b7, b6	CCHW3[1:0]	GPT3.GTCNT Hardware Source Count Clear	b7 b6 0 0: Count is not cleared by a hardware source. 0 1: Count is cleared at the rising edge of a hardware source. 1 0: Count is cleared at the falling edge of a hardware source. 1 1: Count is cleared at both rising and falling edges of a hardware source.	R/W
b8	CCSW0	GPT0.GTCNT Counter Clear	When 1 is written to this bit, the count is cleared. This bit automatically returns to 0 after the writing of 1. These bits are read as 0.	R/W
b9	CCSW1	GPT1.GTCNT Counter Clear	When 1 is written to this bit, the count is cleared. This bit automatically returns to 0 after the writing of 1. These bits are read as 0.	R/W
b10	CCSW2	GPT2.GTCNT Counter Clear	When 1 is written to this bit, the count is cleared. This bit automatically returns to 0 after the writing of 1. These bits are read as 0.	R/W
b11	CCSW3	GPT3.GTCNT Counter Clear	When 1 is written to this bit, the count is cleared. This bit automatically returns to 0 after the writing of 1. These bits are read as 0.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The GTHCCR register sets a hardware source to clear the GPTn.GTCNT counter (n = 0 to 3).
Once the clearing of GPTn.GTCNT counter by a hardware source is set, count clearing by the hardware source is executed whether the GPTn.GTCNT counter is started (GTSTR.CSTn = 1; n = 0 to 3) or stopped (GTSTR.CSTn = 0; n = 0 to 3).

When the count direction is down-counting (GTST.TUCF flag is 0) in saw-wave mode, the GPTn.GTCNT counter is set to the value set in the GTPR register (the GTPBR register in buffer operation). In other cases, the GPTn.GTCNT counter is set to 0000h when count clearing is executed.

CCHWn[1:0] Bits (GPTn.GTCNT Hardware Source Count Clear) (n = 0 to 3)

The GPTn.GTCNT is cleared by a hardware source.
The hardware source can be selected by GTHPSR. The hardware source is accepted repeatedly when the CCHWn[1:0] bits are set to 01b, 10b, or 11b.

CCSWn Bit (GPTn.GTCNT Counter Clear) (n = 0 to 3)

When 1 is written to this bit, the GPTn.GTCNT counter is cleared. This bit automatically returns to 0 after the writing of 1. This bit is read as 0.

26.2.5 General PWM Timer Hardware Start Source Select Register (GTHSSR)

Address(es): GPT.GTHSSR 000C 2008h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

The GTHSSR register sets the hardware source to start the GPTn.GTCNT counter (n = 0 to 3).
Use the GTHSCR register to set the edge polarity of the hardware source.
To change the source, set the GTHSCR.CSHWn[1:0] bits to 00b before changing the source.

CSHSLn[3:0] Bits (GPTn.GTCNT Hardware Count Start Source Select) (n = 0 to 3)

These bits select the hardware source to start the GPTn.GTCNT.
When 1000b is selected as the hardware source, set the GPT3.GTIOR.GTIOA[5] bit and the GPT3.GTONCR.OAE bit to 0. When 1001b is selected as the hardware source, set the GPT3.GTIOR.GTIOB[5] bit and the GPT3.GTONCR.OBE bit to 0.
If a hardware source to start count operation is not selected in the GTHSCR register, it is not necessary to change the value of these bits from their initial value.

26.2.6 General PWM Timer Hardware Stop/Clear Source Select Register (GTHPSR)

Address(es): GPT.GTHPSR 000C 200Ah

R/W
b15 to b12	CSHPL3[3:0]	GPT3.GTCNT Hardware Count Stop/ Clear Source Select	b15 b12 1 0 0 0: GTIOC3A pin input 1 0 0 1: GTIOC3B pin input 1 0 1 0: GTIOC3A internal output (output compare) 1 0 1 1: GTIOC3B internal output (output compare) 1 1 0 0: GTETRG pin input Settings other than the above are prohibited when count operation is stopped or cleared by a hardware source.	R/W

The GTHPSR register sets the hardware source to stop or clear the GPTn.GTCNT counter (n = 0 to 3).
Use the GTHSCR register to set the edge polarity of the hardware source to stop count operation. Use the GTHCCR register to set the edge polarity of the hardware source to clear the count.
To change the source, set the GTHSCR.CPHWn[1:0] bits and GTHCCR.CCHWn[1:0] bits to 00b before changing the source.

CSHPLn[3:0] Bits (GPTn.GTCNT Hardware Count Stop/Clear Source Select) (n = 0 to 3)

This bit selects the hardware source to stop or clear the GPTn.GTCNT counter.
When 1000b is selected as the hardware source, set the GPT3.GTIOR.GTIOA[5] bit and the GPT3.GTONCR.OAE bit to 0. When 1001b is selected as the hardware source, set the GPT3.GTIOR.GTIOB[5] bit and the GPT3.GTONCR.OBE bit to 0.
If a hardware source to stop or clear count operation is not selected in the GTHSCR or GTHCCR register, it is not necessary to change the value of these bits from their initial value.

26.2.7 General PWM Timer Write-Protection Register (GTWP)

Address(es): GPT.GTWP 000C 200Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	WP3	WP2	WP1	WP0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	WP0	GPT0 Register Write Disable	0: Write to the register is enabled 1: Write to the register is disabled	R/W
b1	WP1	GPT1 Register Write Disable	0: Write to the register is enabled 1: Write to the register is disabled	R/W
b2	WP2	GPT2 Register Write Disable	0: Write to the register is enabled 1: Write to the register is disabled	R/W
b3	WP3	GPT3 Register Write Disable	0: Write to the register is enabled 1: Write to the register is disabled	R/W
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

GTWP enables or disables writing to registers to prevent accidental modification.

For registers that are write enabled or disabled depending on the setting of the GPWP register, see section 26.7.1, Write-Protection for Registers.

26.2.8 General PWM Timer Sync Register (GTSYNC)

Address(es): GPT.GTSYNC 000C 200Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b9, b8	SYNC2[1:0]	GPT2.GTCNT Counter Synchronous Clear Source Select	b9 b8 0 0: GPT2.GTCNT is synchronously cleared by a GPT0 clearing source. 0 1: GPT2.GTCNT is synchronously cleared by a GPT1 clearing source. 1 0: Synchronous clear is not performed. 1 1: GPT2.GTCNT is synchronously cleared by a GPT3 clearing source.	R/W
b11, b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13, b12	SYNC3[1:0]	GPT3.GTCNT Counter Synchronous Clear Source Select	b13 b12 0 0: GPT3.GTCNT is synchronously cleared by a GPT0 clearing source. 0 1: GPT3.GTCNT is synchronously cleared by a GPT1 clearing source. 1 0: GPT3.GTCNT is synchronously cleared by a GPT2 clearing source. 1 1: Synchronous clear is not performed	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

GTSYNC sets the clearing source of the GPTn.GTCNT counter for synchronous clearing/synchronous operation. This register should be modified while the GPTn.GTCNT counter is stopped (n = 0 to 3).

SYNCn[1:0] Bits (GPTn.GTCNT Counter Synchronous Clear Source Select) (n = 0 to 3)

These bits select which channel's counter clearing source is used to clear the GPTn.GTCNT counter. When setting the SYNCn[1:0] bits, first set the GPTn.GTCR.CCLR[1:0] bits to 11b (cleared by counter clearing in another channel performing synchronous clearing/synchronous operation).

26.2.9 General PWM Timer External Trigger Input Interrupt Register (GTETINT)

Address(es): GPT.GTETINT 000C 2010h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	GTETRGEN	GTENFCS[1:0]		—	—	—	—	—	—	—	—	—	—	—	ETINEN	ETIPEN

b1	ETINEN	External Trigger Falling Input Interrupt Request Enable	0: Interrupt request is disabled 1: Interrupt request is enabled	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	—	Reserved	The read value is undefined. The write value should be 1.	R/W
b12 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14, b13	GTENFCS[1:0]	GTETRG Noise Filter Sampling Clock Select	b14 b13 0 0: PCLKA/1 0 1: PCLKA/2 1 0: PCLKA/4 1 1: PCLKA/32	R/W
b15	GTETRGEN	GTETRG Noise Filter Enable	0: The noise filter for the GTETRG pin is disabled. 1: The noise filter for the GTETRG pin is enabled.	R/W

GTETINT enables or disables interrupts through the external trigger input pin (GTETRG).

ETIPEN Bit (External Trigger Rising Input Interrupt Request Enable)

This bit enables or disables an interrupt request generated at the rising edge of an external trigger input.

ETINEN Bit (External Trigger Falling Input Interrupt Request Enable)

This bit enables or disables an interrupt request generated at the falling edge of an external trigger input.

GTENFCS[1:0] Bits (GTETRG Noise Filter Sampling Clock Select)

These bits set the sampling interval for the noise filters. After setting these bits, wait for two selected sampling periods, set the GTHSCR, GTHCCR, and GTHSSR registers to enable the counter operation by a hardware source of GTETRG.

GTETRGEN Bit (GTETRG Noise Filter Enable)

This bit disables or enables the noise filter for input from the GTETRG pin. Since changing the value of the bit may lead to the internal generation of an unexpected edge, set the GTHSCR, GTHCCR, and GTHSSR registers to disable the counter operation by a hardware source of GTETRG before changing the value.

26.2.10 General PWM Timer Buffer Operation Disable Register (GTBDR)

Address(es): GPT.GTBDR 000C 2014h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b10	BD22	GPT2.GTADTR Buffer Operation Disable	0: Buffer operation is enabled 1: Buffer operation is disabled	R/W
b11	BD23	GPT2.GTDV Buffer Operation Disable	0: Buffer operation is enabled 1: Buffer operation is disabled	R/W
b12	BD30	GPT3.GTCCR Buffer Operation Disable	0: Buffer operation is enabled 1: Buffer operation is disabled	R/W
b13	BD31	GPT3.GTPR Buffer Operation Disable	0: Buffer operation is enabled 1: Buffer operation is disabled	R/W
b14	BD32	GPT3.GTADTR Buffer Operation Disable	0: Buffer operation is enabled 1: Buffer operation is disabled	R/W
b15	BD33	GPT3.GTDV Buffer Operation Disable	0: Buffer operation is enabled 1: Buffer operation is disabled	R/W

The GTBDR register collectively enables or disables buffer operation of each channel. Even though a bit in the GTBDR register is set to 0 (buffer operation is enabled), buffer operation is not performed unless buffer operation is enabled by the GTBER register.

BDn0 Bit (GPTn.GTCCR Buffer Operation Disable) (n = 0 to 3)

This bit disables buffer operation using the GTCCRA, GTCCRC, and GTCCRD registers of GPTn together and buffer operation using the GTCCRB, GTCCRE, and GTCCRF registers of GPTn together.

BDn1 Bit (GPTn.GTPR Buffer Operation Disable) (n = 0 to 3)

This bit disables buffer operation using the GTPR, GTPBR, and GTPDBR registers of GPTn together.

BDn2 Bit (GPTn.GTADTR Buffer Operation Disable) (n = 0 to 3)

This bit disables buffer operation using the GTADTRA, GTADTBRA, and GTADTDBRA registers of GPTn together and buffer operation using the GTADTRB, GTADTBRB, and GTADTDBRB registers of GPTn together.

BDn3 Bit (GPTn.GTDV Buffer Operation Disable) (n = 0 to 3)

This bit disables buffer operation using the GTDVU and GTDBU registers of GPTn together and buffer operation using the GTDVD and GTDBD registers of GPTn together.

26.2.11 General PWM Timer Start Write-Protection Register (GTSWP)

Address(es): GPT.GTSWP 000C 2018h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	SWP3	SWP2	SWP1	SWP0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SWP0	GTSTR.CST0 Bit Write Disable	0: Writing to the register bit is enabled 1: Writing to the register bit is disabled	R/W
b1	SWP1	GTSTR.CST1 Bit Write Disable	0: Writing to the register bit is enabled 1: Writing to the register bit is disabled	R/W
b2	SWP2	GTSTR.CST2 Bit Write Disable	0: Writing to the register bit is enabled 1: Writing to the register bit is disabled	R/W
b3	SWP3	GTSTR.CST3 Bit Write Disable	0: Writing to the register bit is enabled 1: Writing to the register bit is disabled	R/W
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The GTSWP register enables or disables writing to the GTSTR register to prevent accidental modification.

SWPn Bit (GTSTR.CSTn Bit Write Disable) (n = 0 to 3)

This bit enables or disables writing to the GTSTR.CSTn bit.

When this bit is set to disable writing, writing to the GTSTR.CSTn bit is ignored.

However, if the GTHSCR register is set to start or stop count operation by a hardware source, the status of count operation (started or stopped by a hardware source) is written to the GTSTR.CSTn bit even if the SWPn bit is set to disable writing to GTSTR.CSTn bit.

26.2.12 General PWM Timer I/O Control Register (GTIOR)

Address(es): GPT0.GTIOR 000C 2100h, GPT1.GTIOR 000C 2180h, GPT2.GTIOR 000C 2200h, GPT3.GTIOR 000C 2280h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	GTIOA[5:0]	GTIOCnA Pin Function Select	See Table 26.4.	R/W
b6	OADFLT	GTIOCnA Pin Output Value Setting at the Count Stop	0: The GTIOCnA pin outputs low when counting is stopped. 1: The GTIOCnA pin outputs high when counting is stopped.	R/W
b7	OAHLD	GTIOCnA Pin Output Setting at the Start/Stop Count	0: The GTIOCnA pin output level at start/stop of counting depends on the register setting. 1: The GTIOCnA pin output level is retained at start/stop of counting.	R/W
b13 to b8	GTIOB[5:0]	GTIOCnB Pin Function Select	See Table 26.4.	R/W
b14	OBDFLT	GTIOCnB Pin Output Value Setting at the Count Stop	0: The GTIOCnB pin outputs low when counting is stopped. 1: The GTIOCnB pin outputs high when counting is stopped.	R/W
b15	OBHLD	GTIOCnB Pin Output Setting at the Start/Stop Count	0: The GTIOCnB pin output level at start/stop of counting depends on the register setting. 1: The GTIOCnB pin output level is retained at start/stop of counting.	R/W

n = 0 to 3

GPTn.GTIOR sets the functions of the GTIOCnA and GTIOCnB pins (n = 0 to 3).
Each channel has one GTIOCnA pin and one GTIOCnB pin. Values written to the GTIOR register of the relevant channel in which write access is disabled by the GTWP.WPn bit are ignored.

GTIOA[5:0] Bits (GTIOCnA Pin Function Select)

These bits select the GTIOCnA pin function. For details, see Table 26.4.

OADFLT Bit (GTIOCnA Pin Output Value Setting at the Count Stop)

This bit sets whether the GTIOCnA pin outputs high or low when counting is stopped.

OAHLD Bit (GTIOCnA Pin Output Setting at the Start/Stop Count)

This bit specifies whether the GTIOCnA pin output level is retained or the level depends on the register setting when counting is started or stopped.
[When the OAHLD bit is set to 0]

- The value specified by the GTIOA[4] bit is output when counting starts.
- The value specified by the OADFLT bit is output when counting stops.
- If the OADFLT bit is modified while counting is stopped, it is immediately reflected in the output.

[When the OAHLD bit is set to 1]

- The output is retained when counting starts or stops.

GTIOB[5:0] Bits (GTIOCnB Pin Function Select)

These bits select the GTIOCnB pin function. For details, see Table 26.4.

OBDFLT Bit (GTIOCnB Pin Output Value Setting at the Count Stop)

This bit sets whether the GTIOCnB pin outputs high or low when counting is stopped.

OBHLD Bit (GTIOCnB Pin Output Setting at the Start/Stop Count)

This bit specifies whether the GTIOCnB pin output level is retained or the level depends on the register setting when counting is started or stopped.

[When the OBHLD bit is set to 0]

- The value specified by the GTIOB[4] bit is output when counting starts.
- The value specified by the OBDFLT bit is output when counting stops.
- If the OBDFLT bit is modified while counting is stopped, it is immediately reflected in the output.

[When the OBHLD bit is set to 1]

- The output is retained when counting starts or stops.

Table 26.4 Settings of GTIOA[5:0] Bits (GTIOB[5:0] Bits) (1/2)

GTIOA[5:0]/GTIOB[5:0] Bits						Function			
b5	**b4**	**b3**	**b2**	**b1**	**b0**	**b5**	**b4**	**b3, b2**	**b1, b0**

0	1	1	0	1	0				High output at GPTn.GTCCRA/GTCCRB compare match
0	1	1	0	1	1				Output toggled at GPTn.GTCCRA/ GTCCRB compare match
0	1	1	1	0	0			Output toggled at the end of a cycle	Output retained at GTPn.GTCCRA/ GTCCRB compare match
0	1	1	1	0	1				Low output at GPTn.GTCCRA/GTCCRB compare match
0	1	1	1	1	0				High output at GPTn.GTCCRA/GTCCRB compare match
0	1	1	1	1	1				Output toggled at GPTn.GTCCRA/ GTCCRB compare match
1	x	x	x	0	0	Input capture	—	—	Input capture at rising edge
1	x	x	x	0	1				Input capture at falling edge
1	x	x	x	1	0				Input capture at both edges
1	x	x	x	1	1				

x: Don't care

Note: In saw-wave mode, “end of a cycle” refers to an overflow (the value of the GTCNT counter changing from that of the GTPR register to 0000h in up-counting), an underflow (the value of the GTCNT counter changing from 0000h to that of the GTPR register in down-counting), or counter clearing by a hardware source, software, event input, or synchronous clearing. It refers to a trough in triangle-wave mode (the value of the GTCNT counter changing from 0000h to 0001h).

Note: When the timing of an end of a cycle and the timing of a GTCCRA/GTCCRB compare match are the same in a compare-match operation, the b3 and b2 settings are given priority in saw-wave PWM mode, and the b1 and b0 settings are given priority in any other mode.

Note: Even though a compare match is set in GTIOR, output will not be made to the pins. GTONCR needs to be set separately.

26.2.13 General PWM Timer Interrupt Output Setting Register (GTINTAD)

Address(es): GPT0.GTINTAD 000C 2102h, GPT1.GTINTAD 000C 2182h, GPT2.GTINTAD 000C 2202h, GPT3.GTINTAD 000C 2282h

b7, b6	GTINTPR[1:0]	GTPR Compare Match Interrupt Enable	b7 b6 0 0: Interrupt request is disabled. 0 1: In saw-wave mode, interrupt requests are enabled at overflows. In triangle-wave mode, interrupt requests are enabled at crests. 1 0: In saw-wave mode, interrupt requests are enabled at underflows. In triangle-wave mode, interrupt requests are enabled at troughs. 1 1: In saw-wave mode, interrupt requests are enabled at both overflows and underflows. In triangle-wave mode, interrupt requests are enabled at both crests and troughs.	R/W
b10 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11	EINT	Dead Time Error Interrupt Enable	0: Interrupt request is disabled. 1: Interrupt request is enabled.	R/W
b12	ADTRAUEN	GTADTRA Compare Match (Up-Counting) A/D Converter Start Request Enable	0: A/D converter start request is disabled. 1: A/D converter start request is enabled.	R/W
b13	ADTRADEN	GTADTRA Compare Match (Down-Counting) A/D Converter Start Request Enable	0: A/D converter start request is disabled. 1: A/D converter start request is enabled.	R/W
b14	ADTRBUEN	GTADTRB Compare Match (Up-Counting) A/D Converter Start Request Enable	0: A/D converter start request is disabled. 1: A/D converter start request is enabled.	R/W
b15	ADTRBDEN	GTADTRB Compare Match (Down-Counting) A/D Converter Start Request Enable	0: A/D converter start request is disabled. 1: A/D converter start request is enabled.	R/W

The GTINTAD register enables or disables interrupt requests and A/D converter start requests. Values written to the GTINTAD register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

GTINTA Bit (GTCCRA Compare Match/Input Capture Interrupt Enable)

This bit enables or disables interrupt requests by GTCCRA compare match/input capture (GTCIA).

GTINTB Bit (GTCCRB Compare Match/Input Capture Interrupt Enable)

This bit enables or disables interrupt requests by GTCCRB compare match/input capture (GTCIB).

GTINTC Bit (GTCCRC Compare Match Interrupt Enable)

This bit enables or disables interrupt requests by GTCCRC compare match (GTCIC).

GTINTD Bit (GTCCRD Compare Match Interrupt Enable)

This bit enables or disables interrupt requests by GTCCRD compare match (GTCIC).

GTINTE Bit (GTCCRE Compare Match Interrupt Enable)

This bit enables or disables interrupt requests by GTCCRE compare match (GTCIE).

GTINTF Bit (GTCCRF Compare Match Interrupt Enable)

This bit enables or disables interrupt requests by GTCCRF compare match (GTCIE).

GTINTPR[1:0] Bits (GTPR Compare Match Interrupt Enable)

These bits enable or disable interrupt requests by a GTPR compare match (GTCNT counter overflow) and those by a GTCNT counter underflow (GTCIV/GTCIU).

EINT Bit (Dead Time Error Interrupt Enable)

This bit enables or disables interrupt requests by a dead time error (GDTE).

ADTRAUEN Bit (GTADTRA Compare Match (Up-Counting) A/D Converter Start Request Enable)

This bit enables or disables A/D converter start requests generated by GTADTRA compare matches during GTCNT up-counting.

ADTRADEN Bit (GTADTRA Compare Match (Down-Counting) A/D Converter Start Request Enable)

This bit enables or disables A/D converter start requests generated by GTADTRA compare matches during GTCNT down-counting.

ADTRBUEN Bit (GTADTRB Compare Match (Up-Counting) A/D Converter Start Request Enable)

This bit enables or disables A/D converter start requests generated by GTADTRB compare matches during GTCNT up-counting.

ADTRBDEN Bit (GTADTRB Compare Match (Down-Counting) A/D Converter Start Request Enable)

This bit enables or disables A/D converter start requests generated by GTADTRB compare matches during GTCNT down-counting.

26.2.14 General PWM Timer Control Register (GTCR)

Address(es): GPT0.GTCR 000C 2104h, GPT1.GTCR 000C 2184h, GPT2.GTCR 000C 2204h, GPT3.GTCR 000C 2284h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	CCLR[1:0]		—	—	TPCS[1:0]		—	—	—	—	—	MD[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	MD[2:0]	Mode Select	b2 b0 0 0 0: Saw-wave PWM mode (single buffer or double buffer possible) 0 0 1: Saw-wave one-shot pulse mode (fixed buffer operation) 0 1 0: Setting prohibited 0 1 1: Setting prohibited 1 0 0: Triangle-wave PWM mode 1 (16-bit transfer at crest) (single buffer or double buffer possible) 1 0 1: Triangle-wave PWM mode 2 (16-bit transfer at crest and trough) (single buffer or double buffer possible) 1 1 0: Triangle-wave PWM mode 3 (32-bit transfer at trough) fixed buffer operation) 1 1 1: Setting prohibited	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	TPCS[1:0]	Timer Prescaler Select	b9 b8 0 0: PCLKA 0 1: PCLKA/2 1 0: PCLKA/4 1 1: PCLKA/8	R/W
b11, b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13, b12	CCLR[1:0]	Count Clear Source Select	b13 b12 0 0: None of the following clearing sources is specified. 0 1: Cleared by GTCCRA input capture 1 0: Cleared by GTCCRB input capture 1 1: Cleared by count clearing in another channel performing synchronous clearing/synchronous operation	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The GTCR register controls the GTCNT counter. The GTCR register should be set while the GTCNT counter is stopped. Values written to the GTCR register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

MD[2:0] Bits (Mode Select)

These bits select the GPT operating mode.

TPCS[1:0] Bits (Timer Prescaler Select)

These bits select a clock for the GTCNT counter. The clock source can be selected independently for each channel.

CCLR[1:0] Bits (Count Clear Source Select)

These bits select a clearing source for the GTCNT counter. The source selected by these bits is added besides counter clearing by a hardware source, software, and an event input.

When clearing in response to input capture is selected, transfer from the buffer registers to the GTCCRA and GTCCRB registers proceeds in response to by the counter clearing and input capture are performed, and other buffer transfer does not proceed. If clearing by a hardware source, software, or an event input is occurs at the same time as clearing by input capture, other buffer transfer proceeds.

When synchronous clearing is selected in saw-wave mode, this is handled as clearing in response to the given counter

overflow or underflow and the pin output and buffer transfers proceed. Even if the GTINTAD.GTINTPR[1:0] bits are set to 01b, 10b, or 11b at this time, the GTCIV or GTCIU interrupt is not requested. In triangle-wave mode, count clearing is only performed and pin output and buffer transfer are not performed. The counter value becomes 0000h, but it is not treated as a trough.

When 01b, 10b, or 11b is selected as a count clear source, count clearing by the source is executed whether the GPTn.GTCNT counter is running (the GTSTR.CSTn bit is 1 (n = 0 to 3)) or stopped (the GTSTR.CSTn bit is 0 (n = 0 to 3)).

When the count direction is down-counting (the GTST.TUCF flag is 0) in saw-wave mode, the GTCNT counter is set to the value set in the GTPR register by executing count clearing. In other cases, the GTCNT counter is set to 0000h.

Do not set the CCLR[1:0] bits for the operating channel to 01b or 10b during synchronous clearing.

26.2.15 General PWM Timer Buffer Enable Register (GTBER)

Address(es): GPT0.GTBER 000C 2106h, GPT1.GTBER 000C 2186h, GPT2.GTBER 000C 2206h, GPT3.GTBER 000C 2286h

b14	ADTDB	GTADTRB Double Buffer Operation	0: Single buffer operation (GTADTBRB ⇒ GTADTRB) 1: Double buffer operation (GTADTDBRB ⇒ GTADTBRB ⇒ GTADTRB)	R/W
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

The GTBER register makes settings for buffer operation.

The GTBER register should be set while the GTCNT counter is stopped. Values written to the GTBER register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

CCRA[1:0] Bits (GTCCRA Buffer Operation)

These bits set buffer operation with the GTCCRA, GTCCRC, and GTCCRD registers combined. When buffer operation is restricted by the operating mode set in the GTCR register, the GTCR setting is given priority.*1

CCRB[1:0] Bits (GTCCRB Buffer Operation)

These bits set buffer operation with the GTCCRB, GTCCRE, and GTCCRF registers combined. When buffer operation is restricted by the operating mode set in the GTCR register, the GTCR setting is given priority.*1

PR[1:0] Bits (GTPR Buffer Operation)

These bits set buffer operation with the GTPR, GTPBR, and GTPDBR registers combined.
Set these bits to 00b when down-counting in saw-wave mode.

CCRSWT Bit (GTCCRA and GTCCRB Forcible Buffer Operation)

Writing 1 to the CCRSWT bit forcibly performs buffer transfer of the GTCCRA and GTCCRB registers. This bit automatically returns to 0 after the writing of 1. This bit is read as 0.
This bit is valid only when counting is stopped with compare match operation specified.

ADTTA[1:0] Bits (GTADTRA Buffer Transfer Timing Select)

These bits set the transfer timing for buffer operation of the GTADTRA, GTADTBRA, and GTADTDBRA registers. When a buffer transfer is performed in saw-wave mode, the source of count clearing is a hardware source, software, event input, or synchronous clearing. During clearing by input capture, buffer transfer does not proceed.

ADTDA Bit (GTADTRA Double Buffer Operation)

These bits set buffer operation with the GTADTRA, GTADTBRA, and GTADTDBRA registers combined.

ADTTB[1:0] Bits (GTADTRB Buffer Transfer Timing Select)

These bits set the transfer timing for buffer operation of the GTADTRB, GTADTBRB, and GTADTDBRB registers. When a buffer transfer is performed in saw-wave mode, the source of count clearing is a hardware source, software, event input, or synchronous clearing. During clearing by input capture, buffer transfer does not proceed.

ADTDB Bit (GTADTRB Double Buffer Operation)

These bits set buffer operation with the GTADTRB, GTADTBRB, and GTADTDBRB registers combined.

Note 1. The buffer operation mode is fixed in saw-wave one-shot pulse mode or triangle-wave PWM mode 3 (32-bit transfer at trough).

26.2.16 General PWM Timer Count Direction Register (GTUDC)

Address(es): GPT0.GTUDC 000C 2108h, GPT1.GTUDC 000C 2188h, GPT2.GTUDC 000C 2208h, GPT3.GTUDC 000C 2288h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	UDF	UD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	UD	Count Direction Setting	0: GTCNT counts down. 1: GTCNT counts up.	R/W
b1	UDF	Forcible Count Direction Setting	0: Not forcibly set 1: Forcibly set	R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The GTUDC register sets the direction in which the GTCNT counter counts (up-counting or down-counting). Values written to the GTUDC register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

- In saw-wave mode

When the UD value is set to 0 during up-counting, the count direction is changed at an overflow (count clock when GTCNT counter value is equal to the GTPR value). When the UD value is set to 1 during down-counting, the count direction is changed at an underflow (count clock when GTCNT counter value is equal to 0000h).
If the UD value is changed from 1 to 0 with the UDF bit being 0 and while counting is stopped, the counter starts up-counting and the count direction is changed at an overflow (count clock when GTCNT counter value is equal to GTPR value).
If the UD value is changed from 0 to 1 with the UDF bit being 0 and while counting is stopped, the counter starts down-counting and the count direction is changed at an underflow (count clock when GTCNT counter value is equal to 0000h).
When the UDF bit is set to 1 while counting is stopped, the UD bit value at that time is reflected in the count direction when counting starts.

- In triangle-wave mode

Even if the UD value is changed during counting, the change will not be reflected in the count direction.
If the UD value is modified while the UDF bit is 0 and counting is stopped, the change will not be reflected in the count direction when counting starts. If the UDF bit is set to 1 while counting is stopped, the UD bit value at that time is reflected in the count direction when counting starts.

UD Bit (Count Direction Setting)

This bit sets the count direction (up-counting or down-counting) for the GTCNT counter.

UDF Bit (Forcible Count Direction Setting)

This bit forcibly sets the count direction when the GTCNT counter starts operation as the UD value.
Only 0 should be written to this bit during count operation.
When 1 has been written to this bit while counting is stopped, this bit should be returned to 0 before counting starts.

26.2.17 General PWM Timer Interrupt and A/D Converter Start Request Skipping Setting Register (GTITC)

Address(es): GPT0.GTITC 000C 210Ah, GPT1.GTITC 000C 218Ah, GPT2.GTITC 000C 220Ah, GPT3.GTITC 000C 228Ah

b15	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

GTITC sets the skipping function for the GTCNT counter overflow (GTPR compare match) interrupt (GTCIV) and underflow interrupt (GTCIU) and also sets whether to link the other interrupts and A/D converter start requests with the GTCIV/GTCIU interrupt skipping function. Note that dead time error interrupts cannot be linked with the GTCIV/GTCIU interrupt skipping function. Values written to the GTITC register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

ITLA Bit (GTCCRA Compare Match/Input Capture Interrupt Link)

This bit specifies whether to link the GTCCRA compare match/input capture interrupt (GTCIA) with the GTCIV/GTCIU interrupt skipping function.

ITLB Bit (GTCCRB Compare Match/Input Capture Interrupt Link)

This bit specifies whether to link the GTCCRB compare match/input capture interrupt (GTCIB) with the GTCIV/GTCIU interrupt skipping function.

ITLC Bit (GTCCRC Compare Match Interrupt Link)

This bit specifies whether to link the GTCCRC compare match interrupt (GTCIC) with the GTCIV/GTCIU interrupt skipping function.

ITLD Bit (GTCCRD Compare Match Interrupt Link)

This bit specifies whether to link the GTCCRD compare match interrupt (GTCID) with the GTCIV/GTCIU interrupt skipping function.

ITLE Bit (GTCCRE Compare Match Interrupt Link)

This bit specifies whether to link the GTCCRE compare match interrupt (GTCIE) with the GTCIV/GTCIU interrupt skipping function.

ITLF Bit (GTCCRF Compare Match Interrupt Link)

This bit specifies whether to link the GTCCRF compare match interrupt (GTCIF) with the GTCIV/GTCIU interrupt skipping function.

