefore, when using ECC error correction, initial writing to the area to be used in the RAM should be done beforehand when ECCs are enabled but error checking is not selected. Since the ECC error correction is done in 8-byte units, the initial write must be done for the 8 × N byte area including the area to be used.

61.3.3 Parity Checking

Enabling and disabling of parity checking can be selected through the RAMMODE register setting. In the initial state, parity checking is disabled. Even parity checking is used in this device.
1-bit parity check code is added to each 1-byte data for writing, and the parity is checked for reading.
If a 1-bit error is detected in the 1 byte when the parity is checked for reading, a RAM error interrupt can be generated. If a 2-bit error or more is detected in the 1 byte, errors cannot be correctly detected.
After power-on, parity check code is undefined until data is written. To use parity checking, write the initial value to all areas while parity checking is enabled before accessing to the RAM immediately after a reset.
Operation cannot be guaranteed if access is made to an area where the initial value is not written.

61.3.4 RAM Error Interrupt Function

A RAM error interrupt is generated if any of the following bits changes to 1:
When ECCs are enabled and error checking is selected
- ECCRAM2STS.ECC2ERR bit indicating an ECC2 bit error
- ECCRAM1STS.ECC1ERR bit indicating an ECC1 bit error

When parity checking is enabled
- RAMSTS.RAMERR bit indicating a parity check error

Writing 0 to a bit that has been set clears the RAM error interrupt due to the corresponding source.
If the error from the other source is still occurring at this time, the RAM error interrupt will remain generated.
When the ECC 1-bit error interrupt is to be masked, set the ECCRAM1STSEN.ECC1STSEN bit to 0 to disable updating of the ECC1ERR bit. A RAM error interrupt will not be generated while ECCs are disabled and when ECCs are enabled but error checking is not selected.

61.3.5 ECC Decoder Testing

In this MCU, the user can test the ECC code control circuit for the ECCRAM.
Figure 61.1 shows the flow for testing of the ECC code control circuit.

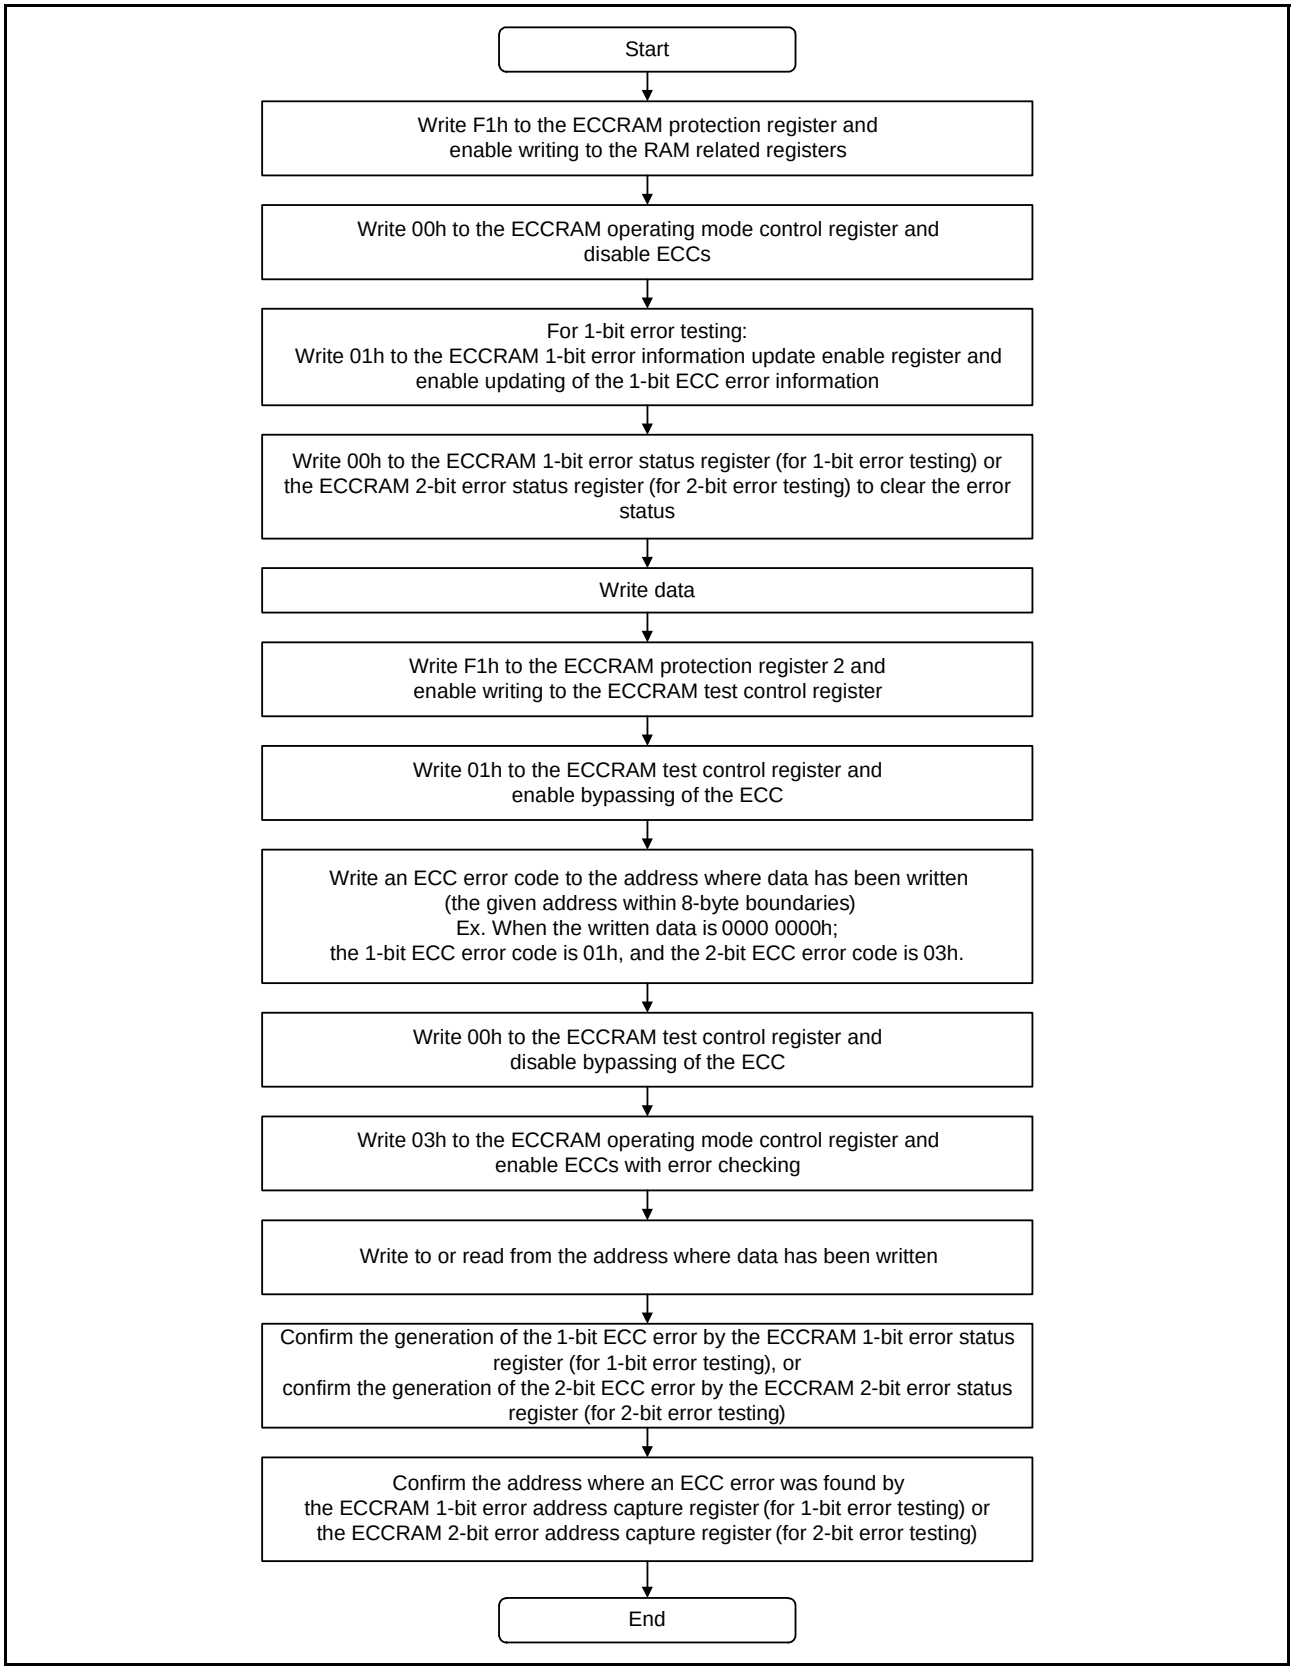


Figure 61.1 Flow for Testing of the ECC Code Control Circuit

61.3.6 Interrupt Source

The RAM has two interrupt sources; RAM error interrupt generated from the RAM when a parity check error occurred, or RAM error interrupt generated from the ECCRAM when an ECC error occurred, and can be used as a non-maskable interrupt or interrupt. For details, see section 15, Interrupt Controller (ICUA).

Table 61.2 RAM Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
RAMERR	ECC error	Not possible	Not possible

61.4 Usage Notes

61.4.1 Low Power Consumption Function

Power consumption can be reduced by setting module stop control register C (MSTPCRC) to stop supply of the clock signal to the RAM and ECCRAM.
Setting the MSTPCRC.MSTPC0 bit to 1 stops supply of the clock signal to the RAM. Setting the MSTPCRC.MSTPC6 bit to 1 stops supply of the clock signal to the ECCRAM.
Stopping supply of the clock signal places the RAM and ECCRAM individually in the module stop state.
The RAM and ECCRAM operate after a reset.
The RAM and ECCRAM are not accessible in the module stop state.
Do not allow transitions to the module stop state while accessing to the RAM or ECCRAM.
For details on the MSTPCRC register, refer to section 11, Low Power Consumption.

61.4.2 Notes on Using Error Checking of RAM0 and ECCRAM

When using RAM0 parity and ECCRAM ECCs for error checking to operate a program in the relevant RAM, initialize RAM0 and ECCRAM so that CPU can correctly prefetch data. If the CPU prefetches from a RAM area that is not initialized, a RAM error may occur.
The RAM0 and ECCRAM should be initialized at the 8-byte boundary. When the end address allocated in the RAM is below the 8-byte boundary, allocate a NOP instruction up to the boundary.

62. Standby RAM

This MCU provides an on-chip static RAM that can retain data in deep software standby (standby RAM).

62.1 Overview

Table 62.1 lists the specifications of the standby RAM.

Table 62.1 Specifications of Standby RAM

Item	Description
RAM capacity	8 Kbytes
RAM address	000A 4000h to 000A 5FFFh
Access	• Both read and write operations take 2 or 3 cycles of PCLKB when ICLK ≥ PCLKB; two cycles of ICLK are needed when ICLK < PCLKB. • Enabling or disabling of RAM access is selectable.*1 • Endian conforms to the endian setting of the chip. • Non-aligned access is prohibited. If non-aligned access is attempted, correct operation is not guaranteed.
Data retention function	Data can be retained in deep software standby mode
Low-power consumption function	The module-stop state is selectable.

Note 1. Selectable by the SBYRAME bit in SYSCR1. For details on SYSCR1, see section 3.2.4, System Control Register 1 (SYSCR1).

62.2 Operation

62.2.1 Data Retention

Whether or not the supply of internal power to the standby RAM continues in deep software standby mode is selectable by the DPSBYCR.DEEPCUT[1:0] bits.
If continuation of the supply of internal power is selected, data in the standby RAM are retained in deep software standby mode.
See section 11, Low Power Consumption, for details on the DPSBYCR.DEEPCUT[1:0] bits.

62.2.2 Low Power Consumption Function

Power consumption can be reduced by setting module stop control register C (MSTPCRC) to stop supply of the clock signal to the standby RAM.
If the MSTPC7 bit in MSTPCRC is set to 1, supply of the clock signal to the standby RAM is stopped.
The standby RAM is thus placed in the module-stop state by stopping supply of the clock signals. The standby RAM operates after a reset.
The standby RAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to the standby RAM is in progress.
For details on the MSTPCRC register, see section 11, Low Power Consumption.

63. Flash Memory

This MCU has a maximum 4-Mbyte code flash memory and a 64-Kbyte data flash memory.
The code flash memory and data flash memory are respectively used to hold instructions, operands, etc. and to hold data.

63.1 Overview

Table 63.1 lists the specifications of the code flash memory/data flash memory, and Figure 63.1 is a block diagram of the flash memory related modules.
The I/O pins used in boot mode, see Table 63.9.
The FCU (flash control unit) controls programming and erasure of the flash memory. The FCU RAM is a RAM to store the firmware (FCU firmware) to be executed by the FCU. The FACI (flash application command interface) controls the FCU according to the specified FACI commands.
Regarding the configuration of the code flash memory, see Figure 63.2, and for the configuration of the data flash memory, see Figure 63.3.

Table 63.1 Specifications of Code Flash Memory and Data Flash Memory

Item	Code Flash Memory	Data Flash Memory
Memory capacity	• User area: 4 Mbytes max. • User boot area: 32 Kbytes	Data area: 64 Kbytes
Read cycle	A high-speed read operation takes one cycle of ICLK	A read operation takes eight cycles of FCLK in word or byte access
Value after erasure	FFh	Undefined
Programming/erasing method	• Programming and erasing the code flash memory/data flash memory is handled by the FACI commands specified in the FACI command issuing area (007E 0000h). • Programming/erasure through transfer by a dedicated flash-memory programmer via a serial interface (serial programming) • Programming/erasure of flash memory by a user program (self-programming)	
Security function	Protects against illicit tampering with or reading out of data in flash memory	
Protection	Protects against erroneous rewriting of the flash memory	
Trusted memory (TM) function	Protects against illicit reading of blocks 8 and 9 in the code flash memory	
Background operations (BGOs)	The code flash memory can be read while the code flash memory is being programmed or erased.*1 The code flash memory can be read while the data flash memory is being programmed or erased.	
Units of programming and erasure	• Units of programming for the user area or user boot area: 256 bytes • Units of erasure for the user area: Block units	• Unit of programming for the data area: 4 bytes • Unit of erasure for the data area: 64 bytes
Other functions	Interrupts can be accepted during self-programming.	
	In the initial settings of this MCU, an expansion area of the option-setting memory can be set.	
On-board programming (four types)	Programming/erasure in boot mode (for the SCI interface) • The asynchronous serial interface (SCI1) is used. • The transfer rate is adjusted automatically. • The user boot area can also be programmed or erased. Programming/erasure in boot mode (for the USB interface) • USBb is used. • Dedicated hardware is not required, so direct connection to a PC is possible. Programming/erasure in user boot mode • Able to create original boot programs of the user's making. Programming/erasure by a routine for code flash memory/data flash memory programming within the user program • This allows code flash memory/data flash memory programming/erasure without resetting the system.	
Programming and Erasure by Dedicated Parallel Programmer	A flash programmer can be used to program or erase the user area and user boot area.	A flash programmer cannot be used to program or erase the data area.
Unique ID	A 12-byte ID code provided for each MCU	

Note 1. Limitations apply to the combinations of the address ranges for programming/erasure process and reading process: see Table 63.16.

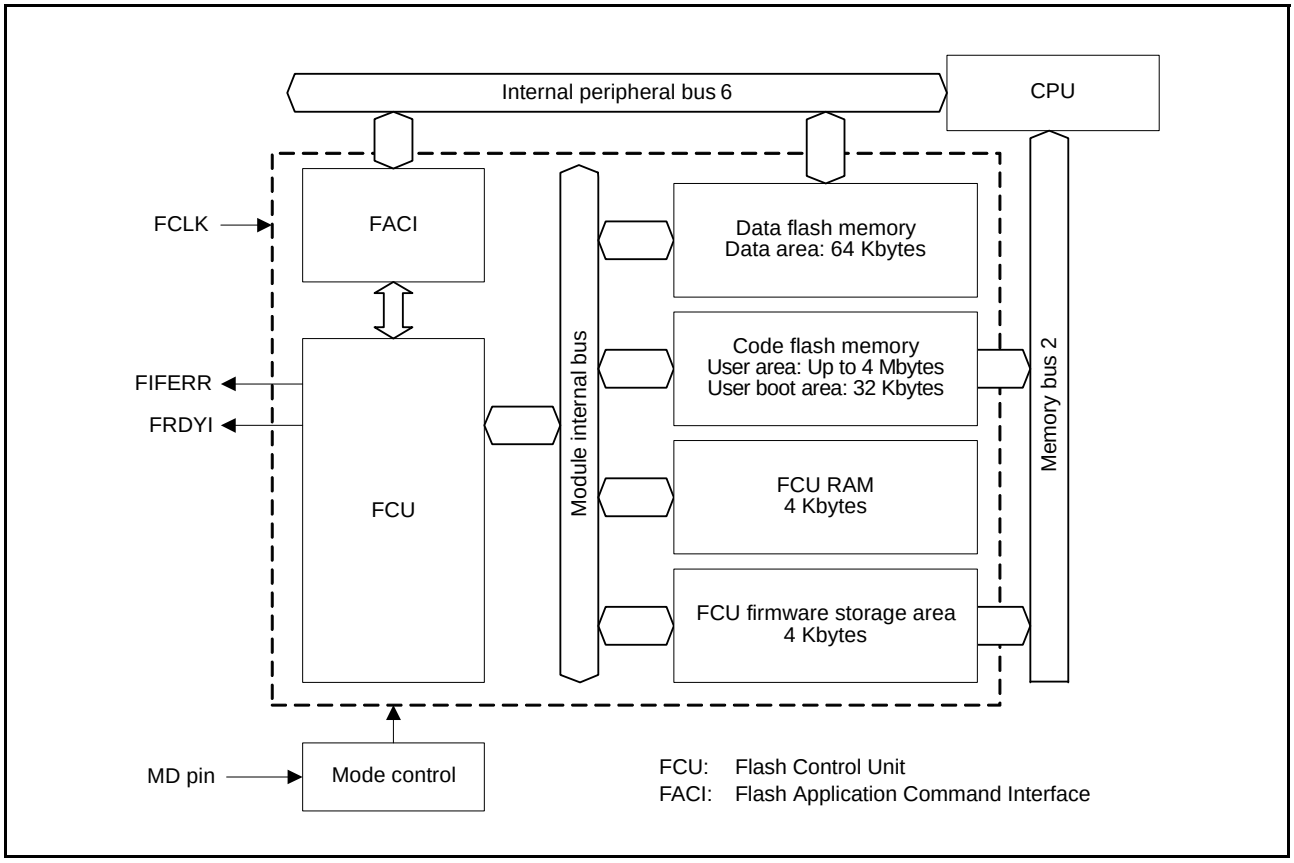

Figure 63.1 Block Diagram of Flash Memory Related Modules

63.2 Structure of Memory

Figure 63.2 illustrates the mapping of the code flash memory. The user area of the code flash memory in this MCU is divided into 8- and 32-Kbyte blocks, which serve as the units of erasure. When the TM function is enabled, blocks 8 and 9 are the TM target areas. A 32-Kbyte user boot area is also incorporated as a single block. The user area and user boot area are available as areas for storing the user program.
Furthermore, a 32-Kbyte user boot area, which is protected against programming by self-programming, is incorporated as a single block. This area is thus available as an area for storing boot programs, etc., for which rewriting while the user program is running has to be prohibited.

	Address	Number of Blocks
4.0-Mbyte product	FFC0 0000h to FFFF FFFFh	0 to 133
3.0-Mbyte product	FFD0 0000h to FFFF FFFFh	0 to 101
2.5-Mbyte product	FFD8 0000h to FFFF FFFFh	0 to 85
2.0-Mbyte product	FFE0 0000h to FFFF FFFFh	0 to 69

Note 1. Both blocks 8 and 9 are the target areas for handling as TM. Setting only block 8 or only block 9 is not allowed.

Figure 63.2 Mapping of the Code Flash Memory

The data area of the data flash memory in this MCU is divided into 64-byte blocks, with each being a unit for erasure. Figure 63.3 shows the mapping of the data flash memory.

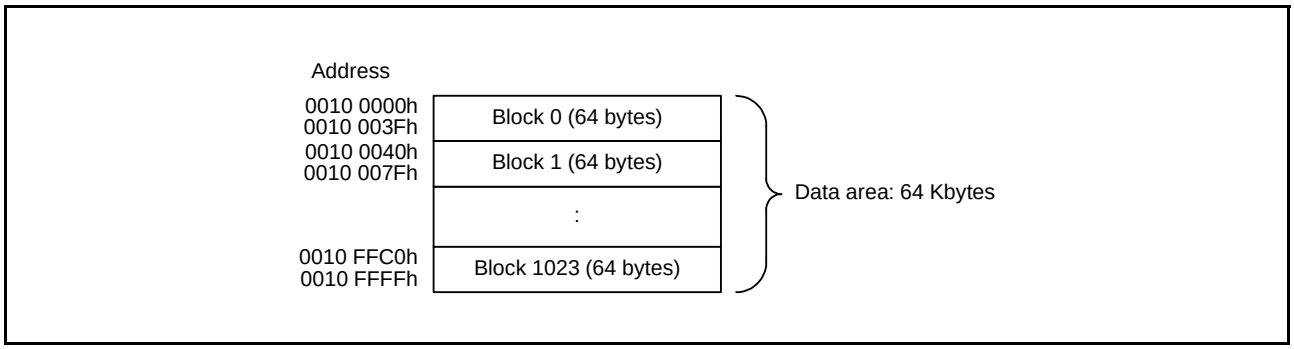

Figure 63.3 Mapping of the Data Flash Memory

63.3 Register Descriptions

There are registers for use in programming and erasure of the code flash, data flash, and option-setting memory. As for the registers for setting when the FACI is to be used, refer to Flash Memory User's Manual: Hardware Interface.

63.3.1 Flash P/E Protect Register (FWEPROR)

Address(es): 0008 C296h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	FLWE[1:0]	
Value after reset:	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	FLWE[1:0]	Flash Programming and Erasure Enable	b1 b0 0 0: Disables programming and erasure, programming and erasure of lock bits, and blank checking. 0 1: Enables programming and erasure, programming and erasure of lock bits, and blank checking. 1 0: Disables programming and erasure, programming and erasure of lock bits, and blank checking. 1 1: Disables programming and erasure, programming and erasure of lock bits, and blank checking.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Programming and erasure of the code flash memory, data flash memory, or option-setting memory, programming and erasure of lock bits, and blank checking are enabled or disabled by hardware.
FWEPROR is initialized by a reset due to the signal on the RES# pin, a power-on reset, a voltage-monitoring 0 reset, an independent watchdog timer reset, a watchdog timer reset, a voltage-monitoring 1 reset, a voltage-monitoring 2 reset, and a software reset, and by transitions to software standby and deep software standby.