IVTC[1:0] Bits (GTCIV/GTCIU Interrupt Skipping Function Select)

These bits set the skipping function for the GTPR compare match (GTCNT counter overflow) interrupt (GTCIV) and GTCNT counter underflow interrupt (GTCIU).

IVTT[2:0] Bits (GTCIV/GTCIU Interrupt Skipping Count Select)

These bits set the skipping count for the GTPR compare match (GTCNT counter overflow) interrupt (GTCIV) and GTCNT counter underflow interrupt (GTCIU).
When modifying the IVTT[2:0] bits, first set the IVTC[1:0] bits to 00b.

ADTAL Bit (GTADTRA A/D Converter Start Request Link)

This bit specifies whether to link the GTADTRA A/D converter start request with GTCIVn/GTCIUn interrupt skipping function (n = 0 to 3).

ADTBL Bit (GTADTRB A/D Converter Start Request Link)

This bit specifies whether to link the GTADTRB A/D converter start request with GTCIVn/GTCIUn interrupt skipping function (n = 0 to 3).

26.2.18 General PWM Timer Status Register (GTST)

Address(es): GPT0.GTST 000C 210Ch, GPT1.GTST 000C 218Ch, GPT2.GTST 000C 220Ch, GPT3.GTST 000C 228Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TUCF	—	—	—	DTEF	ITCNT[2:0]			—	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	The read value is undefined. The write value should be 1.	R/W
b10 to b8	ITCNT[2:0]	GTCIV/GTCIU Interrupt Skipping Count Counter	Counter for counting the number of times a timer interrupt has been skipped.	R
b11	DTEF	Dead Time Error Flag	0: No dead time error has occurred. 1: A dead time error has occurred.	R
b14 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	TUCF	Count Direction Flag	0: The GTCNT counter counts downward. 1: The GTCNT counter counts upward.	R

GTST indicates the status of the GPT. Values written to the GTST register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

ITCNT[2:0] Bits (GTCIV/GTCIU Interrupt Skipping Count Counter)

When the GTCIV/GTCIU interrupt skipping function is used (the GTITC.IVTC[1:0] bits are set to a value other than 00b), the counter is incremented by 1 every time the GTCIV/GTCIU interrupt source is generated.
[Clearing conditions]

- The GTCIV/GTCIU interrupt skipping function is not used (the GTITC.IVTT[2:0] bits are 000b when the GTITC.IVTC[1:0] bits are 00b).
- The GTCIV/GTCIU interrupt skipping count matches the specified count (the ITCNT[2:0] bits match the skipping count specified by the GTITC.IVTT[2:0] bits).

DTEF Flag (Dead Time Error Flag)

This flag indicates that the timer output toggle point after the automatic addition of dead time has exceeded the count period.
This flag returns to 0 when the timer output toggle point after the automatic addition of dead time is back within the period. This flag can only be read from. (Writing 0 to clear the flag is not allowed.)
When an interrupt by the DTEF flag is enabled (the GTINTAD.EINT bit is 1), a GDTE interrupt is generated every time the DTEF flag changes from 0 to 1.
[Setting condition]

- When a change point of the waveform after the automatic setting of dead time has exceeded the count period

[Clearing condition]

- The timer output toggle point after the automatic addition of dead time is within the count period.

TUCF Flag (Count Direction Flag)

This flag indicates the count direction of the GTCNT counter.
When the GTUDC.UDF bit is set to 1 while the count operation is stopped, the value of the GTUDC.UD bit at that time is set to the flag.
In triangle-wave mode whether count operation is stopped or in progress, the flag is set to 1 by clearing (a hardware

source, software, event input, input capture, or synchronous clearing). In saw-wave mode, the TUCF flag is not updated by clearing.
In saw-wave mode during count operation, the value of the GTUDC.UD bit is set to the TUCF flag at an overflow in up-counting or an underflow in down-counting. In triangle-wave mode, the flag is set to 0 at a crest, to 1 at a trough, and to 0 when a value larger than the value of the GTCNT counter is set to the GTPR register.

26.2.19 General PWM Timer Counter (GTCNT)

Address(es): GPT0.GTCNT 000C 210Eh, GPT1.GTCNT 000C 218Eh, GPT2.GTCNT 000C 220Eh, GPT3.GTCNT 000C 228Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The GTCNT counter is a 16-bit readable/writable counter. There is one GTCNT counter for each channel. The GTCNT counter can be written only when count operation is stopped and cannot be written during count operation.
Access in 8-bit units to the GTCNT counter is prohibited, and it should be accessed in 16-bit units. Values written to the GTCNT counter of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

26.2.20 General PWM Timer Compare Capture Register m (GTCCRm) (m = A to F)

Address(es): GPT0.GTCCRA 000C 2110h, GPT1.GTCCRA 000C 2190h, GPT2.GTCCRA 000C 2210h, GPT3.GTCCRA 000C 2290h,
GPT0.GTCCRB 000C 2112h, GPT1.GTCCRB 000C 2192h, GPT2.GTCCRB 000C 2212h, GPT3.GTCCRB 000C 2292h,
GPT0.GTCCRC 000C 2114h, GPT1.GTCCRC 000C 2194h, GPT2.GTCCRC 000C 2214h, GPT3.GTCCRC 000C 2294h,
GPT0.GTCCRD 000C 2116h, GPT1.GTCCRD 000C 2196h, GPT2.GTCCRD 000C 2216h, GPT3.GTCCRD 000C 2296h,
GPT0.GTCCRE 000C 2118h, GPT1.GTCCRE 000C 2198h, GPT2.GTCCRE 000C 2218h, GPT3.GTCCRE 000C 2298h,
GPT0.GTCCRF 000C 211Ah, GPT1.GTCCRF 000C 219Ah, GPT2.GTCCRF 000C 221Ah, GPT3.GTCCRF 000C 229Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The GTCCRm registers are 16-bit readable/writable registers. There are six GTCCRm registers for each channel.
The GTCCRA and GTCCRB registers are registers used for both output compare and input capture.
The GTCCRC and GTCCRE registers are compare match registers, and can also function as buffer registers for the GTCCRA and GTCCRB registers.
The GTCCRD and GTCCRF registers are compare match registers, and can also function as buffer registers for the GTCCRC and GTCCRE registers (double buffer registers for the GTCCRA and GTCCRB registers). Values written to the GTCCRm register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

26.2.21 General PWM Timer Period Setting Register (GTPR)

Address(es): GPT0.GTPR 000C 211Ch, GPT1.GTPR 000C 219Ch, GPT2.GTPR 000C 221Ch, GPT3.GTPR 000C 229Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The GTPR register is a 16-bit readable/writable register that sets the maximum count value of the GTCNT counter. There is one GTPR register for each channel.
In saw-wave mode, the value of (GTPR + 1) is the count period. In triangle-wave mode, the value of (GTPR value × 2) is the count period. Values written to the GTPR register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.
Do not modify the GTPR register during down-counting in saw-wave mode.

26.2.22 General PWM Timer Period Setting Buffer Register (GTPBR)

Address(es): GPT0.GTPBR 000C 211Eh, GPT1.GTPBR 000C 219Eh, GPT2.GTPBR 000C 221Eh, GPT3.GTPBR 000C 229Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The GTPBR register is a 16-bit readable/writable register that functions as a buffer register for the GTPR register. There is one GTPBR register for each channel. Values written to the GTPBR register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

26.2.23 General PWM Timer Period Setting Double Buffer Register (GTPDBR)

Address(es): GPT0.GTPDBR 000C 2120h, GPT1.GTPDBR 000C 21A0h, GPT2.GTPDBR 000C 2220h, GPT3.GTPDBR 000C 22A0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The GTPDBR register is a 16-bit readable/writable register that functions as a buffer register for the GTPBR register (a double buffer register for the GTPR register). There is one GTPDBR register for each channel. Values written to the GTPDBR register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

26.2.24 A/D Converter Start Request Timing Register m (GTADTRm) (m = A, B)

Address(es): GPT0.GTADTRA 000C 2124h, GPT1.GTADTRA 000C 21A4h, GPT2.GTADTRA 000C 2224h, GPT3.GTADTRA 000C 22A4h, GPT0.GTADTRB 000C 212Ch, GPT1.GTADTRB 000C 21Ach, GPT2.GTADTRB 000C 222Ch, GPT3.GTADTRB 000C 22ACh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The GTADTRm registers are 16-bit readable/writable registers that set the timing of A/D converter start request generation. When the GTADTRm value matches the GTCNT counter value, an A/D converter start request is generated. There are two GTADTRm registers for each channel.

Access in 8-bit units to the GTADTRm registers is prohibited, and they should be accessed in 16-bit units. Values written to the GTADTRm register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

26.2.25 A/D Converter Start Request Timing Buffer Register m (GTADTBRm) (m = A, B)

Address(es): GPT0.GTADTBRA 000C 2126h, GPT1.GTADTBRA 000C 21A6h, GPT2.GTADTBRA 000C 2226h, GPT3.GTADTBRA 000C 22A6h, GPT0.GTADTBRB 000C 212Eh, GPT1.GTADTBRB 000C 21AEh, GPT2.GTADTBRB 000C 222Eh, GPT3.GTADTBRB 000C 22AEh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The GTADTBRm registers are 16-bit readable/writable registers that function as buffer registers for the GTADTRm register. There are two GTADTBRm registers for each channel.

Access in 8-bit units to the GTADTBRm registers is prohibited, and they should be accessed in 16-bit units. Values written to the GTADTBRm register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

26.2.26 A/D Converter Start Request Timing Double Buffer Register m (GTADTDBRm) (m = A, B)

Address(es): GPT0.GTADTDBRA 000C 2128h, GPT1.GTADTDBRA 000C 21A8h, GPT2.GTADTDBRA 000C 2228h, GPT3.GTADTDBRA 000C 22A8h, GPT0.GTADTDBRB 000C 2130h, GPT1.GTADTDBRB 000C 21B0h, GPT2.GTADTDBRB 000C 2230h, GPT3.GTADTDBRB 000C 22B0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The GTADTDBRm registers are 16-bit readable/writable registers that function as buffer registers for the GTADTBRm registers (double buffer registers for the GTADTRm registers). There are two GTADTDBRm registers for each channel.

Access in 8-bit units to the GTADTDBRm registers is prohibited, and they should be accessed in 16-bit units. Values written to the GTADTDBRm register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

26.2.27 General PWM Timer Output Negate Control Register (GTONCR)

Address(es): GPT0.GTONCR 000C 2134h, GPT1.GTONCR 000C 21B4h, GPT2.GTONCR 000C 2234h, GPT3.GTONCR 000C 22B4h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OBE	OAE	—	SWN	—	—	—	NFV	NFS[3:0]				NVB	NVA	NEB	NEA
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	NEA	GTIOCnA Pin Negate Control Enable	0: Negate is disabled 1: Negate is enabled	R/W
b1	NEB	GTIOCnB Pin Negate Control Enable	0: Negate is disabled 1: Negate is enabled	R/W
b2	NVA	GTIOCnA Pin Negate Value Setting	0: GTIOCnA pin is set to 0 when negate control is performed. 1: GTIOCnA pin is set to 1 when negate control is performed.	R/W
b3	NVB	GTIOCnB Pin Negate Value Setting	0: GTIOCnB pin is set to 0 when negate control is performed. 1: GTIOCnB pin is set to 1 when negate control is performed.	R/W
b7 to b4	NFS[3:0]	GTIOC Output Negate Source Select	b7 b4 0 1 1 1: GTETRG pin input 1 x x x: Software control (control through SWN bit) Settings other than the above are prohibited when negate control is enabled by the NEA or NEB bit.	R/W
b8	NFV	Negate Source Polarity Select	0: Negate control is provided when the negate source has become 0. 1: Negate control is provided when the negate source has become 1.	R/W
b11 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	SWN	Software Negate Control	When NFV bit is 0: 0: Negate control is provided. 1: Negate control is not provided. When NFV bit is 1: 0: Negate control is not provided. 1: Negate control is provided.	R/W
b13	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b14	OAE	GTIOCnA Pin Output Enable	0: Output is disabled 1: Output is enabled	R/W
b15	OBE	GTIOCnB Pin Output Enable	0: Output is disabled 1: Output is enabled	R/W

n = 0 to 3

The GTONCR register controls negate of the GTIOCnA pin output and GTIOCnB pin output. Values written to the GTONCR register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

NEA Bit (GTIOCnA Pin Negate Control Enable)

This bit enables negate control of the GTIOCnA pin output.

NEB Bit (GTIOCnB Pin Negate Control Enable)

This bit enables negate control of the GTIOCnB pin output.

NVA Bit (GTIOCnA Pin Negate Value Setting)

This bit sets the output value of the GTIOCnA pin at negate control.

NVB Bit (GTIOCnB Pin Negate Value Setting)

This bit sets the output value of the GTIOCnB pin at negate control.

NFS[3:0] Bits (GTIOC Output Negate Source Select)

These bits select the negate source for the GTIOCnA pin output and GTIOCnB pin output.
If negate control is not enabled by the NEA or NEB bit, it is not necessary to change the value of these bits from their initial value.

NFV Bit (Negate Source Polarity Select)

This bit selects the negate source polarity for the GTIOCnA pin output and GTIOCnB pin output.

SWN Bit (Software Negate Control)

This bit specifies whether to provide negate control for the GTIOCnA pin output and GTIOCnB pin output.
This bit setting is valid when software control is selected as the negate source (NFS[3] bit is set to 1).

OAE Bit (GTIOCnA Pin Output Enable)

This bit selects whether to output the GTIOCnA pin output. This bit setting is valid only when compare match has been set (the GTIOR.GTIOA[5] bit is 0).

OBE Bit (GTIOCnB Pin Output Enable)

This bit selects whether to output the GTIOCnB pin output.This bit setting is valid only when compare match has been set (the GTIOR.GTIOB[5] bit is 0).

26.2.28 General PWM Timer Dead Time Control Register (GTDTCR)

Address(es): GPT0.GTDTCR 000C 2136h, GPT1.GTDTCR 000C 21B6h, GPT2.GTDTCR 000C 2236h, GPT3.GTDTCR 000C 22B6h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	TDFER	—	—	TDBDE	TDBUE	—	—	—	TDE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TDE	Negative-Phase Waveform Setting	0: GTCCRB is set without using GTDVU and GTDVD. 1: GTDVU and GTDVD are used to set the compare match value for negative-phase waveform with dead time automatically in GTCCRB.	R/W
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	TDBUE	GTDVU Buffer Operation Enable	0: GTDVU buffer operation is disabled 1: GTDVU buffer operation is enabled	R/W
b5	TDBDE	GTDVD Buffer Operation Enable	0: GTDVD buffer operation is disabled 1: GTDVD buffer operation is enabled	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	TDFER	GTDVD Setting	0: GTDVU and GTDVD are set separately. 1: The value written to GTDVU is automatically set to GTDVD.	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The GTDTCR register enables automatic setting of a compare match value for negative-phase waveform with dead time. Values written to the GTDTCR register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

TDE Bit (Negative-Phase Waveform Setting)

This bit sets whether to use the GTDVU and GTDVD registers. When the GTDVU and GTDVD registers are used, the compare match value for a negative-phase waveform with dead time that was obtained by the compare match value of a positive-phase waveform (GTCCRA) and the dead time value (GTDVU and GTDVD) is automatically set in the GTCCRB register.

This bit is enabled in saw-wave one-shot pulse mode and all triangle-wave PWM modes. The TDE bit setting is ignored in saw-wave PWM mode, and automatic setting does not take place.

The automatically set GTCCRB value has the following upper and lower limit values.

- Saw-wave one-shot pulse mode
  Upper limit value: the value set in the GTPR register
  Lower limit value: 0000h
- Triangle wave PWM mode
  Upper limit value: the value set in the GTPR register - 1
  Lower limit value: 0001h in up-counting, 0000h in down-counting

If the obtained GTCCRB value is not within the range between the upper and lower limits, the upper or lower limit is set in the GTCCRB register, and the GTST.DTEF flag becomes 1. However, if the obtained GTCCRB value exceeds the upper limit in triangle-wave PWM mode, the GTST.DTEF flag becomes 0.

TDBUE Bit (GTDVU Buffer Operation Enable)

This bit enables buffer operation with the GTDVU and GTDBU registers combined.

The buffer transfer timing is at an overflow or underflow for saw waves, and the trough for triangle waves.

TDBDE Bit (GTDVD Buffer Operation Enable)

This bit enables buffer operation with the GTDVD and GTDBD registers combined.
The buffer transfer timing is at an overflow or underflow for saw waves, and the trough for triangle waves.
When this bit and the TDFER bit are set to 1 simultaneously, the TDFER bit setting is given priority.

TDFER Bit (GTDVD Setting)

This bit sets whether or not the value written to the GTDVU register is also set to the GTDVD register automatically.

26.2.29 General PWM Timer Dead Time Value Register m (GTDVm) (m = U, D)

Address(es): GPT0.GTDVU 000C 2138h, GPT1.GTDVU 000C 21B8h, GPT2.GTDVU 000C 2238h, GPT3.GTDVU 000C 22B8h, GPT0.GTDVD 000C 213Ah, GPT1.GTDVD 000C 21Bah, GPT2.GTDVD 000C 223Ah, GPT3.GTDVD 000C 22BAh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The GTDVm registers are 16-bit readable/writable registers that set the dead time for generating PWM waveforms with dead time.
There are two GTDVm registers for each channel: the GTDVU register used for up-counting and the GTDVD register used for down-counting.
When using the dead-time automatic setting function, do not set a value that makes a change point of the waveform exceeding the count period. The change point of the negative-phase waveform, which is automatically calculated, is obtained by reading the GTCCRB register. When using the GTDVm register, writing to the GTCCRB register is prohibited. When setting this register to 0000h, waveforms without dead time are output.
Access in 8-bit units to the GTDVm registers is prohibited, and they should be accessed in 16-bit units. Values written to the GTDVm register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

26.2.30 General PWM Timer Dead Time Buffer Register m (GTDBm) (m = U, D)

Address(es): GPT0.GTDBU 000C 213Ch, GPT1.GTDBU 000C 21BCh, GPT2.GTDBU 000C 223Ch, GPT3.GTDBU 000C 22BCh, GPT0.GTDBD 000C 213Eh, GPT1.GTDBD 000C 21Beh, GPT2.GTDBD 000C 223Eh, GPT3.GTDBD 000C 22BEh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The GTDBm registers are 16-bit readable/writable registers that function as buffer registers for the GTDVm registers.
There are two GTDBm registers for each channel.
Values written to the GTDBm register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

26.2.31 General PWM Timer Output Protection Function Status Register (GTSOS)

Address(es): GPT0.GTSOS 000C 2140h, GPT1.GTSOS 000C 21C0h, GPT2.GTSOS 000C 2240h, GPT3.GTSOS 000C 22C0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SOS[1:0]	
Value after reset:	0	0	0	0	0	0	x	x	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b1, b0	SOS[1:0]	Output Protection Function Status	b1 b0 0 0: Normal operation 0 1: Protected state (GTCCRA = 0 is set during transfer at trough or crest) 1 0: Protected state (GTCCRA ≥ GTPR is set during transfer at trough) 1 1: Protected state (GTCCRA ≥ GTPR is set during transfer at crest)	R
b7 to b2	—	Reserved	These bits are read as 0 and cannot be modified.	R
b9, b8	—	Reserved	The read value is undefined. These bits cannot be modified.	R
b15 to b10	—	Reserved	These bits are read as 0 and cannot be modified.	R

The GTSOS register is a status register that indicates the status of the output protection function. The output protection function is enabled only when the dead time is automatically set (the GTDTCR.TDE bit is 1) in triangle-wave mode.

SOS[1:0] Bits (Output Protection Function Status)

This bit indicates the status of the output protection function in triangle-wave PWM mode. For details of the output protection function, see section 26.7.4, Output Protection Function for GTIOC Pin Output.

26.2.32 General PWM Timer Output Protection Function Temporary Release Register (GTSOTR)

Address(es): GPT0.GTSOTR 000C 2142h, GPT1.GTSOTR 000C 21C2h, GPT2.GTSOTR 000C 2242h, GPT3.GTSOTR 000C 22C2h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SOTR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SOTR	Output Protection Function Temporary Release	0: Protected state is not released 1: Protected state is released	R/W
b15 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The GTSOTR register temporarily releases the protected state of GTIOCnB pin output when output protection has been set.

The protected state can be released only for the case of the GTSOS.SOS[1:0] bits are 10b (protected state in which GTCCRA ≥ GTPR has occurred during transfer at trough). The protected state cannot be released for any other case.

Values written to the GTSOTR register of the relevant channel in which write access is disabled by the GTWP.WPn bit (n = 0 to 3) are ignored.

SOTR Bit (Output Protection Function Temporary Release)

This bit sets whether to temporarily release the protected state of the GTIOCnB pin output in an output protected state. After the SOTR bit has been set to 1, the output protection function is canceled from the first trough. After the SOTR bit has been set to 0, output protection is resumed from the first trough.

26.3 Operation

26.3.1 Basic Operation

Each channel has a GTCNT counter, GTPR register, and GTCCRm register (m = A to F). The GTCNT counter performs up-counting, down-counting, or up-/down-counting, available for periodic count operation. The timer period is set by the GTPR register.
In this section, up-counting and down-counting operation is referred to as saw-wave (half-wave) operation. Up-/down-counting operation is referred to as triangle-wave (full-wave) operation.

26.3.1.1 Counter Operation

(1) Periodic Count Operation (in Up-Counting)

The GTCNT counter in each channel starts up-counting when the corresponding GTSTS.CSTn bit is set to 1. When the GTCNT counter value changes from the GTPR register value to 0000h (overflow), a GTCIV interrupt is requested if the GTINTAD.GTINTPR[0] bit is 1. After GTCNT overflows, up-counting is resumed from 0000h.
Figure 26.2 shows an example of periodic count operation in up-counting.

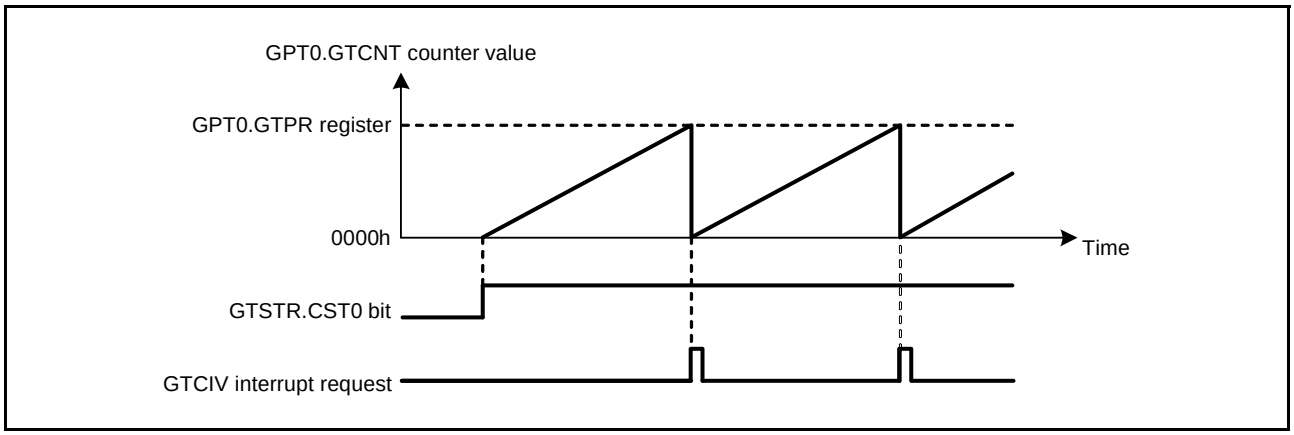

Figure 26.2 Example of Periodic Count Operation (in Up-Counting)

Figure 26.3 shows an example for setting periodic count operation in up-counting.

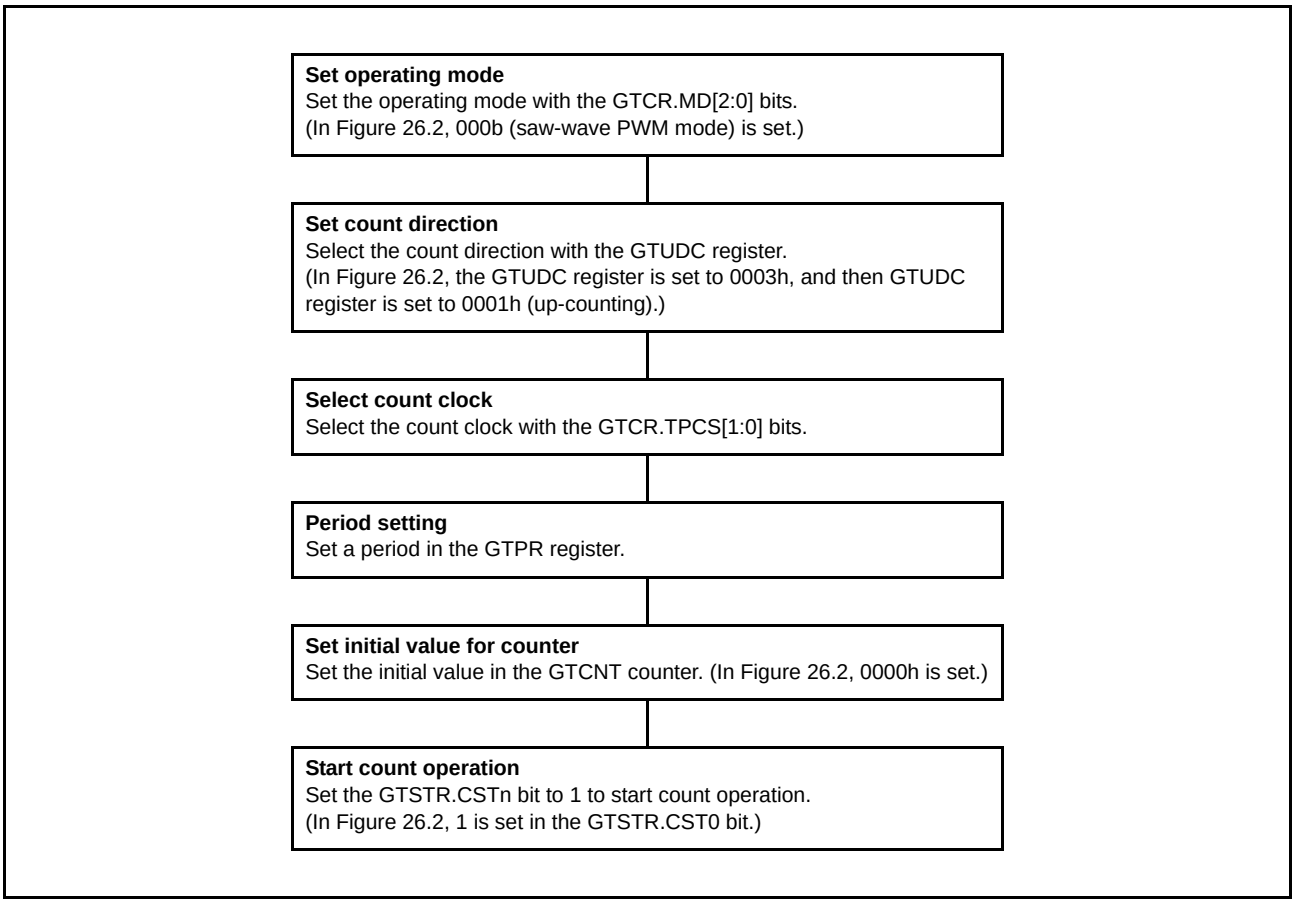

Figure 26.3 Example for Setting Periodic Count Operation (in Up-Counting)

(2) Periodic Count Operation (in Down-Counting)

The GTCNT counter in each channel can perform down-counting by setting GTUDC.
When the GTCNT counter value changes from 0000h to the GTPR register value (underflow), a GTCIU interrupt is requested if the GTINTAD.GTINTPR[1] bit is 1. After the GTCNT counter underflows, down-counting is resumed from the GTPR value.
Figure 26.4 shows an example of periodic count operation in down-counting.

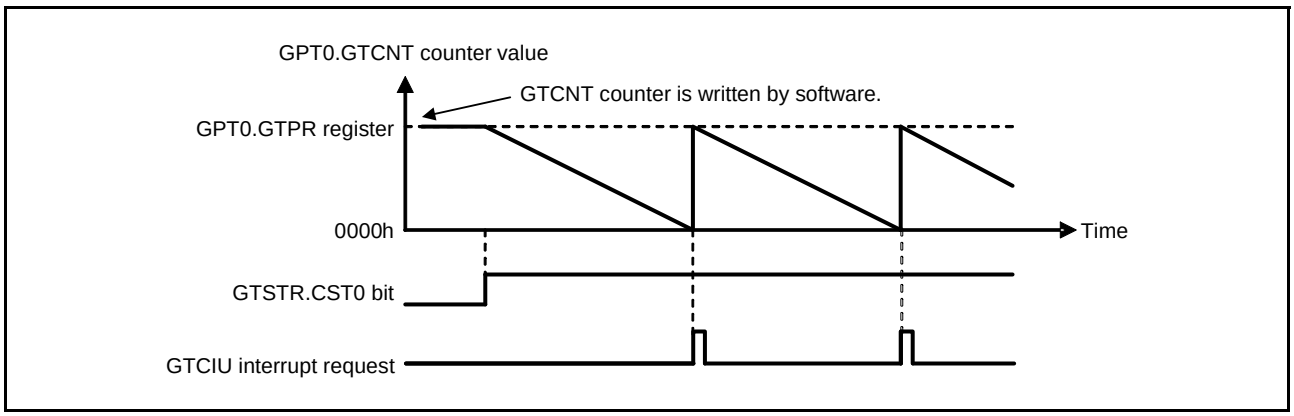

Figure 26.4 Example of Periodic Count Operation (in Down-Counting)

Figure 26.5 shows an example for setting periodic count operation in down-counting.

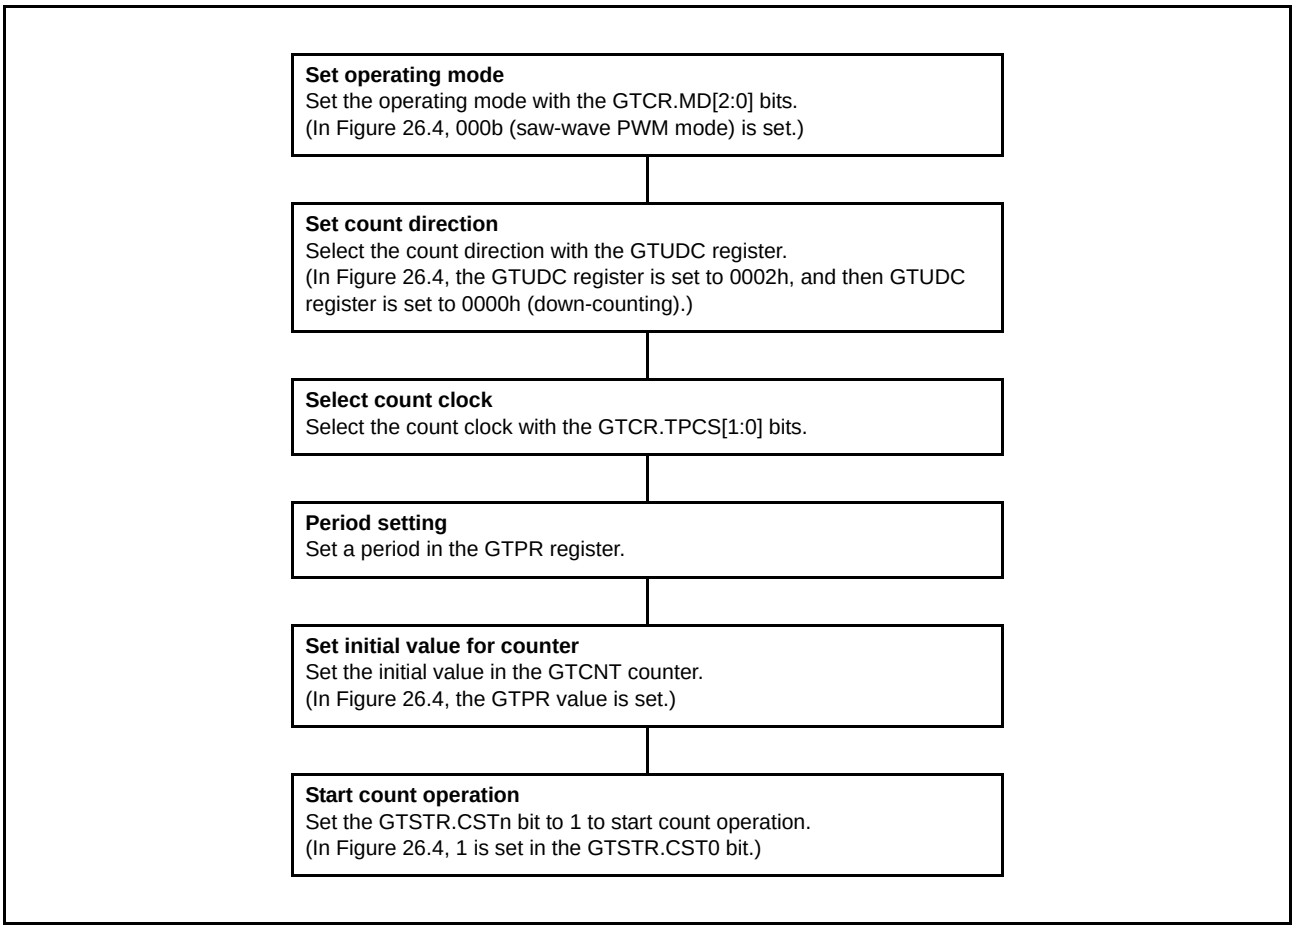

Figure 26.5 Example for Setting Periodic Count Operation (in Down-Counting)

26.3.1.2 Waveform Output by Compare Match

Compare match refers to when the GPTn.GTCNT counter value matches the GPTn.GTCCRA or GPTn.GTCCRB register value (n = 0 to 3). Low, high, or toggle output can be performed from the GTIOCnA or GTIOCnB pin in synchronization with the count clock after a compare match occurs.
In addition, the GTIOCnA or GTIOCnB pin output can be low, high, or toggled at the “end of the cycle” which is determined by the GPTn.GTPR register.
The end of the cycle is:

- For saw waves in up-counting: When the GPTn.GTCNT counter value changes from the GPTn.GTPR register value to 0 (overflow)
- For saw waves in down-counting: When the GPTn.GTCNT counter value changes from 0000h to the GPTn.GTPR register value (underflow)
- For triangle waves: When the GPTn.GTCNT counter value changes from 0000h to 0001h (trough)

(1) Low Output and High Output

Figure 26.6 shows an example of low output and high output operation by a compare match of GTCCRA and GTCCRB.
In this example, the GPT0.GTCNT counter performs up-counting, and settings have been made so that high is output from the GTIOC0A pin by a GPT0.GTCCRA compare match, and low is output from the GTIOC0B pin by a GPT0.GTCCRB compare match. The pin level does not change when the specified level and pin level match.

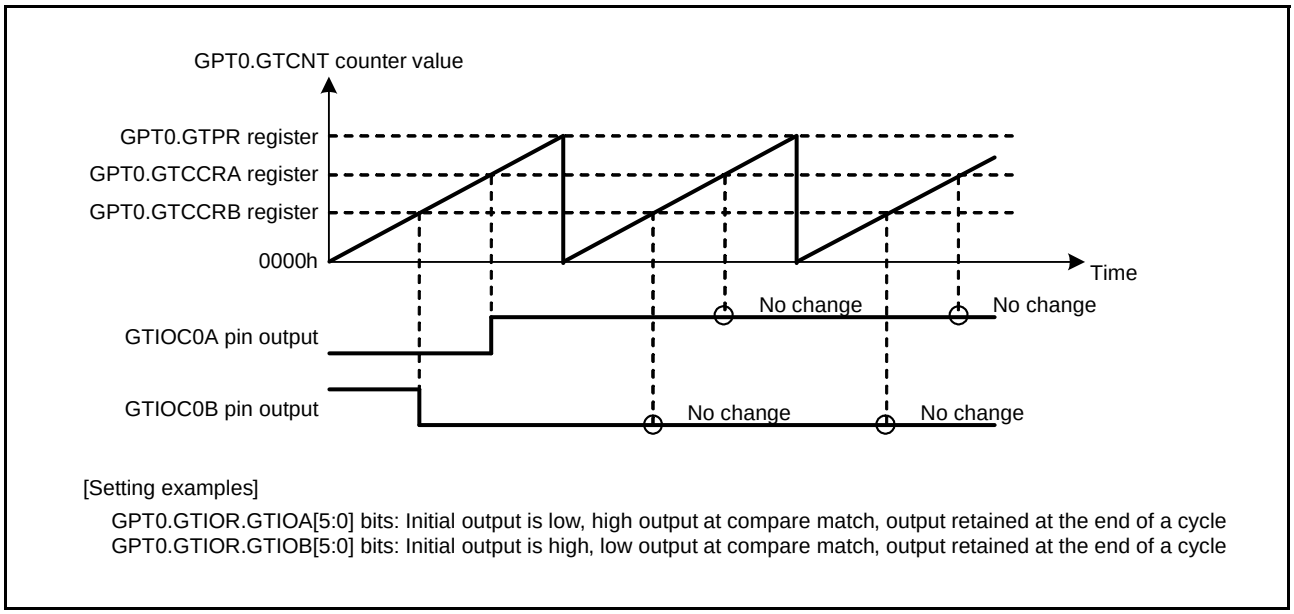

Figure 26.6 Example of Low Output and High Output Operation

Figure 26.7 shows an example for setting low output and high output operation.

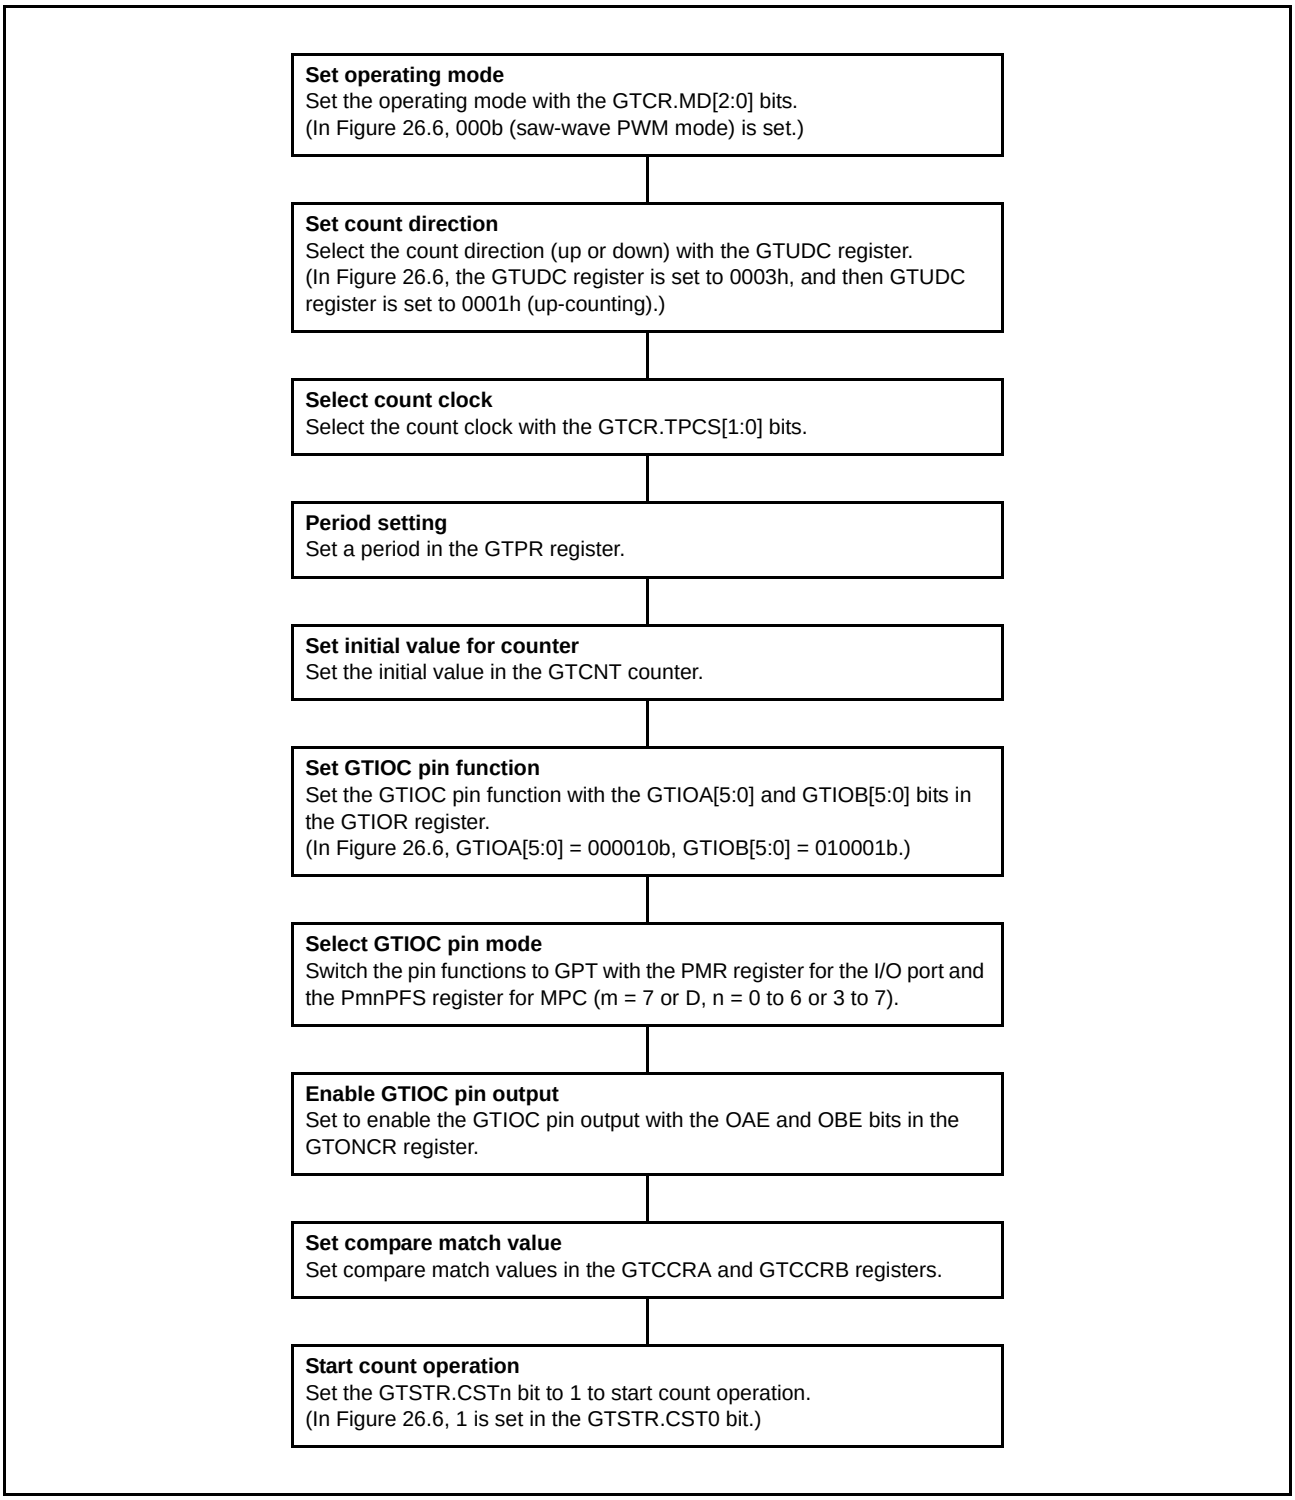

Figure 26.7 Example for Setting Low Output and High Output Operation

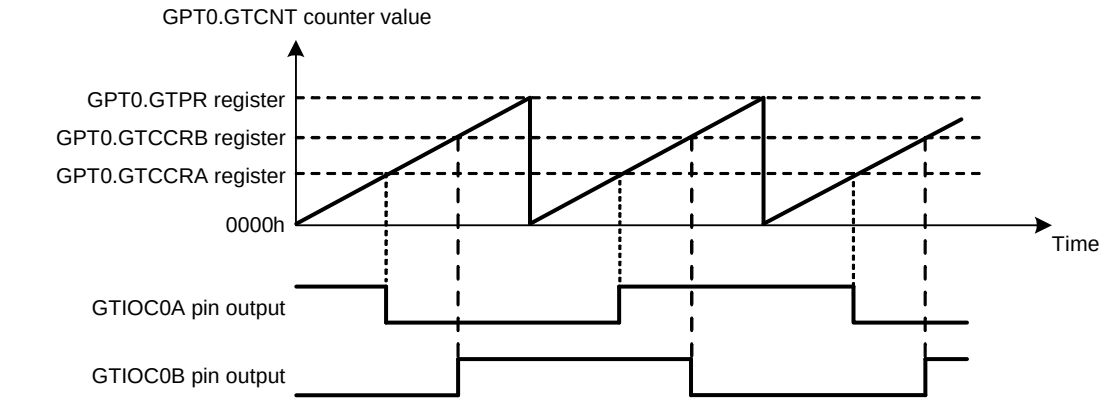
(2) Toggled Output

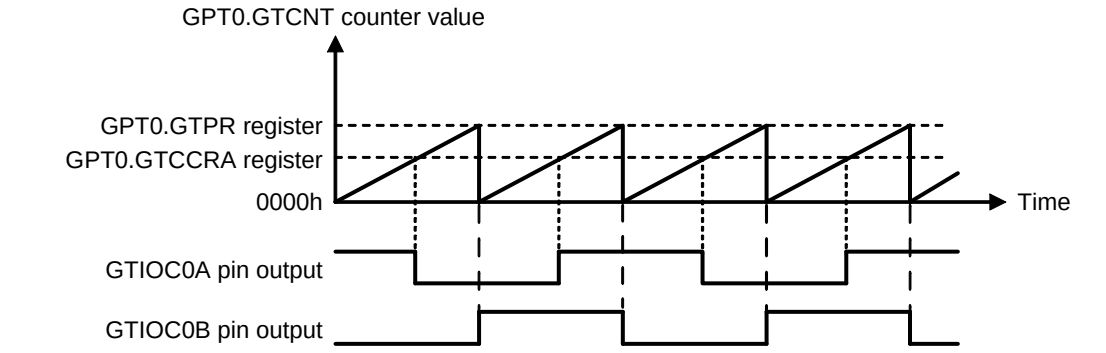
Figure 26.8 and Figure 26.9 show examples of toggled output operation by compare matches of GTCCRA and GTCCRB. In Figure 26.8, the GPT0.GTCNT counter performs up-counting, and settings have been made so that the GTIOC0A pin output by a GPT0.GTCCRA compare match and GTIOC0B pin output by a GPT0n.GTCCRB compare match are toggled.

In Figure 26.9, the GPT0.GTCNT counter performs up-counting, and settings have been made so that the GTIOC0A output is toggled by a compare match of GPT0.GTCCRA and the GTIOC0B output is toggled at the end of the cycle.



[Setting examples]
GPT0.GTIOR.GTIOA[5:0] bits: Initial output is high, output toggled at compare match, output retained at the end of a cycle
GPT0.GTIOR.GTIOB[5:0] bits: Initial output is low, output toggled at compare match, output retained at the end of a cycle

Figure 26.8 Example of Toggled Output Operation (1)



[Setting examples]
GPT0.GTIOR.GTIOA[5:0] bits: Initial output is high, output toggled at compare match, output retained at the end of a cycle
GPT0.GTIOR.GTIOB[5:0] bits: Initial output is low, output retained at compare match, output toggled at the end of a cycle

Figure 26.9 Example of Toggled Output Operation (2)

Figure 26.10 shows an example for setting toggled output operation.

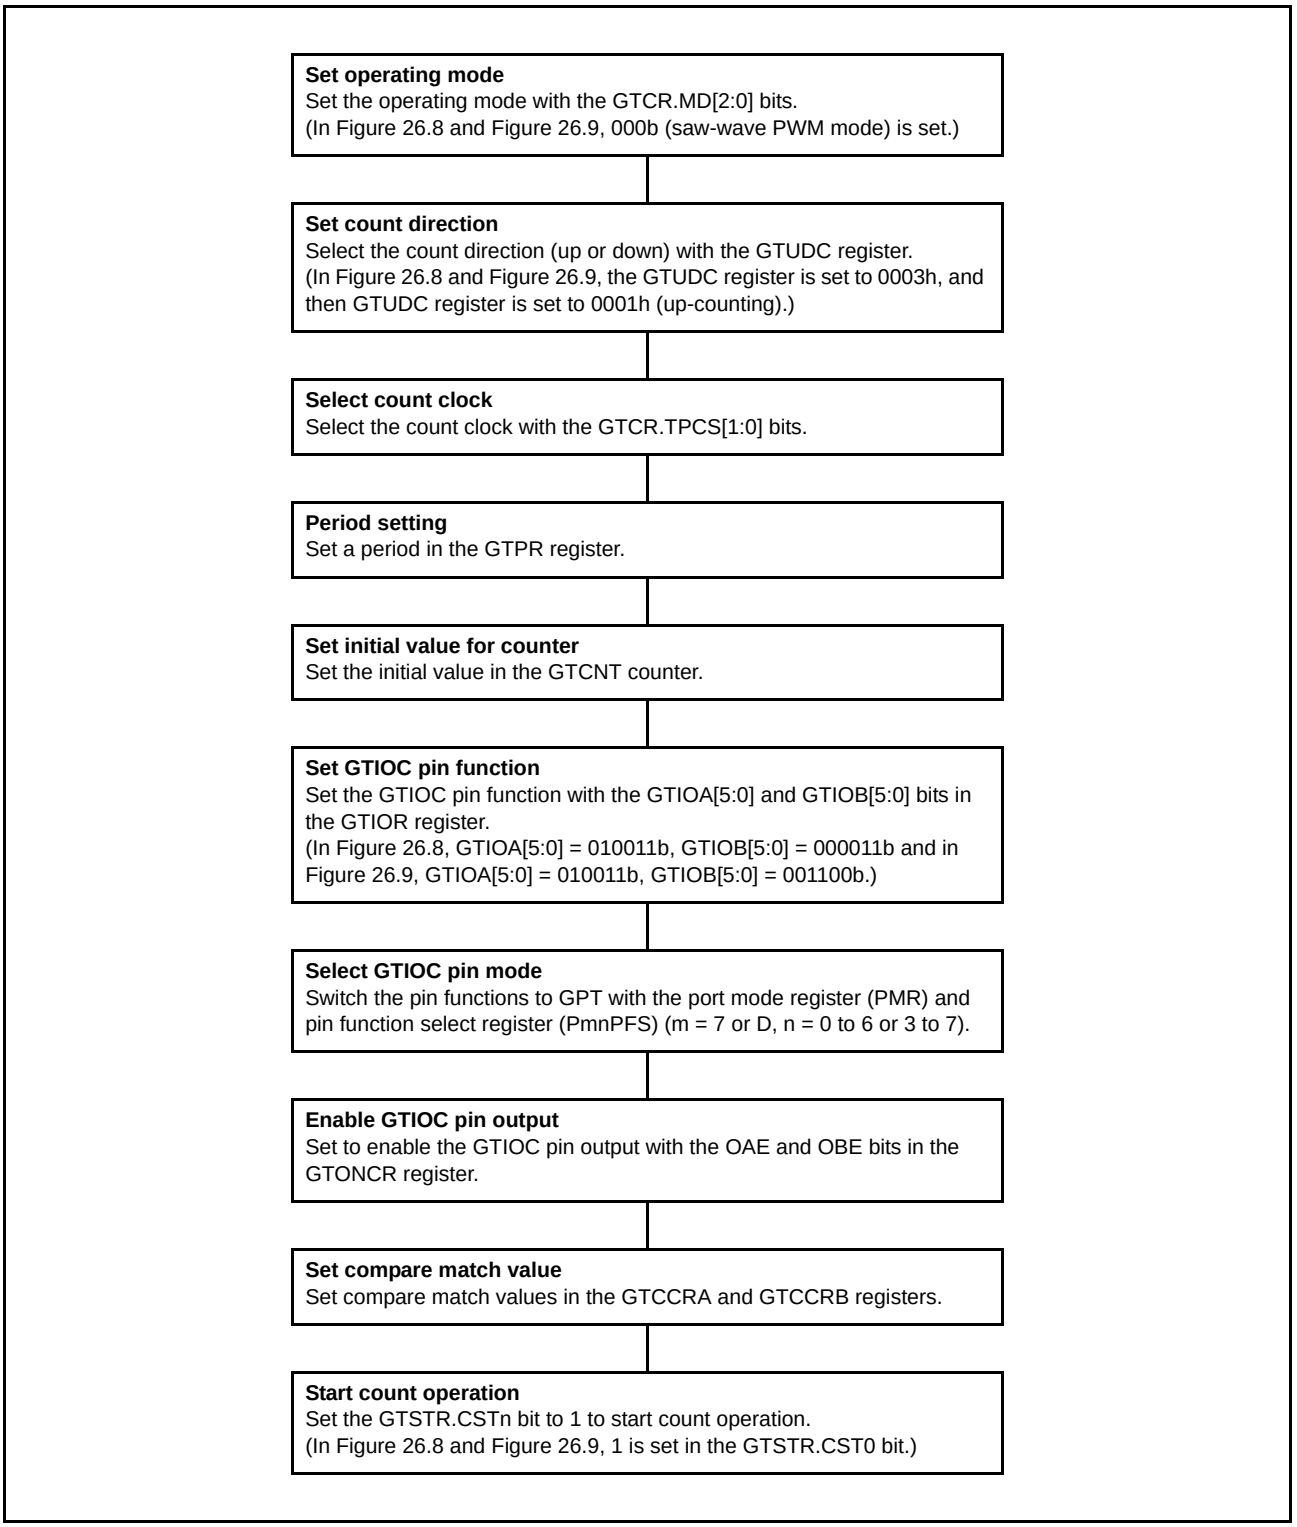


Figure 26.10 Example for Setting Toggled Output Operation

26.3.1.3 Input Capture Function

The GPTn.GTCNT counter value can be transferred to either GPTn.GTCCRA or GPTn.GTCCRB on detection of the input edge of the GTIOCnA input pin or GTIOCnB input pin, respectively (n = 0 to 3). The rising edge, falling edge, or both edges can be selected as the detection edge.

Figure 26.11 shows an example of the input capture function. In this example, the GPT0.GTCNT counter performs up-counting, and settings have been made so that an input capture is performed at both edges of the GTIOC0A input pin and at the rising edge of the GTIOC0B input pin.

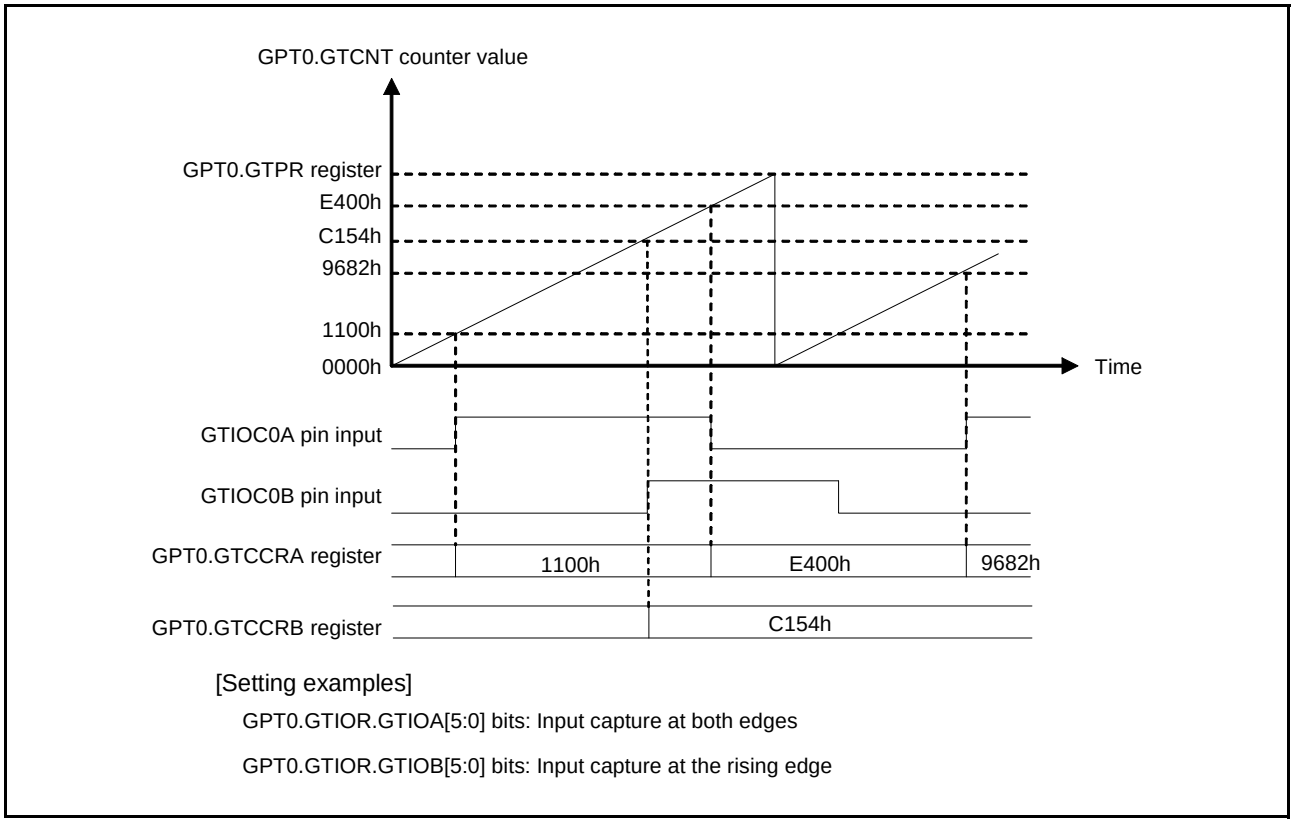

Figure 26.11 Example of Input Capture Operation

Figure 26.12 shows an example for setting input capture operation.

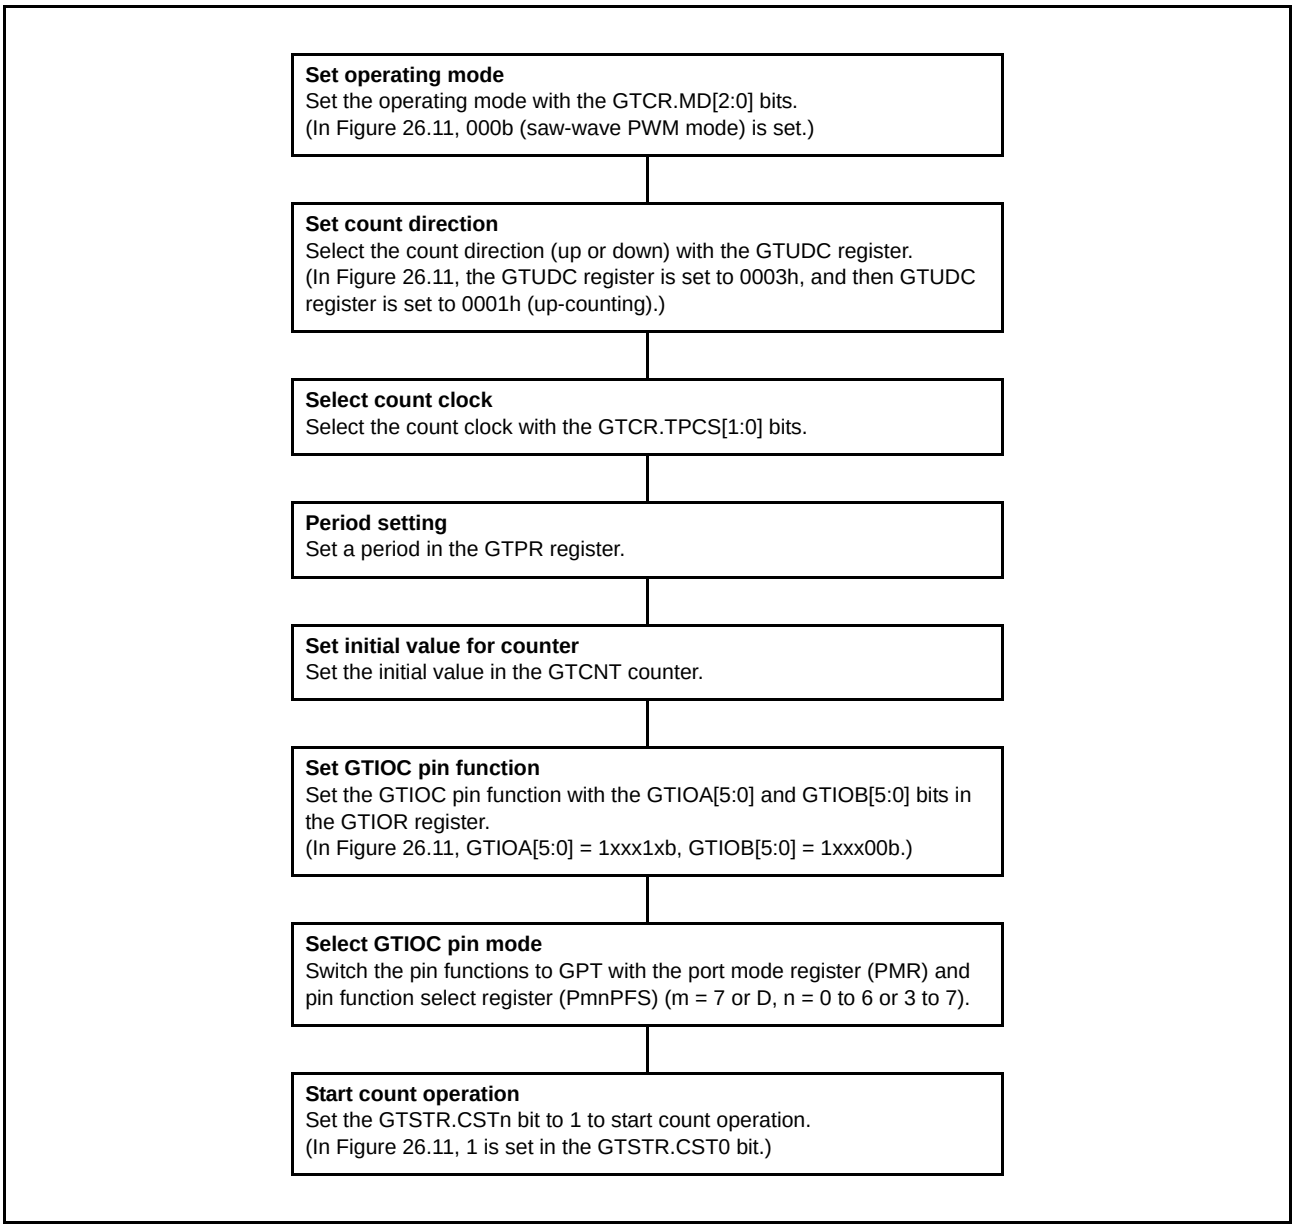

Figure 26.12 Example for Setting Input Capture Operation

26.3.2 Buffer Operation

The following buffer operation can be set with the GTBER register.

- Buffer operation with the GTPR, GTPBR, and GTPDBR registers used together
- Buffer operation with the GTCCRA, GTCCRC, and GTCCRD registers used together
- Buffer operation with the GTCCRB, GTCCRE, and GTCCRF registers used together
- Buffer operation with the GTADTRA, GTADTBRA, and GTADTDBRA registers used together
- Buffer operation with the GTADTRB, GTADTBRB, and GTADTDBRB registers used together

The following buffer operation can be set with the GTDTCR register.