63.3.2 Unique ID Register n (UIDRn) (n = 0 to 2)

Address(es): UIDR0 007F B174h, UIDR1 007F B1E4h, UIDR2 007F B1E8h

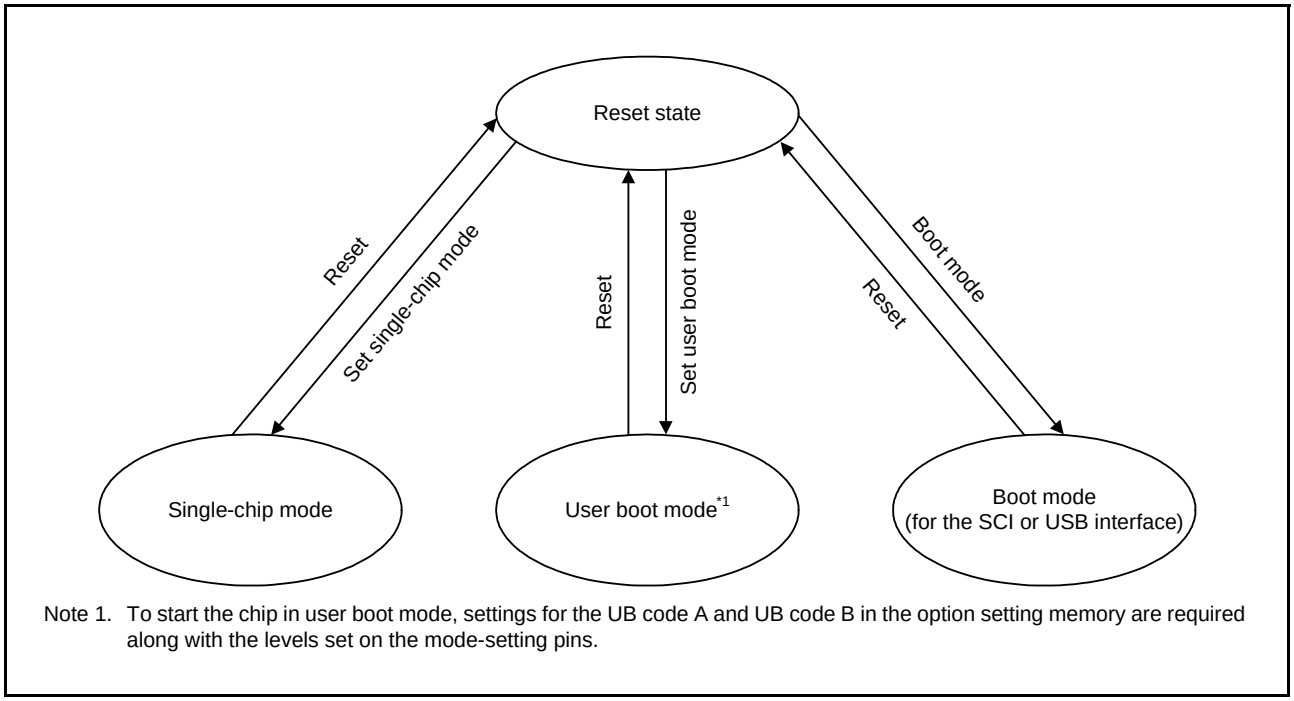
b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	Unique value for each chip														

b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	Unique value for each chip														

The UIDRn is a read-only register that stores a 12-byte ID code (unique ID) for identifying the individual MCU. Use longword access to read the UIDRn register.

63.4 Operating Modes Associated with Flash Memory

Figure 63.4 is a diagram of the mode transitions associated with the flash memory. For the procedures for setting the modes, refer to section 3, Operating Modes.



Note 1. To start the chip in user boot mode, settings for the UB code A and UB code B in the option setting memory are required along with the levels set on the mode-setting pins.

Figure 63.4 Mode Transitions Associated with Flash Memory

The flash memory area where programming and erasure are permitted and the boot program after a reset are different according to each mode. The differences between modes are listed in Table 63.2.

Table 63.2 Differences between Modes

Item	Single-chip Mode	User Boot Mode	Boot Mode (for the SCI or USB Interface)
Programmable and erasable area	Code flash memory Data flash memory	Code flash memory Data flash memory	Code flash memory Data flash memory User boot area
Boot program at a reset	User area program	User boot area program	Boot program

63.4.1 Result of Reference by the ID Code Protection

Table 63.3 lists the operating mode at the time of booting up, ID code protection enable/disable, and access limitation in the code flash memory/data flash memory/user boot area by the reference result of the ID code.
For ID code security function settings, see Table 7.2, Settings of the Option-Setting Memory and ID Code Authentication, Reading, Programming, and Erasure, in section 7, Option-Setting Memory.

Table 63.3 Operating Mode at the Time of Booting up, ID Code Protection, and Access Limitation

Operating Mode at the Time of Booting Up	Matching or Non-Matching ID Codes	Access Limitation		
		Code Flash Memory	Data Flash Memory	User Boot Area
Boot mode (for the SCI or USB interface)	Matching	Access not limited	Access not limited	Access not limited
	Non-matching three consecutive times	Access disabled	Access disabled	Access disabled
User boot mode	The ID code protection is not available.			

63.5 Overview of Functions

By using a dedicated flash-memory programmer to program the flash memory of this MCU via a serial interface (serial programming), the device can be rewritten regardless of whether this is before or after it is mounted on the target system. Furthermore, security functions to prohibit overwriting or reading of the user program written to the flash memory are incorporated, and this can prevent falsification and illicit reading of the programs by third parties. Blocks 8 and 9 of the code flash memory can also be protected against reading by using the TM function.
Programming by the user program (self-programming) is available to suit applications where the application on the target system may require updating after manufacturing or shipment. Protection features for the safe overwriting of the flash memory area are also incorporated. Furthermore, interrupt processing during self-programming is supported, so programming can proceed at the same time as processing for external communications, etc., and this is the case in various situations. Table 63.4 lists the overview of the methods of programming and the corresponding operating modes.

Table 63.4 Methods of Programming

Method of Programming	Functional Overview	Operating Mode
Serial programming	A dedicated flash-memory programmer is capable of on-board programming of the flash memory after the device is mounted on the target system. The TM function can be in enabled or disabled at this time.	Boot mode
	A dedicated flash-memory programmer and dedicated programming adapter board allow off-board programming of the flash memory, i.e. programming of the device before it is mounted on the target system.	
Self-programming	The execution of the user program that is written to code flash memory in advance by serial programming executing is also capable of programming the flash memory. The TM function can be in the enabled state at this time. The background operation capability makes it possible to fetch instructions or otherwise read data from code flash memory while the data flash memory is being programmed. Therefore, the data flash memory can be rewritten by executing a program for writing contained by the code flash memory. Furthermore, background operation can also be used for reading and writing to code flash memory alone, but only when the address range of code flash memory that is the target for programming and the address range of code flash memory that is the target for reading satisfy particular conditions (see Table 63.16). When this is the case, at the time of self-programming, a program for programming that is in the code flash memory can be executed to rewrite the code flash memory. In cases where background operation is not possible, instructions in the code flash memory cannot be fetched and data cannot be accessed while code flash memory is being re-written by self-programming. In such cases, a program for programming must be transferred to the internal RAM or external memory in advance and executed.	Normal operating mode and user boot mode

This MCU supports FACI commands for self-programming. For details of the FACI commands, refer to Flash Memory User's Manual: Hardware Interface.

Table 63.5 lists the functions of the flash memory. Serial programmer commands realize each function of serial programming, while reading of the flash memory by an FACI command or the user program realizes each function of self-programming.
For security function settings, see section 7.2.1, Serial Programmer Command Control Register (SPCC), in section 7, Option-Setting Memory.

Table 63.5 List of Basic Functions

Function	Functional Overview	Support Status	
		Serial Programming	Self-programming
Blank check	This is used to check a specified block to ensure that writing to it has not already proceeded. Results of reading from data flash memory to which nothing has been written after erasure are not guaranteed, so use blank checking to confirm that programming to memory has not proceeded after erasure.	Supported	Supported
Block erasure	Erases the memory contents in the specified block.	Supported	Supported
Programming	Write to the specified address.	Supported	Supported
Verify/Checksum	Compares the data read from flash memory and the data transferred from a flash memory programmer.	Supported	Not supported (read by user program is possible)
Read	Read data programmed to flash memory.	Supported	Supported
ID configuration	An ID setting is made for use in controlling the connection of a serial programmer for serial programming.	Supported	Supported
Security configuration	Configures the security function for serial programming.	Supported	Supported with conditions (Only switching the configuration from enabled to disabled is possible)
Protection configuration	Configures lock bits for each block in code flash memory.	Supported	Supported
Option bytes configuration	Configures the option bytes, and modifies the initial settings of this MCU.	Supported	Supported
Configuration clearing	Initializes the ID configuration, security configuration, protection configuration, and option-setting memory. The TM function can be disabled.	Supported	Not supported
Enabling the TM function	The TM function can be enabled.	Supported	Supported

For details on serial programming, refer to PG-FP5 Flash Memory Programmer User's Manual and Renesas Flash Programmer Flash Programming Software User's Manual.
For details on self-programming, refer to Flash Memory User's Manual: Hardware Interface.

The flash memory supports various security functions.
Authentication of the ID code is a security function for use with serial programming.
In serial programming, authentication of the ID code prohibiting connection of a serial programmer, and prohibition of commands (for block erasure, programming, and reading) are available for use as security functions.
Table 63.6 lists the security functions supported by the flash memory, and Table 63.7 lists the operations with security settings.

Table 63.6 Lists of Security Functions

Function	Description
ID authentication	The result of ID authentication can be used to control the connection of a serial programmer for serial programming.
Prohibition of the connection of a serial programmer	The connection of a serial programmer for serial programming is prohibited. Since execution of the configuration clearing command is also prohibited when the connection of a serial programmer is prohibited, changing a security setting from “disabled” to “enabled” is not possible.
Prohibition of block erase commands	Block erase commands at the time of serial programming are prohibited. Since execution of the configuration clearing command is also prohibited when block erase commands are prohibited, changing a security setting from “disabled” to “enabled” is not possible.
Prohibition of programming commands	Programming commands are prohibited at the time of serial programming, and a condition applies to the execution of block erasure commands. Only through execution of the configuration clearing command can the prohibition be lifted.
Prohibition of read commands	Read commands at the time of serial programming are prohibited. Only through execution of the configuration clearing command can the prohibition be lifted.

Table 63.7 Operations with Security Settings

Function	Programming/Erasing/Reading with Respective Security Settings		Notes for Security Setting	
	Serial Programming	**Self-Programming**	**Serial Programming**	**Self-Programming**
ID authentication	(When the ID codes do not match) Block erase commands: Not supported Programming commands: Not supported Read commands: Not supported (When the ID codes match) Block erase commands: Supported Programming commands: Supported Read commands: Supported	(ID authentication is not performed) Block erase commands: Supported Programming commands: Supported Read commands: Supported	The configuration clearing command can initialize the setting for prohibition. The setting for prohibition of block erase commands is not available. The setting for prohibition of programming commands is not available. The setting for prohibition of read commands is not available.	(ID authentication is not performed)
Prohibition of the connection of a serial programmer	Block erase commands: Not supported Programming commands: Not supported Read commands: Not supported	Block erase commands: Supported Programming commands: Supported Read commands: Supported	Since execution of the configuration clearing command is prohibited, initialization of the setting for prohibition is not possible.	Since the configuration clearing command is not supported, initialization of the setting for prohibition is not possible.
Prohibition of block erase commands	Block erase commands: Not supported Programming commands: Supported Read commands: Supported	Block erase commands: Supported Programming commands: Supported Read commands: Supported	Since execution of the configuration clearing command is prohibited, initialization of the setting for prohibition is not possible. The setting to prohibit connection of a serial programmer is not available. The setting for ID authentication to be effective for serial programming is not available.	Since the configuration clearing command is not supported, initialization of the setting for prohibition is not possible.
Prohibition of programming commands	Block erase commands: Supported with conditions*1 Programming commands: Not supported Read commands: Supported	Block erase commands: Supported Programming commands: Supported Read commands: Supported	The configuration clearing command can initialize the setting for prohibition. The setting to prohibit connection of a serial programmer is not available. The setting for ID authentication to be effective for serial programming is not available.	Since the configuration clearing command is not supported, initialization of the setting for prohibition is not possible.
Prohibition of read commands	Block erase commands: Supported Programming commands: Supported Read commands: Not supported	Block erase commands: Supported Programming commands: Supported Read commands: Supported		

Note 1. For details, see section 63.12.41, Flow for Erasure when Programming Commands are Prohibited.

The flash memory supports various protection functions.
Table 63.8 lists the protection functions supported by the flash memory.

Table 63.8 Lists of Protection Functions

Function	Description
Block protection	Block protection settings can be individually made to enable or disable reading or verification of each block of the user area of code flash memory. Programming and erasure by serial programming and self-programming of an area for which the lock bit is set and the lock bit function is enabled are prohibited. Programming or erasure can proceed again when a lock bit function is disabled after having been enabled. When a block of code flash memory is erased, the lock bit for that block is also erased.
User boot protection	Programming and erasure of the user boot area by self-programming are prohibited. Programming and erasure of the user boot area by serial programming are permitted.

63.6 FACI

The FACI controls the FCU according to the specified FACI commands.
For details on the FACI, refer to Flash Memory User's Manual: Hardware Interface.

63.7 Suspend Operation

Reading from the code flash memory/data flash memory is not possible during programming or erasure if the conditions for background operation given in Table 63.16 are not satisfied. When a P/E suspend command is issued to suspend the programming or erasure of the code flash memory/data flash memory, reading from the code flash memory/data flash memory is enabled. Regarding P/E suspend commands, there are one suspend command mode for programming and two suspend command modes for erasure (suspension priority mode and erasure priority mode). To resume suspended programming or erasure, the P/E resume command is available.
For details on the suspend operation, refer to Flash Memory User's Manual: Hardware Interface.

63.8 Protection

This MCU provides three types of protection; software protection, error protection, and boot program protection.
For details on the protection, refer to Flash Memory User's Manual: Hardware Interface.

63.9 User Boot Mode

If the low level is on the MD pin and the high level is on the PC7 pin at the time of release from the reset state, the chip starts in user boot mode.
The reset vector at this time points to the address FF7F FFFCh of the user boot area. For other vectors, refer to a normal vector table. See section 15, Interrupt Controller (ICUA).
In user boot mode, a program can be created by using any interface and the programming or erasure of the code flash memory/data flash memory is enabled by issuing the FACI command. Note that the programming to the user boot area should be performed in boot mode.
In addition, the settings for UB code A and UB code B are required. See section 7.3, UB Codes.

63.10 Boot Mode

There are two serial programming modes; the boot mode (for the SCI interface) with SCI and the boot mode (for the USB interface) with USB. Table 63.9 lists the I/O pins used in boot mode.

Table 63.9 I/O Pins Used in Boot Mode

Pin Name	I/O	Mode to be Used	Use
MD	Input	Boot mode (for the SCI interface) User boot mode Boot mode (for the USB interface)	Selection of operating mode
PC7/UB	Input		Selection of boot mode (for the SCI interface) or user boot mode*1/boot mode (for the USB interface)
PF2/RXD1 (177/176-pin packages) P30/RXD1 (145/144/100-pin packages)	Input	Boot mode (for the SCI interface)	For host communication (to receive data through SCI)
PF0/TXD1 (177/176-pin packages) P26/TXD1 (145/144/100-pin packages)	Output		For host communication (to transmit data through SCI)
USB0_DP, USB0_DM	I/O	Boot mode (for the USB interface)	Data input/output of USB
P16/USB0_VBUS	Input		Detection of connection and disconnection of USB cables
P35/UPSEL	Input		Selection of USB bus-power mode or self-power mode

Note 1. To enable user boot mode, the settings for UB code A and UB code B are required.

63.10.1 Boot Mode (for the SCI Interface)

In boot mode (for the SCI interface), the host sends control commands and data for programming, and the user boot area in the code flash memory or data flash memory is programmed or erased accordingly. An on-chip SCI handles transfer between the host and this MCU in asynchronous mode. Tools for transmission of control commands and the data for programming must be prepared in the host.

When this MCU is activated in boot mode (for the SCI interface), the program in a dedicated area within the MCU is executed. The boot program automatically adjusts the bit rate of the SCI and controls programming/erasure by receiving control commands from the host.

Figure 63.5 shows the system configuration for operations in boot mode (for the SCI interface).

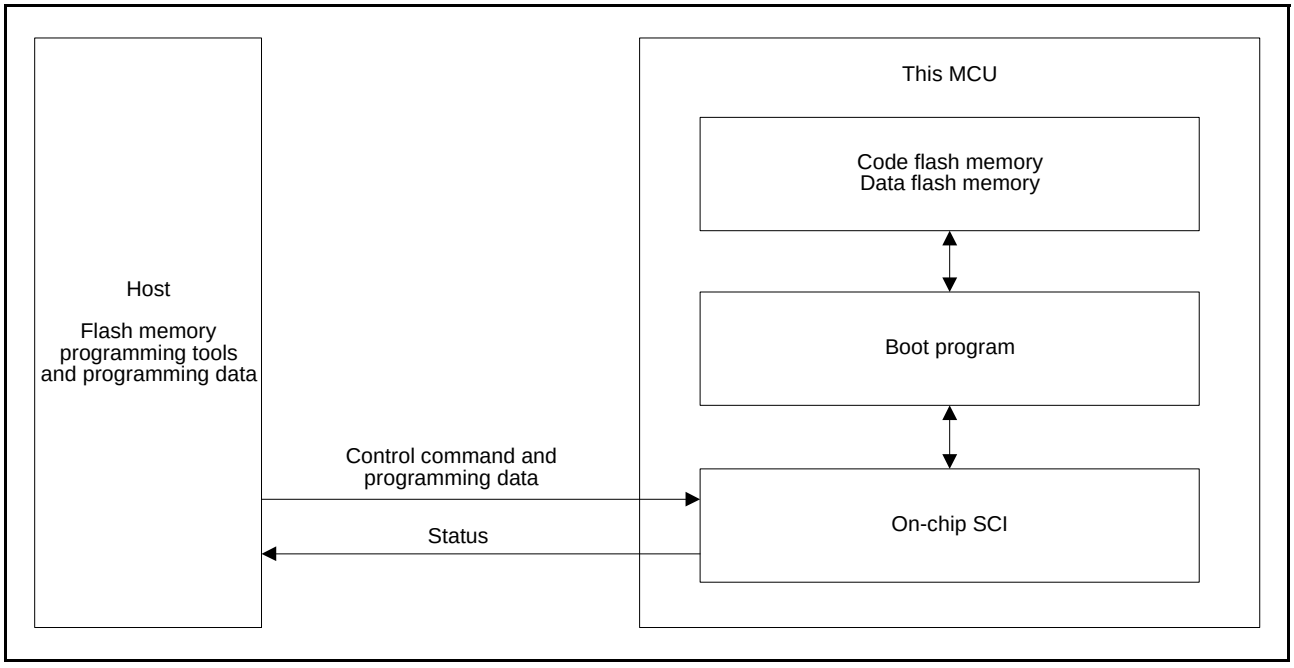


Figure 63.5 System Configuration for Operations in Boot Mode (for the SCI Interface)

63.10.2 Boot Mode (for the USB Interface)

In boot mode (for the USB interface), the code flash memory/data flash memory is programmed or erased by control commands and data for programming transmitted from an externally connected host via the USB.
Using boot mode (for the USB interface) requires preparation on the host side of tools for transmitting the control commands and data for programming, and of the data. Figure 63.6 shows the configuration of a system for use in boot mode (for the USB interface).

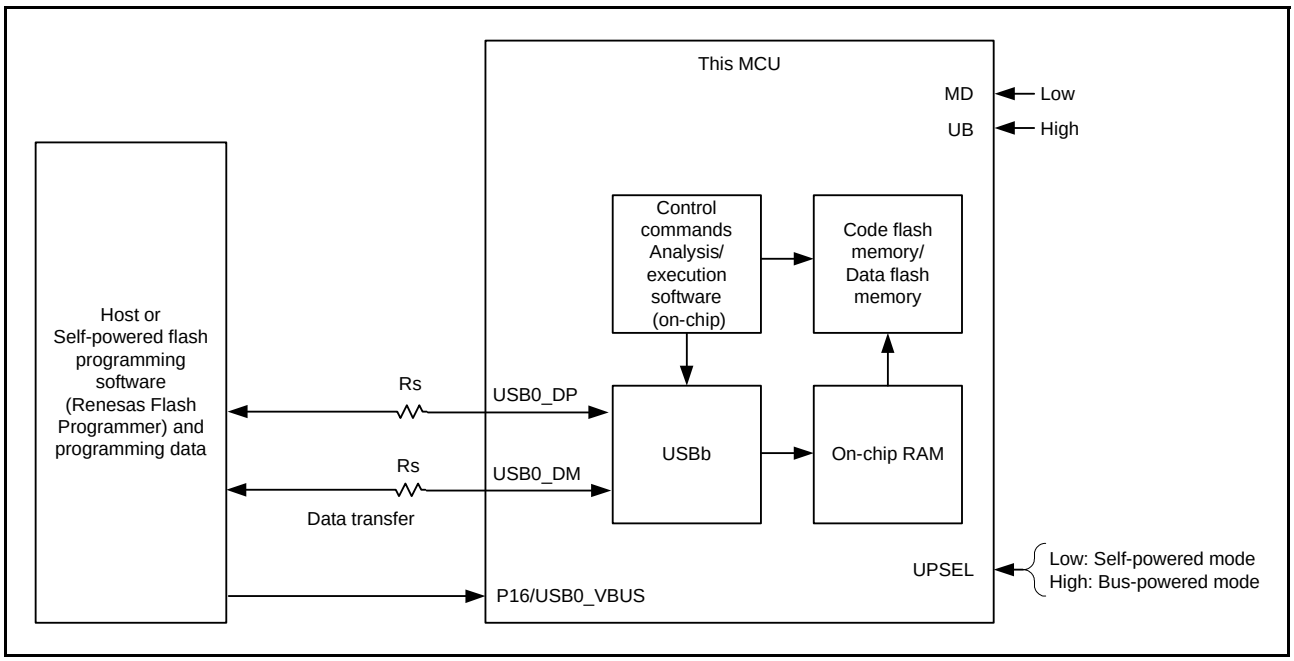

Figure 63.6 System Configuration in Boot Mode (for the USB Interface)

In boot mode (for the USB interface), self-power mode or bus power mode is selected for operation. Release from the reset state while the low level is being applied to the MD and UPSEL pins and the high level is being applied to the UB pin selects self-powered mode. Release from the reset state while the low is being applied to the MD pin and the high level is being applied to the UB and UPSEL pins are high selects bus-power mode.
Table 63.10 shows the enumeration information for each mode.

Table 63.10 Enumeration Information

USB Specification	Ver.2.0 (Full-Speed)	
Maximum current	Self-powered mode (pins P35 and UPSEL = Low)	100 mA
	Bus-powered mode (pins P35 and UPSEL = High)	500 mA

63.11 ID Code Protection

There are three types of ID code protection: on-chip debugger ID code protection, ID code protection, and ROM code protection.

63.11.1 ID Code Protection on Connection of the On-Chip Debugger

This function is used to prohibit connection with the on-chip debugger. When connecting an on-chip debugger, the control code and ID code that have been written to the option-setting memory are used to determine whether ID code protection on connection of the on-chip debugger is enabled or disabled and to judge ID code protection on connection of the on-chip debugger.
When the ID code protection is enabled, the code sent from the on-chip debugger is compared with the control code and ID code in the option-setting memory to determine whether they match. If they match, connection with the on-chip debugger is allowed.
If they do not match, the on-chip debugger cannot be connected.

63.11.2 ID Code Protection

This function is used to prohibit connection with the serial programmer. When connecting a serial programmer, the ID code set in the OCD/serial programmer ID setting register (OSIS) and written in the option-setting memory is used to judge ID code protection on connection of the serial programmer.
When the ID code protection is enabled, the code sent from the serial programmer is compared with the ID code set in the OCD/serial programmer ID setting register (OSIS) to determine whether they match. If they match, connection with the serial programmer is allowed. If they do not match, the serial programmer cannot be connected.

63.11.3 ROM Code Protection

ROM code protection is a function to prohibit reading from or programming/erasure to the flash memory when the parallel programmer is used during off-board programming. The ROM code in flash memory is a 32-bit code.
Figure 63.7 shows the configuration of the ROM code and Table 63.11 shows the specifications for ROM code protection. Set the ROM code in 32-bit units.
For release from ROM code protection, erase the block 0 of the user area that contains the ROM code in boot mode or by user program.