- Buffer operation with the GTDVU and GTDBU registers used together
- Buffer operation with the GTDVD and GTDBD registers used together

26.3.2.1 GTPR Register Buffer Operation

The GTPBR register can function as a buffer register for the GTPR register, and the GTPDBR register can function as a buffer register for the GTPBR register (double buffer register for the GTPR register). When the count direction is down-counting in saw-wave mode, buffer operation setting is prohibited.
The buffer transfer is performed at an overflow or count clearing in saw-wave mode, and at a trough in triangle-wave mode.
To set the GTPR register to function as double buffer, set the GTBER.PR[1:0] bits to 10b or 11b. For single buffer operation, set 01b. Not to function as buffer, set 00b.
Figure 26.13 to Figure 26.14 show examples of GTPR buffer operation and Figure 26.15 shows an example for setting GTPR buffer operation.

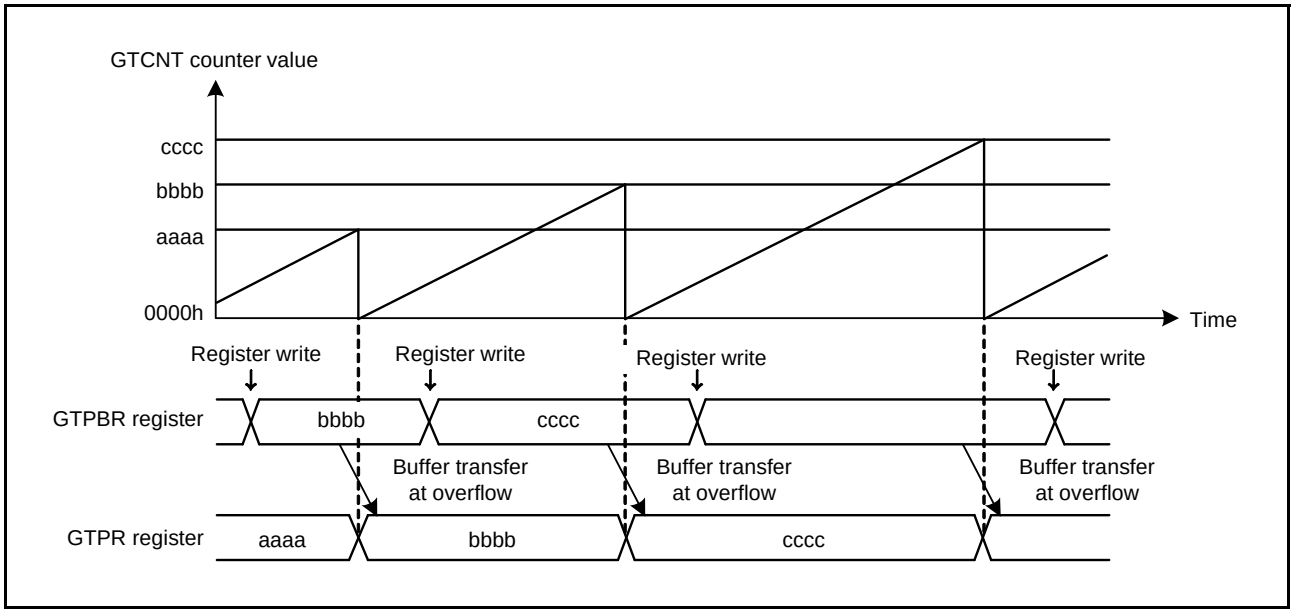

Figure 26.13 Example of GTPR Buffer Operation (Saw Waves in Up-Counting)

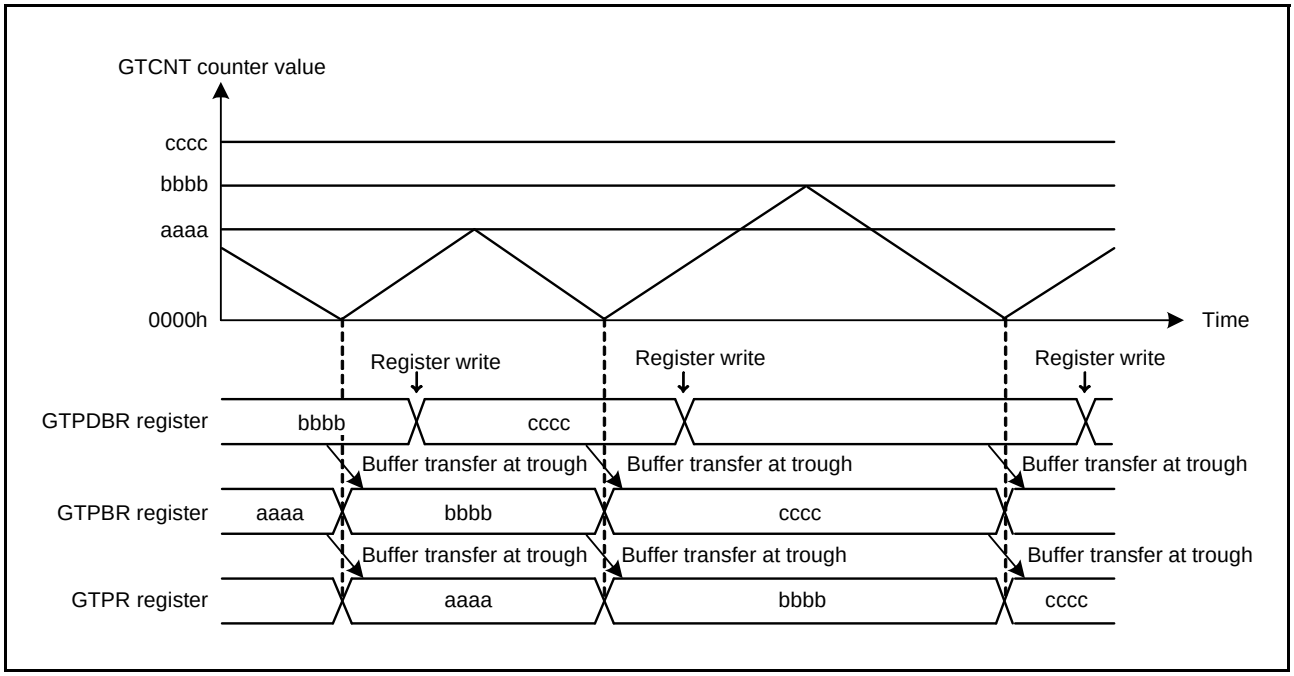

Figure 26.14 Example of GTPR Double Buffer Operation (Triangle Waves)

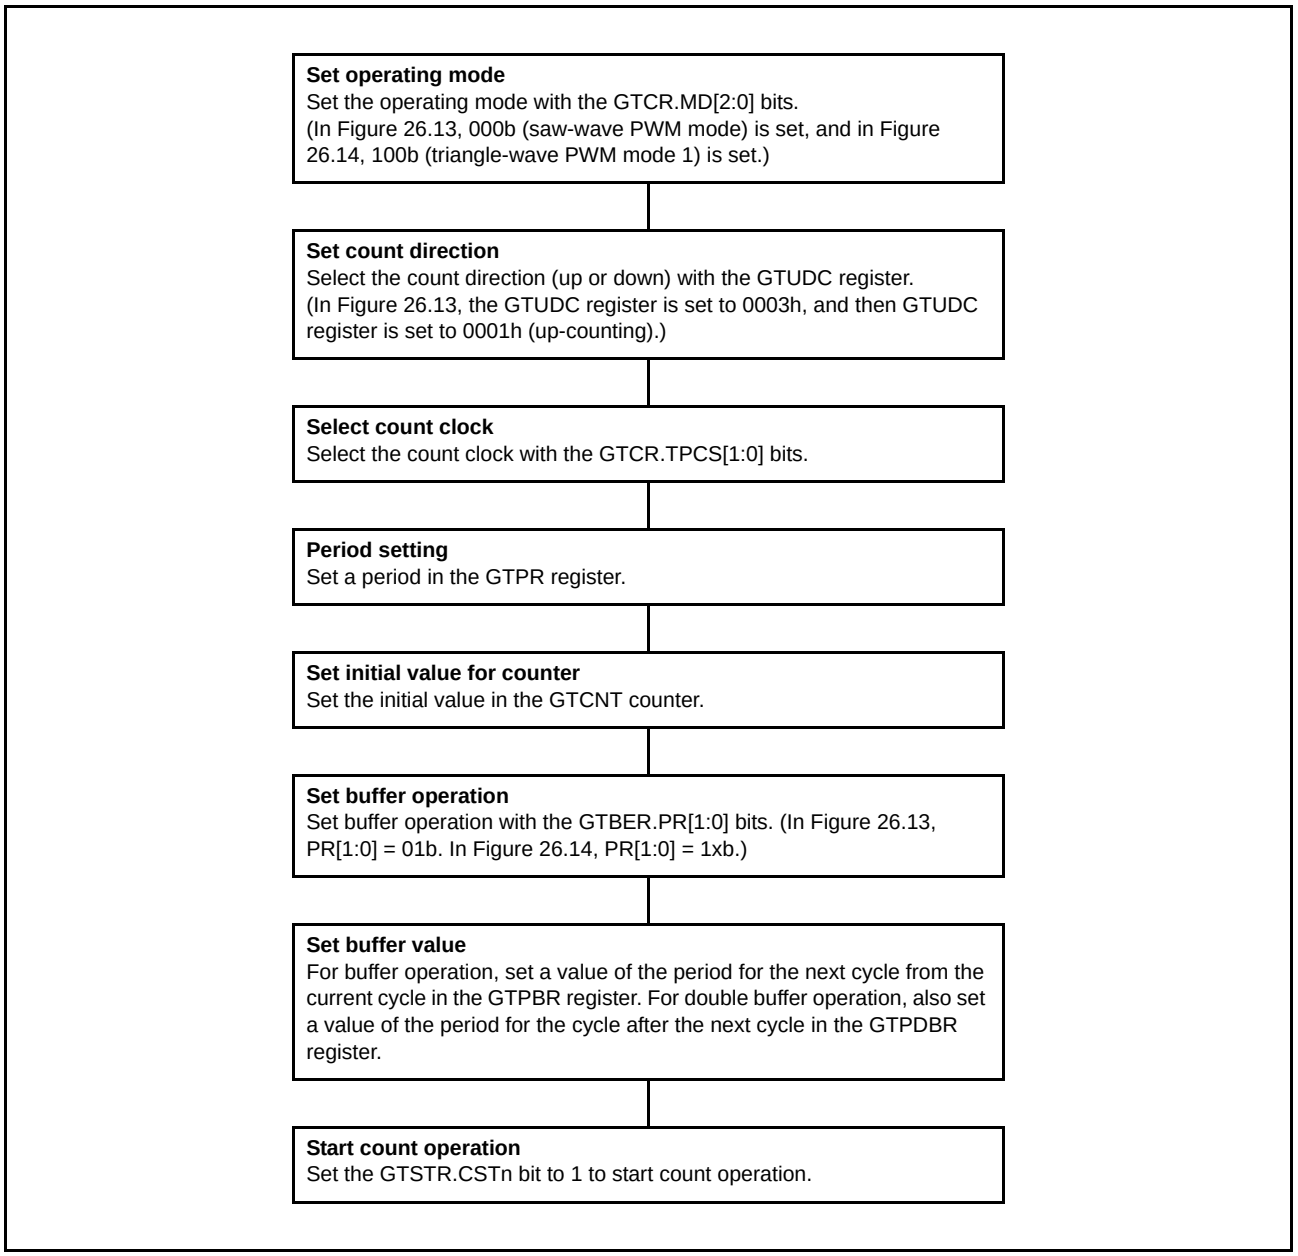

Figure 26.15 Example for Setting GTPR Buffer Operation

26.3.2.2 Buffer Operation for the GTCCRA and GTCCRB Registers

The GTCCRC register can function as the GTCCRA buffer register and the GTCCRD register can function as the GTCCRC buffer register (double buffer register for the GTCCRA register). Similarly, the GTCCRE register can function as the GTCCRB buffer register and the GTCCRF register can function as the GTCCRE buffer register (double buffer register for the GTCCRB register).
To set the GTCCRA or GTCCRB register to function as a double buffer, set the GTBER.CCRA[1:0] or GTBER.CCRB[1:0] bits to 10b or 11b. For single buffer operation, set 01b. Not to function as buffer, set 00b.
The following describes buffer operation during output compare and input capture operation.

(1) When the GTCCRA or GTCCRB Register Functions as Output Compare Register

Buffer transfer is performed at an overflow (in up-counting), underflow (in down-counting), count clearing in saw-wave mode, and at a crest or trough in triangle-wave mode. In both saw-wave mode and triangle-wave mode, buffer transfer of the GTCCRA and GTCCRB registers is forcibly performed by writing 1 to the GTBER.CCRSWT bit while counting is stopped.
In saw-wave one-shot pulse mode and triangle-wave PWM mode 3, buffer transfer from the GTCCRD register to temporary register A and the GTCCRF register to temporary register B is performed using the forcible buffer operation while counting is stopped.
Figure 26.16 to Figure 26.18 show examples of GTCCRA and GTCCRB buffer operation and Figure 26.19 shows an example for setting GTCCRA and GTCCRB buffer operation.

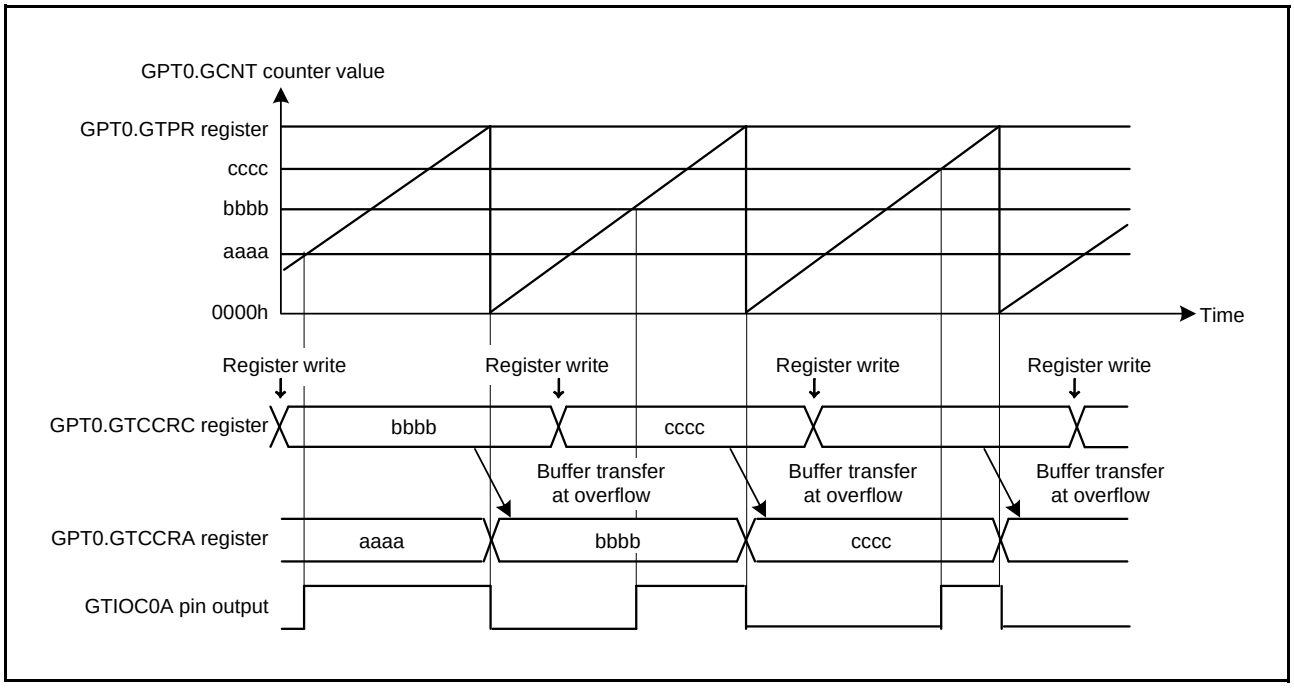

Figure 26.16 Example of GTCCRA and GTCCRB Buffer Operation (Output Compare, Saw Waves in Up-Counting, High Output at GTCCRA Compare Match, Low Output at the End of the Cycle)

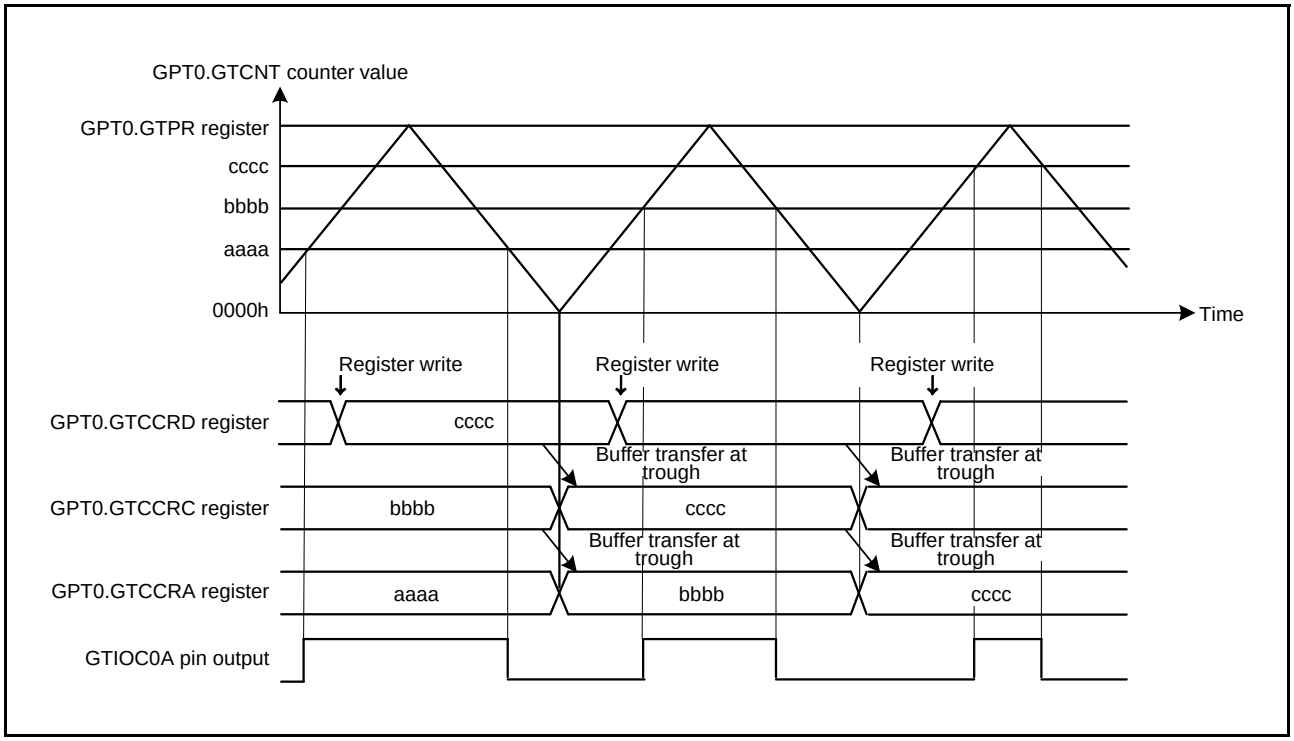

Figure 26.17 Example of GTCCRA and GTCCRB Double Buffer Operation (Output Compare, Triangle Waves, Buffer Operation at Trough, Output Toggled at GTCCRA Compare Match, Output Retained at the End of the Cycle)

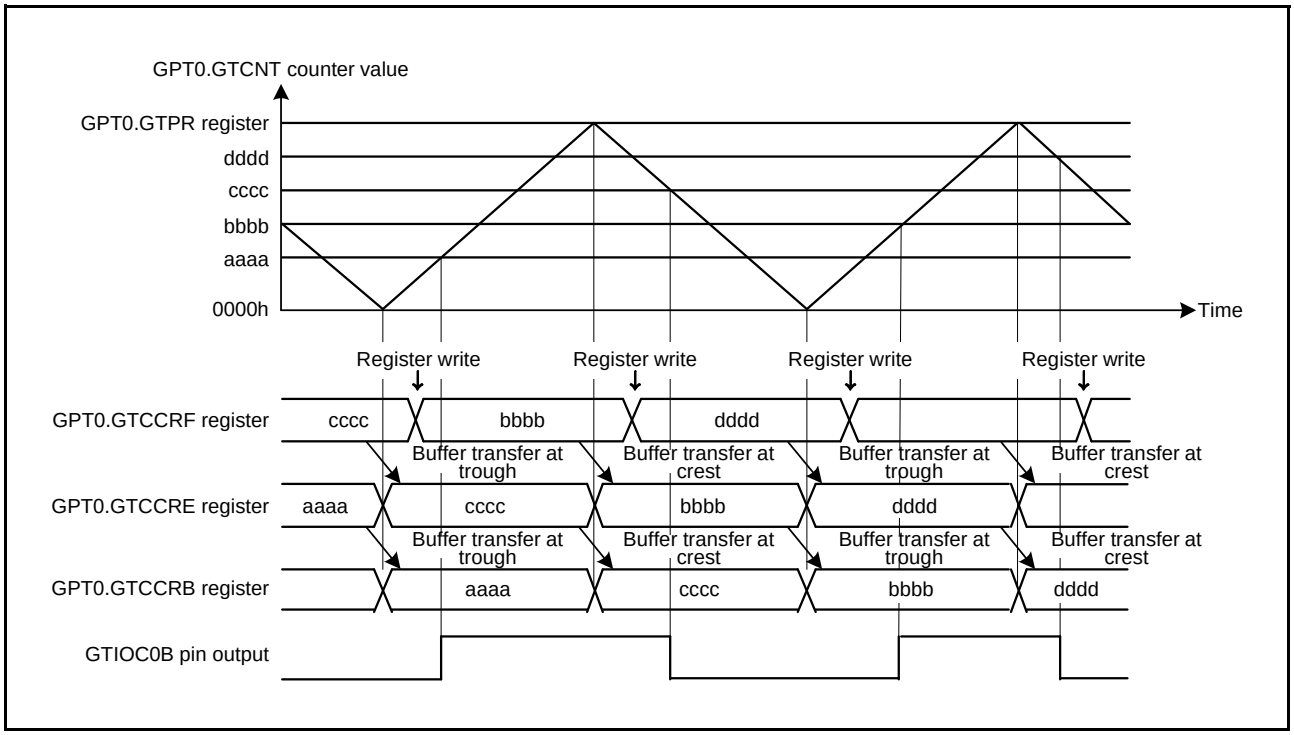

Figure 26.18 Example of GTCCRA and GTCCRB Double Buffer Operation (Output Compare, Triangle Waves, Buffer Operation at Both Troughs and Crests, Output Toggled at GTCCRB Compare Match, Output Retained at the End of the Cycle)

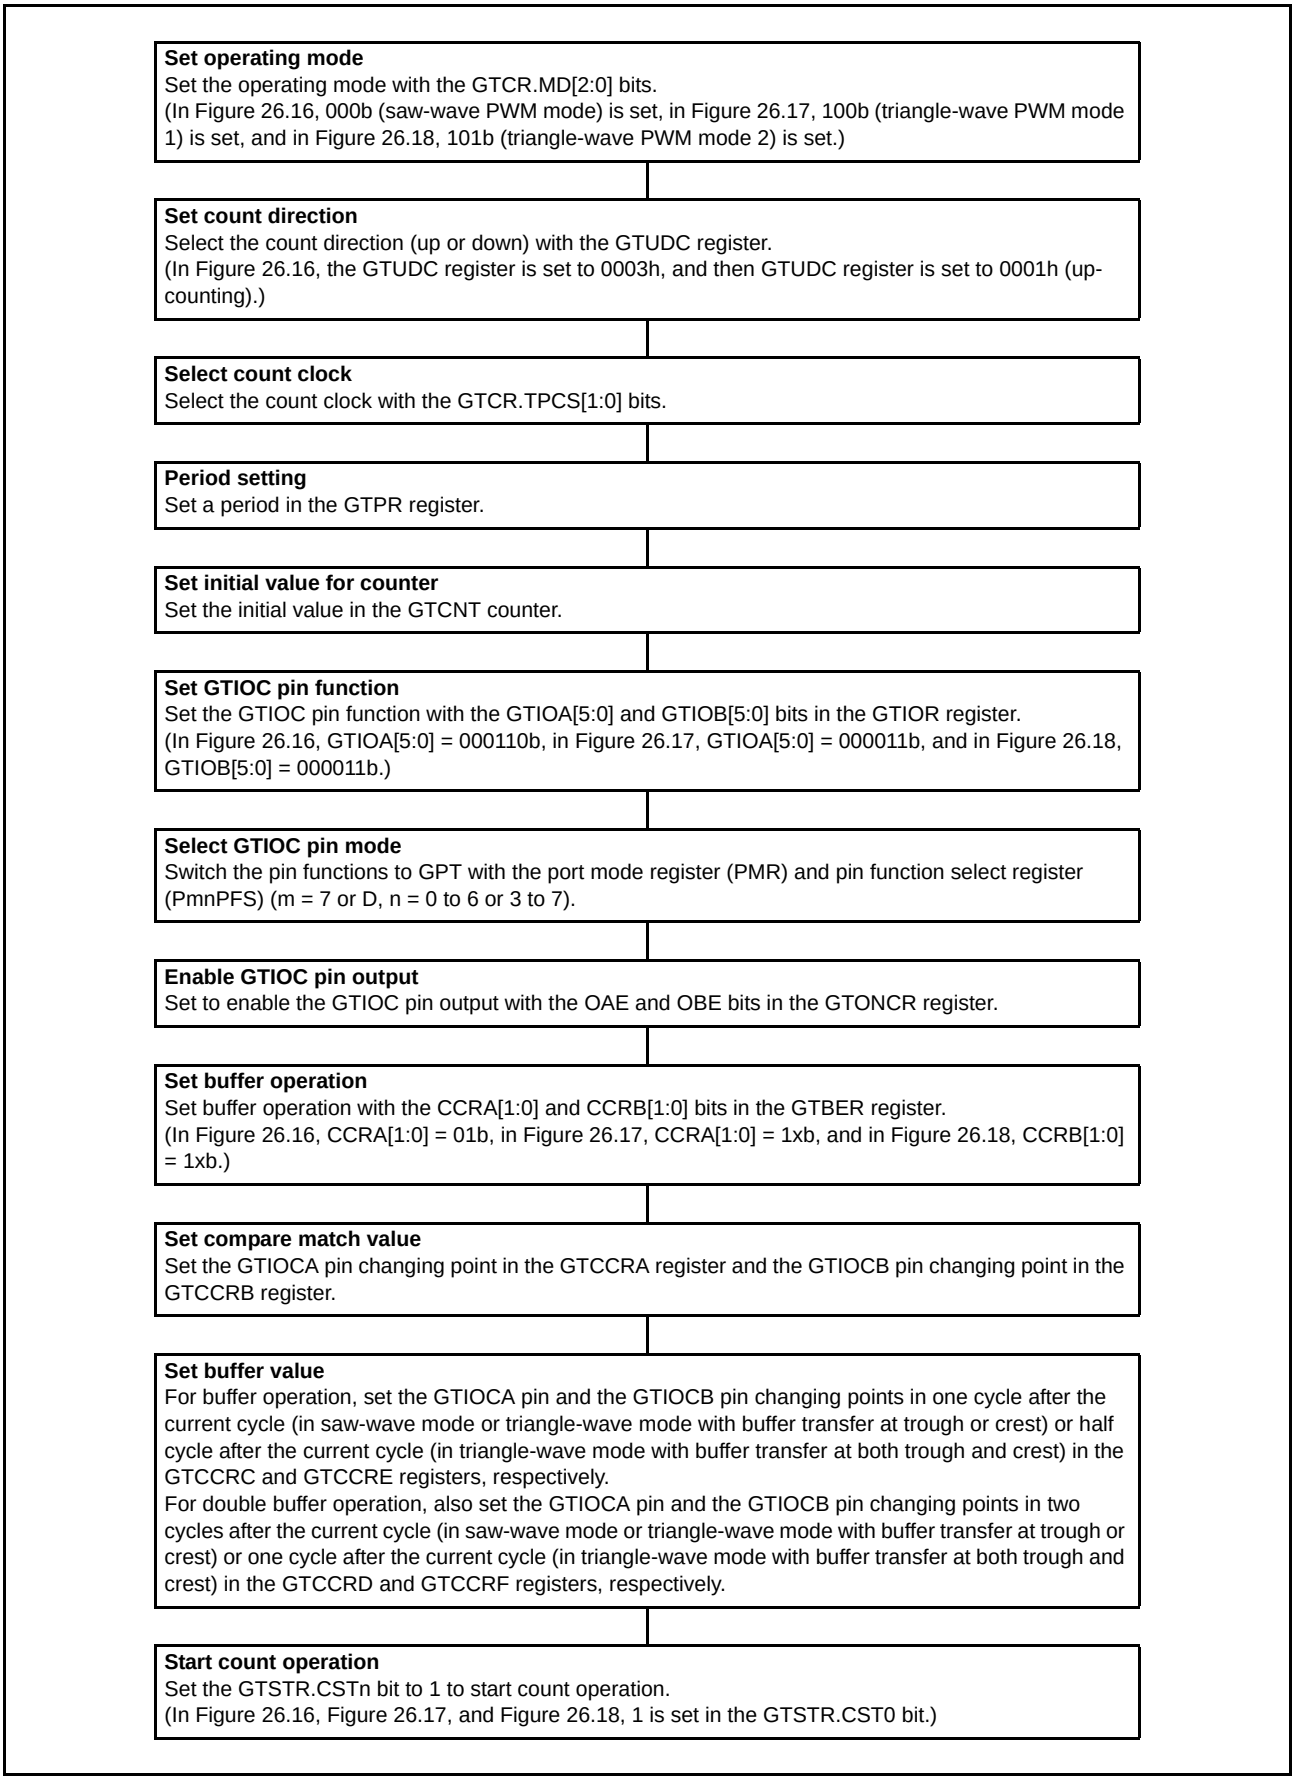

Figure 26.19 Example for Setting GTCCRA and GTCCRB Buffer Operation (for Output Compare)

(2) When the GTCCRA or GTCCRB Register Functions as Input Capture Register

When an input capture is generated, the GTCNT counter value is transferred to GTCCRA and GTCCRB and the stored GTCCRA and GTCCRB register values are transferred to buffer registers.
Figure 26.20 and Figure 26.21 show examples of GTCCRA and GTCCRB buffer operation and Figure 26.22 shows an example for setting GTCCRB buffer operation.

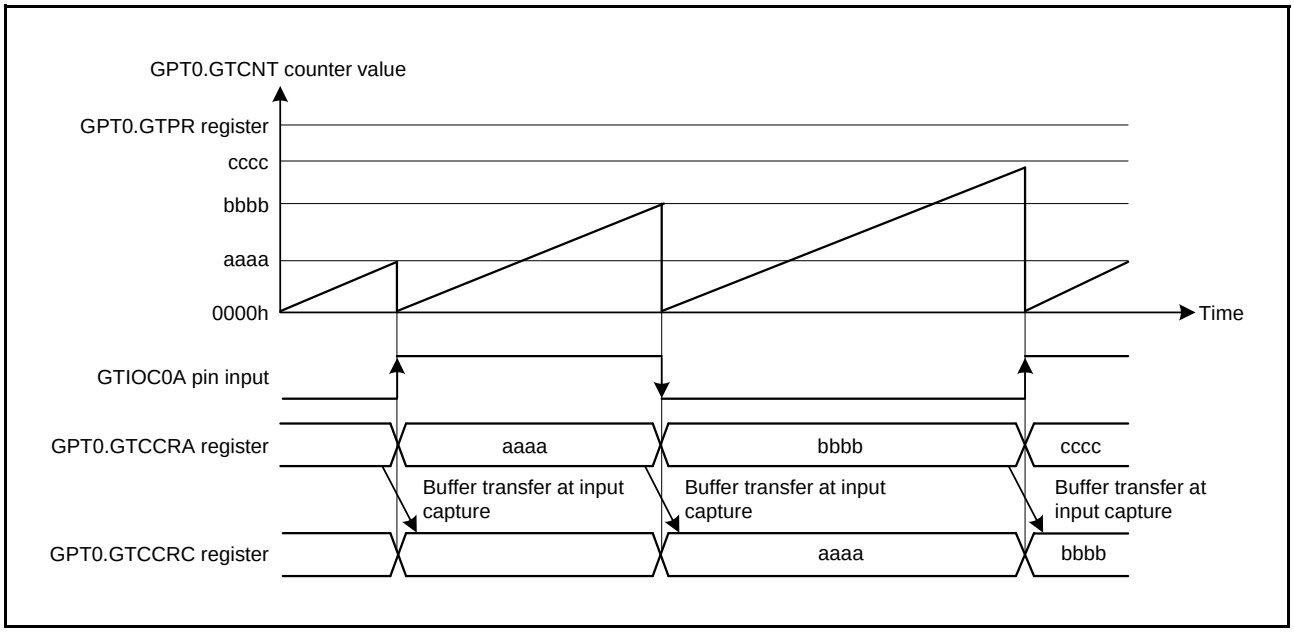

Figure 26.20 Example of GTCCRA and GTCCRB Buffer Operation (Input Capture at Both Edges of GTIOC0A Input, Saw Waves in Up-Counting, GTCNT Counter Cleared at GTCCRA Input Capture)

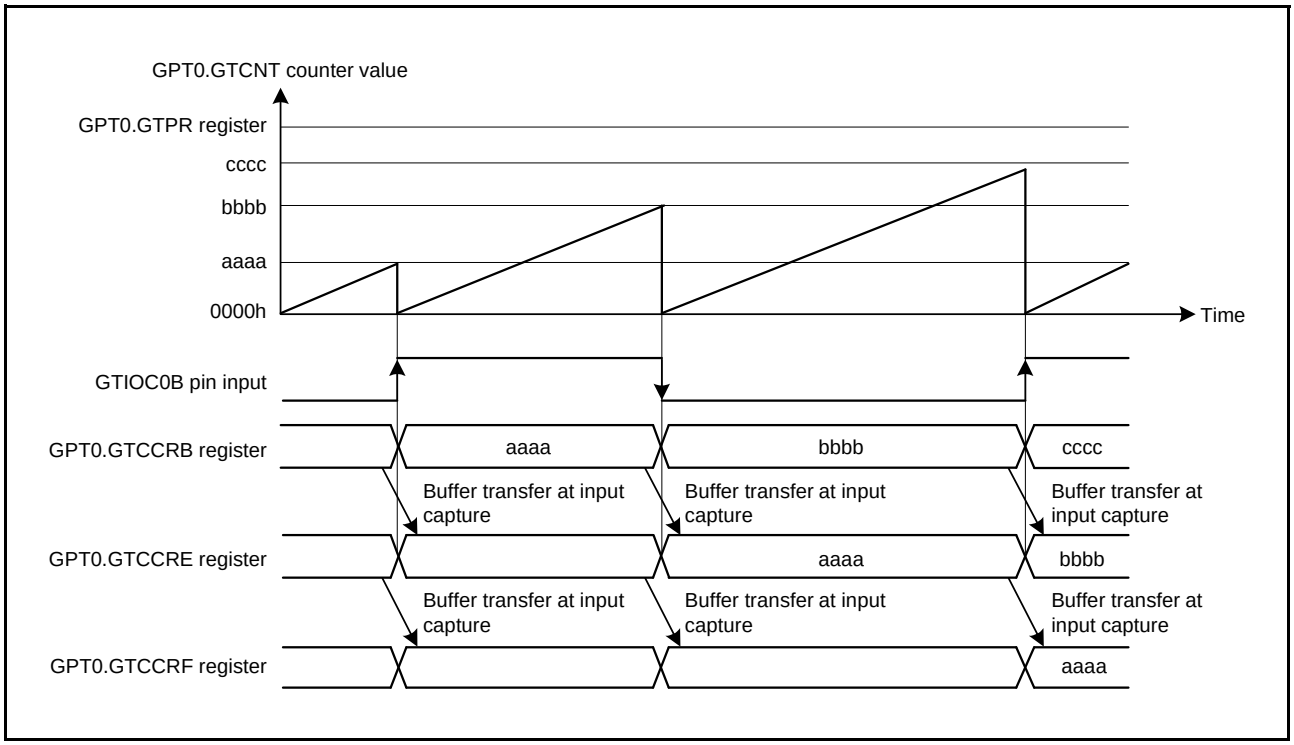

Figure 26.21 Example of GTCCRA and GTCCRB Double Buffer Operation (Input Capture at Both Edges of GTIOC0B Input, Saw Waves in Up-Counting, GTCNT Counter Cleared at GTCCRB Input Capture)

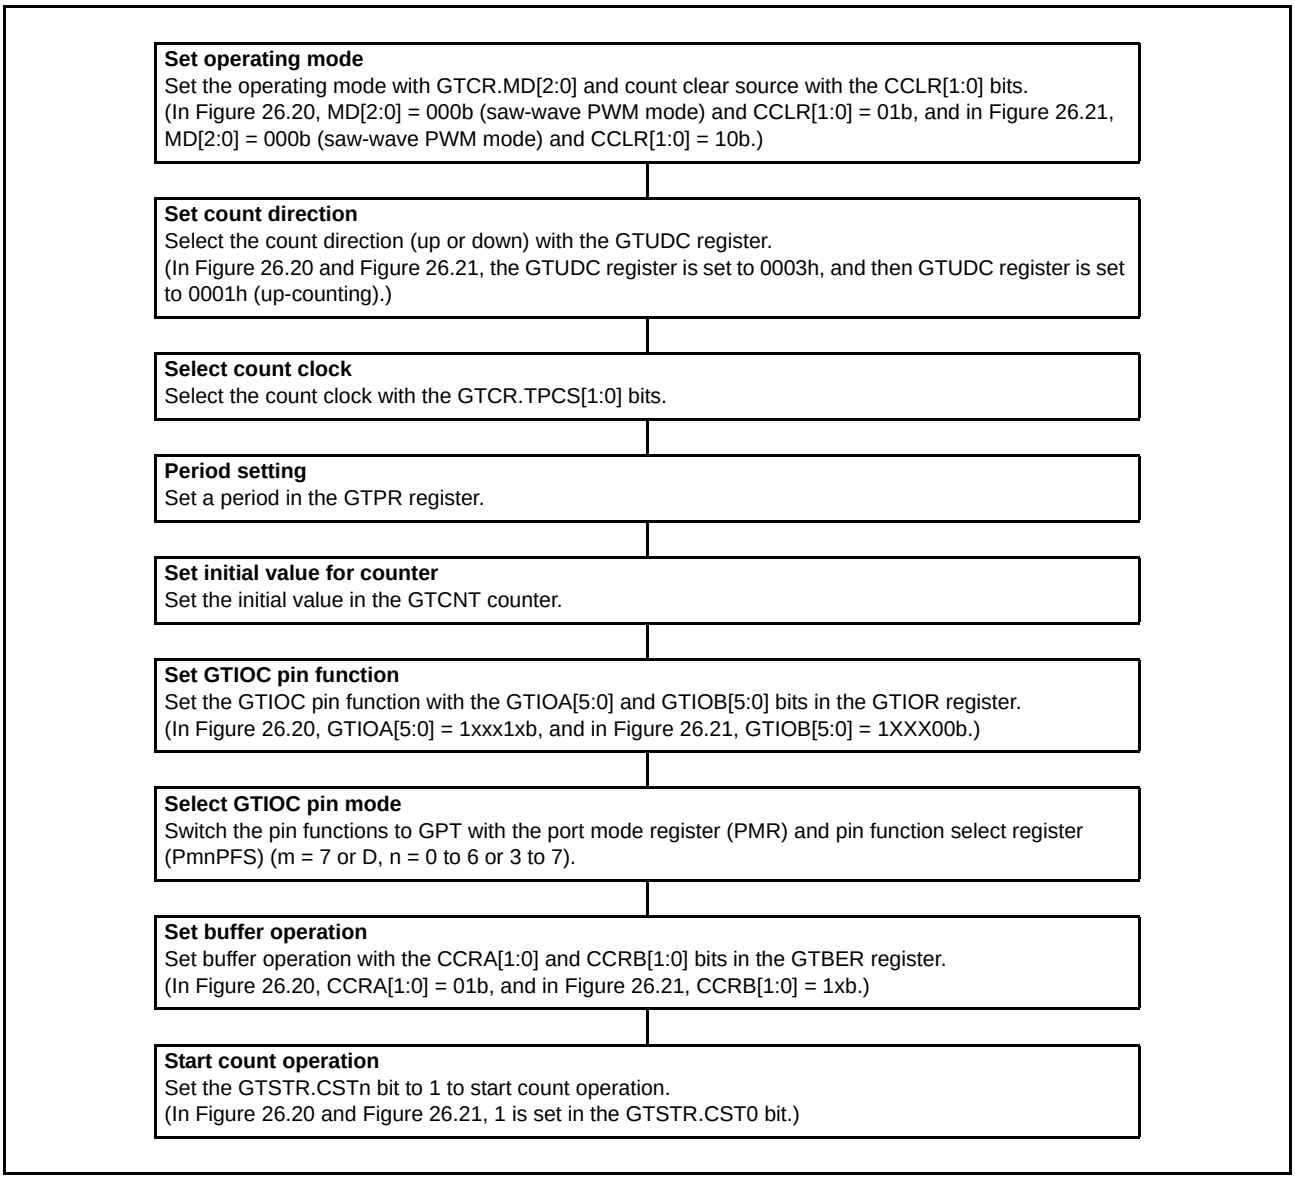

Figure 26.22 Example for Setting GTCCRA and GTCCRB Buffer Operation (for Input Capture)

26.3.2.3 Buffer Operation for the GTADTRA and GTADTRB Registers

The GTADTBRA register can function as the GTADTRA buffer register and the GTADTDBRA register can function as the GTADTBRA buffer register (double buffer register for the GTADTRA register). Similarly, the GTADTBRB register can function as the GTADTRB buffer register and the GTADTDBRB register can function as the GTADTBRB buffer register (double buffer register for the GTADTRB register).

To set the GTADTRA or GTADTRB register to function as a double buffer, set the GTBER.ADTDA or GTBER.ADTDB bit to 1. For single buffer operation, set 0. Not to function as buffer, set the GTBER.ADTTA[1:0] or GTBER.ADTTB[1:0] bits to 00b.

The buffer transfer timing can be set with the GTBER.ADTTn[1:0] bits. For saw waves, overflows (during up-counting), underflows (during down-counting), or count clearing can be selected. For triangle waves, crests are selected when GTBER.ADTTn[1:0] = 01b, troughs are selected when GTBER.ADTTn[1:0] = 10b, and both crests and troughs are selected when GTBER.ADTTn[1:0] = 11b (n =A, B).

Figure 26.23 to Figure 26.25 show examples of GTADTRA and GTADTRB buffer operation and Figure 26.26 shows an example for setting GTDTRA and GTADTRB buffer operation.

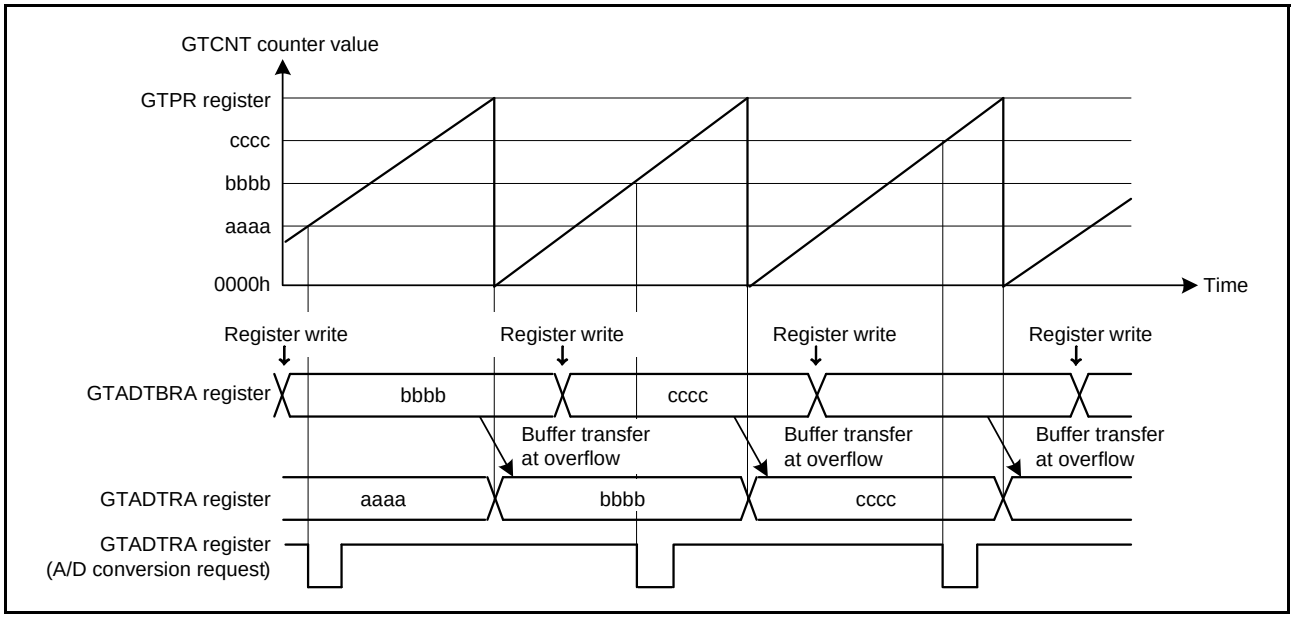

Figure 26.23 Example of GTADTRA and GTADTRB Buffer Operation (Saw Waves in Up-Counting, A/D Converter Start Request Generated by Up-Counting)

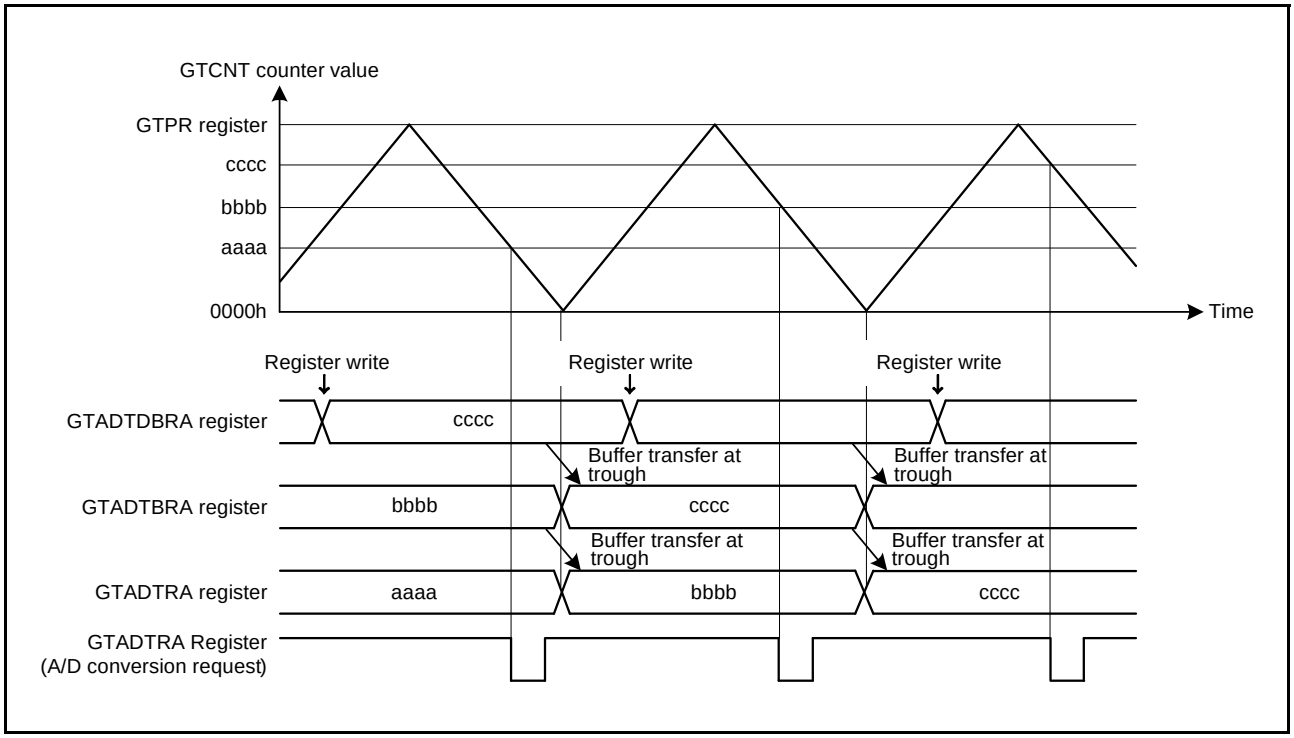

Figure 26.24 Example of GTADTRA and GTADTRB Double Buffer Operation (Triangle Waves, Buffer Transfer at Troughs, A/D Converter Start Request Generated by Down-Counting)

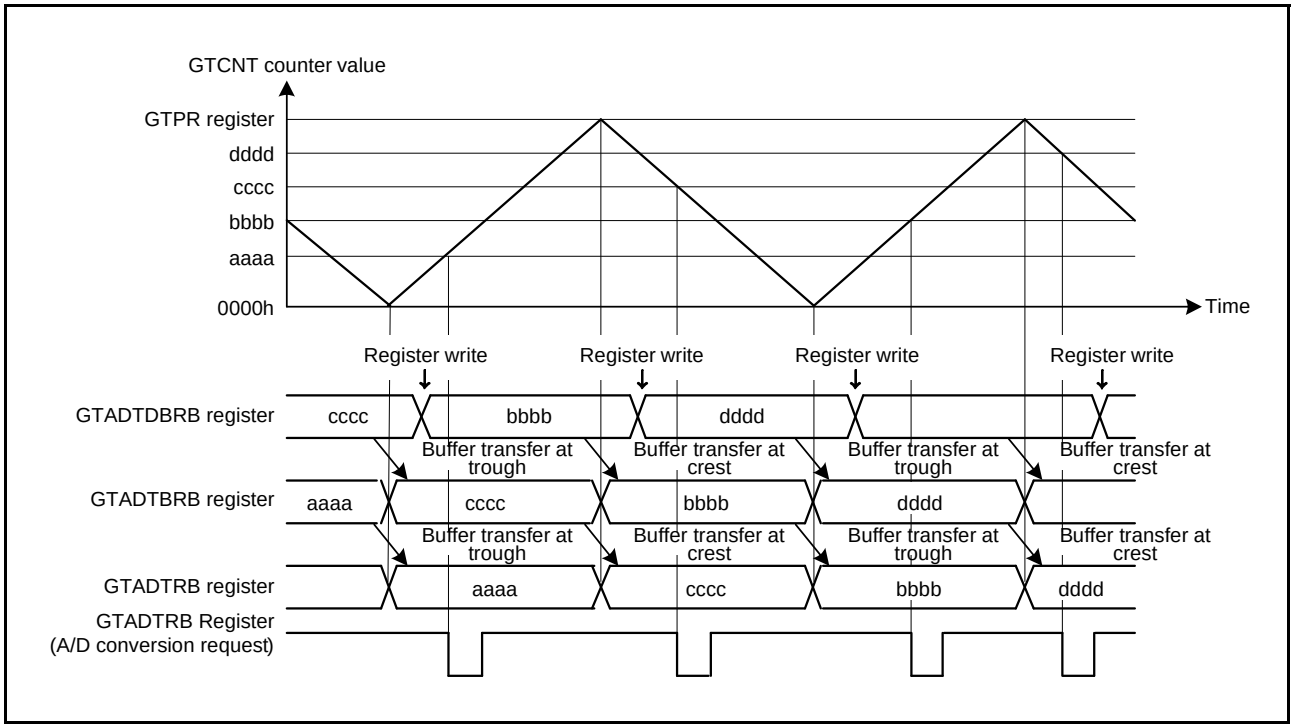

Figure 26.25 Example of GTADTRA and GTADTRB Double Buffer Operation (Triangle Waves, Buffer Transfer at Both Troughs and Crests, A/D Converter Start Request Generated by Both Up- and Down-Counting)

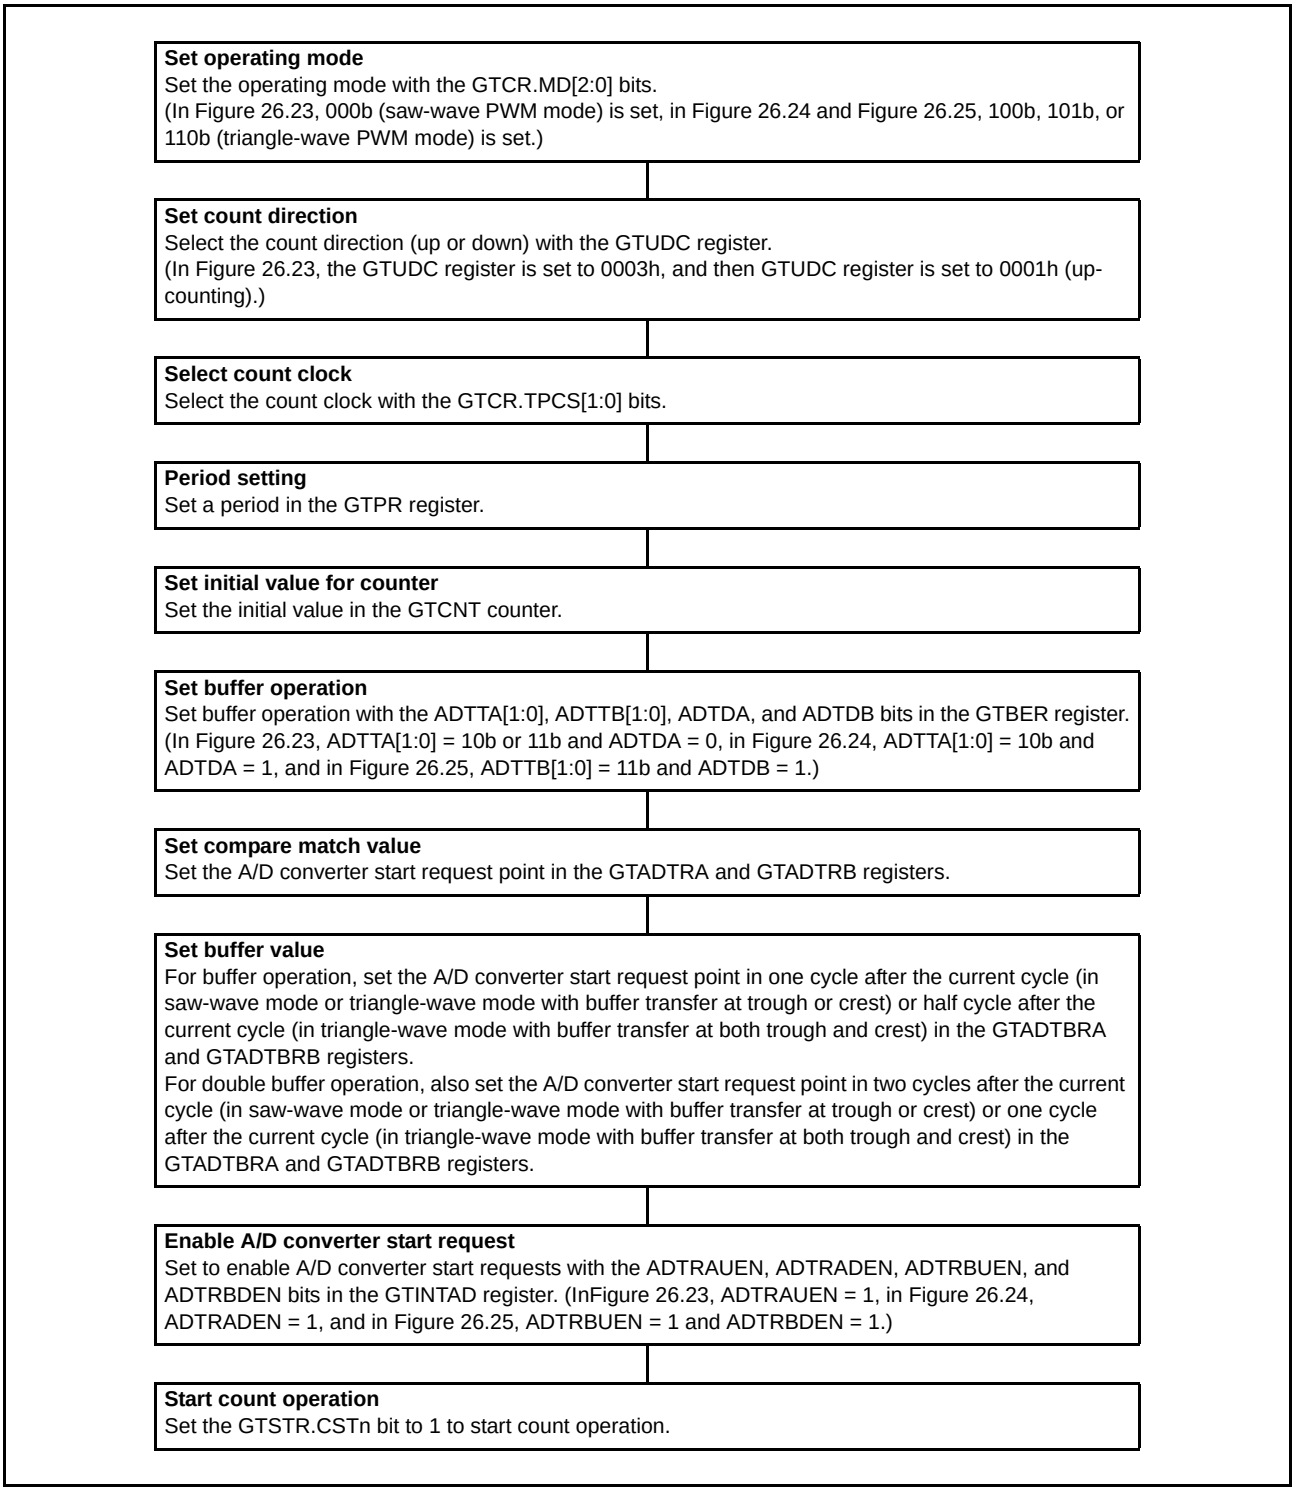

Figure 26.26 Example for Setting GTADTRA and GTADTRB Buffer Operation

26.3.3 PWM Output Operating Mode

The GPT can output PWM waveforms to the GTIOCnA pin or GTIOCnB pin by a compare match between the GPTn.GTCNT counter and the GPTn.GTCCRA or GPTn.GTCCRB register (n = 0 to 3). An operating mode can be set independently for each channel, and synchronous operation on channels is also possible.
By setting the GTDTCR, GTDVU, and GTDVD registers, the compare match value for a negative-phase waveform with dead time can automatically be set to the GTCCRB register.

(1) Saw-Wave PWM Mode (GTCR.MD = 000b)

In saw-wave PWM mode, the GPTn.GTCNT counter performs saw-wave (half-wave) operation by setting the period in the GTPR register and a PWM waveform is output to the GTIOCnA or GTIOCnB pin when a GPTn.GTCCRA or GPTn.GTCCRB compare match occurs (n = 0 to 3). The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the end of the cycle according to the GTIOR setting
Figure 26.27 shows an example of saw-wave PWM mode operation, and Figure 26.28 shows an example for setting saw-wave PWM mode.