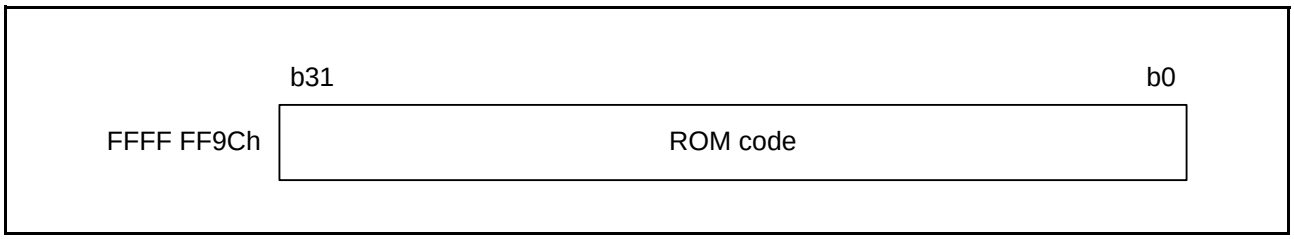

Figure 63.7 Configuration of the ROM Code

Table 63.11 Specifications for ROM Code Protection

ROM Code	State of Protection	Operations at the Time of Connection with the Flash Programmer
0000 0000h	Protection enabled (ROM code protection 1)	Access (both reading and programming/erasure) to the user area and the user boot area are prohibited.
0000 0001h	Protection enabled (ROM code protection 2)	Reading from the user area and the user boot area are prohibited.
Other than above	Protection disabled	Access (both reading and programming/erasure) to the user area and the user boot area are permitted.

63.12 Boot Mode Communications Protocol

This section describes the communications protocol for use in boot mode. When developing a programmer, use this communications protocol to control it.

63.12.1 How to Start the Chip Up in Boot Mode (for the SCI Interface)

The chip starts up in boot mode (for the SCI interface) if both the MD and PC7 pins are at the low level on release from the reset state (i.e. when the level on the RES# pin changes from low to high). A waiting time of at least 400 ms is required while the RES# pin is held at the high level after the chip starts up in boot mode (for the SCI interface) until communications with the MCU can proceed.

Figure 63.8 shows the states of pins up to communications (through the SCI interface) in boot mode becoming possible.

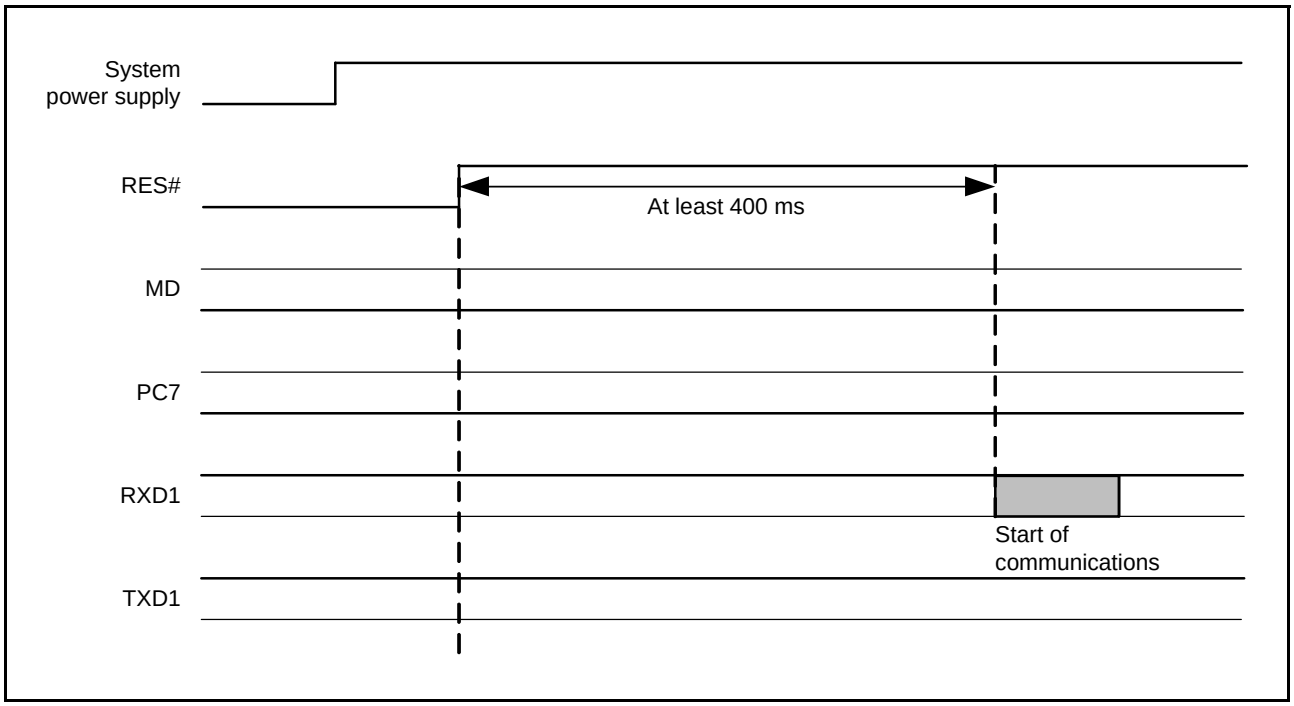

Figure 63.8 States of Pins Up to Communications (through the SCI Interface) in Boot Mode Becoming Possible

63.12.2 State Transitions in Boot Mode (for the SCI Interface)

Figure 63.9 is a diagram of the state transitions in boot mode (for the SCI interface).

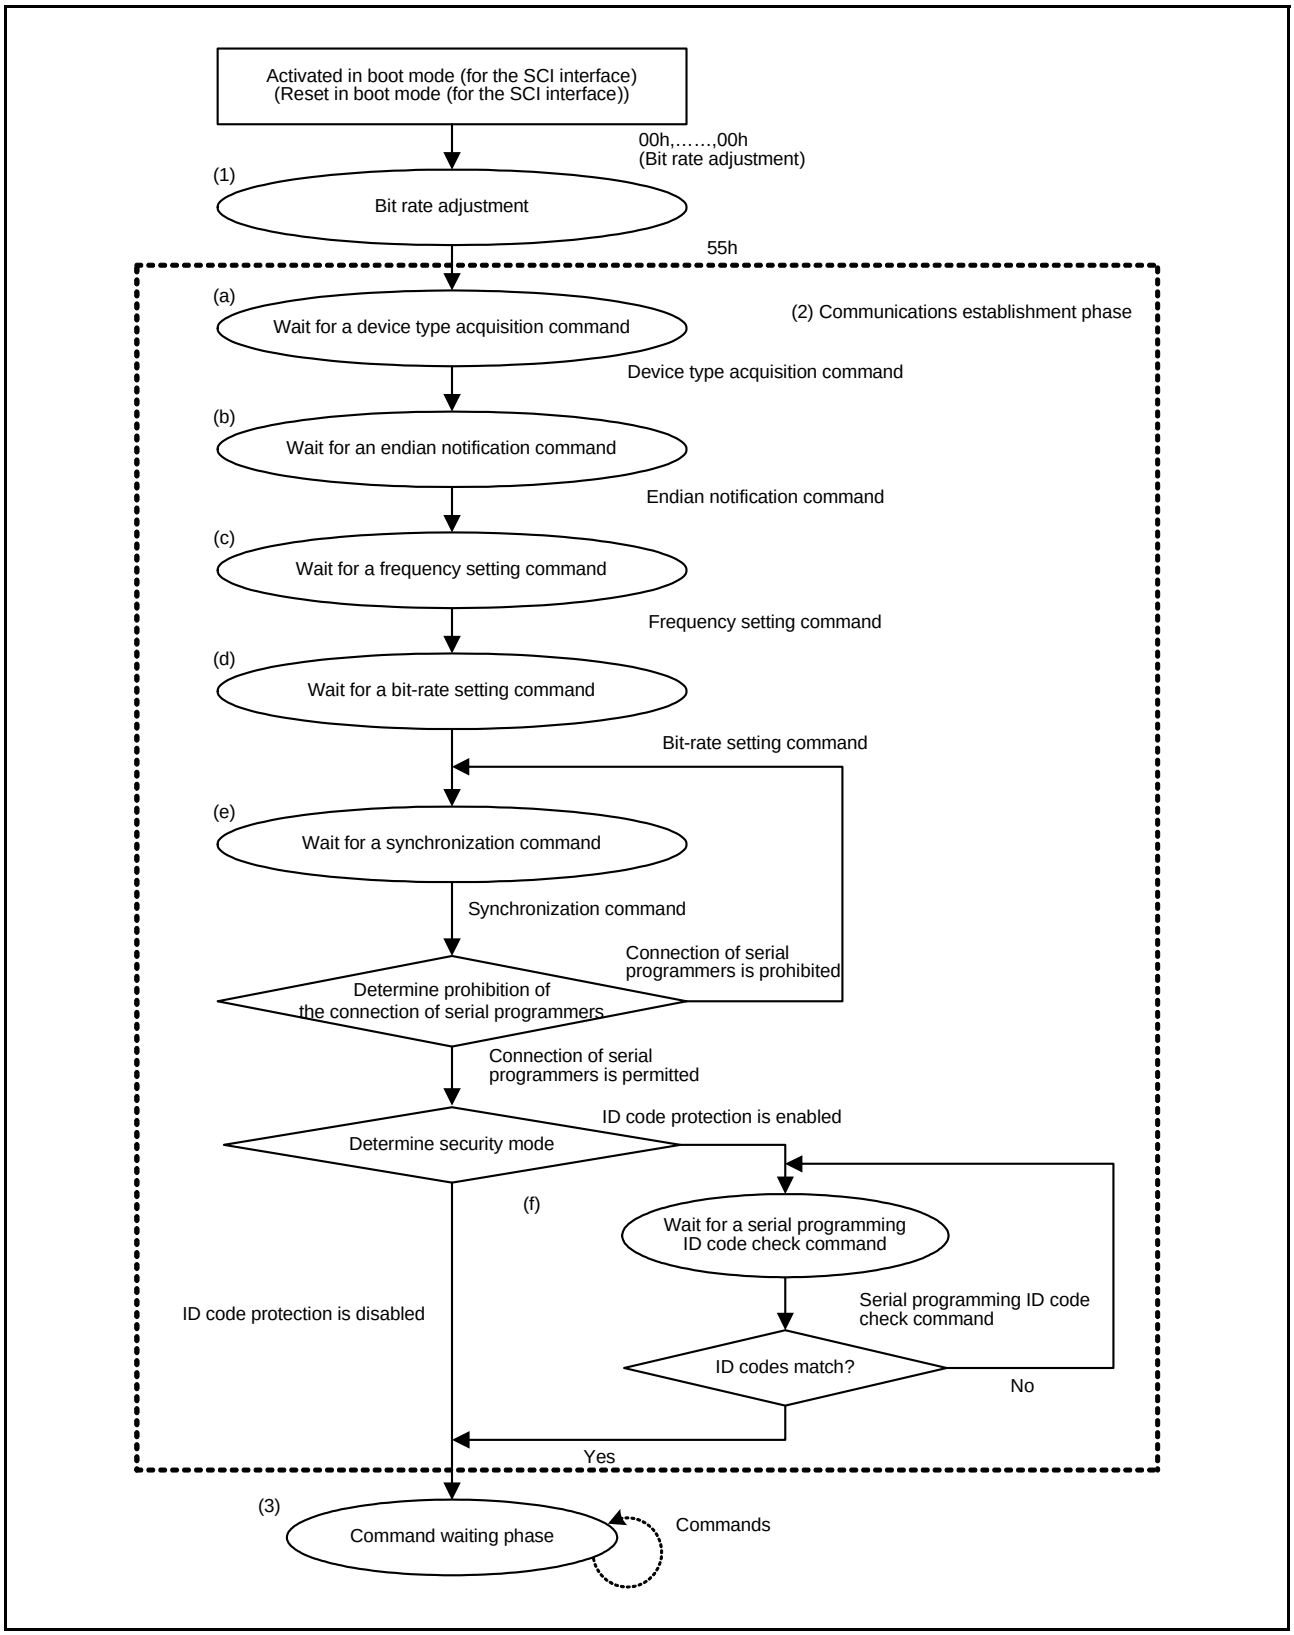

Figure 63.9 State Transitions in Boot Mode (for the SCI Interface)

(1) Matching the bit rates

When this MCU is activated in boot mode, the bit rate of the SCI is automatically adjusted to match that of the host. On completion of this automatic bit rate adjustment, this MCU transmits the value 00h to the host. On subsequent correct reception of the value 55h sent from the host, this MCU enters the communications establishment phase. For details on matching of the bit rates, see section 63.12.3, Automatic Adjustment of the Bit Rate.

(2) Communications establishment phase

The device, endian, frequency, and bit rate are selected in this phase. ID authentication also proceeds if ID code protection is enabled. For the commands to use in the communications establishment phase, see section 63.12.5, Communications Establishment Phase.

(a) Waiting for a device type acquisition command

In this state, the MCU is waiting for a device type acquisition command to be sent. When it receives a device type acquisition command from the host, the state shifts to waiting for an endian notification command. For details of the device type acquisition command, see section 63.12.9, Device Type Acquisition Command.

(b) Waiting for an endian notification command

In this state, the MCU is waiting for an endian notification command to be sent. When it receives an endian notification command from the host, the state shifts to waiting for a frequency setting command. For details of the endian notification command, see section 63.12.10, Endian Notification Command.

(c) Waiting for a frequency setting command

In this state, the MCU is waiting for a frequency setting command to be sent. When it receives a frequency setting command from the host, the state shifts to waiting for a bit-rate setting command. For details of the frequency setting command, see section 63.12.11, Frequency Setting Command.

(d) Waiting for a bit-rate setting command

In this state, the MCU is waiting for a bit-rate setting command to be sent. When it receives a bit-rate setting command from the host, the state shifts to waiting for a synchronization command. For details of the bit-rate setting command, see section 63.12.12, Bit-Rate Setting Command.

(e) Waiting for a synchronization command

In this state, the MCU is waiting for a synchronization command to be sent. When it receives a synchronization command from the host, it determines whether ID code protection is enabled or disabled. When ID code protection is disabled, the MCU enters the command waiting phase. When ID code protection is enabled, it enters the state of waiting for a serial programming ID code check command. If the MCU has been set to prohibit the connection of a serial programmer, this MCU transmits an error code to indicate that connecting a serial programmer is prohibited and remains in the state of waiting for a synchronization command. For details of the synchronization command, see section 63.12.13, Synchronization Command.

(f) Waiting for a serial programming ID code check command

In this state, the MCU is waiting for a serial programming ID code check command to be sent. The ID code sent from the host is compared with the ID code written in the option-setting memory area, and the command waiting phase is entered if the two match. If they do not match, the next transition is back to the state of waiting for a serial programming ID code check command. For details of the ID code check command, see section 63.12.15, Serial Programming ID Code Check Command.

(3) Phase of waiting for commands

In this state, programming and erasure proceed in accord with commands from the host. For details of the commands that can be issued in the command waiting phase, see section 63.12.6, Command Waiting Phase.

63.12.3 Automatic Adjustment of the Bit Rate

When this MCU is booted up in boot mode (for the SCI interface), asynchronous transfer by the SCI is used to measure the periods at low level of consecutive bytes with value 00h that are sent from the host. While the period at low level is being measured, set the host's SCI transfer format to 8-bit data, one stop bit, no parity, and a transfer rate of 9,600 bps. This MCU measures the periods at low level in the signal from the host, adjusts the bit rate of its SCI, and then sends the value 00h to the host.

If reception of the value 00h by the host is successful, the host responds by sending the value 55h to this MCU. If successful reception of 00h by the host is not possible, reboot this MCU in boot mode, and then repeat the process of automatically adjusting the bit rate. If reception of the value 55h by this MCU is successful, it responds by sending C1h to the host, and if successful reception of 55h by this MCU is not possible, it responds by sending FFh to the host.

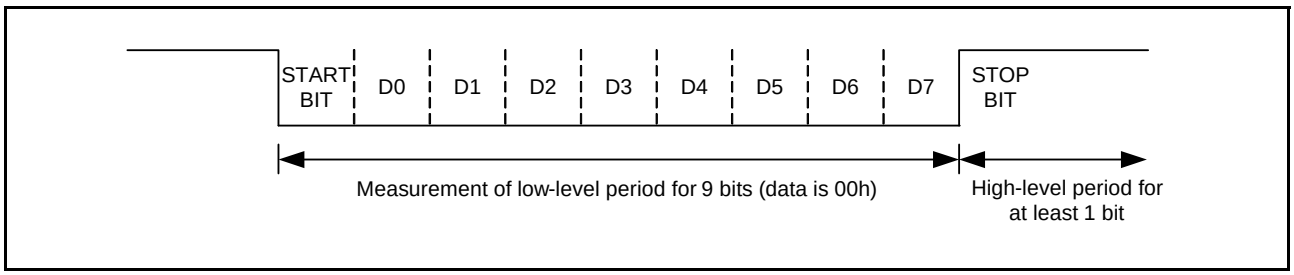

Figure 63.10 Transfer Format Used by SCI in Automatic Adjustment of Bit Rate

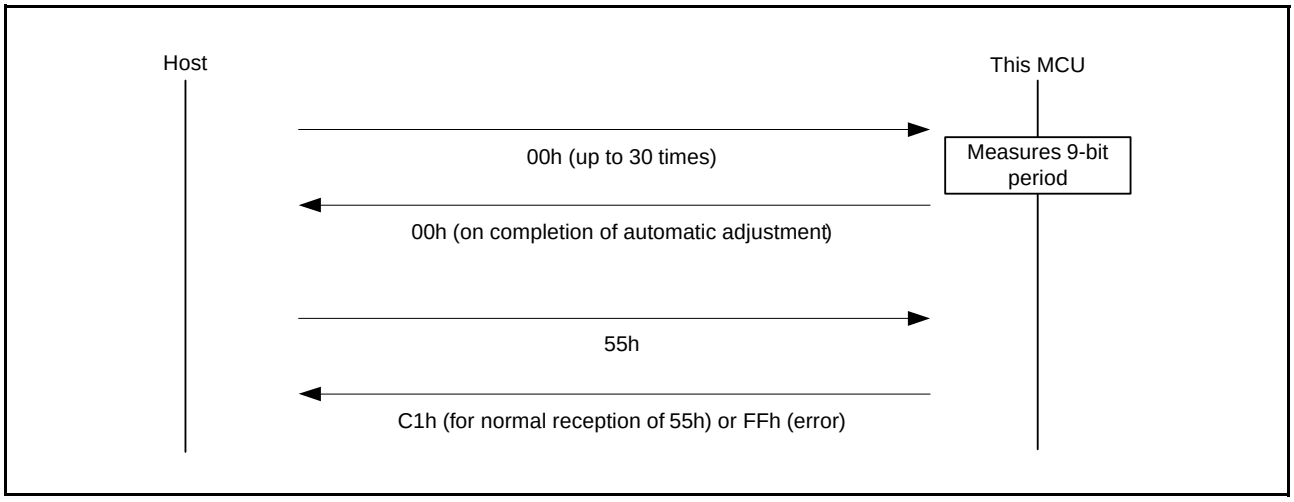

Figure 63.11 Sequence of Transfer between Host and This MCU

For the host's SCI bit rate, ensure that SCI communications proceed under the conditions given in Table 63.12.

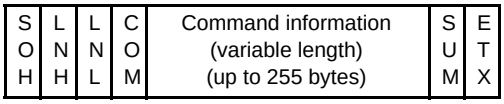
Table 63.12 Conditions for Automatic Bit-Rate Adjustment

Bit Rate of SCI in Host
9,600 bps

63.12.4 Packet Format

(1) Command packet

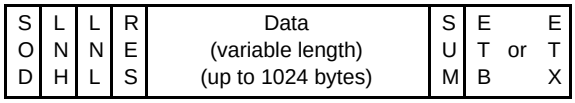
The host sends commands to this MCU in the format below.



Symbol	Code	Description
SOH	01h	Start of a packet (1 byte)
LNH	—	Packet length (length of COM and the command information) (8 to 15 bits) (1 byte)
LNL	—	Packet length (length of COM and the command information) (0 to 7 bits) (1 byte)
COM	—	Command code (1 byte)
Command information	—	Command information (up to 255 bytes)
SUM	—	Sum of values of LNH, LNL, COM, and the command information (1 byte)
ETX	03h	End of a packet (1 byte)

(2) Status packet and data packet

Data transmission proceeds between the host and this MCU in the format below.



Symbol	Code	Description
SOD	81h	Start of a packet (1 byte)
LNH	—	Packet length (length of RES and the data) (8 to 15 bits) (1 byte)
LNL	—	Packet length (length of RES and the data) (0 to 7 bits) (1 byte)
RES	—	Response code (1 byte)
Data	—	Data (up to 1024 bytes)
SUM	—	Sum of values of LNH, LNL, RES, and the data (1 byte)
ETB	17h	End of a packet (1 byte)
ETX	03h	End of the last packet (1 byte)

63.12.5 Communications Establishment Phase

Table 63.13 lists the commands available in the commands establishment phase.
The synchronization command and ID authentication mode acquisition command can also be used in the command waiting phase.

Table 63.13 Commands Available in the Communications Establishment Phase

Command Name	Function
Device type acquisition	Transmits the oscillation frequency and CPU operating frequency (in Hz) supported by boot mode to the host.
Endian notification	Indicates whether big-endian or little-endian is to be used.
Frequency setting	Sets the values of the oscillation frequency and CPU operating frequency (in Hz).
Bit-rate setting	Changes the bit rate.
Synchronization	This command is used in processing for communications synchronization. It is also used when confirming whether the MCU can accept commands.
ID authentication mode acquisition	Transmits an indication of whether ID authentication is enabled or disabled in boot mode to the host.
Serial programming ID code check	Determines whether the ID code written in the option-setting memory matches the ID code sent by the host.

In the communications establishment phase, send commands from the host in the order of the device type acquisition, endian notification, frequency setting, bit-rate setting, and synchronization commands according to the responses to commands. When ID authentication in boot mode is enabled, send the ID authentication mode acquisition or serial programming ID code check command following the synchronization command.
If commands are issued in an incorrect order or other commands are issued, this MCU returns a response indicating a flow error.

63.12.6 Command Waiting Phase

Table 63.14 lists the commands available in the command waiting phase.
The synchronization command and ID authentication mode acquisition command can also be used in the communications establishment phase.

Table 63.14 Commands Available in the Command Waiting Phase

Command Name	Function
Synchronization	See Table 63.13.
Blank check	Check that a selected area is blank.
Block erase	Erases a selected single block.
Area erasure	Erases the specified area.
Programming	Programs the selected area.
Read	Reads data from a selected area.
Lock-bit setting	Sets the lock bits.
Lock-bit acquisition	Obtains the settings of lock bits.
Lock bit enable	Enables the setting of lock bits.
Lock bit disable	Disables the setting of lock bits.
ID authentication mode acquisition	See Table 63.13.
Command protection setting	Enables prohibition of block erase commands, programming commands, or read commands.
Command protection acquisition	Obtains the settings for protection against block erase commands, programming commands, and read commands.
Boot mode ID code setting	Sets the ID code and enables ID authentication in boot mode.
ID code setting	Sets the ID code.
ID code acquisition	Obtains the ID code setting.
Serial programmer connection prohibition	Prohibits the connection of serial programmers.
OFS setting	Sets the OFS0 and OFS1 registers.
OFS acquisition	Obtains the setting of the OFS0 and OFS1 registers.
Endian setting	Sets the MDE register.
Endian acquisition	Obtain the setting of the MDE register.
Configuration clearing	Clears the security function, ID code, endian, and OFS.
TM setting	Enables the TM function and sets the TMINF register.
TM acquisition	Acquires an indicator of whether the TM function is currently enabled or disabled, the contents of the TMINF register, and the addresses where the TM target areas start and end.
Simple addition checksum	Calculates the sum of values in a selected area.
Signature acquisition	Obtains information of the flash memory configuration.

If the host has sent an undefined command, this MCU returns a response indicating an error in the form of a non-supported command.

63.12.7 Command Transfer Sequence

Though the sequence of transfer differs from command to command, common transfer sequences are used for the commands that only make settings for this MCU and for the commands that obtain information on the settings in this MCU. However, as the contents of the command packet, status packet, and data packet differ for each command, see the sections on the individual commands for details.