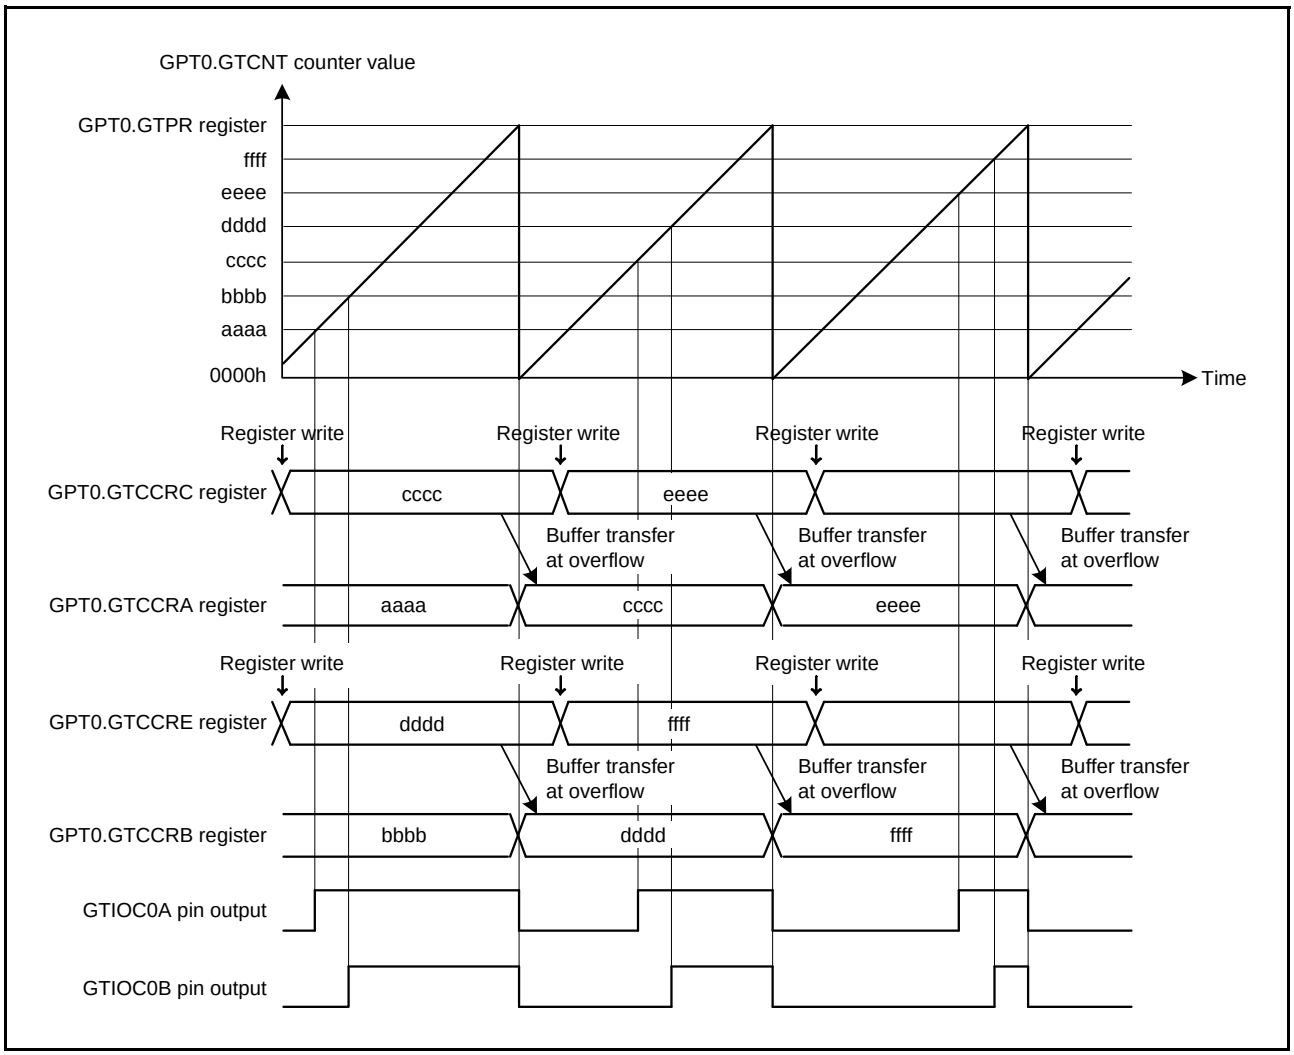

Figure 26.27 Example of Saw-Wave PWM Mode Operation (Up-Counting, Buffer Operation, High Output at GTCCRA/GTCCRB Compare Match, Low Output at the End of the Cycle)

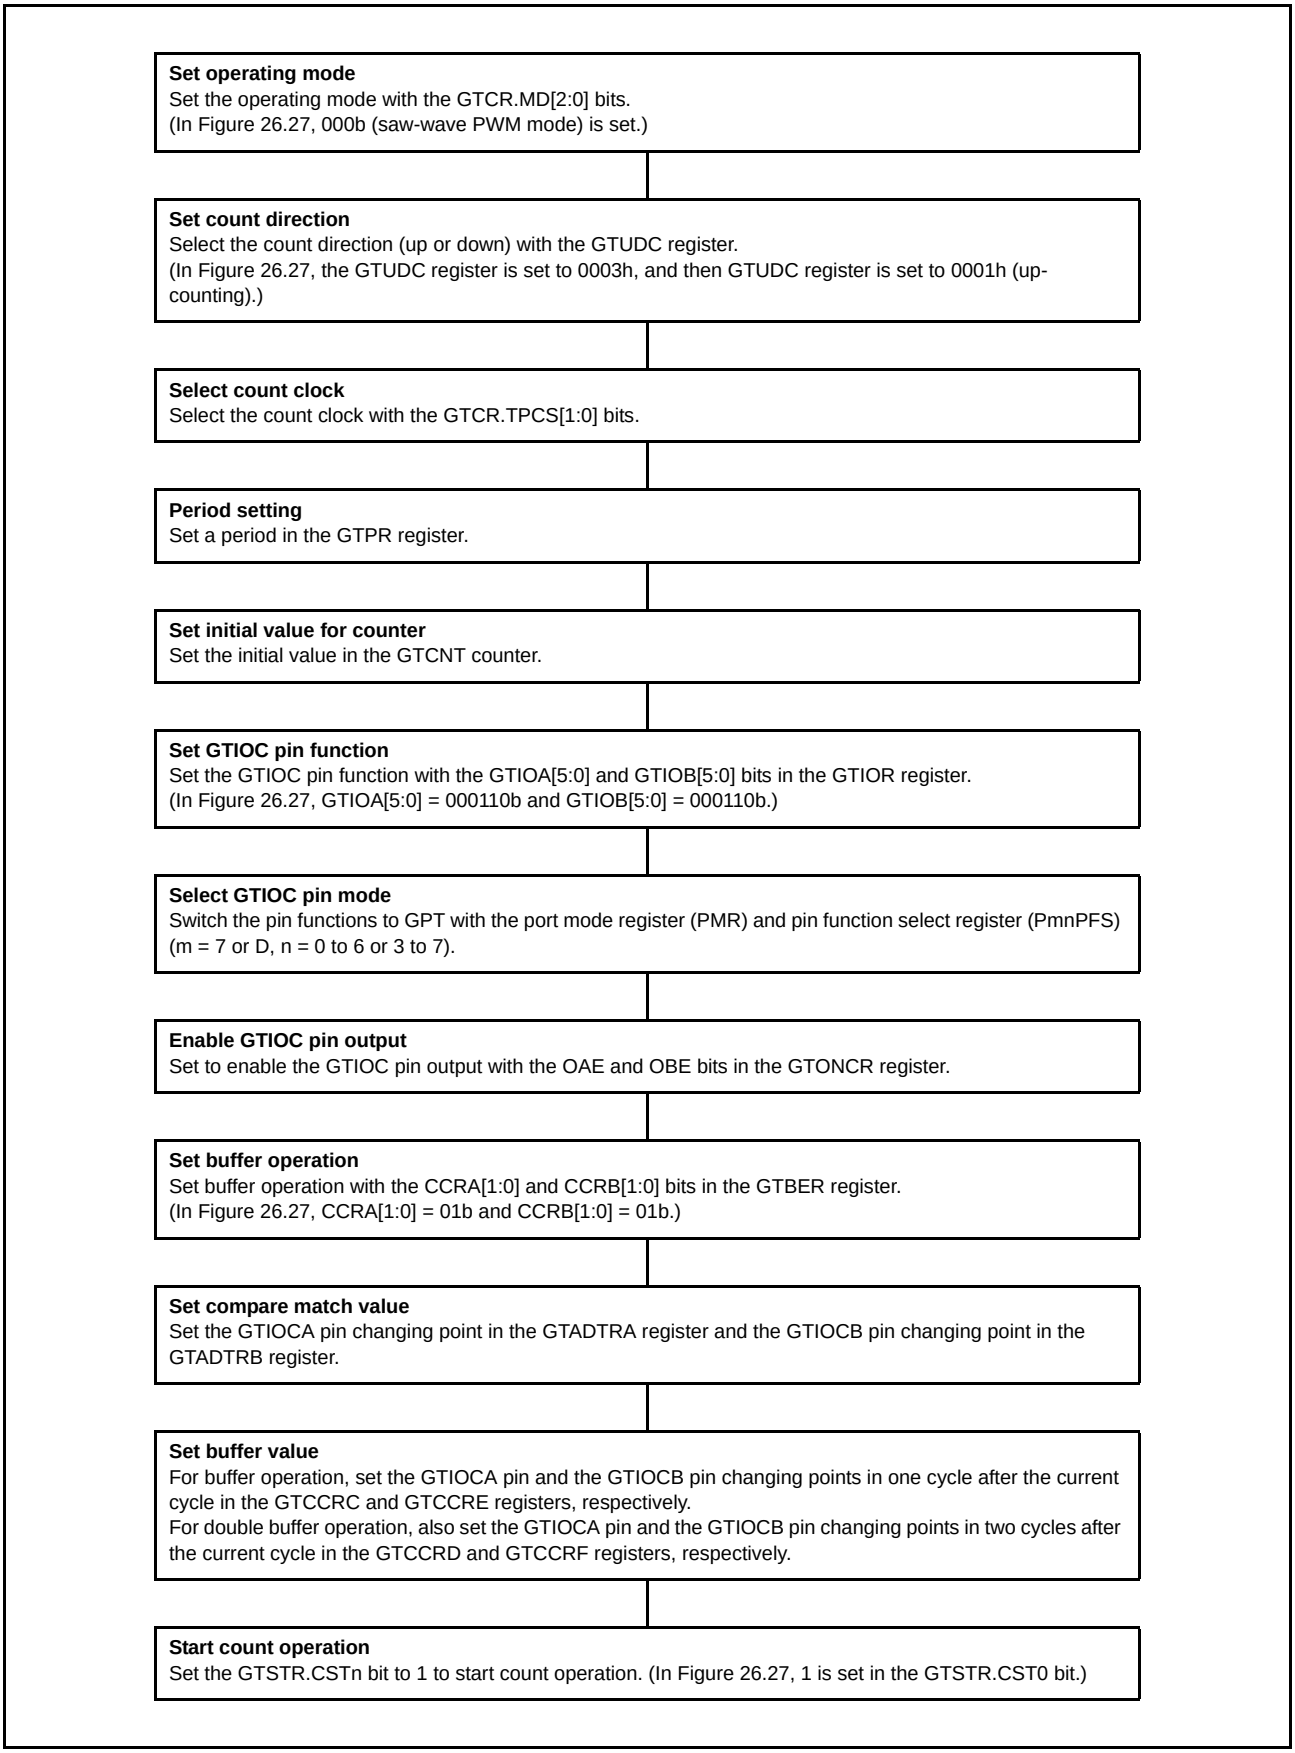

Figure 26.28 Example for Setting Saw-Wave PWM Mode

(2) Saw-Wave One-Shot Pulse Mode

The saw-wave one-shot pulse mode is a mode in which the period is set in the GPTn.GTPR register, the GPTn.GTCNT counter performs saw-wave (half-wave) operation and a PWM waveform is output to the GTIOCnA or GTIOCnB pin at a compare match of the GPTn.GTCCRA or GPTn.GTCCRB register with buffer operation fixed (n = 0 to 3).

Buffer operation in saw-wave one-shot pulse mode is different from the usual buffer operation. Buffer transfer is performed from GTCCRC to GTCCRA, from GTCCRE to GTCCRB, from GTCCRD to temporary register A, and from GTCCRF to temporary register B at the end of the cycle, and from temporary register A to GTCCRA at a GTCCRA compare match and from temporary register B to GTCCRB at a GTCCRB compare match. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and the end of the cycle according to the GTIOR setting.

By setting GTDTCR, GTDVU, and GTDVD, a compare match value for a negative-phase waveform with dead time can automatically be set to GTCCRB.

Figure 26.29 shows an example of saw-wave one-shot pulse mode operation, and Figure 26.30 shows an example for setting saw-wave one-shot pulse mode.

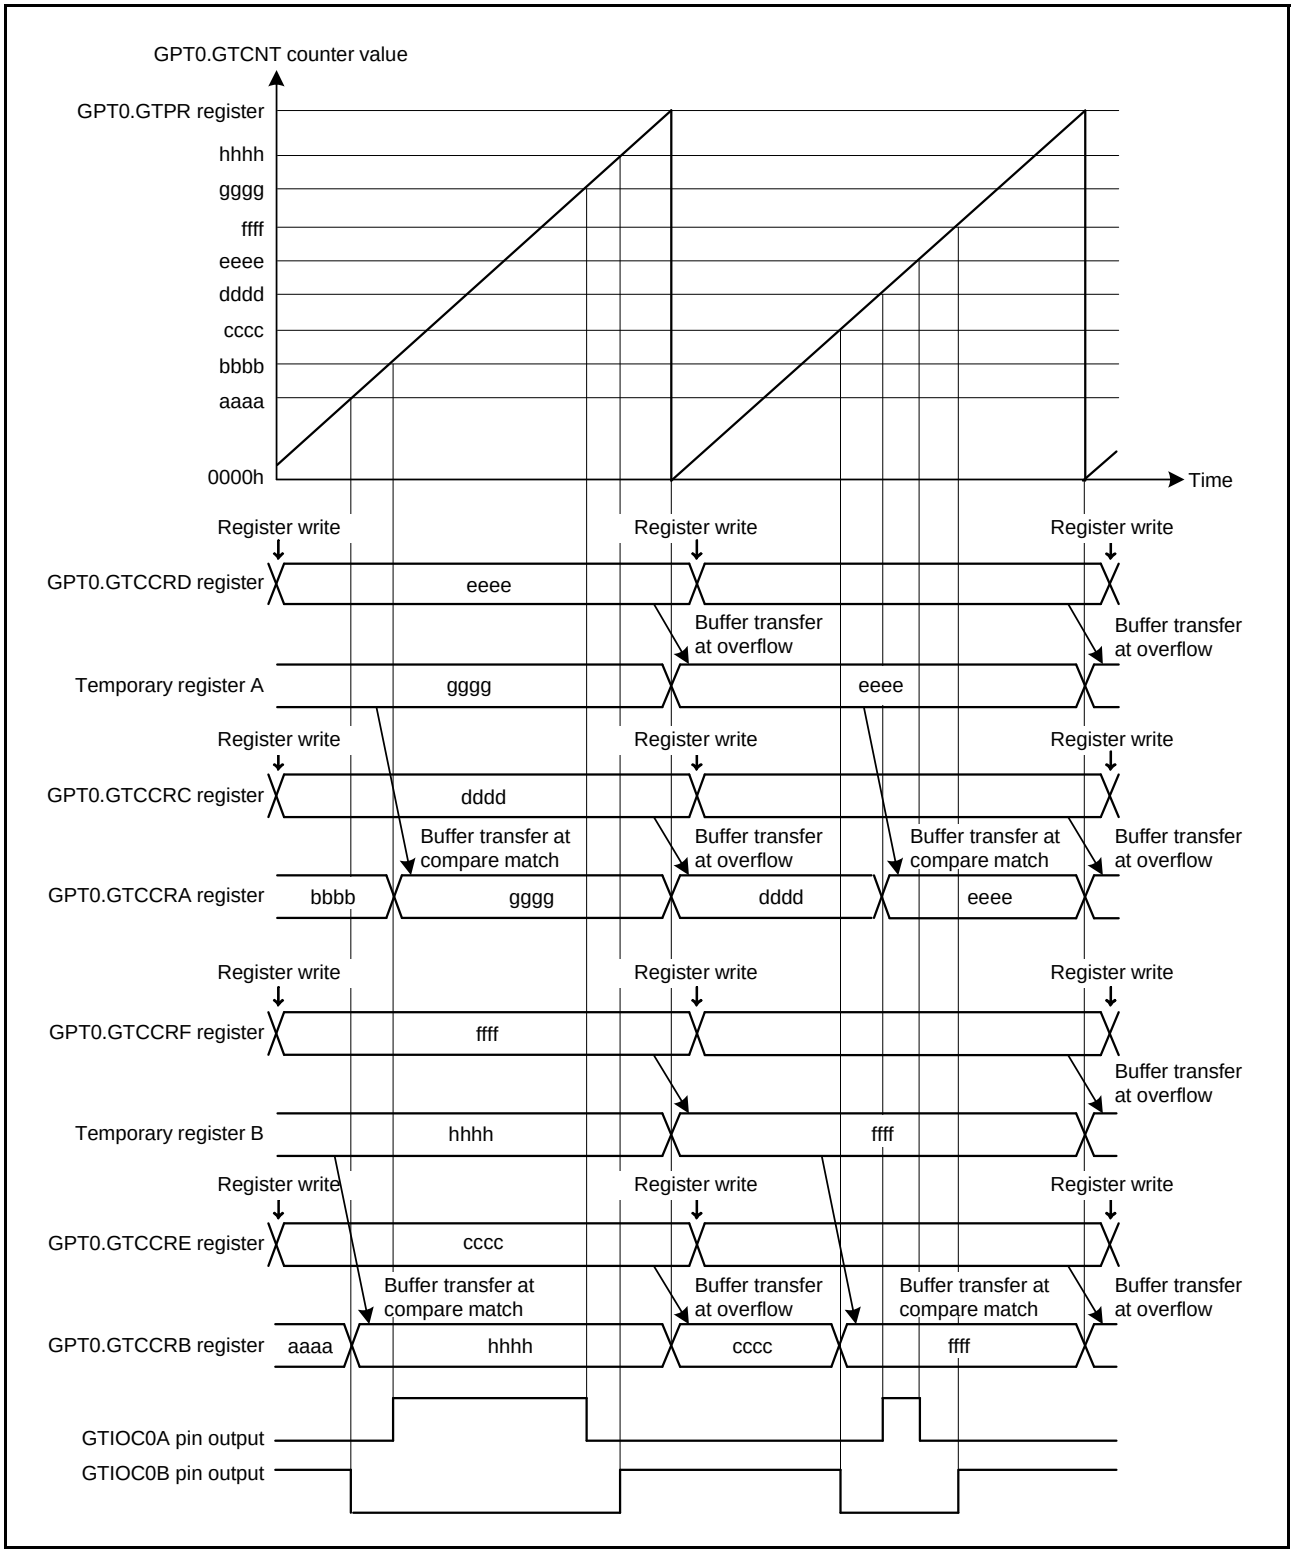

Figure 26.29 Example of Saw-Wave One-Shot Pulse Mode Operation (Up-Counting, Low Output from the GTIOC0A Pin and High Output from the GTIOC0B Pin at Initial Output, Output Toggled at GTCCRA/GTCCRB Compare Match, Output Retained at the End of the Cycle)

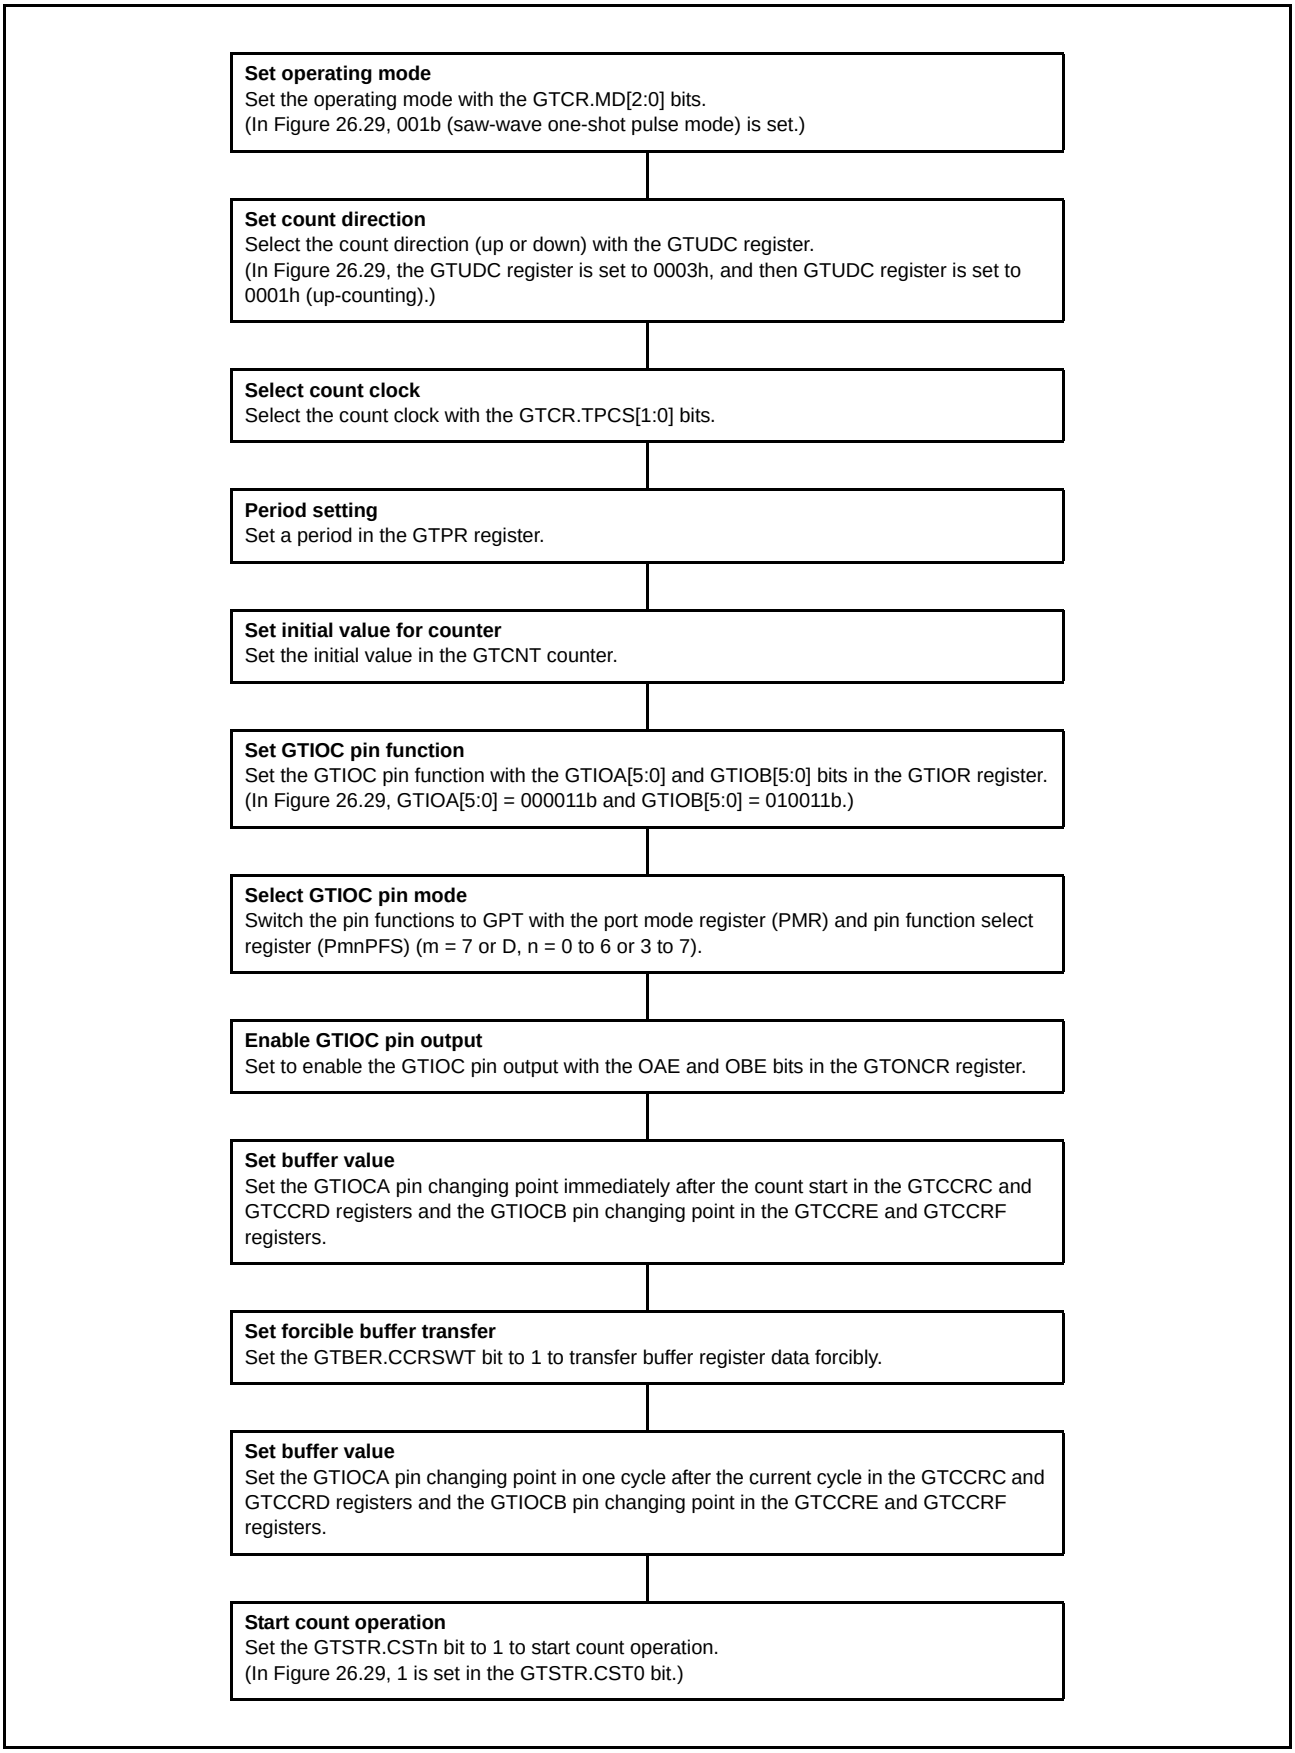

Figure 26.30 Example for Setting Saw-Wave One-Shot Pulse Mode

(3) Triangle-Wave PWM Mode 1 (16-Bit Transfer at Trough)

The triangle-wave PWM mode 1 is a mode in which the period is set in the GPTn.GTPR register, the GPTn.GTCNT counter performs triangle-wave (full-wave) operation, and a PWM waveform is output to the GTIOCnA or GTIOCnB pin when a GPTn.GTCCRA or GPTn.GTCCRB compare match occurs (n = 0 to 3). Buffer transfer is performed at the trough. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the end of the cycle according to the GTIOR setting.

By setting the GTDTCR, GTDVU, and GTDVD registers, a compare match value for a negative-phase waveform with dead time can automatically be set to the GTCCRB register.

Figure 26.31 shows an example of triangle-wave PWM mode 1 operation, and Figure 26.32 shows an example for setting triangle-wave PWM mode 1.

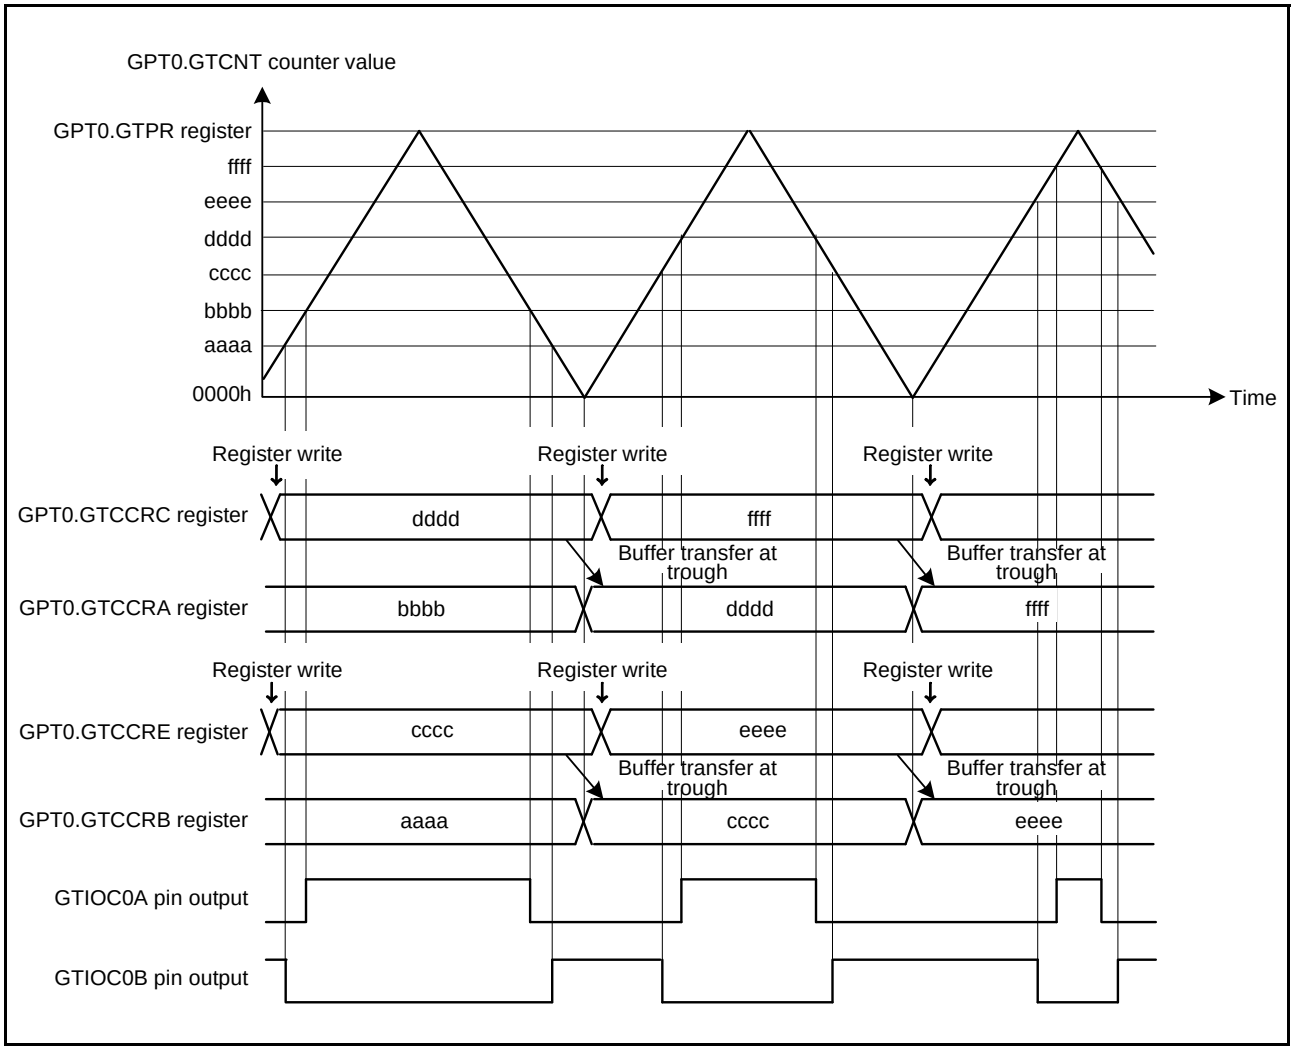

Figure 26.31 Example of Triangle-Wave PWM Mode 1 Operation (Buffer Operation, Low Output from the GTIOC0A Pin and High Output from the GTIOC0B Pin at Initial Output, Output Toggled at GTCCRA/GTCCRB Register Compare Match, Output Retained at the End of the Cycle)

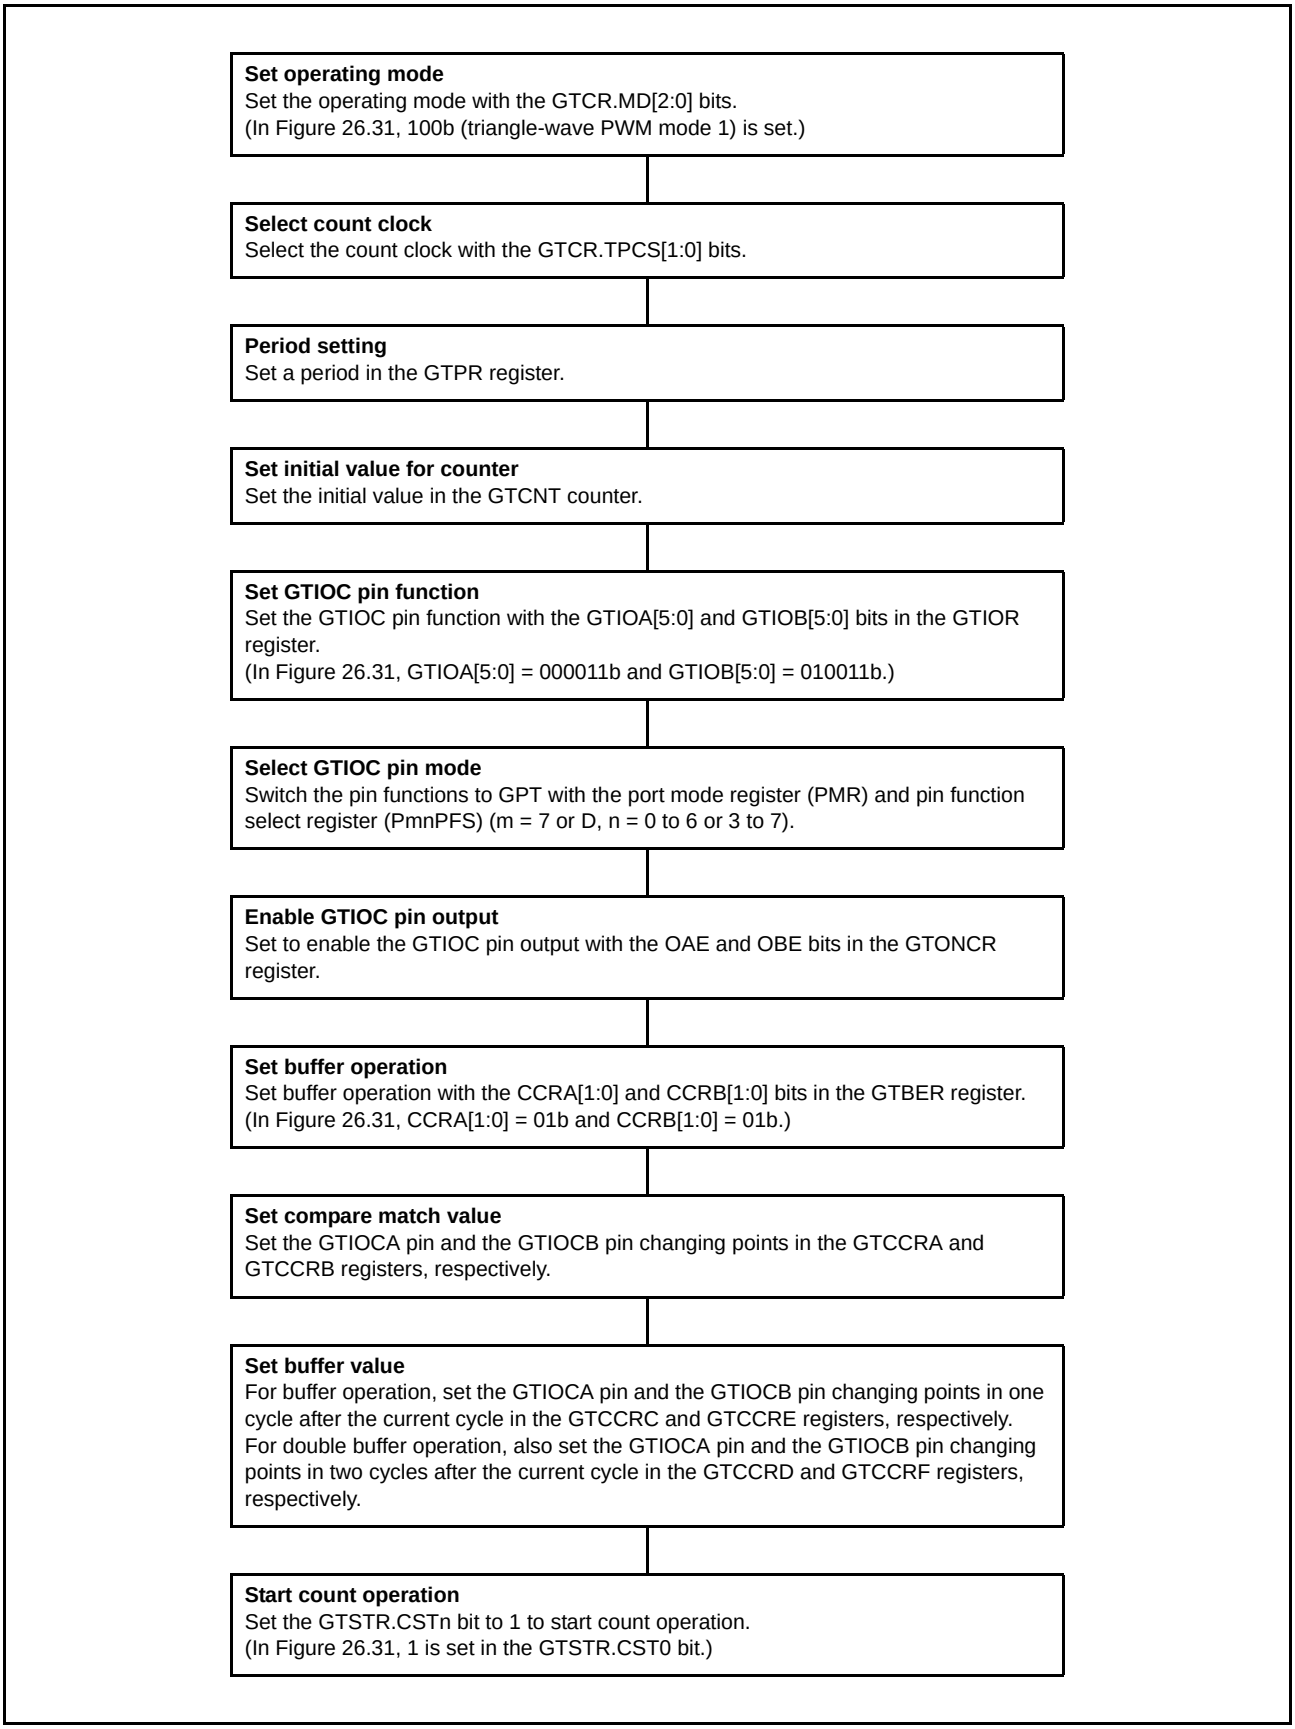

Figure 26.32 Example for Setting Triangle-Wave PWM Mode 1

(4) Triangle-Wave PWM Mode 2 (16-Bit Transfer at Crest and Trough)

Similarly to triangle-wave PWM mode 1, in triangle-wave PWM mode 2 the period is set in the GPTn.GTPR register, the GPTn.GTCNT counter performs triangle-wave (full-wave) operation, and a PWM waveform is output to the GTIOCnA or GTIOCnB pin when a GPTn.GTCCRA or GPTn.GTCCRB compare match occurs (n = 0 to 3). The buffer transfer is performed at both crests and troughs. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the end of the cycle according to the GTIOR setting.
By setting the GTDTCR, GTDVU, and GTDVD registers, a compare match value for a negative-phase waveform with dead time can automatically be set to the GTCCRB register.
Figure 26.33 shows an example of triangle-wave PWM mode 2 operation, and Figure 26.34 shows an example for setting triangle-wave PWM mode 2.

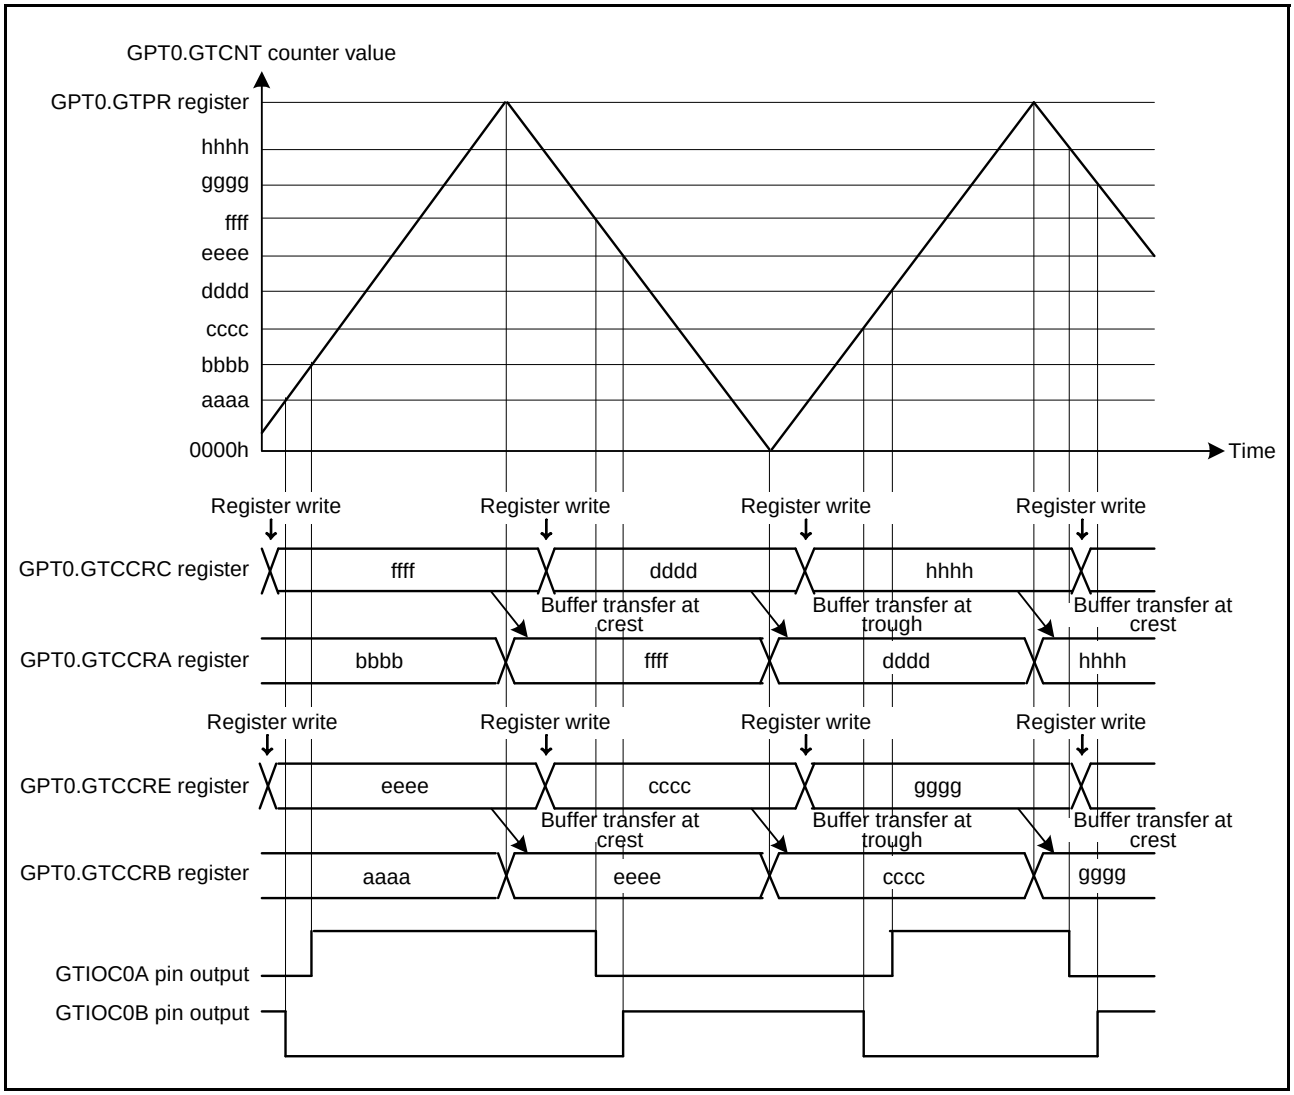

Figure 26.33 Example of Triangle-Wave PWM Mode 2 Operation (Buffer Operation, Low Output from the GTIOC0A Pin and High Output from the GTIOC0B Pin at Initial Output, Output Toggled at GTCCRA/GTCCRB Compare Match, Output Retained at the End of the Cycle)

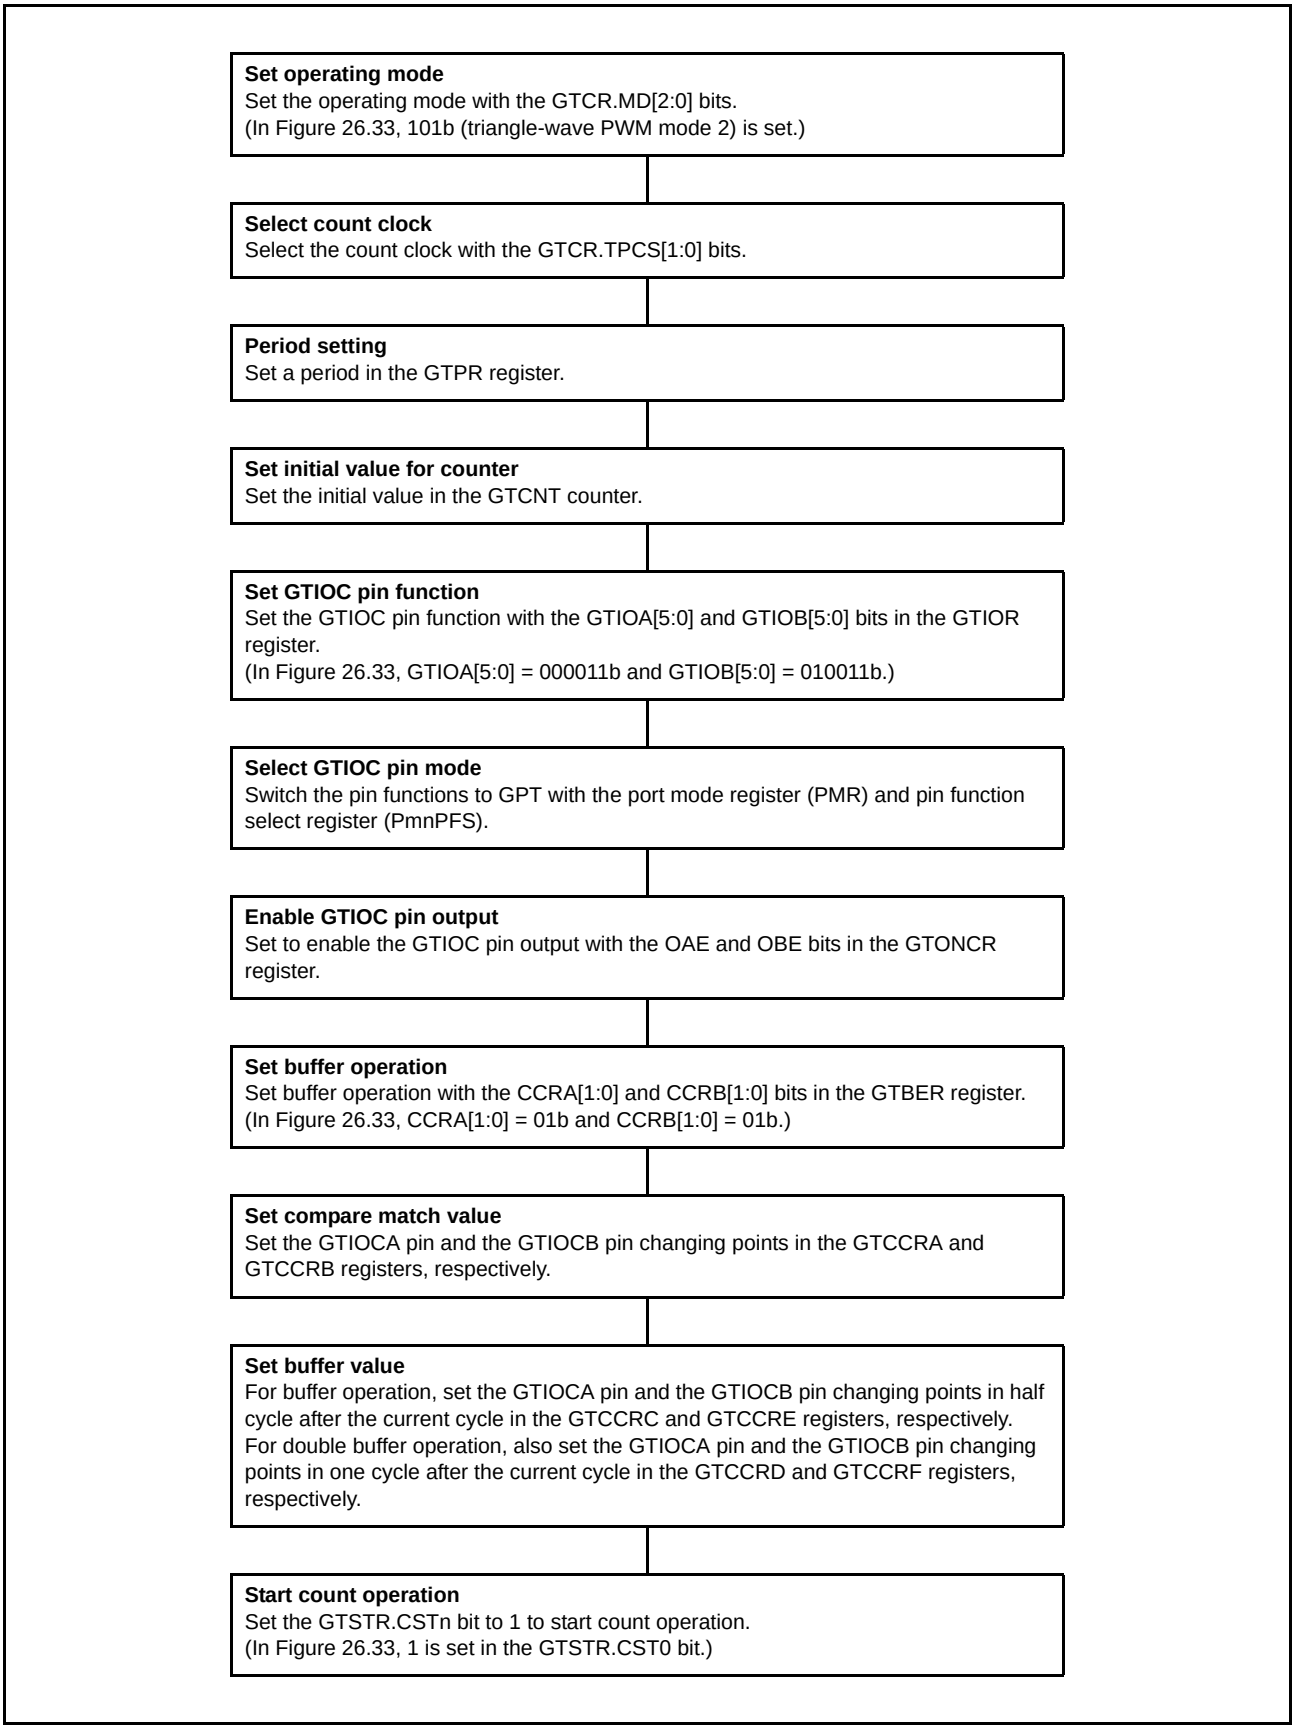

Figure 26.34 Example for Setting Triangle-Wave PWM Mode 2

(5) Triangle-Wave PWM Mode 3 (32-Bit Transfer at Trough)

The triangle-wave PWM mode 3 is a mode in which the period is set in the GPTn.GTPR register, the GPTn.GTCNT counter performs triangle-wave (full-wave) operation and a PWM waveform is output to the GTIOCnA or GTIOCnB pin at a compare match of the GPTn.GTCCRA or GPTn.GTCCRB register with buffer operation fixed (n = 0 to 3). Buffer operation in triangle-wave PWM mode 3 is different from the usual buffer operation. Buffer transfer is performed from the GTCCRC register to the GTCCRA register, from the GTCCRE register to the GTCCRB register, from the GTCCRD register to temporary register A, and from the GTCCRF register to temporary register B at the trough, and from temporary register A to the GTCCRA register and from temporary register B to the GTCCRB register at the crest. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the end of the cycle according to the GTIOR setting.

By setting the GTDTCR, GTDVU, and GTDVD registers, a compare match value for a negative-phase waveform with dead time can automatically be set to the GTCCRB register.

Figure 26.35 shows an example of triangle-wave PWM mode 3 operation, and Figure 26.36 shows an example for setting triangle-wave PWM mode 3.

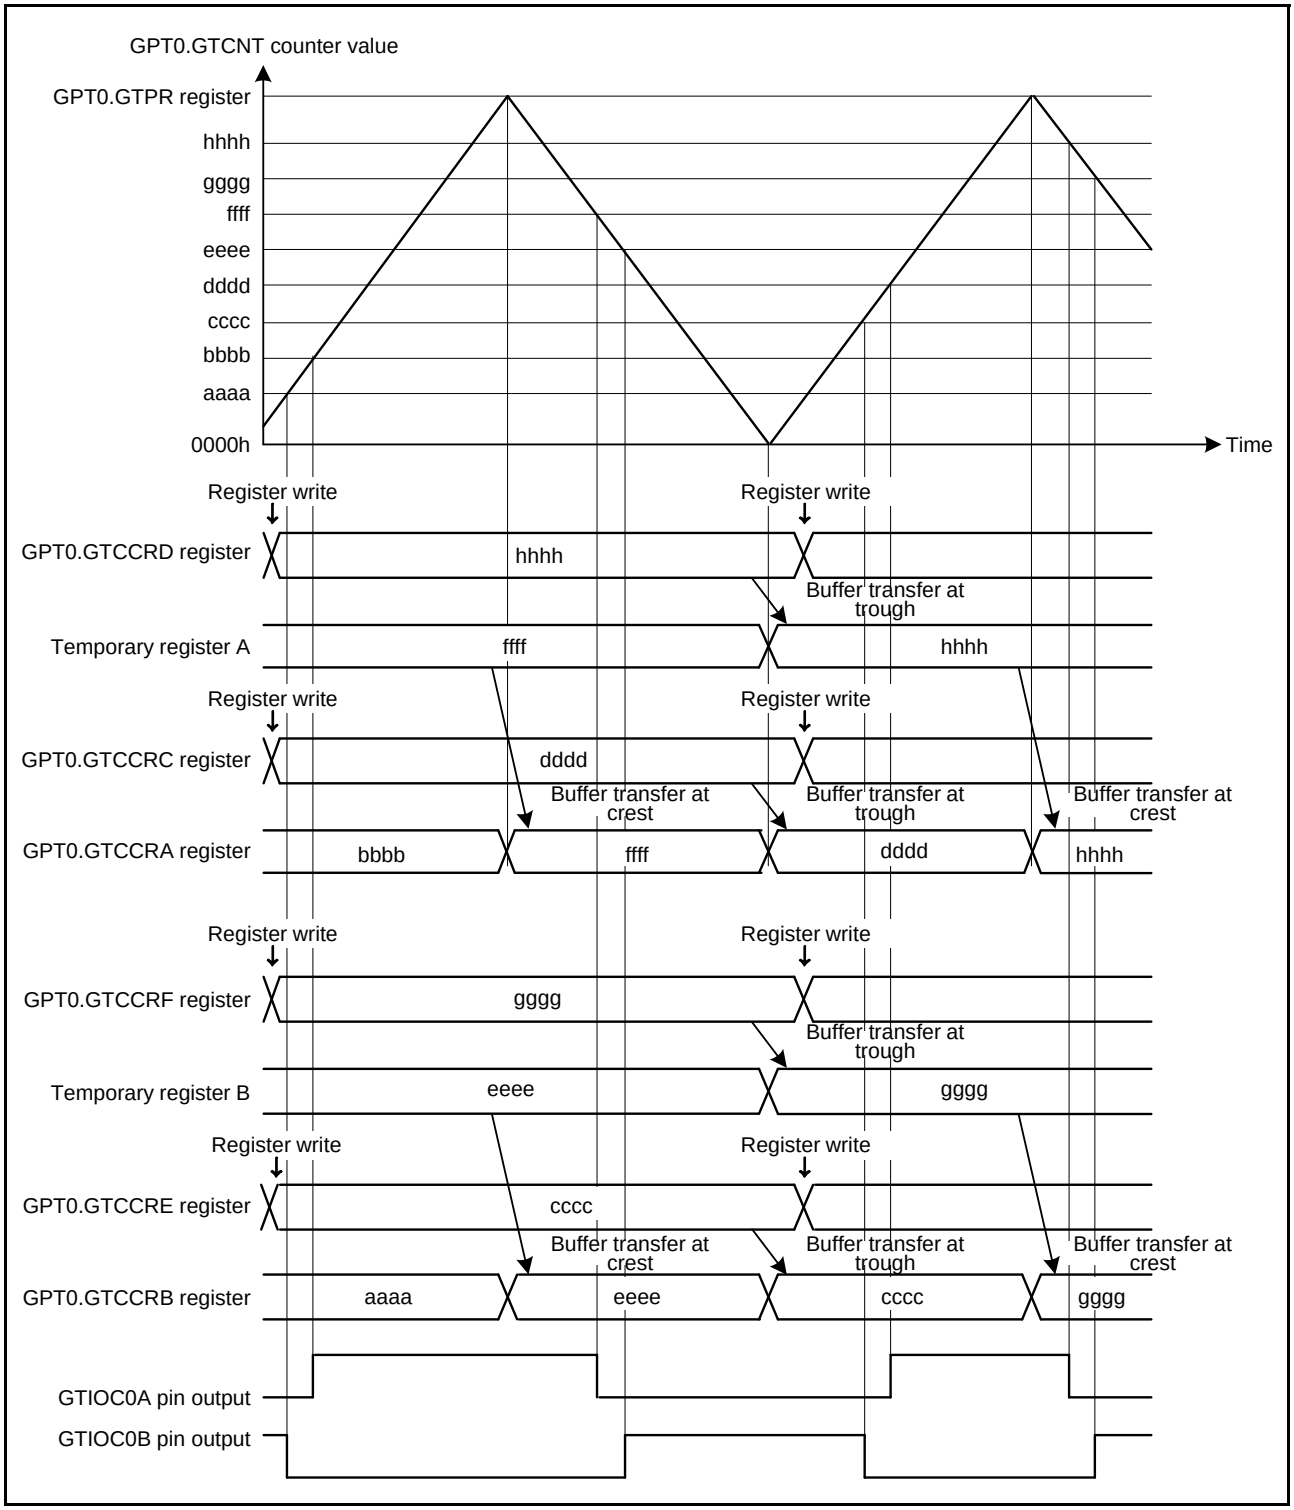

Figure 26.35 Example of Triangle-Wave PWM Mode 3 Operation (Low Output from the GTIOC0A Pin and High Output from the GTIOC0B Pin at Initial Output, Output Toggled at GTCCRA/GTCCRB Compare Match, Output Retained at the End of the Cycle)

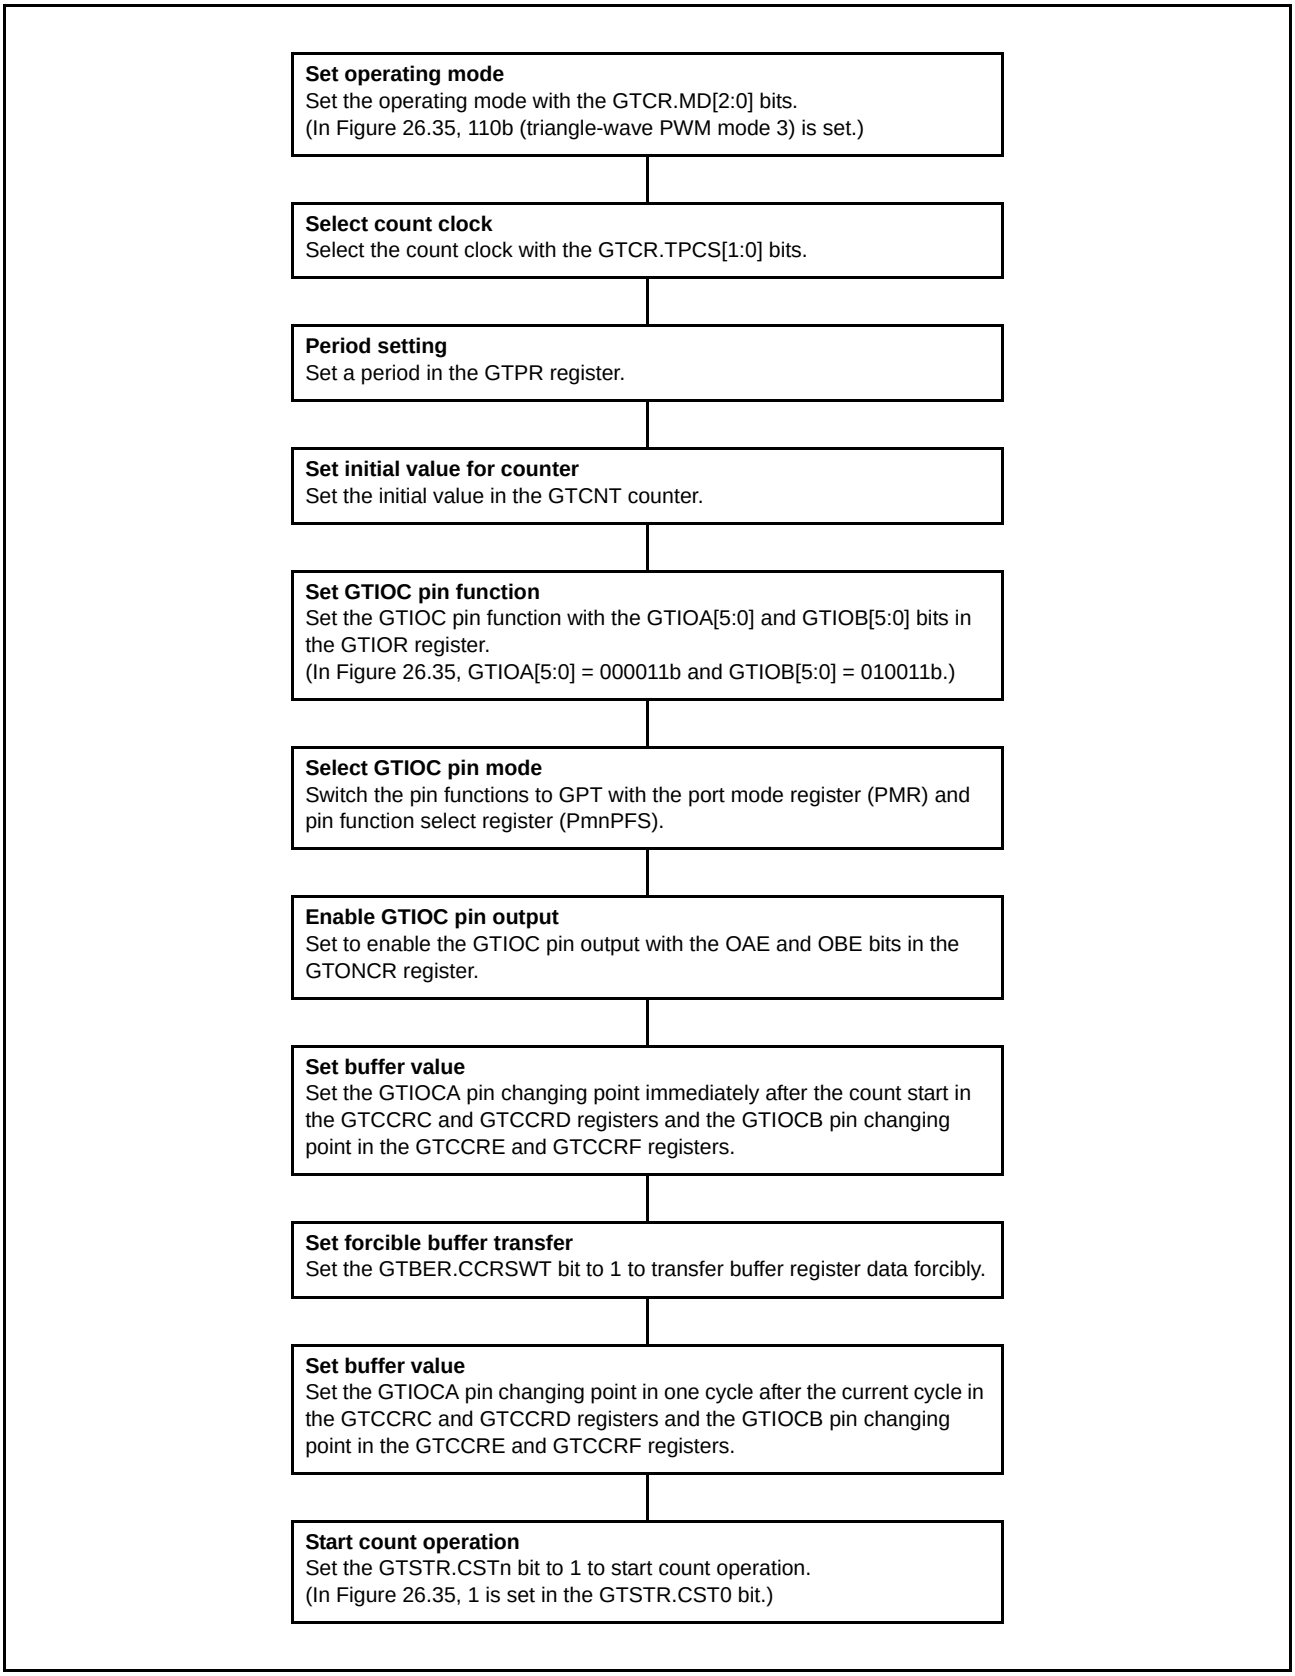

Figure 26.36 Example for Setting Triangle-Wave PWM Mode 3

26.3.4 Automatic Dead Time Setting Function

By setting the GTDTCR register, a compare match value for a negative waveform with dead time obtained by a compare match value for a positive waveform (the GTCCRA value) and specified dead time values (the GTDVU and GTDVD values) can automatically be set to the GTCCRB register.

The automatic dead time setting function can be used in saw-wave one-shot pulse mode and all the triangle PWM modes. Dead time can be separately set for the first half and second half of a waveform. Dead time for the changing point in the first half of a negative waveform is set in the GTDVU register and that in the second half is set in the GTDVD register. The same dead time can also be set for the first and second halves.

The GTDBU register can be used as a buffer register of the GTDVU register, and the GTDBD register can be used as a buffer register of the GTDVD register. Buffer transfer is performed at the end of the cycle (in saw-wave mode, either of an overflow of the GTCNT counter (up-counting), an underflow (down-counting), or counter clearing by a hardware source, software, event input, or synchronous clearing; in triangle-wave mode, a trough).

The change point of the negative-phase waveform, which is automatically calculated, is obtained by reading the GTCCRB register. Writing to the GTCCRB register is prohibited when the automatic dead time setting function is used. In addition, do not set the dead-time that makes the change point of the waveform exceeding the count period.

Figure 26.37 to Figure 26.40 show examples of automatic dead time setting function operation. Figure 26.41 and Figure 26.42 show the setting examples.