(1) Common transfer sequence for the commands that only make settings

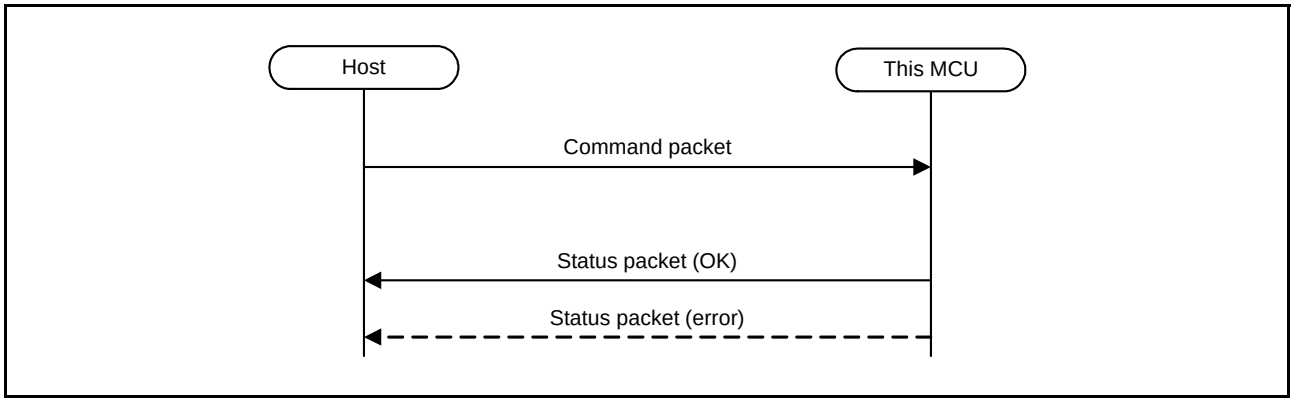


Figure 63.12 Common Transfer Sequence for the Commands that Only Make Settings

(2) Common transfer sequence for the commands that obtain information on settings

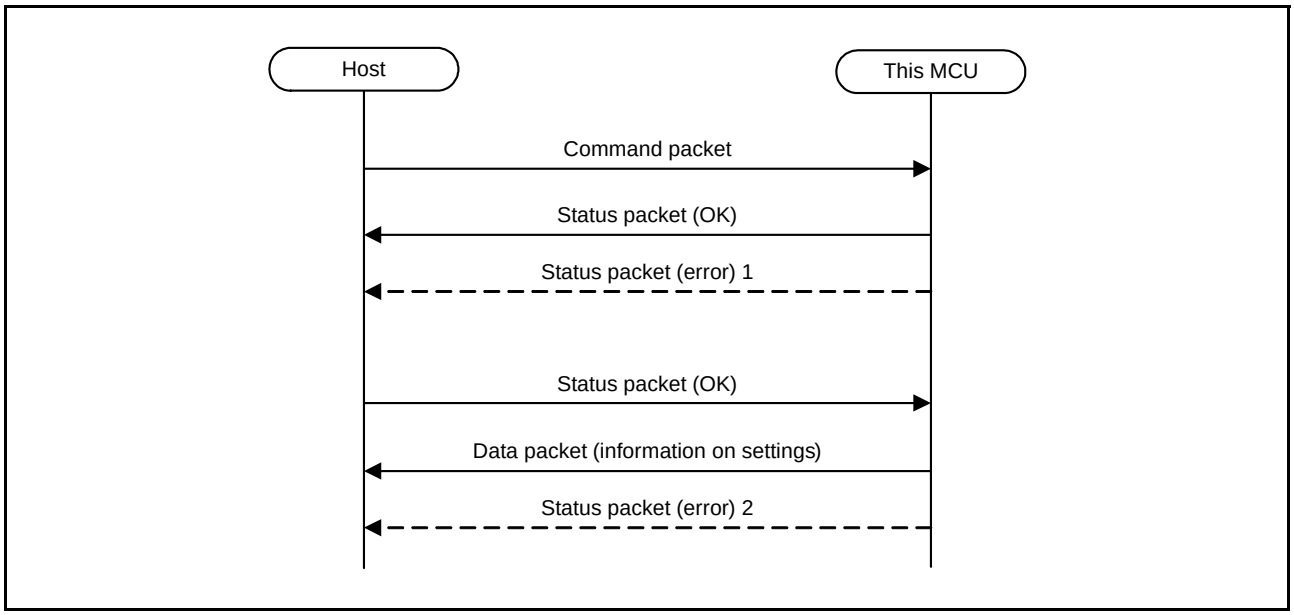

Figure 63.13 Common Transfer Sequence for the Commands that Obtain Information on Settings

Table 63.15 Common Transfer Sequence

Command Name	Common Transfer Sequence Type
Device type acquisition	Command that obtains information on settings
Endian notification	Command that only makes a setting
Frequency setting	Command that obtains information on settings
Bit rate setting	Not in a common transfer sequence
Synchronization	Command that only makes a setting
ID authentication mode acquisition	Command that obtains information on settings
Serial programming ID code check	Command that only makes a setting
Blank check	Command that only makes a setting
Block erase	Command that only makes a setting
Area erasure	Command that only makes a setting
Programming	Not in a common transfer sequence
Read	Not in a common transfer sequence
Lock-bit setting	Command that only makes a setting
Lock-bit acquisition	Command that obtains information on settings
Lock bit enable	Command that only makes a setting
Lock bit disable	Command that only makes a setting
Command protection setting	Command that only makes a setting
Command protection acquisition	Command that obtains information on settings
Boot mode ID code setting	Command that only makes a setting
ID code setting	Command that only makes a setting
ID code acquisition	Command that obtains information on settings
Serial programmer connection prohibition	Command that only makes a setting
OFS setting	Command that only makes a setting
OFS acquisition	Command that obtains information on settings
Endian setting	Command that only makes a setting
Endian acquisition	Command that obtains information on settings
Configuration clearing	Command that only makes a setting
TM setting	Command that only makes a setting
TM acquisition	Command that obtains information on settings
Simple addition checksum	Command that obtains information on settings
Signature acquisition	Command that obtains information on settings

For the command transfer sequences that are not in a common transfer sequence, see the sections on the individual commands.

63.12.8 Non-supported Commands

If an undefined command packet is sent, this MCU returns the “non-supported” error code (C0h) and returns to the command waiting state.

(1) Command packet structure

SOH	LNH	LNL	COM	SUM	ETX

SOH: 01h
LNH: Packet length (8 to 15 bits)
LNL: Packet length (0 to 7 bits)
COM: Command code*1
SUM: Sum of values
ETX: 03h

Note 1. Command code other than those specified in Table 63.14.

(2) Status packet structure

SOD	LNH	LNL	RES	ERR	SUM	ETX

SOD: 81h
LNH: 00h
LNL: 02h
RES: 80h | COM (command code)
ERR: Error code
C0h (“non-supported” error)
C1h (packet error)
C2h (checksum error)
C3h (flow error)
SUM: Sum of values
ETX: 03h

63.12.9 Device Type Acquisition Command

This command is used to make the MCU send the input frequency and system clock frequency (in Hz) supported by boot mode (for the SCI interface).
This command can only be accepted in the communications establishment phase.

(1) Command packet structure

SOH	LNH	LNL	COM	SUM	ETX

SOH: 01h
LNH: 00h
LNL: 01h

63.12.11 Frequency Setting Command

This command is used to set the values of oscillation frequency and CPU operating frequency (in Hz).
In boot mode, the HOCO runs at 16 MHz and the ICLK at 120 MHz, so set the input frequency and system clock frequency bytes to the hexadecimal values corresponding to 16 MHz and 120 MHz, respectively. Additionally, since the FCLK and PCLKB run at 60 MHz in boot mode, the MCU returns the hexadecimal value corresponding to 60 MHz to indicate the peripheral clock frequency.
This command can only be accepted in the communications establishment phase.

63.12.16 Blank Check Command

This command checks whether the specified area is blank.
Specify a range in the user area or user boot area with addresses on 256-byte boundaries or in the data area with addresses on 16-byte boundaries. When the TM function is enabled, an attempt at blank checking of the code flash memory in blocks 8 and 9 leads to an error since they are being handled as TM target area.
This command can only be accepted in the command waiting phase.

(1) Command packet structure

After the error code is returned, the chip returns to the command waiting state.

63.12.17 Block Erase Command

This command is used to erase a specified single block.
Specify the block for erasure as the first address in the block.
If the lock-bit function is disabled and the lock bit of a block for erasure is set, the lock bit is also erased so the block is released from locking. While the TM function is enabled, blocks 8 and 9 in the code flash memory are handled as TM target areas and so cannot be erased.
To erase areas being handled as TM target, use the configuration clearing command described in section 63.12.35, Configuration Clearing Command to restore them to normal handling.
If programming commands are prohibited, follow the procedure for erasure prescribed in section 63.12.41, Flow for Erasure when Programming Commands are Prohibited.
This command cannot be used when block erase commands are prohibited.
If processing of erasure is forcibly stopped in response to a command due to a reset, the lock bit may be set. In such a case, see (6) Abnormal Termination During Programming/Erasure or Blank Checking in section 63.17, Usage Notes.
This command can only be accepted in the command waiting phase.

(1) Command packet structure

E1h (erase error)
SUM: Sum of values
ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

63.12.18 Area Erase Command

The area erase command erases the specified area successively, block by block, in ascending order of addresses.
The target area can be selected as the user area or user boot area, or as the data flash area.
When an area for which the lock bit function is disabled and the lock bit has been set is erased, the lock-bit setting is cleared.
When the TM function is enabled, only the blocks other than those in the TM target areas are erased.
This command can only be accepted in the command waiting phase.
If processing in response to the command is forcibly stopped due to a reset, etc., while erasure is in progress, the lock bit may be set. In this case, see section 63.17, Usage Notes, (6) Abnormal Termination During Programming/Erasure or Blank Checking.

63.12.19 Programming Command

This command sets up the MCU for data to be programmed to its flash memory and specifies the area where the data are to be programmed.
Specify addresses for a data length that is a multiple of 256 bytes for the user area or user boot area, or a multiple of 16 bytes for the data area. Furthermore, as the address where programming is to start, specify an address on a 256-byte boundary for the user area or user boot area or on a 16-byte boundary for the data area. When the TM function is enabled, blocks 8 and 9 in the code flash memory are handled as TM target areas and so cannot be programmed.
This command cannot be used when programming commands are prohibited.
This command can only be accepted in the command waiting phase.

63.12.20 Read Command

This command is used to read data from the specified area in the flash memory and send it to the host.
Specify addresses for a data length that is a multiple of 256 bytes for the user area or user boot area, or a multiple of 16 bytes for the data area. Furthermore, as the address where reading is to start, specify an address on a 256-byte boundary for the user area or user boot area or on a 16-byte boundary for the data area. When the TM function is enabled, reading blocks 8 and 9 in the code flash memory being handled as TM target areas returns 0.
This command cannot be used when read commands are prohibited.
This command can only be accepted in the command waiting phase.

63.12.21 Lock-Bit Setting Command

This command is used to set lock bits for the user area.
When the chip starts up in boot mode, programming or erasure of blocks for which the lock bit has been set is possible since the lock bit function is disabled. To enable the lock bit function during operation in boot mode, use the lock-bit enable command.
This command cannot be used to clear a lock bit that has already been set. Canceling the setting of a lock bit requires erasure of the target block.
This command can only be accepted in the command waiting phase.

(1) Command packet structure

63.12.27 Serial Programming ID Code Setting Command

This command is used to set the ID code in boot mode and by the on-chip debugger (OCD) to enable ID authentication in boot mode.
After this command is issued, ID authentication is required for reconnection in boot mode.
This command cannot be used if block erase commands, programming commands, or read commands are prohibited.
Apply a reset after executing this command.
This command can only be accepted in the command waiting phase.

(1) Command packet structure

63.12.35 Configuration Clearing Command

This command is used to clear configuration data. When the TM function is enabled, the command can also be used to erase blocks 8 and 9 in the code flash memory being handled as TM target areas.
For the states after execution of this command, see (4) Configuration data after clearing.
This command cannot be issued in the following cases: the user area, user boot area, and data area are not blank; the lock bit is set for any block; or prohibition of block erase commands is enabled.
When ID authentication in boot mode is enabled, a reset is required to disable ID authentication.
This command can only be accepted in the command waiting phase.

Prohibition of the connection of serial programmers	Disabled
ID code	All FFh
MDE	Little-endian
OFS0 and OFS1	All FFh
TM function	Disabled

63.12.36 TM Setting Command

The TM setting command writes 000b to the TMEF.TMEF[2:0] bits and the desired 4-byte value to the TMINF register to enable the TM function. The TMINF register is used to store codes for identification of the programs, etc., in the areas being handled as TM. The TM function is enabled after a reset.
This command can only be accepted in the command waiting phase.

63.12.37 TM Acquisition Command

The TM acquisition command acquires an indicator of whether the TM function is enabled or disabled, the setting of the TMINF register, and the addresses where the areas being handled as TM target start and end, and conveys the results to the programmer.
This command can only be accepted in the command waiting phase.

63.12.38 Simple Addition Checksum Command

This command is used to calculate the sum of values in the specified area and send the result to the host. While the TM function is enabled, however, the values in the TM target areas are not included in the calculation.
The target area of this command can be selected from the user area, user boot area, and data area. Calculation is by simple addition. The initial value is 0 and the sum of values in the specified area is obtained by adding the values of all bytes.
If this command is issued for a data area that includes erased blocks, the result is undefined. When a simple addition checksum is to be executed for the data area, make sure that data have been written throughout the specified area.
This command can only be accepted in the command waiting phase.

63.12.40 Usage Example

(1) Example of the Procedure for Reprogramming

Figure 63.18 shows an example of the procedure for reprogramming.

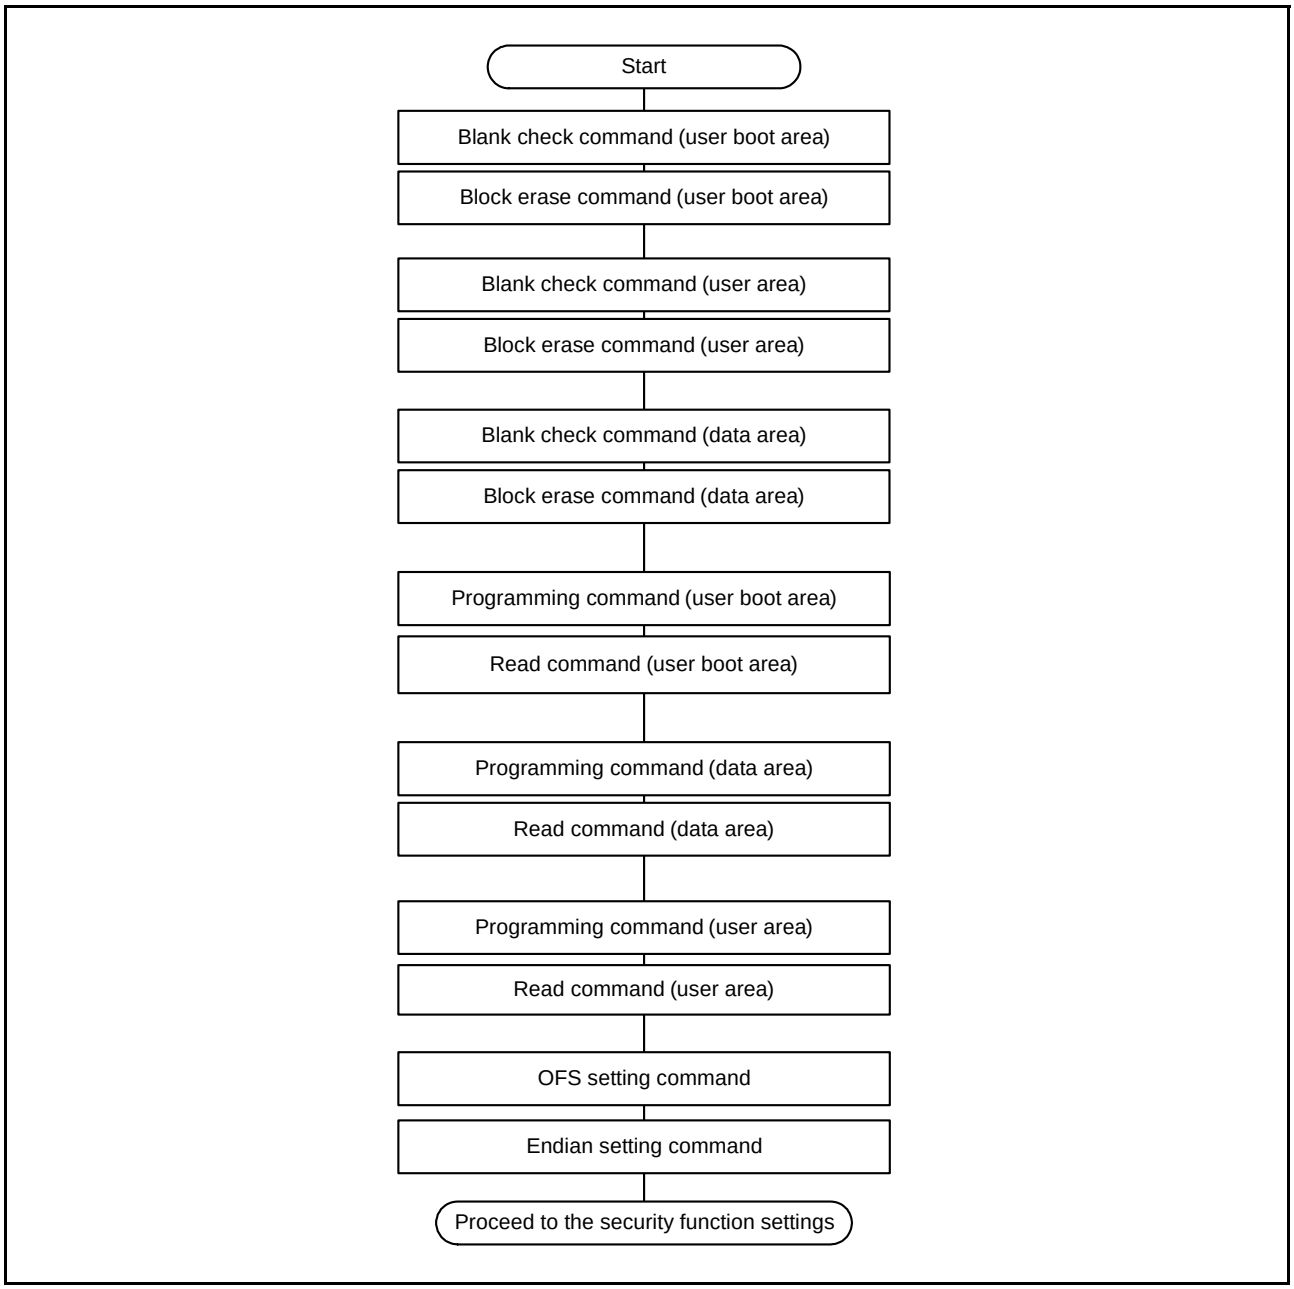

Figure 63.18 Example of Reprogramming Procedure

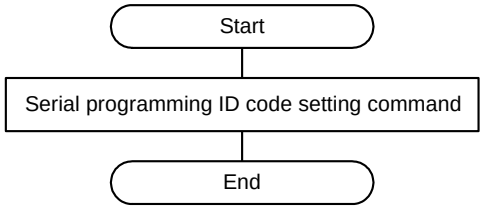
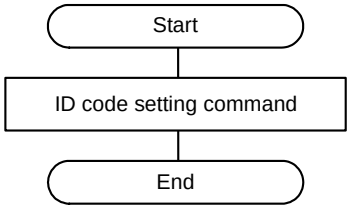
(2) Security Function Settings

When the security functions are to be used, follow any of the procedures below to set the required security functions.

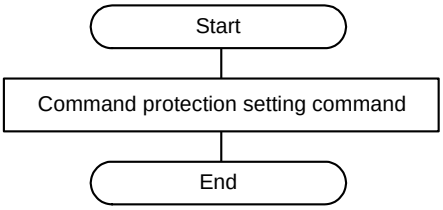
1. Setting the OCD ID code and enabling ID authentication in boot mode



2. Setting the OCD ID code



3. Prohibiting block erase commands, programming commands, and read commands



4. Prohibiting the connection of serial programmers

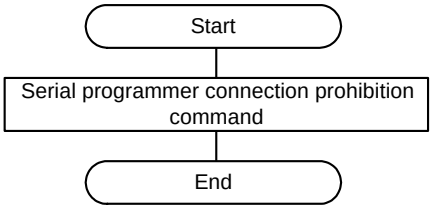


Figure 63.19 Settings for Use of the Security Functions

63.12.41 Flow for Erasure when Programming Commands are Prohibited

When programming commands are prohibited, follow the procedure below for erasure.

1. Erase the user boot area.
2. Erase the data area in order from the first block.
3. Erase the user area in order from the last block.

Note that neither a reset nor interrupts, including NMI, should be applied during the steps from erasure of the user boot area to erasure of the user area.

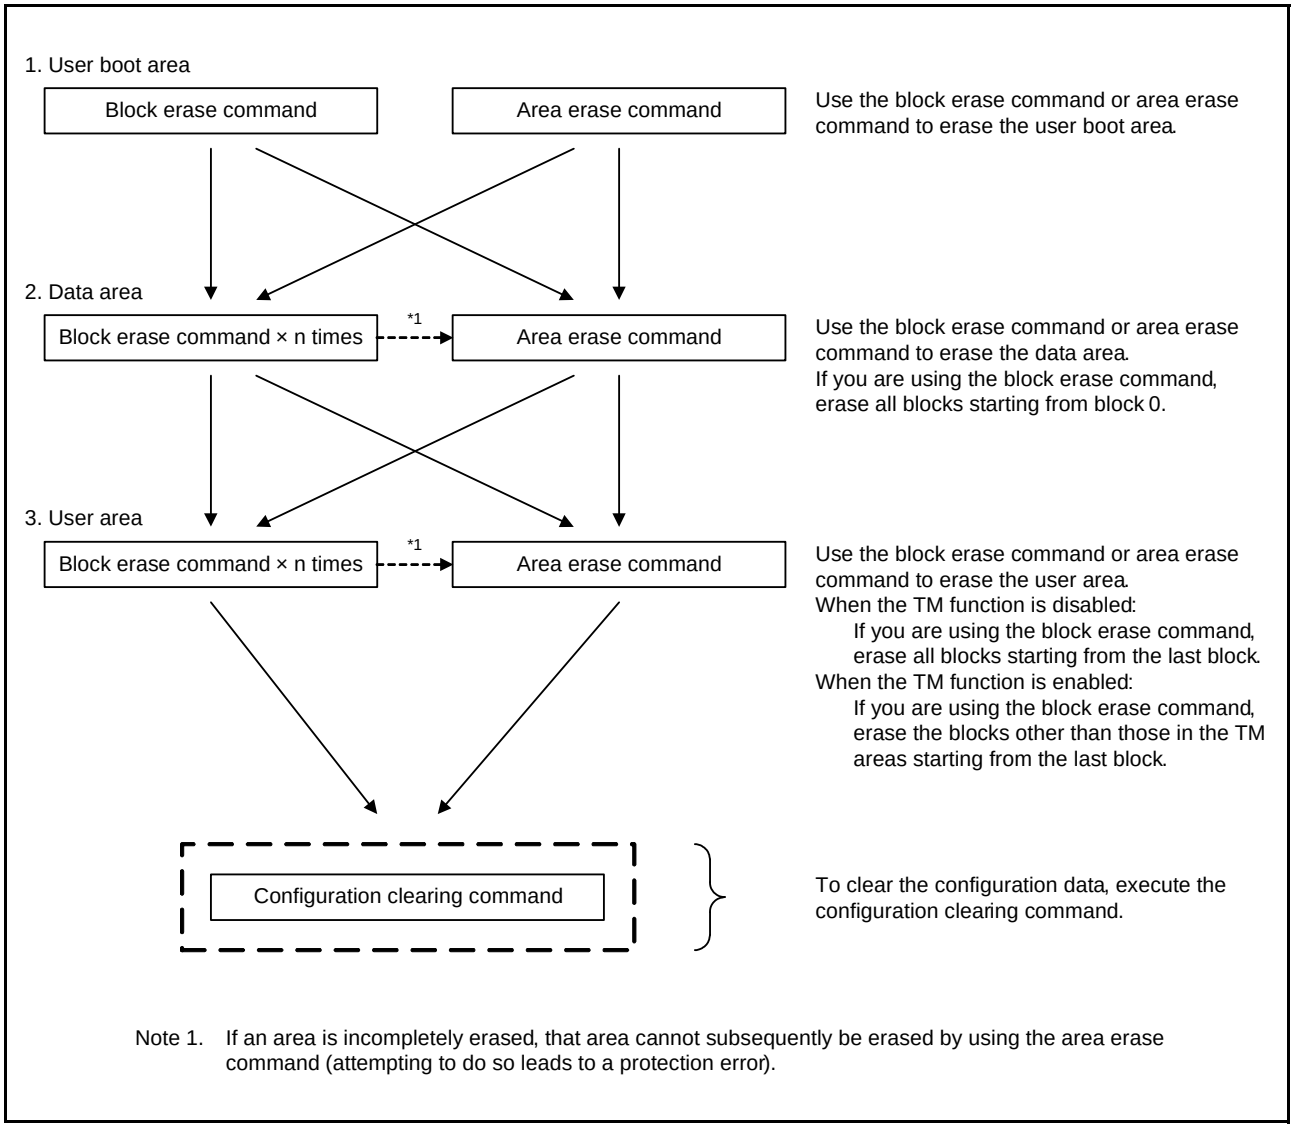

Figure 63.20 Flow for Erasure when Programming Commands are Prohibited

63.13 Using the Serial Programmer for Rewriting

A dedicated flash memory programmer can be used to rewrite flash memory in boot mode.

(1) Serial Programming

A flash programmer can program this MCU by providing a connector to the board while the MCU is implemented to the board that the user will use.

63.13.1 Environments for Serial Programming

The recommended environments for rewriting the flash memory of the MCU with data are described below.

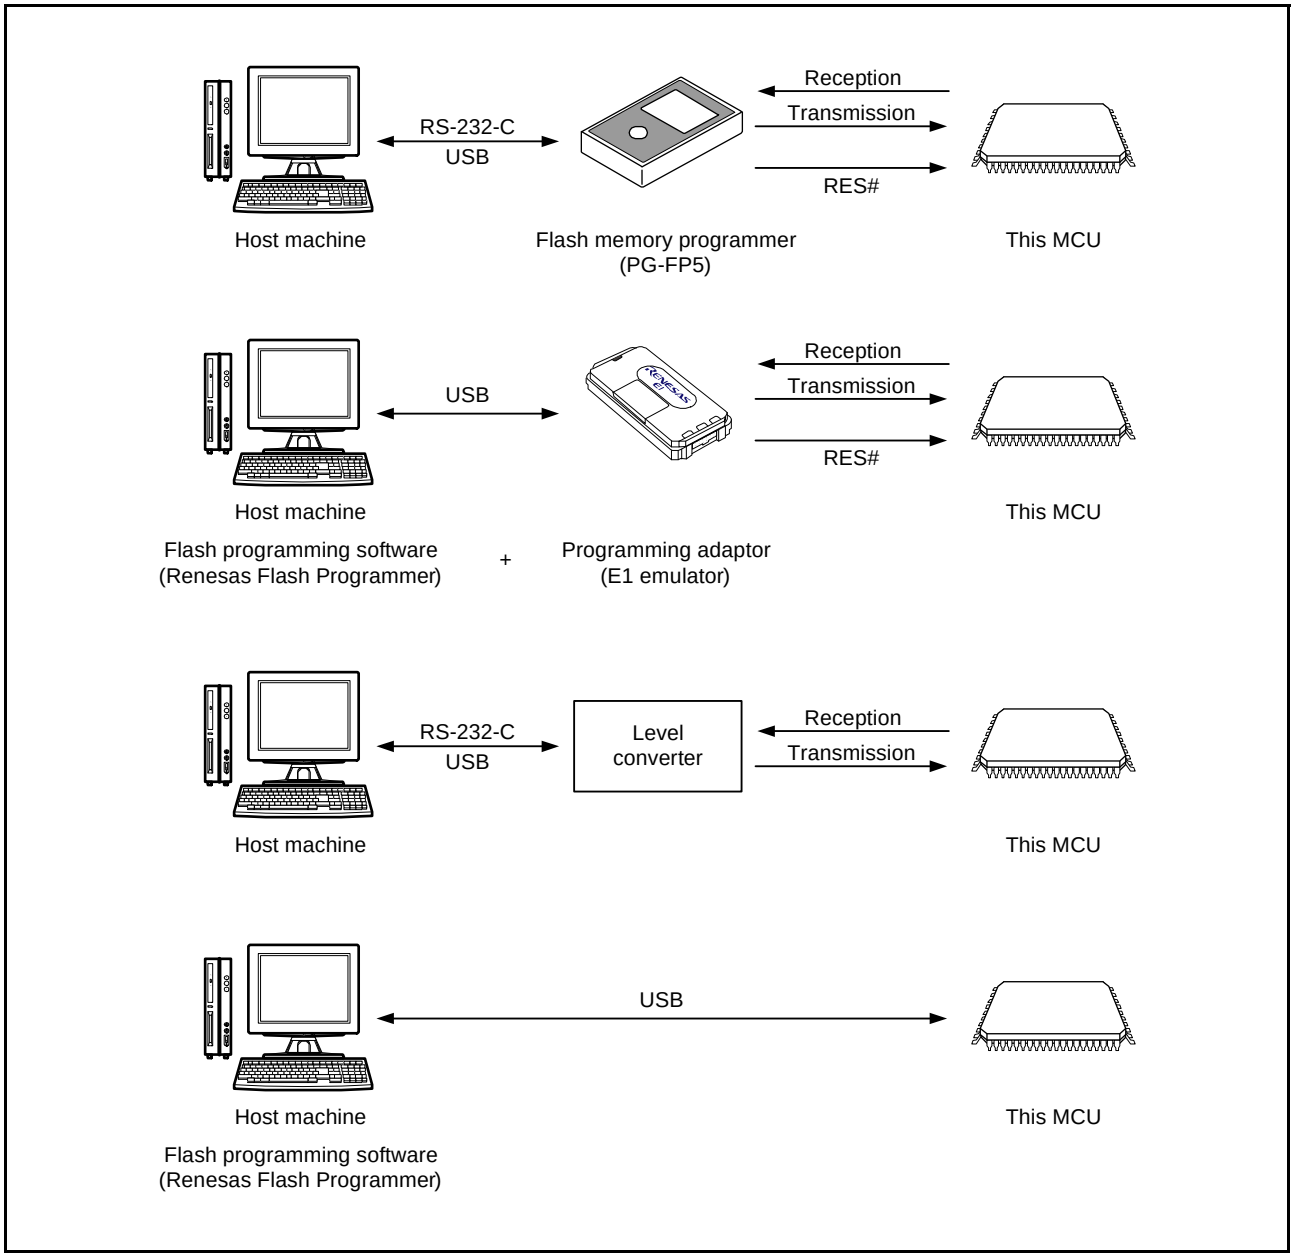

Figure 63.21 Environments for Rewriting Programs to the Flash Memory

By using the PG-FP5 flash memory programmer or the combination of the Renesas Flash Programmer (software for programming to flash memory) running on the host machine and the E1 emulator as an programming adaptor, the user is easily able to program, erase, and verify the contents of the on-chip memory of flash-memory-equipped microcontrollers from Renesas Electronics.
The PG-FP5 flash memory programmer handles rewriting the flash memory from a host machine or in stand-alone mode.
The flash programming software (Renesas Flash Programmer) handles rewriting the flash memory from a host machine.

Note: For details of the PG-FP5, refer to the PG-FP5 Flash Memory Programmer User's Manual; for details of the Renesas Flash Programmer flash programming software, refer to the Renesas Flash Programmer Flash Programming Software User's Manual.

63.14 Programming through Self-Programming

63.14.1 Overview

This MCU supports programming of the flash memory by the user program itself. The FACI commands can be used with user programs for writing to the code flash memory and to the data flash memory. This allows upgrading of user programs and overwriting of constant data fields.
When the data flash memory is programmed, the background operation facility makes it possible to execute a programming program from the code flash memory to program the data flash memory. Furthermore, the programming program can be copied to internal RAM or external memory in advance of the programming operation, and executed from the given destination to perform the programming.
Background operation is also available for use when the address ranges of the area of code flash memory to be programmed and the area of code flash memory to be read satisfy particular conditions (see Table 63.16). At the time of self-programming in this case, a programming program in code flash memory can be used to program the code flash memory. Also, the programming program can be copied to internal RAM or external memory in advance of the programming operation, and executed from the given destination to program the code flash memory. This is useful when the address ranges do not satisfy the conditions for background operation.

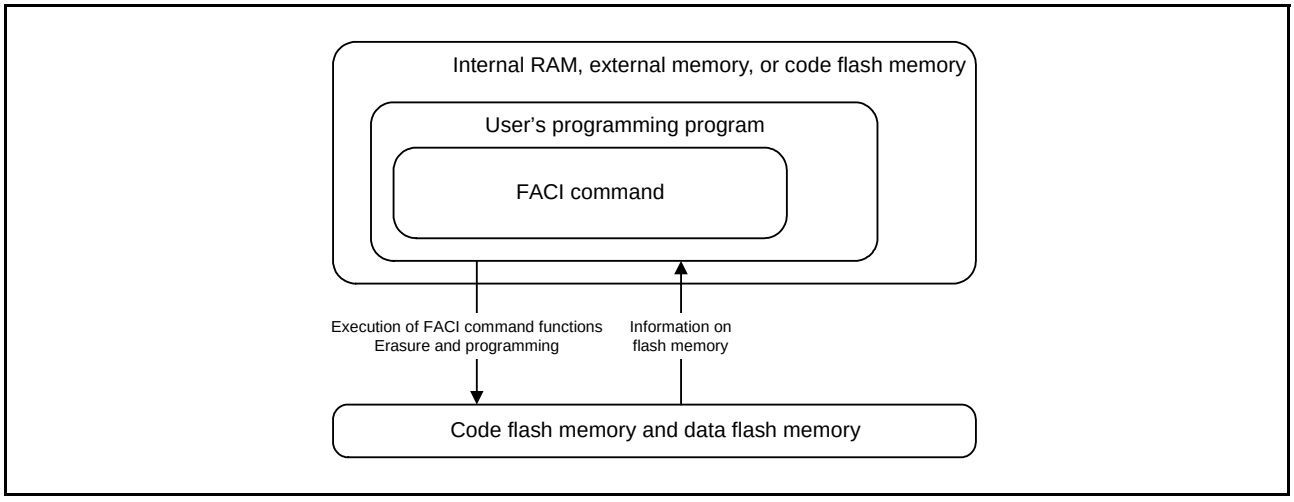

Figure 63.22 Schematic View of Self-Programming

For comprehensive information on the self-programming of flash memory, refer to Flash Memory User's Manual: Hardware Interface.

63.14.2 Background Operation

Background operations can be used when the combination of the flash memory for rewriting and the flash memory for reading is any of those listed below.

Table 63.16 Conditions under which Background Operation is Usable

	Range for Rewriting	Range for Reading
Common to all products	Data flash memory	Code flash memory
2.5-Mbyte product	First half (0.5 Mbytes) of the user area of the code flash memory (addresses FFD8 0000h to FFDF FFFFh)	Second half (2 Mbytes) of the user area of the code flash memory (addresses FFE0 0000h to FFFF FFFFh) or user boot area of the code flash memory
	Second half (2 Mbytes) of the user area of the code flash memory (addresses FFE0 0000h to FFFF FFFFh)	First half (0.5 Mbytes) of the user area of the code flash memory (addresses FFD8 0000h to FFDF FFFFh)
3-Mbyte product	First half (1 Mbyte) of the user area of the code flash memory (addresses FFD0 0000h to FFDF FFFFh)	Second half (2 Mbytes) of the user area of the code flash memory (addresses FFE0 0000h to FFFF FFFFh) or user boot area of the code flash memory
	Second half (2 Mbytes) of the user area of the code flash memory (addresses FFE0 0000h to FFFF FFFFh)	First half (1 Mbyte) of the user area of the code flash memory (addresses FFD0 0000h to FFDF FFFFh)
4-Mbyte product	First half (2 Mbytes) of the user area of the code flash memory (addresses FFC0 0000h to FFDF FFFFh)	Second half (2 Mbytes) of the user area of the code flash memory (addresses FFE0 0000h to FFFF FFFFh) or user boot area of the code flash memory
	Second half (2 Mbytes) of the user area of the code flash memory (addresses FFE0 0000h to FFFF FFFFh)	First half (2 Mbytes) of the user area of the code flash memory (addresses FFC0 0000h to FFDF FFFFh)

63.15 Reading Flash Memory

63.15.1 Reading Code Flash Memory

Special settings are not required to read code flash memory in normal mode or user boot mode. Data can simply be read out through access to addresses in the code flash memory.
When reading code flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state), all bits are read as 1.

63.15.2 Reading Data Flash Memory

Special settings are not required to read data flash memory in normal mode or user boot mode. Data can simply be read out through access to addresses in the data flash memory.
Values read from data flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state) are undefined. Use blank checking when you need to confirm that an area is in the non-programmed state.

63.16 Trusted Memory

This MCU has a trusted memory (hereafter called TM) facility to prevent the reading of blocks 8 and 9 in the code flash memory by third party software. When set as trusted memory, these areas are suitable for storing software that handles processing for encryption algorithms, device control software that is associated with proprietary or confidential know-how, purchased middleware, and so on.

Table 63.17 lists the specifications of the TM, Table 63.18 lists access restrictions within the TM target area when TM is enabled, and Figure 63.23 shows the cases where the CPU is able to operate in relation to the TM target area.

Table 63.17 TM Specifications

Item	Description
TM target area	Blocks 8 and 9 in the code flash memory (64 Kbytes in total)
Access restrictions when TM is enabled	See Table 63.18, Restrictions on Access to the TM Area while TM is Enabled.
How to run program code when the TM function is enabled	When TM is enabled, starting to run program code in an area being handled as TM is only possible with a branch instruction from program code outside the areas being handled as TM.
Interrupt processing during the execution of program code in an area being handled as TM while the TM function is enabled	Both the acceptance of requests for interrupt processing and return from interrupt processing are possible.
Security function	Enabling the TM function restricts access to program code in the areas for handling as TM to instruction fetching only
Protection functions	• Restrictions on access by a program running in an area other than the areas being handled as TM to data in those areas while the TM function is enabled*1 • Once enabled, the TM function prevents its own disabling until the areas being handled as TM are erased. • Once enabled, the TM function prevents further writing to the areas being handled as TM

Note 1. Access to data in operations that include the borders of the TM areas is also not allowed.

Table 63.18 Restrictions on Access to the TM Area while TM is Enabled

Type of Access	CPU	DMAC/DTC/EXDMAC/EDMAC
Instruction fetching	Yes	—
Access to data	No*1	No

Note: The same restrictions apply to on-chip debuggers as to the DMAC in the table above. For the operation of the OCD you are using in relation to the TM area, see the manual of the given OCD.

Note 1. Place data to which access will be required in areas other than the TM areas.

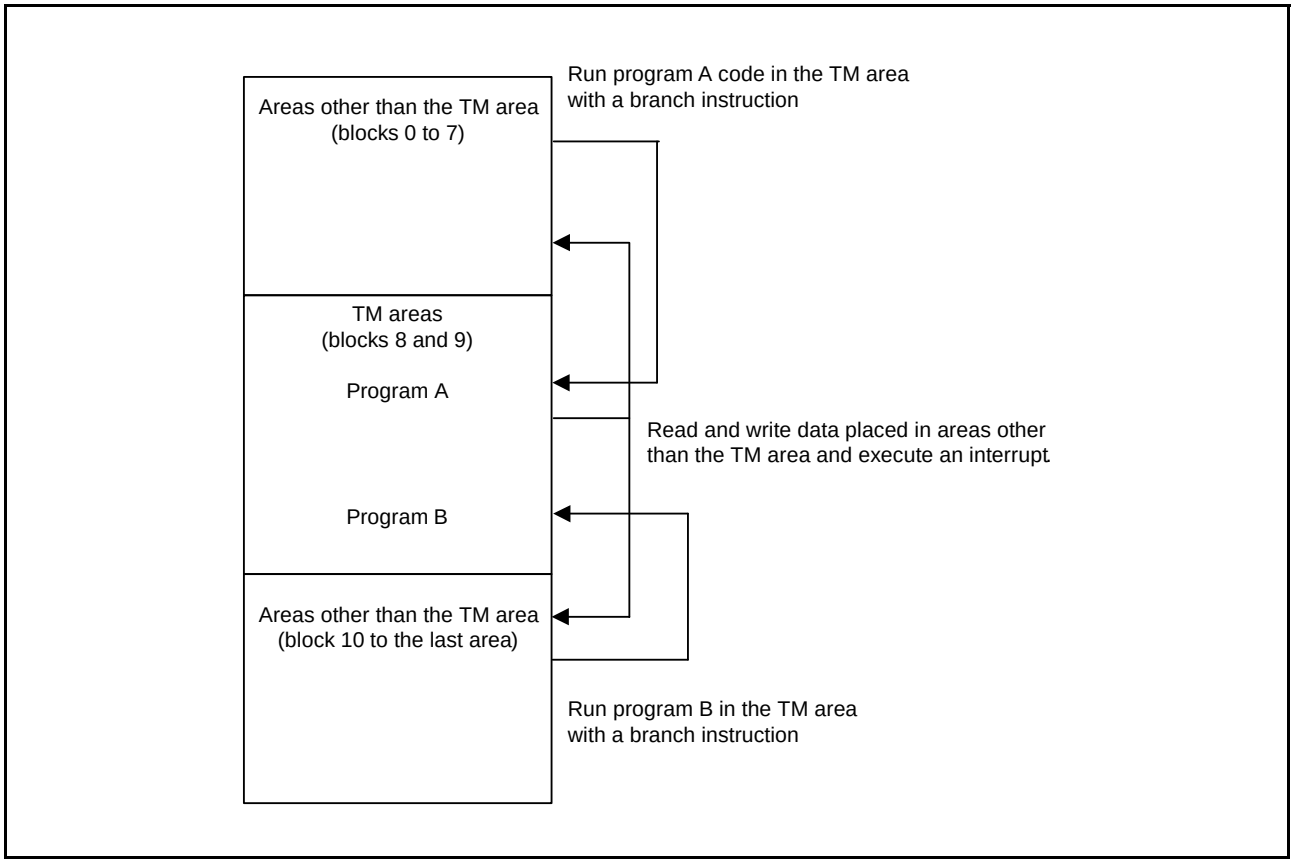

Figure 63.23 Cases where CPU is Allowed to Operate in Relation to the TM Area when the TM Function is Enabled

63.16.1 Allocating Program Code to the TM Area

When the TM function is enabled, implement countermeasures in the form of software for the TM area as required as further measures to prevent the running of programs for access to consecutive addresses in the TM areas from areas outside the TM areas.

63.16.2 How to Enable the TM Function

63.16.2.1 By Self-Programming

After writing to blocks 8 and 9 of the code flash memory, i.e. the target areas for TM, use the configuration setting command of the FACI to enable the TM function.
For the configuration setting command of the FACI, refer to Flash Memory User's Manual: Hardware Interface.
Figure 63.24 is a flowchart of the procedure for enabling the TM function by self-programming.

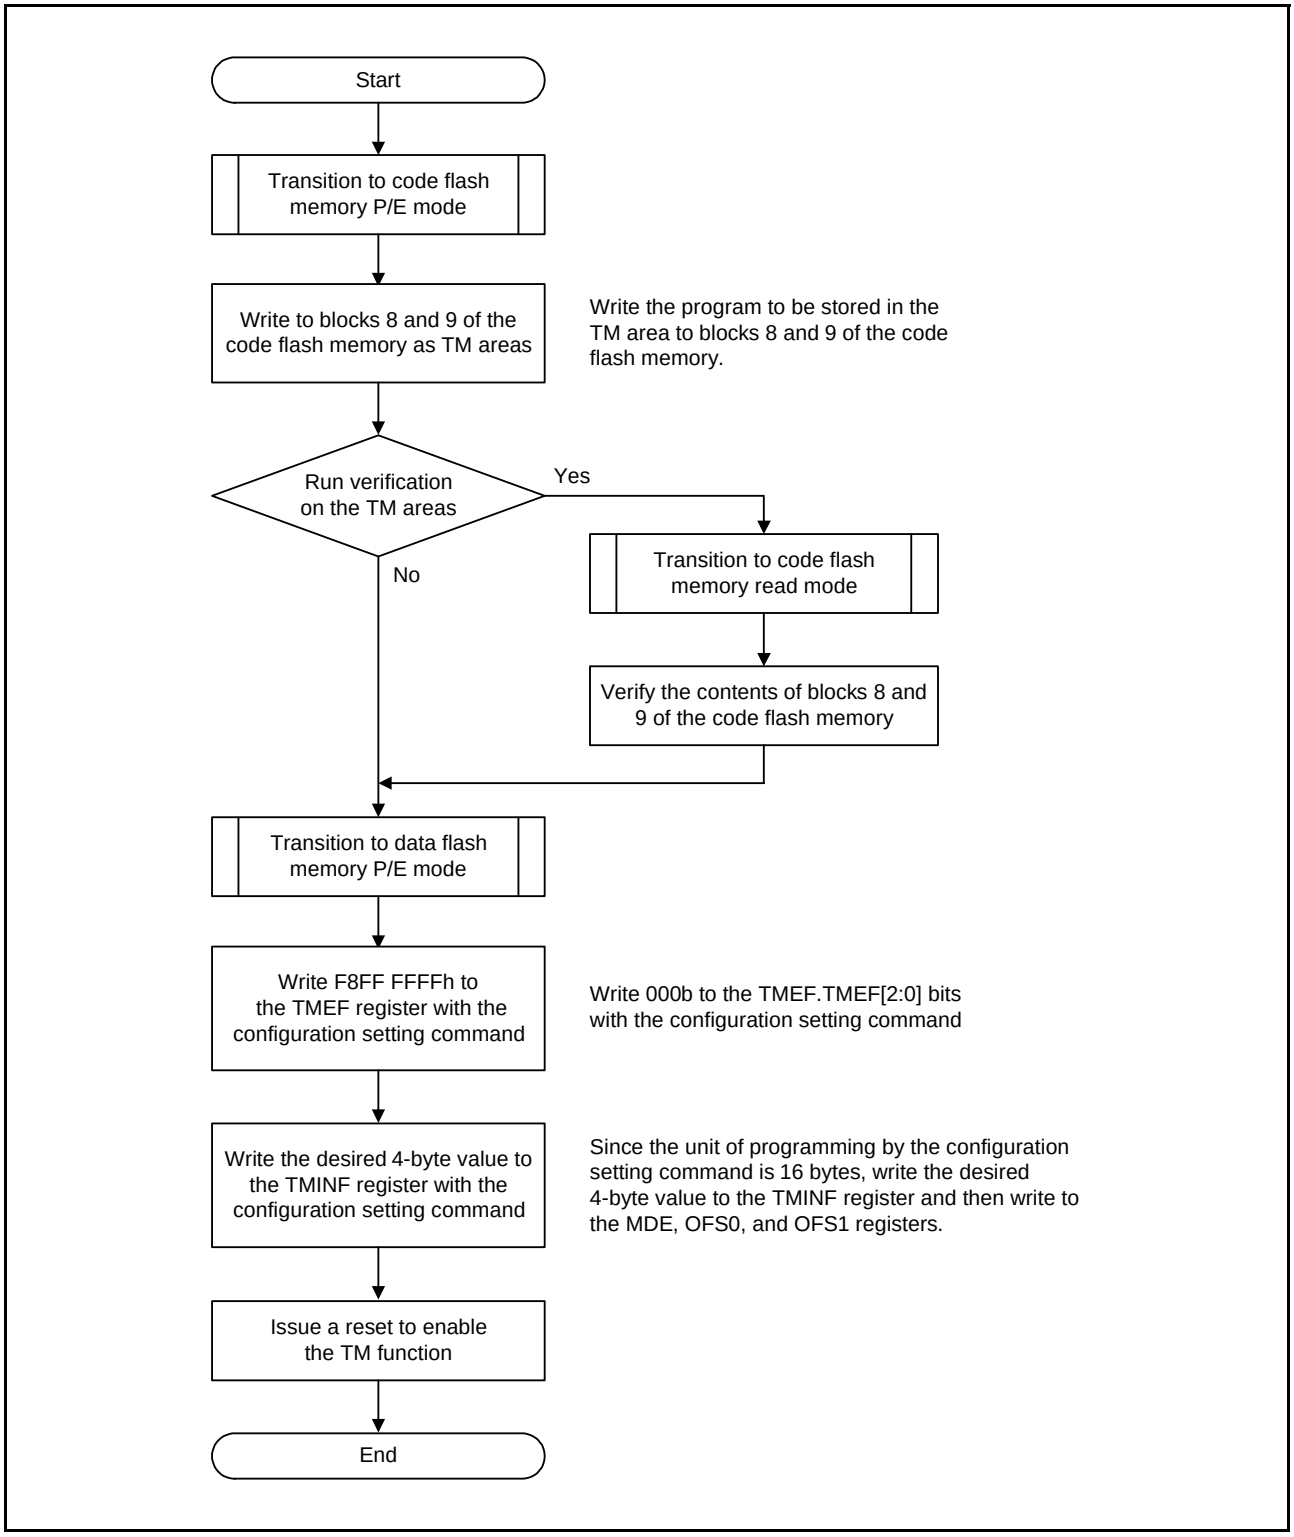

Figure 63.24 Flowchart for Enabling the TM Function by Self-Programming

63.16.3 By Using Boot Mode

In boot mode, use the TM setting command among the boot commands to enable the TM function after writing to blocks 8 and 9 of the code flash memory.

For the TM setting command among the boot commands, see section 63.12.36, TM Setting Command.

Figure 63.25 is a flowchart of enabling the TM function in boot mode.

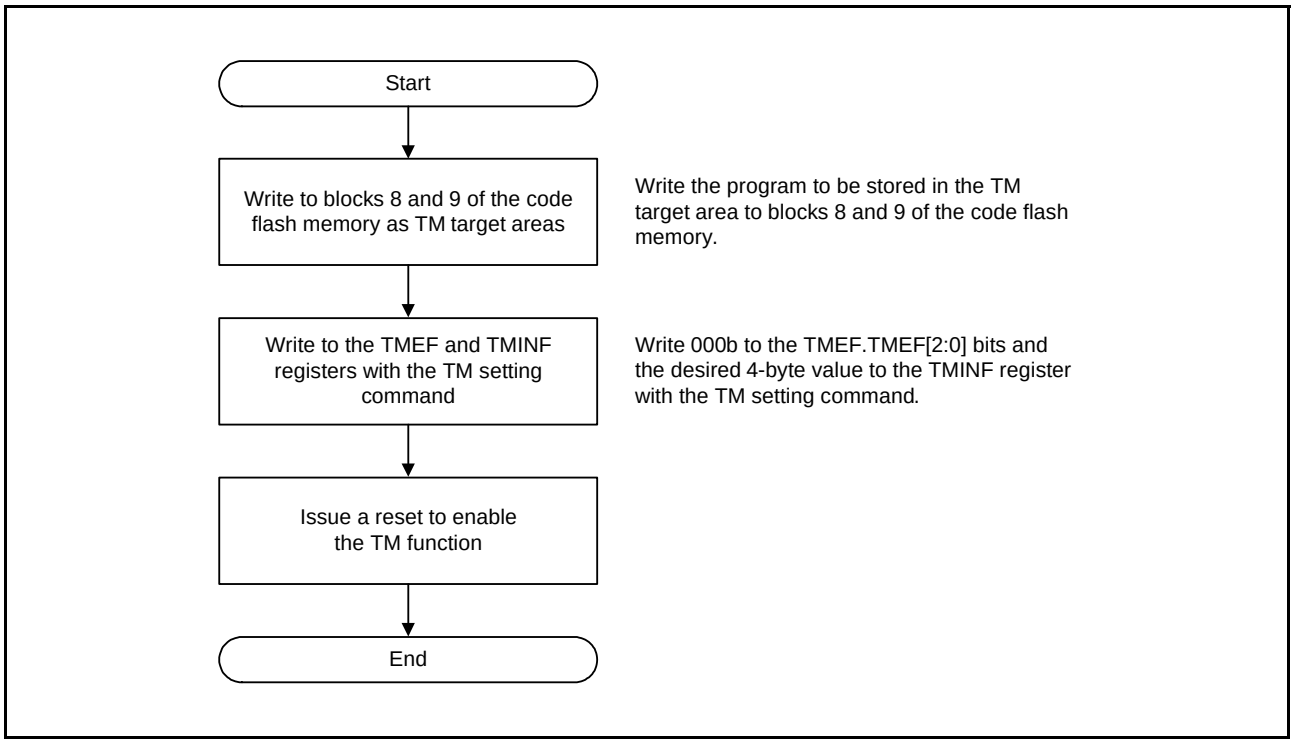

Figure 63.25 Flowchart for Enabling the TM Function by Using Boot Mode

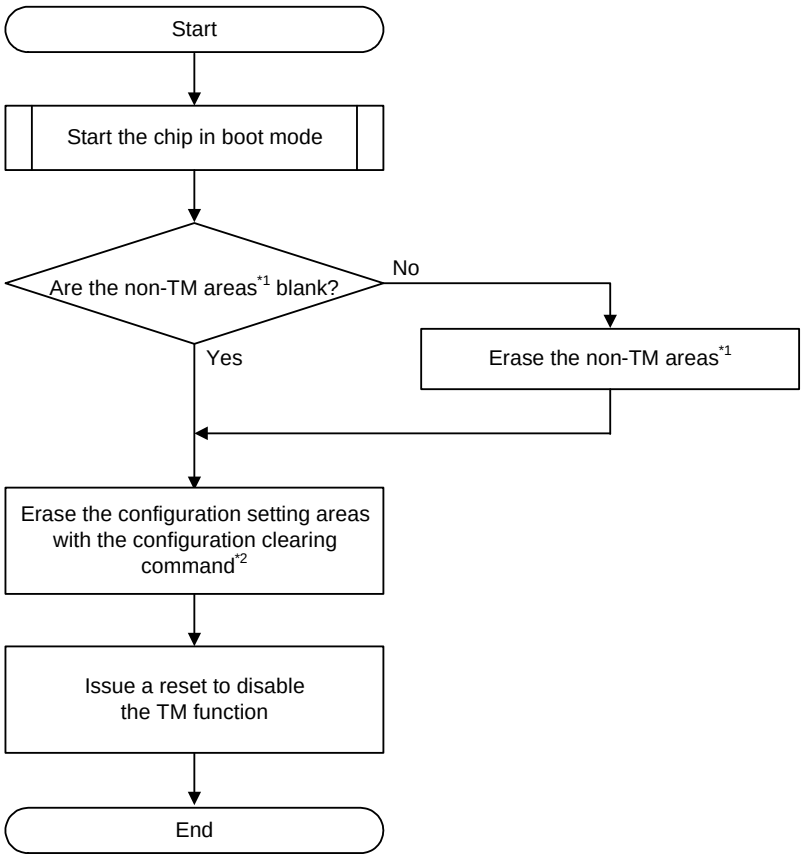
63.16.4 How to Disable the TM function

The TM function cannot be disabled unless the TM target areas are first erased with the configuration clearing command. Do not use the configuration clearing command for this purpose unless the TM function is to be disabled.
Figure 63.26 is a flowchart of disabling the TM function in boot mode.



Note 1. Non-TM areas are the data flash, user boot area, and user area other than blocks 8 and 9 of the user area.
Note 2. Issuing the configuration clearing command leads to erasure of the configuration setting areas, including the TMEF and TMINF registers, as well as the TM areas (blocks 8 and 9 of the code flash memory).

Figure 63.26 Flowchart for Disabling the TM Function in Boot Mode

63.16.5 Notes on Enabling the TM function

63.16.5.1 Protection against Access to the TM Areas

While the TM function is enabled, the only type of access to the TM areas is instruction fetching by the CPU, so do not allocate data to the TM areas.
If the CPU, DMAC, DTC, EXDMAC, or EDMAC, or OCD attempt access to data in the TM areas while the TM function is enabled, values are always read as 0 instead of the actual values.

63.16.5.2 Further Writing to the TM Areas

Further writing to the TM areas is not allowed as long as the TM function is enabled.
If you do need to write further data, follow the procedure described in section 63.16.4, How to Disable the TM function, to disable the TM function, write the modified or extended data to blocks 8 and 9 of the code flash memory, and then follow the procedure described in section 63.16.2, How to Enable the TM Function, to enable the TM function.
To erase the user area, user boot area, and data area, see section 63.12.41, Flow for Erasure when Programming Commands are Prohibited.

63.16.5.3 Executing the Configuration Clearing Command

Follow the procedure in section 63.16.4, How to Disable the TM function, before issuing the configuration clearing command.

63.16.5.4 When the MPU Setting is for Access to the TM Areas

When the TM function is enabled, even if the MPU is set to allow access to the TM target areas, the TM function takes priority.

63.16.5.5 FACI Block Erase Command for the TM Areas

There are no special restrictions on block erasure of the TM areas with the FACI block erase command. Accordingly, since each area corresponds to an erase block, the areas can be erased by issuing the block erase command.

63.16.5.6 Effect on the Setting for Command Protection

Executing the configuration clearing command to disable the TM function also initializes the command protected state at the same time.

63.16.5.7 Conditions for Correct Operation of the TM Function

The TM function operates normally under the conditions prescribed in section 64, Electrical Characteristics.

63.17 Usage Notes

(1) Reading Area Where Programming/Erasure was Interrupted and Area Targeted for Suspension

The data stored in the area where programming or erasure has been suspended or the area where programming or erasure has been suspended by using the suspend command are undefined. To avoid faulty operation caused by reading undefined data, take care not to fetch instructions or read data from areas where programming or erasure was suspended and where programming or erasure was suspended by using the suspend command.

(2) Suspension During Programming/Erasure

When processing of programming/erasure is stopped by issuing the P/E suspend command, the programming/erasure processing can be resumed by issuing the P/E resume command. If the flash sequencer enters the command-locked state for any reason and issues the forced stop command after the suspended processing is normally completed and the ERSSPD flag or PRGSPD flag is set to 1, the suspended processing cannot be resumed. In addition, the values in the area where the processing was suspended are not guaranteed. Erase that area.

(3) Prohibition of Additional Programming

Programming a given area twice is not possible. Erase the area first before programming an area of flash memory after programming to the area has been completed.

(4) Resets During Programming/Erasure or Black Checking

In the case of a reset due to the signal on the RES# pin during programming/erasure or black checking, wait for at least t_{RESWF} (see section 64, Electrical Characteristics) of the reset input period once the operating voltage is within the range stipulated in the electrical characteristics after assertion of the reset signal, and then release the device from the reset state.

(5) Allocation of Vectors for Interrupts and Other Exceptions During Programming/Erasure

Generation of an interrupt or other exception during programming/erasure may lead to fetching of the vector from the code flash memory. If the conditions for using the background operation (BGO) are not satisfied, set the address for vector to an address that is not in the code flash memory.

(6) Abnormal Termination During Programming/Erasure or Blank Checking

Even if programming/erasure ends abnormally due to the generation of a reset by the RES# pin, the programming/erasure state of the flash memory with undefined data cannot be verified or checked. For the area where programming/erasure ends abnormally, the blank check function cannot judge whether the area is erased successfully or not. Erase the area again and confirm that the corresponding area is completely erased before using.
When programming/erasure or blank checking is not completed successfully due to a voltage change that exceeds the operational voltage range, a reset on the RES# pin, the command locked state in response to error detection, or prohibited actions described in (7), the lock bit may be enabled.
In this case, erase the target block while the lock bit is disabled to erase the lock bit.

(7) Items Prohibited During Programming/Erasure or Blank Checking

High voltage is applied to the flash memory during programming/erasure or blank checking. To prevent damage to the flash memory, do not perform the following operations.

- Have the operating voltage from the power supply go beyond the permitted range.
- Change the FWEPROR.FLWE[1:0] bits.
- Change the SYSCR0.ROME bit.
- Change the OPCCR.OPCM[2:0] bits.
- Change the SCKCR.FCK[3:0] and PCLKB[3:0] bits.
- Change the SCKCR3.CKSEL[2:0] bits.

- Change the RSTCKCR.RSTCKEN bit.
- Transition to the all module clock stop mode, software standby mode, or deep software standby mode.

(8) Notes on Program Execution in Boot Mode (for the USB Interface)

- An oscillator is usable in boot mode (USB interface) when its frequency is 20 or 24 MHz and when the setting value of the main clock oscillator driving ability 2 switching bits (MOFCR.MODRV2[1:0]) are 00b in the result of the matching test conducted by the oscillator manufacturer (the recommended setting value).
- To ensure that the power supply is stable during programming/erasure of flash memory, do not connect a cable via a bus-powered HUB.

(9) Programming/Erasure in Low-Speed Operating Modes 1 and 2

Do not programming/erasure the flash memory when low-speed operating mode 1 or 2 is selected with the operating power control register (OPCCR).

Operating temperature	T_{opr}	–40 to +85	°C
Operating temperature (high-temperature products)	T_{opr}	–40 to +105 (Under planning)	°C
Storage temperature	T_{stg}	–55 to +125	°C

Caution: Permanent damage to the LSI may result if absolute maximum ratings are exceeded.

Note 1. Ports 07, 11 to 17, 20, 21, 30 to 33, 67, and C0 to C3 are 5 V tolerant.

Note 2. Connect the AVCC0, AVCC1, and VCC_USB pins to VCC, and the AVSS0, AVSS1, and VSS_USB pins to VSS.
When the A/D converter unit 0 is not to be used, connect the VREFH0 pin to VCC and the VREFL0 pin to VSS, respectively. Do not leave these pins open.
When the USBA is not to be used, connect the VCC_USBA and AVCC_USBA pins to VCC and the VSS1_USBA, VSS2_USBA, PVSS_USBA, and AVSS_USBA pins to VSS, respectively. Do not leave these pins open.

64.2 DC Characteristics

Table 64.2 DC Characteristics (1)

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 ≤ VREFH0 ≤ AVCC0,
VCC_USBA = AVCC_USBA = 3.0 to 3.6 V,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = VSS1_USBA = VSS2_USBA = PVSS_USBA = AVSS_USBA = 0 V,
$T_a = T_{opr}$

Item		Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Schmitt trigger input voltage	IRQ input pin*1 MTU input pin*1 GPT input pin*1 POE3 input pin*1 TPU input pin*1 TMR input pin*1 SCI input pin*1 ADTRG# input pin*1 RES#, NMI	V_{IH}	VCC × 0.8	—	VCC + 0.3	V

	Ports 03, 05, 12, 13, 16, 17, EMLE, BSCANP, USB0_DP, USB0_DM, USBA_DP, and USBA_DM		—	—	16		

Note 1. The input leakage current value at the EMLE and BSCANP pins are only when V_{in} = 0 V.

Table 64.4 DC Characteristics (3)

Conditions: VCC = AVCC0 = AVCC1 = VREFH0 = VCC_USB = 2.7 to 3.6 V, 2.7 ≤ VREFH0 ≤ AVCC0,
VCC_USBA = AVCC_USBA = 3.0 to 3.6 V,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = VSS1_USBA = VSS2_USBA = PVSS_USBA = AVSS_USBA = 0 V,
$T_a = T_{opr}$

Item				Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Supply current*1	High-speed operating mode	Max.*2		I_{CC}*3	—	—	110	mA	ICLK = 120 MHz PCLKA = 120 MHz PCLKB = 60 MHz PCLKC = 60 MHz PCLKD = 60 MHz FCLK = 60 MHz BCLK = 120 MHz BCLK pin = 60 MHz
		Normal	Peripheral function clock signal supplied*4		—	39	—		
			Peripheral function clock signal stopped*4		—	16	—		
		Coremark	Peripheral function clock signal stopped*4		—	21	—		
		Sleep mode: Supply of the clock signal to peripheral modules is stopped*4				32	61		
		All-module-clock-stop mode (reference value)			—	10	28		
		Increased by BGO operation *5	Reading from the code flash memory while the data flash memory is being programmed		—	7	—		
			Reading from the code flash memory while the code flash memory is being programmed		—	10	—		
	Low-speed operating mode 1: Supply of the clock signal to peripheral modules is stopped*4				—	3	—		All clocks 1 MHz
	Low-speed operating mode 2: Supply of the clock signal to peripheral modules is stopped*4				—	1.2	—		All clocks 32.768 kHz
	Software standby mode				—	0.7	10		
	Deep software standby mode	Power supplied to standby RAM and USB resume detecting unit (USB0 only)			—	22	63	μA	
		Power not supplied to standby RAM and USB resume detecting unit (USB0 only)	Power-on reset circuit and low-power consumption function disabled*6		—	12.5	26		
			Power-on reset circuit and low-power consumption function enabled*7		—	3.1	13.5		
		Increased by RTC operation	When a crystal resonator for low clock loads is in use		—	0.6	—		
			When a crystal resonator for standard clock loads is in use		—	2.0	—		
	RTC operating while VCC is off (with the battery backup function, only the RTC and sub-clock oscillator operate)		When a crystal resonator for low clock loads is in use		—	0.9	—		V_{BATT} = 2.0 V, VCC = 0 V
					—	1.6	—		V_{BATT} = 3.3 V, VCC = 0 V
			When a crystal resonator for standard clock loads is in use		—	1.7	—		V_{BATT} = 2.0 V, VCC = 0 V
					—	3.3	—		V_{BATT} = 3.3 V, VCC = 0 V

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. Supply of the clock signal to peripheral modules is stopped in this state. This does not include operations as BGO (background operations).
Note 3. I_{CC} depends on f (ICLK) as follows. (ICLK/PCLKA:PCLKB/PCLKC/PCLKD:BCLK:BCLK pin = 10:5:10:5 when EXTAL = 12 MHz)
I_{CC} Max. = 0.77 × f + 18 (max. operation in high-speed operating mode)
I_{CC} Typ. = 0.08 × f + 6 (normal operation in high-speed operating mode)
I_{CC} Typ. = 0.5 × f + 2.6 (low-speed operating mode 1)
I_{CC} Max. = 0.36 × f + 18 (sleep mode)
Note 4. This does not include operations as BGO (background operations). Whether supply of the clock signal to peripheral modules continues or is stopped only depends on the state determined by the settings of the bits in module stop control registers A to D. The setting for the peripheral module clock stopped state is FCLK = BCLK = PCLKA = PCLKB = PCLKC = PCLKD = BCLK pin = 3.75 MHz (division by 64).
Note 5. This is the increase for programming or erasure of the code flash memory (limitations apply to the combinations of ranges in which writing proceed) or data flash memory during program execution in the code flash memory.
Note 6. The low power consumption function is disabled and DEEPCUT[1:0] = 01b.
Note 7. The low power consumption function is enabled and DEEPCUT[1:0] = 11b.

Table 64.5 DC Characteristics (4)

Conditions: VCC = AVCC0 = AVCC1 = VREFH0 = VCC_USB = 2.7 to 3.6 V, 2.7 ≤ VREFH0 ≤ AVCC0,
VCC_USBA = AVCC_USBA = 3.0 to 3.6 V,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = VSS1_USBA = VSS2_USBA = PVSS_USBA = AVSS_USBA = 0 V,
$T_a = T_{opr}$

Item			Symbol	Min.	Typ.	Max.	Unit	Test Conditions

	During 12-bit A/D conversion (unit 0) with the channel-dedicated sample-and-hold circuits for 3 channels operating			—	1.7	2.5	mA	IAVCC0_AD+SH
	During 12-bit A/D conversion (unit 1)			—	0.6	1.0	mA	IAVCC1_AD
	During 12-bit A/D conversion (unit 1) with the temperature sensor operating			—	0.7	1.1	mA	IAVCC1_AD+TEMP
	During D/A conversion (per unit)	Without AMP output		—	0.24	0.4	mA	IAVCC1_DA
		With AMP output		—	0.4	0.7	mA	
	Waiting for A/D, D/A, or temperature sensor conversion (all units)			—	0.9	1.4	mA	IAVCC0 + IAVCC1
	A/D, D/A converter, temperature sensor in standby mode (all units)			—	1.3	3.0	µA	IAVCC0 + IAVCC1
Reference power supply current	During 12-bit A/D conversion (unit 0)		AI_{REFH}	—	70	120	µA	IVREFH0
	Waiting for 12-bit A/D conversion (unit 0)			—	0.07	0.4	µA	IVREFH0
	12-bit A/D converter in standby mode (unit 0)			—	0.07	0.2	µA	IVREFH0
USB operating current	Low speed	USB0	$I_{CCUSBLS}$	—	3.5	6.5	mA	VCC_USB
		USBA		—	8.5	12.0	mA	VCC_USBA = AVCC_USBA (PHYSET.HSEB = 0)
		USBA		—	2.8	3.6	mA	VCC_USBA = AVCC_USBA (PHYSET.HSEB = 1)
	Full speed	USB0	$I_{CCUSBFS}$	—	4.0	10.0	mA	VCC_USB
		USBA		—	12.0	20.0	mA	VCC_USBA = AVCC_USBA (PHYSET.HSEB = 0)
		USBA		—	6.5	13.0	mA	VCC_USBA = AVCC_USBA (PHYSET.HSEB = 1)
	Standby mode (direct power down)	USBA	$I_{CCUSBSBY}$	—	0.1	3.0	µA	VCC_USBA = AVCC_USBA
RAM standby voltage			V_{RAM}	2.7	—	—	V	
VCC rising gradient			SrVCC	8.4	—	20000	µs/V	
VCC falling gradient*2			SfVCC	8.4	—	—	µs/V	

Note 1. The reference power supply current is included in the power supply current value for 12-bit A/D conversion (unit 1) and D/A conversion.

Note 2. This applies when V_{BATT} is used.

Table 64.6 Permissible Output Currents

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 ≤ VREFH0 ≤ AVCC0,
VCC_USBA = AVCC_USBA = 3.0 to 3.6 V,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = VSS1_USBA = VSS2_USBA = PVSS_USBA = AVSS_USBA = 0 V,
$T_a = T_{opr}$

Item			Symbol	Min.	Typ.	Max.	Unit
Permissible output low current (average value per pin)	All output pins*1	Normal drive	I_{OL}	—	—	2.0	mA
	All output pins*2	High drive	I_{OL}	—	—	3.8	mA
Permissible output low current (max. value per pin)	All output pins*1	Normal drive	I_{OL}	—	—	4.0	mA
	All output pins*2	High drive	I_{OL}	—	—	7.6	mA
Permissible output low current (total)	Total of all output pins		ΣI_{OL}	—	—	80	mA
Permissible output high current (average value per pin)	All output pins*1	Normal drive	I_{OH}	—	—	–2.0	mA
	USB_DPUPE pin*2	High drive	I_{OH}	—	—	–3.8	mA
Permissible output high current (max. value per pin)	All output pins*1	Normal drive	I_{OH}	—	—	–4.0	mA
	All output pins*2	High drive	I_{OH}	—	—	–7.6	mA
Permissible output high current (total)	Total of all output pins		ΣI_{OH}	—	—	–80	mA

Caution: To protect the LSI's reliability, the output current values should not exceed the values in this table.

Note 1. This is the value when normal driving ability is set with a pin for which normal driving ability is selectable.

Note 2. This is the value when high driving ability is set with a pin for which normal driving ability is selectable or the value of the pin to which high driving ability is fixed.

64.3 AC Characteristics

Table 64.7 Operating Frequency (High-Speed Operating Mode)

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 ≤ VREFH0 ≤ AVCC0,
VCC_USBA = AVCC_USBA = 3.0 to 3.6 V,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = VSS1_USBA = VSS2_USBA = PVSS_USBA = AVSS_USBA = 0 V,
$T_a = T_{opr}$

Item			Symbol	Min.	Typ.	Max.	Unit

VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = VSS1_USBA = VSS2_USBA = PVSS_USBA = AVSS_USBA = 0 V,
V_{BATT} = 2.0 to 3.6 V, $T_a = T_{opr}$

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Sub-clock oscillation frequency	f_{SUB}	—	32.768	—	kHz	
Sub-clock oscillation stabilization time	t_{SUBOSC}	—	—	*1	s	Figure 64.11
Sub-clock oscillation stabilization wait time	$t_{SUBOSCWT}$	—	—	*2	s	

Note 1. When using a sub-clock, ask the manufacturer of the oscillator to evaluate its oscillation. Refer to the results of evaluation provided by the manufacturer for the oscillation stabilization time.

Note 2. The number of cycles selected by the value of the SOSCWTCR.SSTS[7:0] bits determines the sub-clock oscillation stabilization wait time in accord with the formula below.
$t_{SUBOSCWT}$ = [(SSTS[7:0] bits × 16384) + 10] / f_{LOCO}

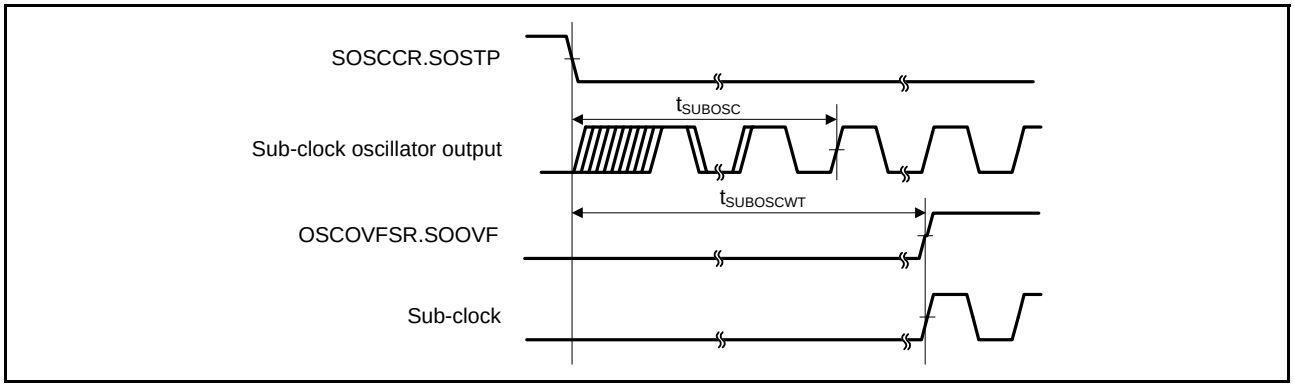

Figure 64.11 Sub-Clock Oscillation Start Timing

64.3.3 Timing of Recovery from Low Power Consumption Modes

Table 64.18 Timing of Recovery from Low Power Consumption Modes (1)

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 ≤ VREFH0 ≤ AVCC0,
VCC_USBA = AVCC_USBA = 3.0 to 3.6 V,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = VSS1_USBA = VSS2_USBA = PVSS_USBA = AVSS_USBA = 0 V,
$T_a = T_{opr}$

Item			Symbol	Min.	Typ.	Max.		Unit	Test Conditions
						$t_{SBYOSCWT}$*2	t_{SBYSEQ}*3		
Recovery time after cancellation of software standby mode*1	Crystal resonator connected to main clock oscillator	Main clock oscillator operating	t_{SBYMC}	—	—	{(MSTS[7:0] bits × 32) + 76 } / 0.216	100 µs + 7/f_{ICLK} + 2n/f_{MAIN}	µs	Figure 64.12
		Main clock oscillator and PLL circuit operating	t_{SBYPC}			{(MSTS[7:0] bits × 32) + 138 } / 0.216	100 µs + 7/f_{ICLK} + 2n/f_{PLL}		
	External clock input to main clock oscillator	Main clock oscillator operating	t_{SBYEX}			352	100 µs + 7/f_{ICLK} + 2n/f_{EXMAIN}		
		Main clock oscillator and PLL circuit operating	t_{SBYPE}			639	100 µs + 7/f_{ICLK} + 2n/f_{PLL}		
	Sub-clock oscillator operating		t_{SBYSC}			{(SSTS[7:0] bits × 16384) + 13 } / 0.216 + 10/f_{FCLK}	100 µs + 4/f_{ICLK} + 2n/f_{SUB}		
	High-speed on-chip oscillator operating	High-speed on-chip oscillator operating	t_{SBYHO}			454	100 µs + 7/f_{ICLK} + 2n/f_{HOCO}		
		High-speed on-chip oscillator operating and PLL circuit operating	t_{SBYPH}			741	100 µs + 7/f_{ICLK} + 2n/f_{PLL}		
	Low-speed on-chip oscillator operating*4		t_{SBYLO}			338	100 µs + 7/f_{ICLK} + 2n/f_{LOCO}		

Note 1. The time for return after release from software standby is determined by the value obtained by adding the oscillation stabilization waiting time ($t_{SBYOSCWTO}$) and the time required for operations by the software standby release sequencer (t_{SBYSEQ}).
Note 2. When several oscillators were running before the transition to software standby, the greatest value of the oscillation stabilization waiting time $t_{SBYOSCWT}$ is selected.
Note 3. For n, the greatest value is selected from among the internal clock division settings.
Note 4. This condition applies when f_{ICLK}:f_{FCLK} = 1:1, 2:1, or 4:1.

Data hold time*3		t_{DRP}	10	—	—	10	—	—	Year
FCU reset time		t_{FCUR}	35	—	—	35	—	—	µs

Note 1. Definition of reprogram/erase cycle:
The reprogram/erase cycle is the number of erasing for each block. When the reprogram/erase cycle is n times (n = 1000), erasing can be performed n times for each block. For instance, when 256-byte programming is performed 32 times for different addresses in 8-Kbyte block and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address for several times as one erasing is not enabled (overwriting is prohibited).

Note 2. This is the minimum number of times to guarantee all the characteristics after reprogramming (guaranteed range is from 1 to the value of the minimum value).

Note 3. This shows the characteristics when reprogramming is performed within the specified range, including the minimum value.

Table 64.54 Data Flash Memory Characteristics

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 ≤ VREFH0 ≤ AVCC0,
VCC_USBA = AVCC_USBA = 3.0 to 3.6 V
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = VSS1_USBA = VSS2_USBA = PVSS_USBA = AVSS_USBA = 0 V,
Temperature range for programming/erasure: $T_a = T_{opr}$

Item		Symbol	FCLK = 4 MHz			20 MHz ≤ FCLK ≤ 60 MHz			Unit
			Min.	Typ.	Max.	Min.	Typ.	Max.	
Programming time	4 bytes	t_{DP4}	—	0.36	3.8	—	0.16	1.7	ms
Erasure time	64 bytes	t_{DE64}	—	3.1	18	—	1.7	10	ms
Blank check time	4 bytes	t_{DBC4}	—	—	84	—	—	30	µs
	64 bytes	t_{DBC64}	—	—	280	—	—	100	µs
	2 Kbytes	t_{DBC2K}	—	—	6169	—	—	2200	µs
Reprogramming/erasure cycle*1		N_{DPEC}	100000 *2	—	—	100000 *2	—	—	—
Suspend delay time during programming		t_{DSPD}	—	—	264	—	—	120	µs
First suspend delay time during erasure (in suspend priority mode)		t_{DSESD1}	—	—	216	—	—	120	µs
Second suspend delay time during erasure (in suspend priority mode)		t_{DSESD2}	—	—	300	—	—	300	µs
Suspend delay time during erasing (in erasure priority mode)		t_{DSEED}	—	—	300	—	—	300	µs
Forced stop command		t_{FD}	—	—	32	—	—	20	µs
Data hold time*3		t_{DDRP}	10	—	—	10	—	—	—

Note 1. Definition of reprogram/erase cycle:
The reprogram/erase cycle is the number of erasing for each block. When the reprogram/erase cycle is n times (n = 100000), erasing can be performed n times for each block. For instance, when 4-byte programming is performed 512 times for different addresses in 2-Kbyte block and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address for several times as one erasing is not enabled (overwriting is prohibited).

Note 2. This is the minimum number of times to guarantee all the characteristics after reprogramming (guaranteed range is from 1 to the value of the minimum value).

Note 3. This shows the characteristics when reprogramming is performed within the specified range, including the minimum value.

USB0_DP	All		Hi-Z	Keep-O *4		Hi-Z*3	Hi-Z	
USBA_DM	All		Hi-Z	Keep-O *4		Hi-Z*5	Hi-Z	
USBA_DP	All		Hi-Z	Keep-O *4		Hi-Z*5	Hi-Z	

H: High-level
L: Low-level
Keep-O: Output pins retain their previous values, and input pins become high-impedance.
Keep: Pin states are retained during periods on software standby.
Hi-Z: High-impedance

Note 1. Retains the I/O port state until the DPSBYCR.IOKEEP bit is cleared to 0.
Note 2. Input is enabled if the pin is specified as the software standby cancelling source while it is used as an external interrupt pin.
Note 3. Input is enabled if the pin is specified as the deep software standby cancelling source.
Note 4. Input is enabled while the pin is used as an input pin.
Note 5. For the host operation, set the DPUSR0R.DRPD0 bit to 1 to enable the DP and DM pull-down resistors.
For the function operation, set the DPUSR0R.RPUE0 bit to 1 to enable the DP pull-up resistor.

Appendix 2. Package Dimensions

REVISION HISTORY	RX64M Group User's Manual: Hardware

Rev.	Date	Description	
		Page	Summary
0.90	Jul 24, 2013	—	First edition, issued
1.00	Jul 31, 2014	1. Overview	
		—	FINEC (Pin), deleted
		70	Table 1.1 Outline of Specifications (1/9), changed
		76	Table 1.1 Outline of Specifications (7/9), changed
		77	Table 1.1 Outline of Specifications (8/9), changed
		93	Table 1.4 Pin Functions (8/8), Note added
		7. Option Setting Memory	
		—	TM Enable Flag Register (TMEF), TM Identification Data Register (TMINF), added
		265	7.2.6 TM Enable Flag Register (TMEF), changed
		8. Voltage Detection Circuit (LVDA)	
		278	8.2.5 Voltage Monitoring Circuit Control Register (LVCMPCR), notes added
		285	Table 8.4 Procedures for Setting Bits Related to the Voltage Monitoring 1 Interrupt and Voltage Monitoring 1 Reset so that Voltage Monitoring Operates, Note 4 added
		288	Table 8.6 Procedures for Setting Bits Related to the Voltage Monitoring 2 Interrupt and Voltage Monitoring 2 Reset so that Voltage Monitoring Operates, Note 4 added
		9. Clock Generation Circuit	
		296	9.2.1 System Clock Control Register (SCKCR), changed
		308	9.2.11 High-Speed On-Chip Oscillator Control Register (HOCOCR), changed
		313	9.2.15 Oscillation Stop Detection Status Register (OSTDSR), changed
		326	9.7.6 USB Clock, changed
		327	9.7.7 USBA Clock, changed
		15. Interrupt Controller (ICUA)	
		460	15.4.5.3 EXDMAC Start Request by Software Configurable Interrupts, changed
		464	15.5.3 Group Interrupts Using Edge Detection, changed
		18. DMA Controller (DMACAa)	
		618	18.2.7 DMA Address Mode Register (DMAMD), changed
		646	Figure 18.15 DMAC Interrupt Handling Routine to Resume/Terminate DMA Transfer, changed
		20. Data Transfer Controller (DTCa)	
		741, 742	20.6.2 Chain Transfer
		24. Multi-Function Timer Pulse Unit (MTU3a)	
		—	Terms unified: Counter clock→Count clock Synchronous presetting→Synchronous setting Preset→Set
		884	24.2.13 Timer Counter (TCNT), changed 24.2.14 Timer Longword Counter (TCNTLW), changed
		885	24.2.15 Timer General Register (TGR), changed
		886	24.2.16 Timer Longword General Register (TGRnLW) (n = A, B)
		972	Figure 24.48 Example of Complementary PWM Mode Setting Procedure, changed
		984, 985	Figure 24.56 Example of Waveform Output in Complementary PWM Mode (MTU3 and MTU4) (1) to Figure 24.58 Example of Waveform Output in Complementary PWM Mode (MTU3 and MTU4) (3), changed
		986 to 988	Figure 24.59 Example of 0% and 100% Waveform Output in Complementary PWM Mode (MTU3 and MTU4) (1) to Figure 24.63 Example of 0% and 100% Waveform Output in Complementary PWM Mode (MTU3 and MTU4) (5), changed
		27. 16-Bit Timer Pulse Unit (TPUa)	
		1325	Table 27.30 Correspondence between Channels and TSTRA.CSTn bit, changed
		1326	Table 27.31 TGR and TIOR Used for Input Capture by ELC, changed
		1328	(3) Input Capture Operation, changed
		28. Programmable Pulse Generator (PPG)	
		1352, 1353	Figure 28.6 Sample Setup Procedure for Normal Pulse Output (PPG0 Setting) and Figure 28.7 Sample Setup Procedure for Normal Pulse Output (PPG1 Setting), changed

Rev.	Date	Description	
		Page	Summary
1.00	Jul 31, 2014	1356, 1357	Figure 28.11 Sample Setup Procedure for Non-Overlapping Pulse Output (PPG0 Setting) and Figure 28.12 Sample Setup Procedure for Non-Overlapping Pulse Output (PPG1 Setting), changed
		32. Realtime Clock (RTCd)	
		1450	32.2.21 Frequency Register H/L (RFRH/RFRL), changed
		33. Watchdog Timer (WDTA)	
		1481	33.2.3 WDT Status Register (WDTSR), changed
		35. Ethernet Controller (ETHERC)	
		1510	Table 35.2 ETHERC I/O Pins (n = 0, 1), changed
		1518	35.2.7 Random Number Generation Counter Limit Setting Register (RDMLR), changed
		1531, 1532	Figure 35.6 MII Frame Transmit Timing During Normal Transmission, changed Figure 35.7 MII Frame Transmit Timing When Collision Occurs, changed Figure 35.8 MII Frame Transmit Timing When Transmit Error Occurs, changed Figure 35.9 MII Frame Receive Timing During Normal Reception, changed Figure 35.10 MII Frame Receive Timing for Receive Error Notification, changed Figure 35.11 MII Fame Receive Timing for False Carrier Notification, changed
		1533	Figure 35.12 RMII Frame Transmit Timing During Normal Transmission, changed Figure 35.13 RMII Frame Receive Timing During Normal Reception, changed Figure 35.14 RMII Frame Receive Timing When False Carrier Is Detected, changed
		36. PTP Module for the Ethernet Controller (EPTPC)	
		1628	36.2.78 Asymmetric Delay Setting Registers (DASYMRU, DASYMRL), changed
		1645	Table 36.17 List of the Registers for which Settings are Required, changed
		1675	36.6.2 Wait Cycles for Register Access, changed
		38. USB 2.0 FS Host/Function Module (USBb)	
		1717	Table 38.1 USB Specifications, changed
		1722	Table 38.4 Status of USB Data Bus Lines (D+ Line, D. Line), changed
		39. USB2.0 Full-Speed Host/Function Module (USBA)	
		1828	Figure 39.1 USBA Block Diagram, changed
		1829, 1830	39.2.1 System Configuration Control Register (SYSCFG), changed
		1832, 1833	39.2.3 System Configuration Status Register (SYSSTS0), changed
		1834 to 1836	39.2.5 Device State Control Register 0 (DVSTCTR0), changed
		1837 to 1839	39.2.6 FIFO Port Registers, changed
		1840, 1841	39.2.7 CFIFO Port Select Register (CFIFOSEL), changed
		1842, 1843	39.2.8 D0FIFO Port Select Register (D0FIFOSEL) D1FIFO Port Select Register (D1FIFOSEL), changed
		1844, 1845	39.2.9 CFIFO Port Control Register (CFIFOCTR) D0FIFO Port Control Register (D0FIFOCTR) D1FIFO Port Control Register (D1FIFOCTR), changed
		1846	39.2.10 Interrupt Enable Register 0 (INTENB0), changed
		1847	39.2.11 Interrupt Enable Register 1 (INTENB1), changed
		1848	39.2.12 BRDY Interrupt Enable Register (BRDYENB), changed 39.2.13 NRDY Interrupt Enable Register (NRDYENB), changed
		1849	39.2.14 BEMP Interrupt Enable Register (BEMPENB), changed
		1850	39.2.15 SOF Output Configuration Register (SOFCFG), changed
		1851	39.2.16 PHY Setting Register (PHYSET), changed
		1852, 1853	39.2.17 Interrupt Status Register 0 (INTSTS0), changed
		1854 to 1856	39.2.18 Interrupt Status Register 1 (INTSTS1), changed
		1857	39.2.19 BRDY Interrupt Status Register (BRDYSTS), changed 39.2.20 NRDY Interrupt Status Register (NRDYSTS), changed
		1858	39.2.21 BEMP Interrupt Status Register (BEMPSTS), changed
		1859	39.2.22 Frame Number Register (FRMNUM), changed
		1860	39.2.23 USB Address Register (USBADDR), changed
		1863	39.2.28 Default Control Pipe Configuration Register (DCPCFG), changed
		1864	39.2.29 Default Control Pipe Maximum Packet Size Register (DCPMAXP), changed
		1868	39.2.31 Pipe Window Select Register (PIPESEL), changed
		1869 to 1871	39.2.32 Pipe Configuration Register (PIPECFG), changed
		1872, 1873	39.2.33 Pipe Buffer Register (PIPEBUF), changed
		1874	39.2.34 Pipe Maximum Packet Size Register (PIPEMAXP), changed
		1875	39.2.35 Pipe Cycle Control Register (PIPEPERI), changed

Rev.	Date	Description	
		Page	Summary
1.00	Jul 31, 2014	1876 to 1880	39.2.36 Pipe n Control Register (PIPEnCTR) (n = 1 to 9), changed
		1881	39.2.37 Pipe n Transaction Counter Enable Register (PIPEnTRE) (n = 1 to 5), changed
		1882	39.2.38 Pipe n Transaction Counter Register (PIPEnTRN) (n = 1 to 5), changed
		1883	39.2.39 Device Address m Configuration Register (DEVADDm) (m = 0 to A), changed
		1884	39.2.40 Low Power Control Register (LPCTRL), changed
		1885	39.2.41 Low Power Status Register (LPSTS), changed
		1886, 1887	39.2.42 Battery Charging Control Register (BCCTRL), changed
		1888, 1889	39.2.43 Function L1 Control Register 1 (PL1CTRL1), changed
		1890	39.2.44 Function L1 Control Register 2 (PL1CTRL2), changed 39.2.45 Host L1 Control Register 1 (HL1CTRL1), changed
		1891, 1892	39.2.46 Host L1 Control Register 2 (HL1CTRL2), changed
		1893	39.2.48 Deep Standby USB Suspend/Resume Interrupt Register (DPUSR1R), changed
		1894	39.3.1.2 Selecting the Controller Function, changed
		1895	Figure 39.2 PHY Clock Settings in Classic-Only Mode, changed
		1896	Figure 39.3 PHY Clock Settings When Not Using Classic-Only Mode, changed
		1897, 1898	39.3.5 Interrupts, changed
		1898	39.3.5.1 Setting the USBAR Interrupt Signal Output Method, changed
		1899	Figure 39.5 Interrupt Association Diagram, changed
		1901, 1902	39.3.6.1 BRDY Interrupt, changed
		1904	39.3.6.2 NRDY Interrupt, changed
		1906	Figure 39.7 NRDY Interrupt Generation Timing (In Function Controller Operation), changed
		1907	39.3.6.3 BEMP Interrupt, changed
		1909	39.3.6.5 Control Transfer Stage Transition Interrupt in Function Controller Operation, changed
		1910	39.3.6.6 Frame Number Refresh Interrupt, changed
		1911	39.3.6.18 L1RSMEND Interrupt, changed
		1912	Table 39.18 Pipe Setting Items, changed
		1914	39.3.7.4 Setting the Maximum Packet Size, changed
		1917	39.3.8.1 FIFO Buffers, changed
		1918	39.3.8.2 Clearing the FIFO Buffers, changed
		1919	39.3.8.3 FIFO Port Functions, changed
		1920	39.3.8.4 DMA/DTC Transfers (D0FIFO and D1FIFO Ports), changed
		1921	39.3.8.5 Allocating the FIFO Buffers, changed Figure 39.12 Example of a FIFO Buffer Memory Map, changed
		1922	39.3.9.1 Control Transfer in Host Controller Operation, changed
		1924	39.3.11 Interrupt Transfer for Pipes 6 to 9, changed 39.3.12 Isochronous Transfer for Pipes 1 and 2, changed
		1926	39.3.12.2 Data PID, changed
		1927	Figure 39.13 Token Issuance When IITV[2:0] Bits are 000b, changed Figure 39.14 Token Issuance When IITV[2:0] Bits are 001b, changed
		1928	Figure 39.15 Relationship between Frames and Token Reception Expectance When the IITV[2:0] Bits are 000b, changed Figure 39.16 Relationship between Frames and Token Reception Expectance When the IITV[2:0] Bits are 001b, changed
		1929	(b) When the selected pipe is for isochronous IN transfers, changed (4) Isochronous Transfer Transmit Data Setup in Function Controller Operation, changed
		1930	Figure 39.17 Example of Data Setup Function Operation, changed
		1931, 1932	(5) Isochronous Transfer Transmit Buffer Flush in Function Controller Operation, changed
		1933	39.3.13 SOF Recovery Function, changed
		1934	39.3.14 Pipe Schedule, changed
		1935, 1936	39.3.15.1 Processing in Function Controller Operation, changed Figure 39.20 Processing as a Portable Device, changed
		1937 to 1939	39.3.15.2 Processing in Host Controller Operation, changed
		1940, 1941	39.3.16 Link Power Management Processing, changed
		1942 to 1945	39.3.17 USB External Connection Circuit, added
		40. Serial Communications Interface (SCIg, SCIh)	
		1946	Table 40.1 SCIg Specifications (2/2), changed
		1971, 1972	40.2.8 Serial Control Register (SCR) (2) Smart Card Interface Mode (SCMR.SMIF = 1), changed
		2041	40.6.5 SCI Initialization (Smart Card Interface Mode), changed

Rev.	Date	Description	
		Page	Summary
1.00	Jul 31, 2014	42. I2C Bus Interface (RIICa)	
		2154	42.2.7 I2C Bus Status Enable Register (ICSER), changed
		2168	Table 42.5 Examples of ICBRH/ICBRL Settings for Transfer Rate, changed
		2176	42.3.4 Master Receive Operation (5), changed
		2181	42.3.5 Slave Transmit Operation (3), changed
		2196	42.8.2 NACK Reception Transfer Suspension Function, changed
		2198	42.9.1 Master Arbitration-Lost Detection (MALE Bit), changed
		2206	42.11.2 Extra SCL Clock Cycle Output Function, changed
		2208	42.12 SMBus Operation, changed
		2209	42.12.3 SMBus Host Notification Protocol (Notify ARP Master Command), changed
		2210	Table 42.6 Interrupt Sources, changed
		43. CAN Module (CAN)	
		2248	BLIF Flag (Bus Lock Detect Flag), changed
		2253	Figure 43.9 Transition between CAN Operating Modes, changed
		2255	Table 43.8 Operation in CAN Reset Mode and CAN Halt Mode, changed
		44. Serial Peripheral Interface (RSPIa)	
		2284	44.2.8 RSPI Bit Rate Register (SPBR), changed
		45. Quad Serial Peripheral Interface (QSPI)	
		2351	Figure 45.1 QSPI Block Diagram, changed
		2359	45.2.8 QSPI Bit Rate Register (SPBR), changed
		2364 to 2366	45.2.13 QSPI Command Register n (SPCMDn) (n = 0 to 3), changed
		2369	45.2.16 QSPI Transfer Data Length Multiplier Setting Register n (SPBMULn) (n = 0 to 3), changed
		2386	(c) Sequence Control, changed
		47. Serial Sound Interface (SSI)	
		2405, 2408	47.2.1 Control Register (SSICR), changed
		2409	47.2.2 Status Register (SSISR), changed
		2411	47.2.3 FIFO Control Register (SSIFCR), changed
		2426	Figure 47.19 Transmission Using the DMAC/DTC, changed
		2427	Figure 47.20 Transmission Using Interrupts, changed
		50. MultiMediaCard Interface (MMCIF)	
		2511	50.2.8 Response Register 0 (CERESP0), Response Register 1 (CERESP1), Response Register 2 (CERESP2), Response Register 3 (CERESP3), changed
		58. 12-Bit D/A Converter (R12DA)	
		2699	58.3 Operation, changed
		63. Flash Memory	
		2726	Table 63.1 Specifications of Code Flash Memory and Data Flash Memory, changed
		2728	63.2 Structure of Memory, changed Figure 63.2 Mapping of the Code Flash Memory, changed
		2732, 2733	63.5 Overview of Functions, changed
		2739	63.11.2 ROM Code Protection, changed
		2746	Table 63.16 Commands Available in the Command Waiting Phase, changed
		2748	Table 63.17 Common Transfer Sequence, changed
		2750	63.12.9 Device Type Acquisition Command, changed
		2759	63.12.16 Blank Check Command, changed
		2760	63.12.17 Erase Command, changed
		2761	63.12.18 Area Erase Command, added
		2762	63.12.19 Programming Command, changed
		2764	63.12.20 Read Command, changed
		2782	63.12.35 Configuration Clear Command, changed
		2783	63.12.36 TM Setting Command, added
		2784, 2785	63.12.37 TM Acquisition Command, added
		2786	63.12.38 Simple Addition Checksum Command, changed
		2789	Figure 63.17 Example of Flash Memory Configuration Information, changed
		2793	63.12.41 Flow for Erasure when Programming Commands are Prohibited, changed Figure 63.20 Flow for Erasure when Programming Commands are Prohibited, changed
		2798 to 2803	63.16 Trusted Memory, added
		2804	(6) Items prohibited during programming and erasure, changed

Rev.	Date	Description	
		Page	Summary
1.00	Jul 31, 2014	64. Electrical Characteristics	
		2806	Table 64.2 DC Characteristics (1), changed
		2808	Table 64.4 DC Characteristics (3), changed
		2817	Table 64.15 Clock Timing (Except for Sub-Clock Related), changed
		2825	Figure 64.18 External Bus Timing/Normal Read Cycle (Bus Clock Synchronized), changed
		2826	Figure 64.19 External Bus Timing/Normal Write Cycle (Bus Clock Synchronized), changed
		2827	Figure 64.20 External Bus Timing/Page Read Cycle (Bus Clock Synchronized), changed Figure 64.21 External Bus Timing/Page Write Cycle (Bus Clock Synchronized), changed
		2847	Table 64.33 RSPI Timing, changed
		2852	Table 64.35 QSPI Timing, changed
		2854	Table 64.36 RIIC Timing (1), changed
		2855	Table 64.37 RIIC Timing (2), changed
		2856	Figure 64.56 RIIC Bus Interface Input/Output Timing and Simple IIC Bus Interface Input/Output Timing, changed
		2859	Table 64.39 MMC Host Interface Timing, changed
		2867	Table 64.42 On-Chip USB Low Speed (Host Only) Characteristics (DP and DM Pin Characteristics), changed
		2873	Table 64.50 Power-on Reset Circuit and Voltage Detection Circuit Characteristics, changed

Classifications

- Items with Technical Update document number: Changes according to the corresponding issued Technical Update
- Items without Technical Update document number: Minor changes that do not require Technical Update to be issued

Rev.	Date	Description		Classification
		Page	Summary	
1.10	Oct 24, 2016	All	Terms unified: GPTa → GPTA LQFP → LFQFP (DTC) DTC Start Enable → DTC Transfer Request Enable (DMAC)(EXDMAC) DMA activation sources → DMA request sources DMAC activation request → DMA transfer request DMA activation, DMAC activation → DMA request DMA start → DMA transfer EXDMAC activation is enabled, EXDMAC activation enable → EXDMAC module start EXDMAC activation → trigger

		220	Table 5.1 List of I/O Registers (Address Order) (49 / 69) 000C 0438h, 000C 046Ch, deleted	
		234	Table 5.1 List of I/O Registers (Address Order) (63 / 69), changed	
		240	Table 5.1 List of I/O Registers (Address Order), Note 6 added	TN-RX*-A152A/E
		6. Resets		
		253	6.4 Usage Notes, added	TN-RX*-A123A/E
		7. Option-Setting Memory		
		264	7.2.6 TM Enable Flag Register (TMEF), changed 7.2.7 TM Identification Data Register (TMINF), changed	
		265	7.3.1 UB Code A, changed 7.3.2 UB Code B, changed	
		9. Clock Generation Circuit		
		299	9.2.4 PLL Control Register (PLLCR), Note 1 added	
		313	9.2.16 Main Clock Oscillator Wait Control Register (MOSCWTCR), changed	
		314	9.2.17 Sub-Clock Oscillator Wait Control Register (SOSCWTCR), changed	
		315	9.2.18 Main Clock Oscillator Forced Oscillation Control Register (MOFCR), changed	TN-RX*-A150A/E

Rev.	Date	Description		Classification
		Page	Summary	
1.10	Oct 24, 2016	317	9.3.1 Connecting a Crystal Resonator, changed Figure 9.2 Example of Crystal Connection, changed	TN-RX*-A150A/E
		318	Table 9.4 Crystal Characteristics (Reference Values), changed	
		327, 328	9.8 Clock Source Switching, changed	
		333	9.10.6 Notes on Using a Low CL Crystal Unit, changed	
		333	9.10.7 Notes on Using Power-On Reset and PLL Circuit Together, added	TN-RX*-A123A/E
		11. Low Power Consumption		
		All	Terms unified: RTC Cycle → RTC Periodic	
		355	11.2.5 Module Stop Control Register D (MSTPCRD), modified (address: 0008 001Ah → 0008 001Ch)	
		383	11.6.3.1 Transition to Software Standby Mode, changed	
		15. Interrupt Controller (ICUA)		
		409	Table 15.1 ICU Specifications (1/2), changed	
		425	15.2.14 Non-Maskable Interrupt Status Register (NMISR), changed	
		473	15.7.5 Setting Non-Maskable Interrupts, changed	
		16. Buses		
		481	Table 16.3 Order of Priority for Bus Masters, changed	
		482	16.2.5 Write Buffer Function (Internal Peripheral Bus), changed	
		514	16.3.21 Bus Error Status Register 1 (BERSR1), changed	
		591	16.9 Usage Notes, added	
		17. Memory-Protection Unit (MPU)		
		599	17.2.5 Memory-Protection Error Status-Clearing Register (MPECLR), changed	
		611	17.4.4 Processing in Response to Memory-Protection Errors, changed	
		18. DMA Controller (DMACAa)		
		All	Terms unified: DMAC activation is disabled → DMAC stops DMAC activation is enabled → DMAC module start	
		613	Table 18.1 Specifications of DMAC, ‘Transfer end interrupt’ changed	
		617	18.2.4 DMA Block Transfer Count Register (DMCRB), changed	
		19. EXDMA Controller (EXDMACa)		
		All	Terms unified: EXDMAC activation is disabled → EXDMAC stops EXDMAC activation is enabled → EXDMAC module start	
		653	Table 19.1 Specifications of EXDMAC (2/2), ‘Transfer end interrupt’ changed	
		658	19.2.4 EXDMA Block Transfer Count Register (EDMCRB), changed	
		659	19.2.5 EXDMA Transfer Mode Register (EDMTMD), changed	
		20. Data Transfer Controller (DTCa)		
		All	Terms unified: a single activation → a single transfer request	
		725	20.2.5 DTC Transfer Count Register A (CRA), changed	
		21. Event Link Controller (ELC)		
		755	Table 21.2 Correspondence between the ELSRn Register and the Peripheral Modules, notes added	
		779	21.3.6 Example of Procedure for Linking Events, Note added	
		780	21.4.1 Setting ELSRn Register, changed	
		22. I/O Ports		
		795	Table 22.3 Handling of Unused Pins, changed 22.5.1 Note on the Port Direction Register (PDR), changed	
		23. Multi-Function Pin Controller (MPC)		
		815	23.2.2 P0n Pin Function Control Register (P0nPFS) (n = 0 to 3, 5, 7), changed	
		825	Table 23.13 Register Settings for Input/Output Pin Function in 177-/145-Pin TFLGA, 176-Pin LFBGA, 176-/144-Pin LFQFP, changed	
		833	23.2.17 PFn Pin Function Control Register (PFnPFS) (n = 0 to 2, 5), changed	TN-RX*-A122A/E
		834	Table 23.24 Register Settings for Input/Output Pin Function in 177-/145-/100-Pin TFLGA, 176-Pin LFBGA, 176-/144-/100-Pin LFQFP, changed	
		847	Table 23.27 Register Settings, modified (External bus)	

Rev.	Date	Description		Classification
		Page	Summary	
1.10	Oct 24, 2016	24. Multi-Function Timer Pulse Unit (MTU3a)		
		All	Terms unified: count clock → count clock source input clock → count clock, internal clock, count clock source input clock edge → clock edge counter input clock → count clock	
		863	24.2.5 Timer Mode Register 3 (TMDR3), changed	
		866	Table 24.13 TIORH (MTU0), Note 1 added Table 24.14 TIORL (MTU0), Note 2 added	
		873, 874	Table 24.27 TIORH (MTU0), Note 1 added Table 24.28 TIORL (MTU0), Note 2 added	
		880	Table 24.41 TIORU, TIORV, and TIORW (MTU5), Note 1 added	
		895	24.2.18 Timer Synchronous Registers (TSYRA, TSYRB), changed	
		900, 901	24.2.21 Timer Output Master Enable Registers (TOERA, TOERB), changed	
		908	24.2.25 Timer Gate Control Register A (TGCRA), changed	
		918 to 921	24.2.35 Timer A/D Converter Start Request Control Register (TADCR), changed	TN-RX*-A119A/E
		931	24.2.43 Bus Master Interface, deleted	
		949, 950, 953	24.3.5 PWM Modes, changed	
		968	24.3.7 Reset-Synchronized PWM Mode, modified	
		1013	Figure 24.92 Example of Procedure for Specifying A/D Converter Start Request Delaying Function (MTU3 and MTU4), notes changed	TN-RX*-A119A/E
		1014	24.3.9 A/D Converter Start Request Delaying Function Figure 24.93 Basic Example of A/D Converter Start Request Signal (TRG4AN) Operation, changed (3) Period in Which A/D Converter Start Requests are Enabled, added	
		1015	24.3.9 A/D Converter Start Request Delaying Function (4) Buffer Transfer, changed	
		1016	24.3.9 A/D Converter Start Request Delaying Function (5) A/D Converter Start Request Delaying Function Linked with Interrupt Skipping Function 1, changed	
		1050	Figure 24.148 Contention between TCNT Write Operation and Overflow, changed	
		1055, 1056	24.6.28 Usage Notes on A/D Converter Delaying Function in Complementary PWM Mode, added	TN-RX*-A119A/E
		1058	24.7.3 Overview of Initialization Procedures and Mode Transitions in Case of Error during Operation, changed	
		25. Port Output Enable 3 (POE3a)		
		1088	Table 25.3 Pin Combinations, changed	
		1094	25.2.6 Input Level Control/Status Register 6 (ICSR6), changed	
		1095	25.2.7 Output Level Control/Status Register 1 (OCSR1), changed	
		1096	25.2.8 Output Level Control/Status Register 2 (OCSR2), changed	
		1120 to 1125	25.3 Operation, changed	TN-RX*-A158A/E
		1130	25.3.7 Release from High-Impedance State, changed	
		26. General PWM Timer (GPTA)		
		1144	26.2.4 General PWM Timer Hardware Source Clear Control Register (GTHCCR), changed	
		1145	26.2.5 General PWM Timer Hardware Start Source Select Register (GTHSSR), b15 to b12 changed	
		1157	26.2.14 General PWM Timer Control Register (GTCR), changed	
		1161	26.2.15 General PWM Timer Buffer Enable Register (GTBER), changed	
		1165, 1166	26.2.18 General PWM Timer Status Register (GTST), changed	
		1171	26.2.28 General PWM Timer Dead Time Control Register (GTDTCR), changed	
		1208	26.3.4 Automatic Dead Time Setting Function, changed	
		1223	26.3.7.1 Synchronous Clear Operation, changed	
		1249	26.6.1 Event Signal Output to the ELC, changed	
		1263, 1264	26.9.4 Order of Priority in Event Counter Operation, added	

Rev.	Date	Description		Classification
		Page	Summary	
1.10	Oct 24, 2016	27. 16-Bit Timer Pulse Unit (TPUa)		
		All	Terms unified: TCNT counter → TCNT presetting → setting counter clock, counter input clock → count clock PCLK → PCLK cycles	
		1329	27.10.11 Conflict between Overflow/Underflow and Counter Clearing, changed	
		29. 8-Bit Timer (TMR)		
		All	Terms unified: Frequency dividing clock → internal clock external reset, external reset input → external counter reset signal external clock → external count clock counter clock → count clock counter external reset → external counter reset TCNT input clock → TCNT count clock	
		1380	29.2.4 Timer Control Register (TCR), Note 1 changed	
		1381	29.2.5 Timer Counter Control Register (TCCR), Note 1 changed	
		1382	Table 29.5 Clock Input to TCNT and Count Condition, Note 1 changed	
		30. Compare Match Timer (CMT)		
		1401	Table 30.1 CMT Specifications, changed Figure 30.1 CMT (Unit 0) Block Diagram, Note 1 added	
		32. Realtime Clock (RTCd)		
		1439	32.2.2 Second Counter (RSECCNT)/Binary Counter 0 (BCNT0), changed	
		1440	32.2.3 Minute Counter (RMINCNT)/Binary Counter 1 (BCNT1), changed	
		1441	32.2.4 Hour Counter (RHRCNT)/Binary Counter 2 (BCNT2), changed	
		1442	32.2.5 Day-of-Week Counter (RWKCNT)/Binary Counter 3 (BCNT3), changed	
		1443	32.2.6 Date Counter (RDAYCNT), changed	
		1444	32.2.7 Month Counter (RMONCNT), changed	
		1445	32.2.8 Year Counter (RYRCNT), changed	
		1446	32.2.9 Second Alarm Register (RSECAR)/Binary Counter 0 Alarm Register (BCNT0AR), changed	
		1447	32.2.10 Minute Alarm Register (RMINAR)/Binary Counter 1 Alarm Register (BCNT1AR), changed	
		1448	32.2.11 Hour Alarm Register (RHRAR)/Binary Counter 2 Alarm Register (BCNT2AR), changed	
		1449	32.2.12 Day-of-Week Alarm Register (RWKAR)/Binary Counter 3 Alarm Register (BCNT3AR), changed	
		1450	32.2.13 Date Alarm Register (RDAYAR)/Binary Counter 0 Alarm Enable Register (BCNT0AER), changed	
		1451	32.2.14 Month Alarm Register (RMONAR)/Binary Counter 1 Alarm Enable Register (BCNT1AER), changed	
		1452	32.2.15 Year Alarm Register (RYRAR)/Binary Counter 2 Alarm Enable Register (BCNT2AER), changed	
		1456, 1457	32.2.18 RTC Control Register 2 (RCR2), changed	
		1458	32.2.19 RTC Control Register 3 (RCR3), changed	
		1460, 1461	32.2.21 Frequency Register H/L (RFRH/RFRL), changed	
		1475	Figure 32.7 Using Alarm Function, changed	
		35. Ethernet Controller (ETHERC)		
		1532	35.2.14 Broadcast Frame Receive Count Setting Register (BCFRR), changed	
		1536	35.2.22 Frame Receive Error Counter Register (FRECR), changed	
		1537	35.2.25 Received Alignment Error Frame Counter Register (RFCR), changed	
		1548, 1549	35.5.3 Handling Errors in Control Information, added	TN-RX*-A125A/E
		36. PTP Module for the Ethernet Controller (EPTPC)		
		1562	36.2.5 STCA Status Register (STSR), changed	
		1580	36.2.21 Negative Gradient Limit Registers (MLIMITRU, MLIMITRM, MLIMITRL), changed	
		1599	36.2.37 SYNFP Status Register (SYSR), changed	TN-RX*-A125A/E

Rev.	Date	Description		Classification

		Page	Summary	
1.10	Oct 24, 2016	2345	Figure 44.38 Flowchart for Master Mode (Error Processing), changed	
		2346, 2349	44.3.10.2 Slave Mode Operation, changed	
		2348	Figure 44.40 Flowchart in Slave Mode (Transmission), changed Figure 44.41 Flowchart in Slave Mode (Reception), changed	
		2349	Figure 44.42 Flowchart for Slave Mode (Error Processing), changed	
		2350	44.3.11.1 Master Mode Operation, changed	
		2354	44.3.11.2 Slave Mode Operation, changed	
		2358	Table 44.13 Interrupt Sources of RSPI, changed	
		2361	44.5.4 Notes on the SPRF and SPTEF flags, added	
		45. Quad Serial Peripheral Interface (QSPI)		
		2369	45.2.5 QSPI Data Register (SPDR), changed	
		2376, 2377	45.2.13 QSPI Command Register n (SPCMDn) (n = 0 to 3), changed Table 45.4 SPI Modes Definitions, added	
		2385	Figure 45.2 Clock Setting and Transfer Timing, changed	
		2407	45.4.3 Notes on Using the Serial Flash Memory, added	TN-RX*-A154A/E
		47. Serial Sound Interface (SSI)		
		2418 to 2421	47.2.1 Control Register (SSICR), changed	
		2420	Table 47.3 SSITXD0, SSIRXD0, and SSIDATA1 Pin States, changed	
		2421	Table 47.4 Setting of SCKP Bit and Signal Timing, added	
		2422	47.2.2 Status Register (SSISR), changed	TN-RX*-A133B/E
		2424, 2425	47.2.3 FIFO Control Register (SSIFCR), changed	
		2426, 2427	47.2.4 FIFO Status Register (SSIFSR), changed	TN-RX*-A133B/E
		2431	47.3.2 Non-Compressed Mode (7) Operating Settings Related to Word Length, changed	
		2436	47.3.3 WS Continue Mode, changed	
		2443	Table 47.7 SSI Interrupt Sources, changed	
		2444 to 2446	47.5.4 Notes Regarding Clearing the Status Flag, added	TN-RX*-A133B/E
		48. Sampling Rate Converter (SRC)		
		2459	48.3.2 Data Input, changed Figure 48.3 Flowchart for Data Input, changed	TN-RX*-A155A/E
		2460	Figure 48.4 Flowchart for Data Output, changed	
		2463	48.5.6 Conversion immediately after the Data Set in the SRCID Register, added	
		49. SD Host Interface (SDHI)		
		2464	Table 49.2 Pin Configuration of the SDHI, changed	
		2469	49.2.5 Response Register 10 (SDRSP10), Response Register 32 (SDRSP32), Response Register 54 (SDRSP54), Response Register 76 (SDRSP76), changed	
		2480	49.2.11 Transfer Data Size Register (SDSIZE), changed	TN-RX*-A122A/E
		2483	49.2.13 SD Error Status Register 1 (SDERSTS1), changed	
		2514	Table 49.8 Interrupt Sources, changed	
		2515	49.4.1 DMA Transfer Triggered by Interrupt Requests, changed	
		52. Boundary Scan		
		2602	52.3.2 List of Commands, modified	
		2603	52.4 Usage Notes, modified	
		57. 12-Bit A/D Converter (S12ADC)		
		2645	57.2.18 A/D Group Scan Priority Control Register (ADGSPCR), Note 2 added	TN-RX*-A124A/E
		2686	57.3.4.3 Operation under Group-A Priority Control, changed	
		2700	Table 57.11 Times for Conversion during Scanning (in Numbers of Cycles of the ADCLK and PCLKB), modified	
		2705	Figure 57.41 Procedures for Clear Operation by Software through the ADCSR.ADST Bit, changed	TN-RX*-A124A/E
		2707	57.5.10 Notes on Noise Prevention, added 57.5.11 Notes on Operating Modes and Status Bits, added	
		58. 12-Bit D/A Converter (R12DA)		
		All	Terms unified: output amplifier → output buffer amplifier (except for used as a register name)	
		2715	58.3 Operation, changed	

Rev.	Date	Description		Classification
		Page	Summary	
1.10	Oct 24, 2016	2716, 2717	58.3.1 Measure against Interference between D/A and A/D Conversion, changed Figure 58.4 Example When the 12-Bit D/A Converter Cannot Capture the 12-Bit A/D Converter Synchronous D/A Conversion Enable Input Signal, deleted	
		2719	58.6.5 Initial Setting Procedure when the Output Buffer Amplifier is Used, changed	TN-RX*-A122A/E
		59. Temperature Sensor (TEMPS)		
		2720	Table 59.1 Specifications of Temperature Sensor, changed	TN-RX*-A127A/E
		2721	59.2.2 Temperature Sensor Calibration Data Register (TSCDR), added	
		2722, 2723	59.3.1 Preparation for Using the Temperature Sensor, changed	
		2723	Figure 59.2 Error in the Measured Temperature, added	
		61. RAM		
		2734	Table 61.1 Specifications of RAM, changed	TN-RX*-A127A/E
		2739	61.2.10 RAM Operating Mode Control Register (RAMMODE), added	
		2740	61.2.11 RAM Error Status Register (RAMSTS), added 61.2.12 RAM Error Address Capture Register (RAMECAD), added	
		2741	61.2.13 RAM Protection Register (RAMPRCR), added	
		2742	61.3.3 Parity Checking, added	
		2743	61.3.4 RAM Error Interrupt Function, changed	
		2745	61.3.6 Interrupt Source, changed 61.4 Usage Notes, added	
		63. Flash Memory		
		All	Terms unified: code flash → code flash memory data flash → data flash memory	
		2747	Table 63.1 Specifications of Code Flash Memory and Data Flash Memory, changed	TN-RX*-A127A/E
		2752	63.3.2 Unique ID Register n (UIDRn) (n = 0 to 2), changed	
		2756	Table 63.6 Lists of Security Functions, changed	
		2760	63.10.2 Boot Mode (for the USB Interface), changed	TN-RX*-A157A/E
		2761	63.11 ID Code Protection, changed 63.11.2 ID Code Protection, added	
		2768	Table 63.14 Commands Available in the Command Waiting Phase, modified	
		2770	Table 63.15 Common Transfer Sequence, modified (Erase command → Block Erase command)	
		2813	Figure 63.18 Example of Reprogramming Procedure, modified (Erase command → Block Erase command)	
		2815	Figure 63.20 Flow for Erasure when Programming Commands are Prohibited, modified (Erase command → Block Erase command)	
		2827, 2828	63.17 Usage Notes, changed (2) Suspension During Programming/Erasure, added (9) Programming/Erasure in Low-Speed Operating Modes 1 and 2, added	
		64. Electrical Characteristics		
		2829	Table 64.1 Absolute Maximum Rating, changed	TN-RX*-A160A/E
		2830	Table 64.2 DC Characteristics (1), changed	TN-RX*-A159A/E TN-RX*-A160A/E
		2831	Table 64.3 DC Characteristics (2), changed	TN-RX*-A159A/E
		2873	Figure 64.48 RSPI Timing (Master, CPHA = 0) (Bit Rate: PCLKB Division Ratio Set to 1/2), changed	
		2896	Table 64.49 Temperature Sensor Characteristics, changed	TN-RX*-A159A/E
		2902	Figure 64.84 Battery Backup Function Characteristics, changed	
		2903	Table 64.53 Code Flash Memory Characteristics, changed	TN-RX*-A146A/E
		2904	Table 64.54 Data Flash Memory Characteristics, changed