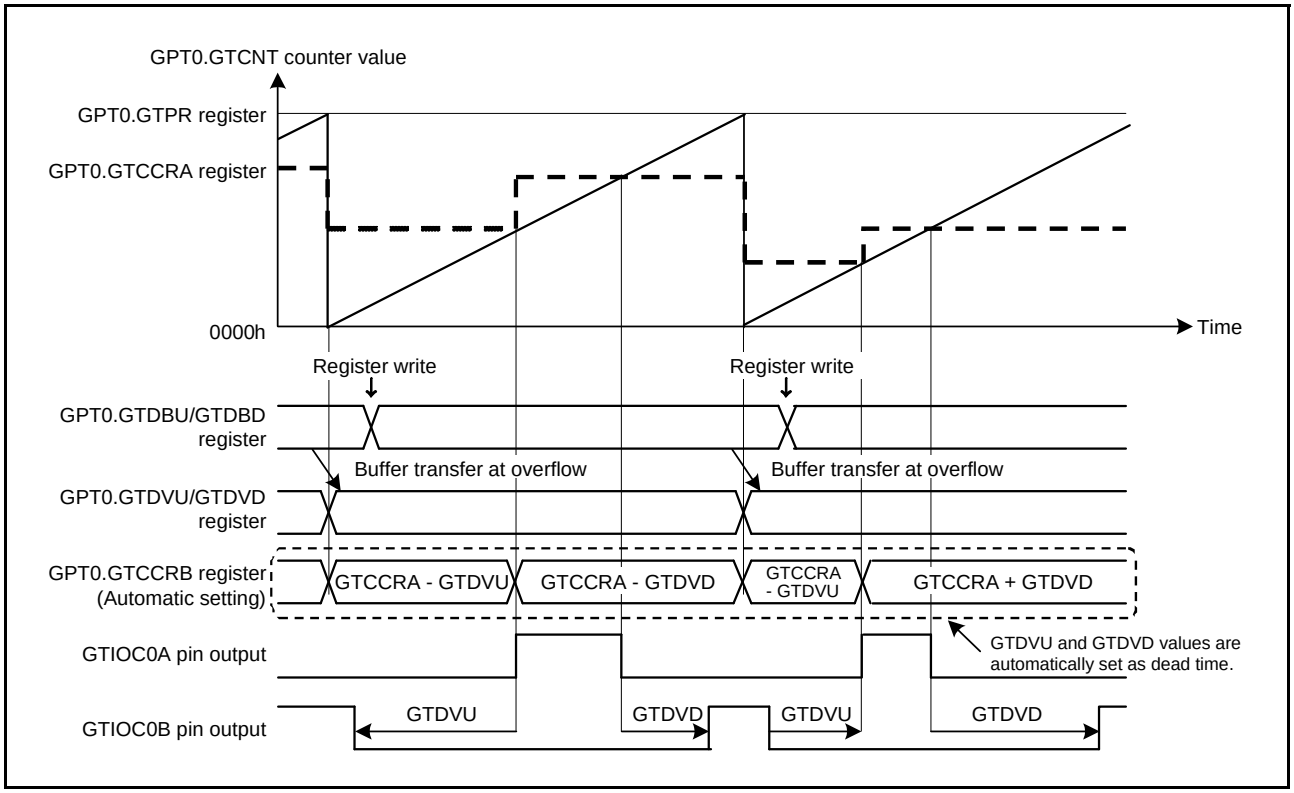

Figure 26.37 Example of Automatic Dead Time Setting Function Operation (Saw-Wave One-Shot Pulse Mode, Up-Counting, GTDVU and GTDVD Set to Buffer Operation, Active Level: High)

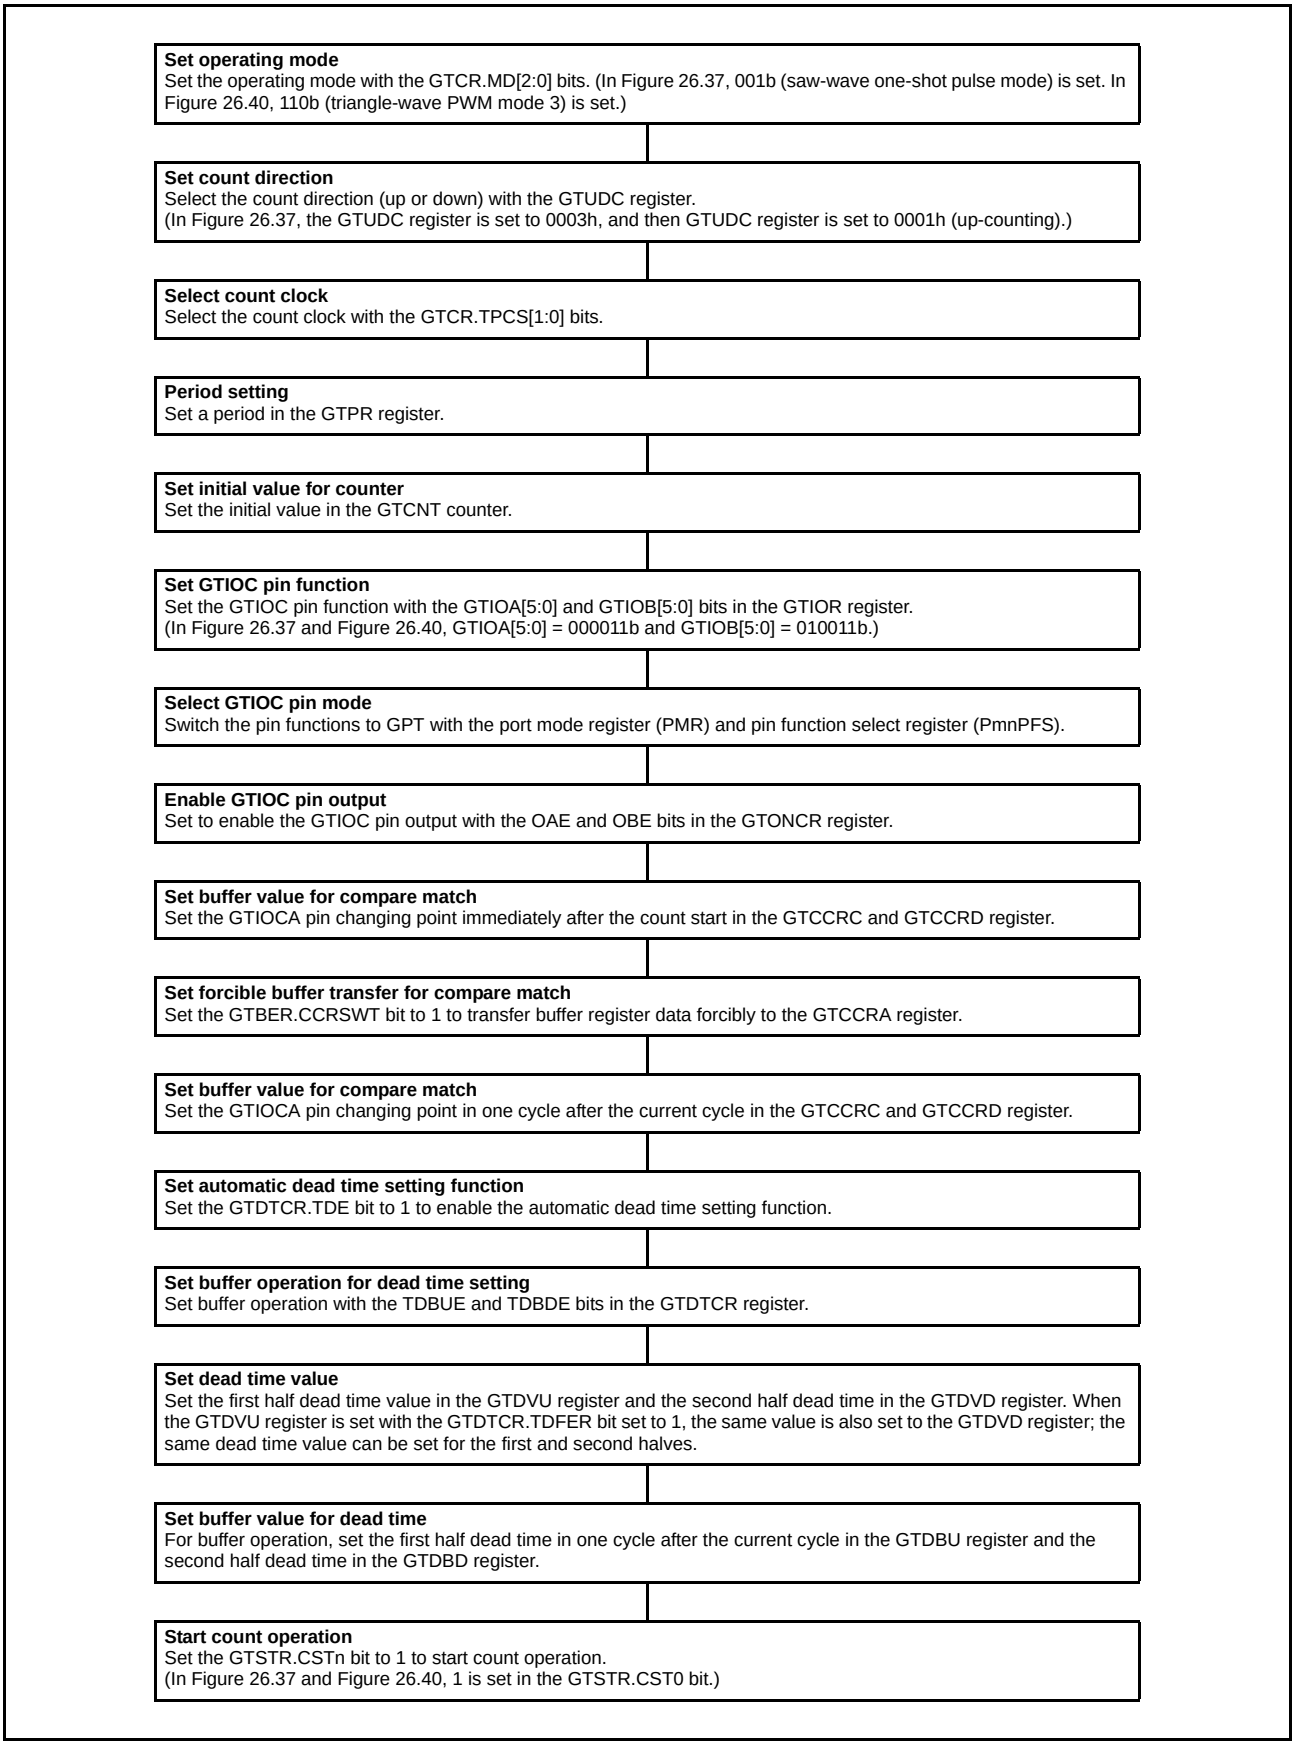

Figure 26.41 Example for Setting Automatic Dead Time Setting Function (Saw-Wave One-Shot Pulse Mode, Triangle-Wave PWM Mode 3)

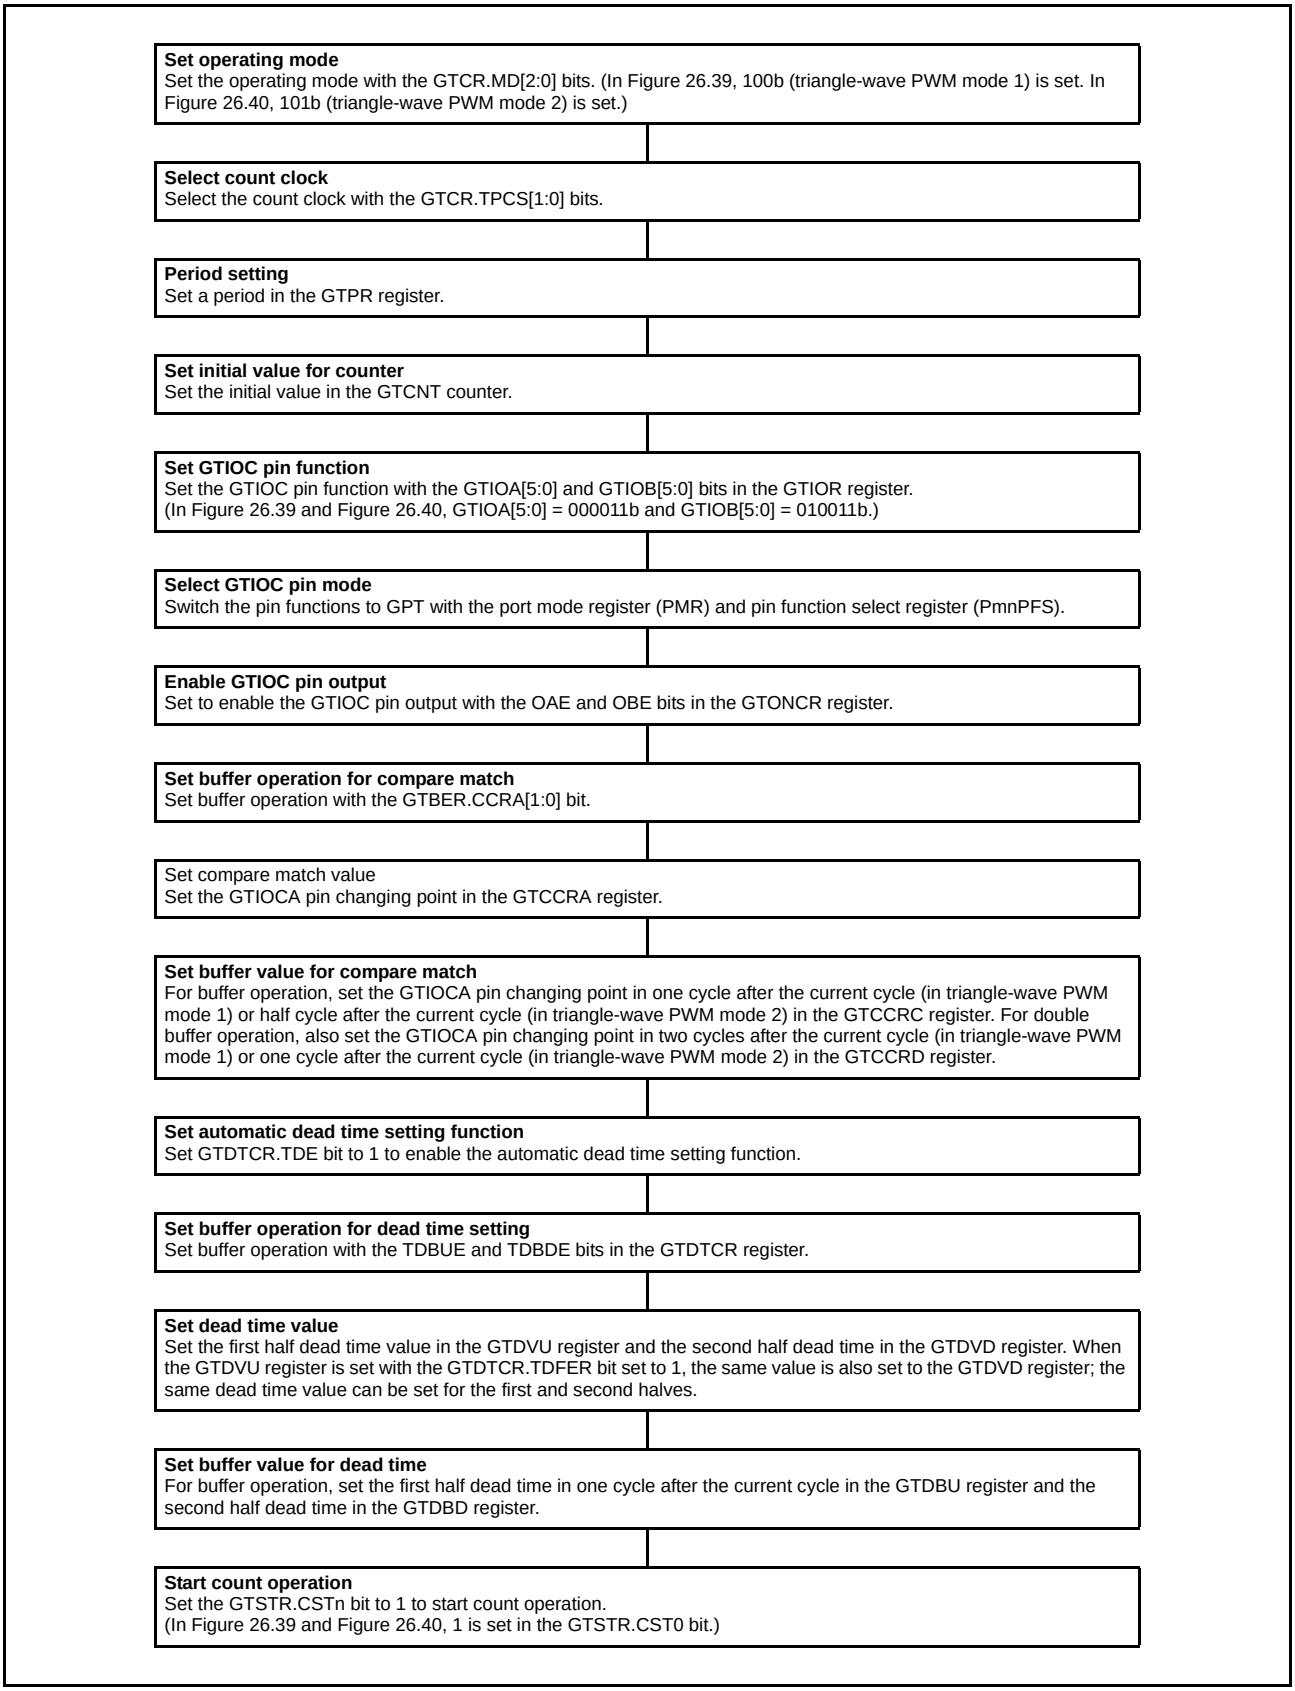

Figure 26.42 Example for Setting Automatic Dead Time Setting Function (Triangle-Wave PWM Mode 1 or 2)

26.3.5 Count Direction Changing Function

The count direction of the GTCNT counter can be changed by modifying the GTUDC.UD bit.
In saw-wave mode, if the GTUDC.UD bit is modified during count operation, the count direction is changed at an overflow (when modified during up-counting) or an underflow (when modified during down-counting). If the UD bit is modified while count operation is stopped and the GTUDC.UDF bit is 0, the UD bit modification is not reflected at the start of counting and the count direction is changed at an overflow or an underflow. If the UDF bit is set to 1 while count operation is stopped, the UD bit value at that time is reflected at the start of counting.
In triangle-wave mode, the count direction is not changed even though the GTUDC.UD bit is modified during count operation. Similarly, even though the UD bit is modified while count operation is stopped and UDF bit is 0, the UD bit value is not reflected to the count operation. If the UDF bit is set to 1 while count operation is stopped, the UD bit value at that time is reflected at the start of counting.
If the count direction is changed from down-counting to up-counting during count operation in saw-wave mode, the GTST.TUCF flag changes from 0 to 1 at the end of the down-counting period (count clock while GTCNT counter value is 0). The GTPR register value after the start of up-counting is reflected in the count period, and the GTCNT counter starts up-counting from 0.
If the count direction is changed from up-counting to down-counting during count operation in saw-wave mode, the GTST.TUCF flag changes from 1 to 0 at the end of the up-counting period (count clock while GTCNT counter value is GTPR value). The GTPR register value before the start of down-counting is reflected in the count period, and the GTCNT counter starts down-counting from the GTPR register value.

Figure 26.43 shows an example of count direction changing function operation.

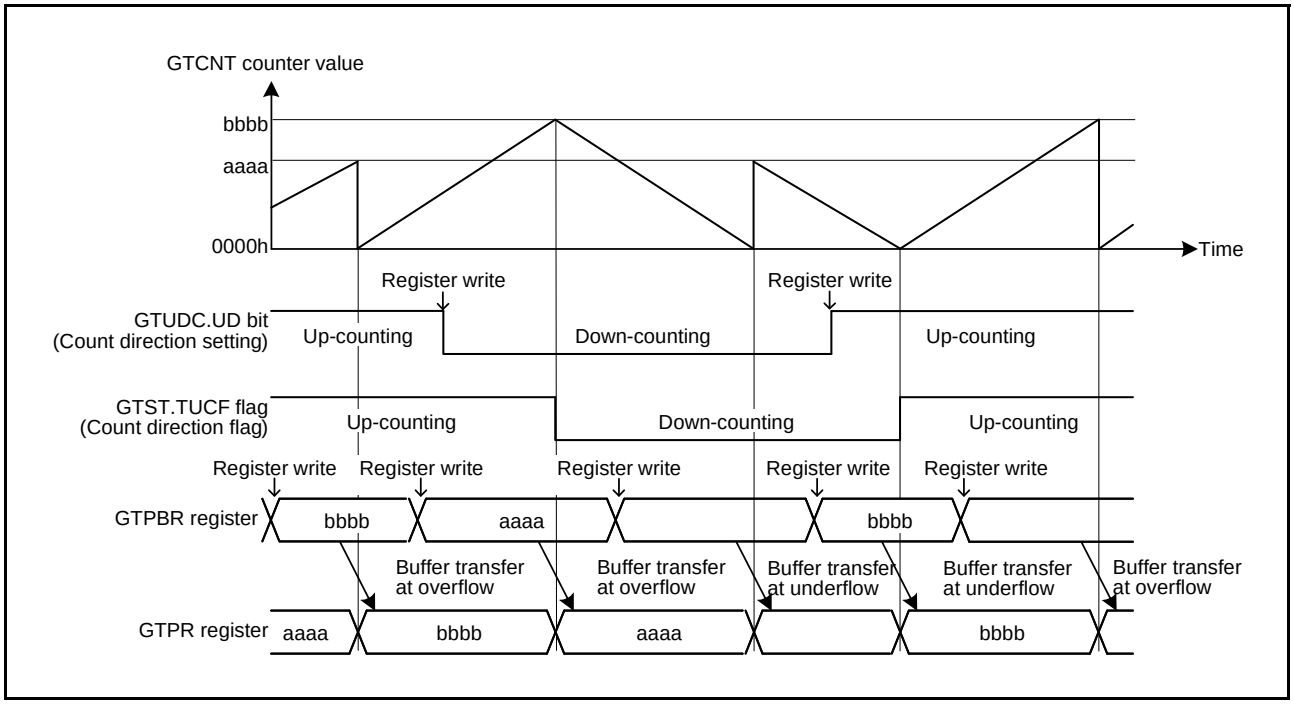

Figure 26.43 Example of Count Direction Changing Function Operation (during Buffer Operation)

26.3.6 Hardware Count Start/Count Stop and Clear Operation

The GTCNT counter can be started, stopped, or cleared by hardware sources in this MCU.
There are 3 types of hardware sources, including GTETRG pin input, GTIOC3A and GTIOC3B pin inputs, and GTIOC3A and GTIOC3B pin internal outputs (output compare).
The GTCNT counter can also be cleared by the GTCCRA or GTCCRB input capture.

26.3.6.1 Hardware Start Operation

The GTCNT counter can be started by a hardware source. Select a hardware source to start counting using the GTHSSR.CSHSLn[3:0] bits (n = 0 to 3), set the edge polarity for the hardware source with the GTHSCR.CSHWn[1:0] bits, and then enable to start counting.
Figure 26.44 shows an example of count start operation by a hardware source. Figure 26.45 shows the setting example.

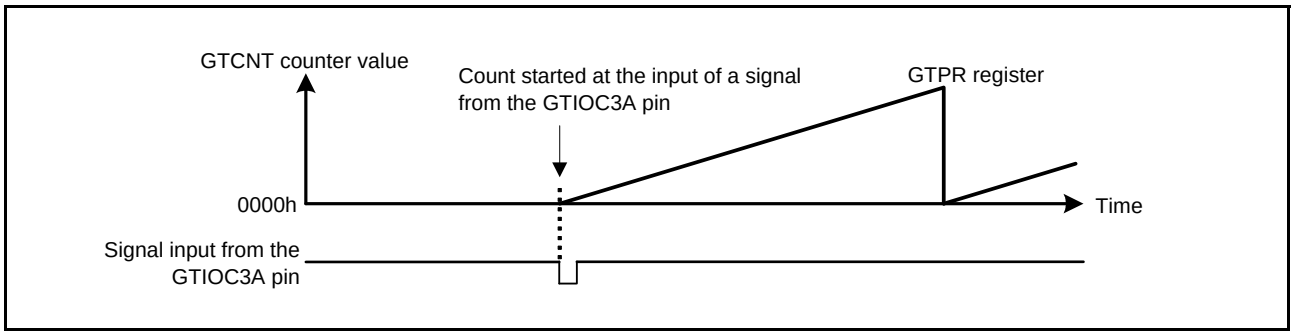

Figure 26.44 Example of Count Start Operation by Hardware Source (Started at Input of Signal from the GTIOC3A Pin)

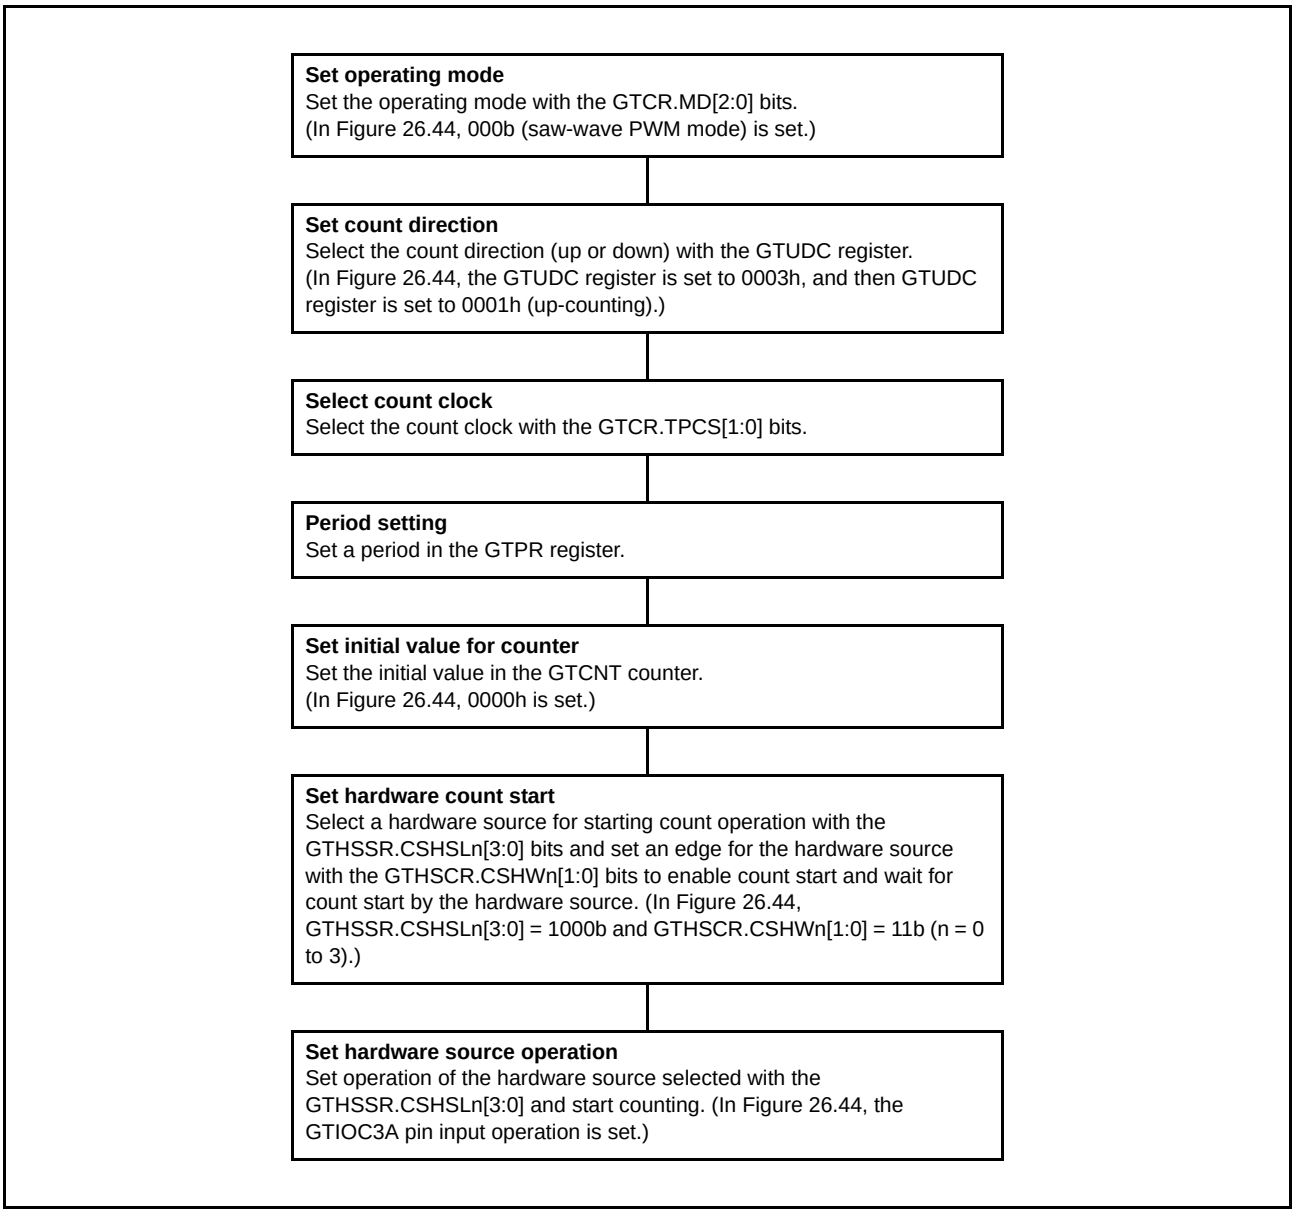

Figure 26.45 Example for Setting Count Start Operation by Hardware Source

26.3.6.2 Hardware Stop Operation

The GTCNT counter can be stopped by a hardware source. Select a hardware source to stop counting using the GTHPSR.CSHPLn[3:0] bits (n = 0 to 3), set the edge polarity for the hardware source with the GTHSCR.CPHWn[1:0] bit, and then enable to stop counting.

Figure 26.46 shows an example of count stop operation by a hardware source. Figure 26.47 shows the setting example. In this example, the count operation is stopped at both edges of the GTIOC3A pin internal output (output compare) and is restarted at both edges of the GTIOC3B pin internal output (output compare).

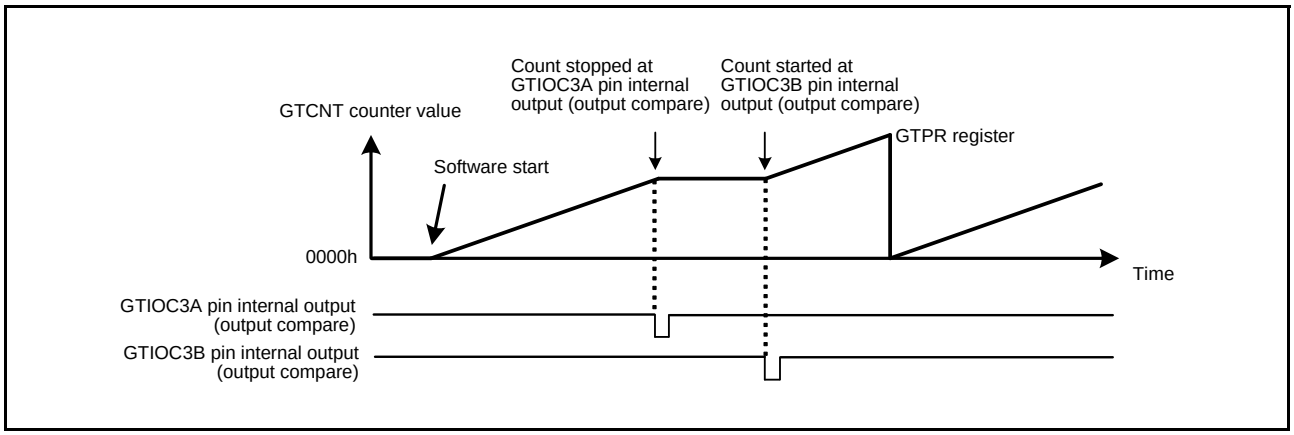

Figure 26.46 Example of Count Stop Operation by Hardware Source (Started by Software, Stopped at GTIOC3A Pin Internal Output (Output Compare), Restarted at GTIOC3B Pin Internal Output (Output Compare))

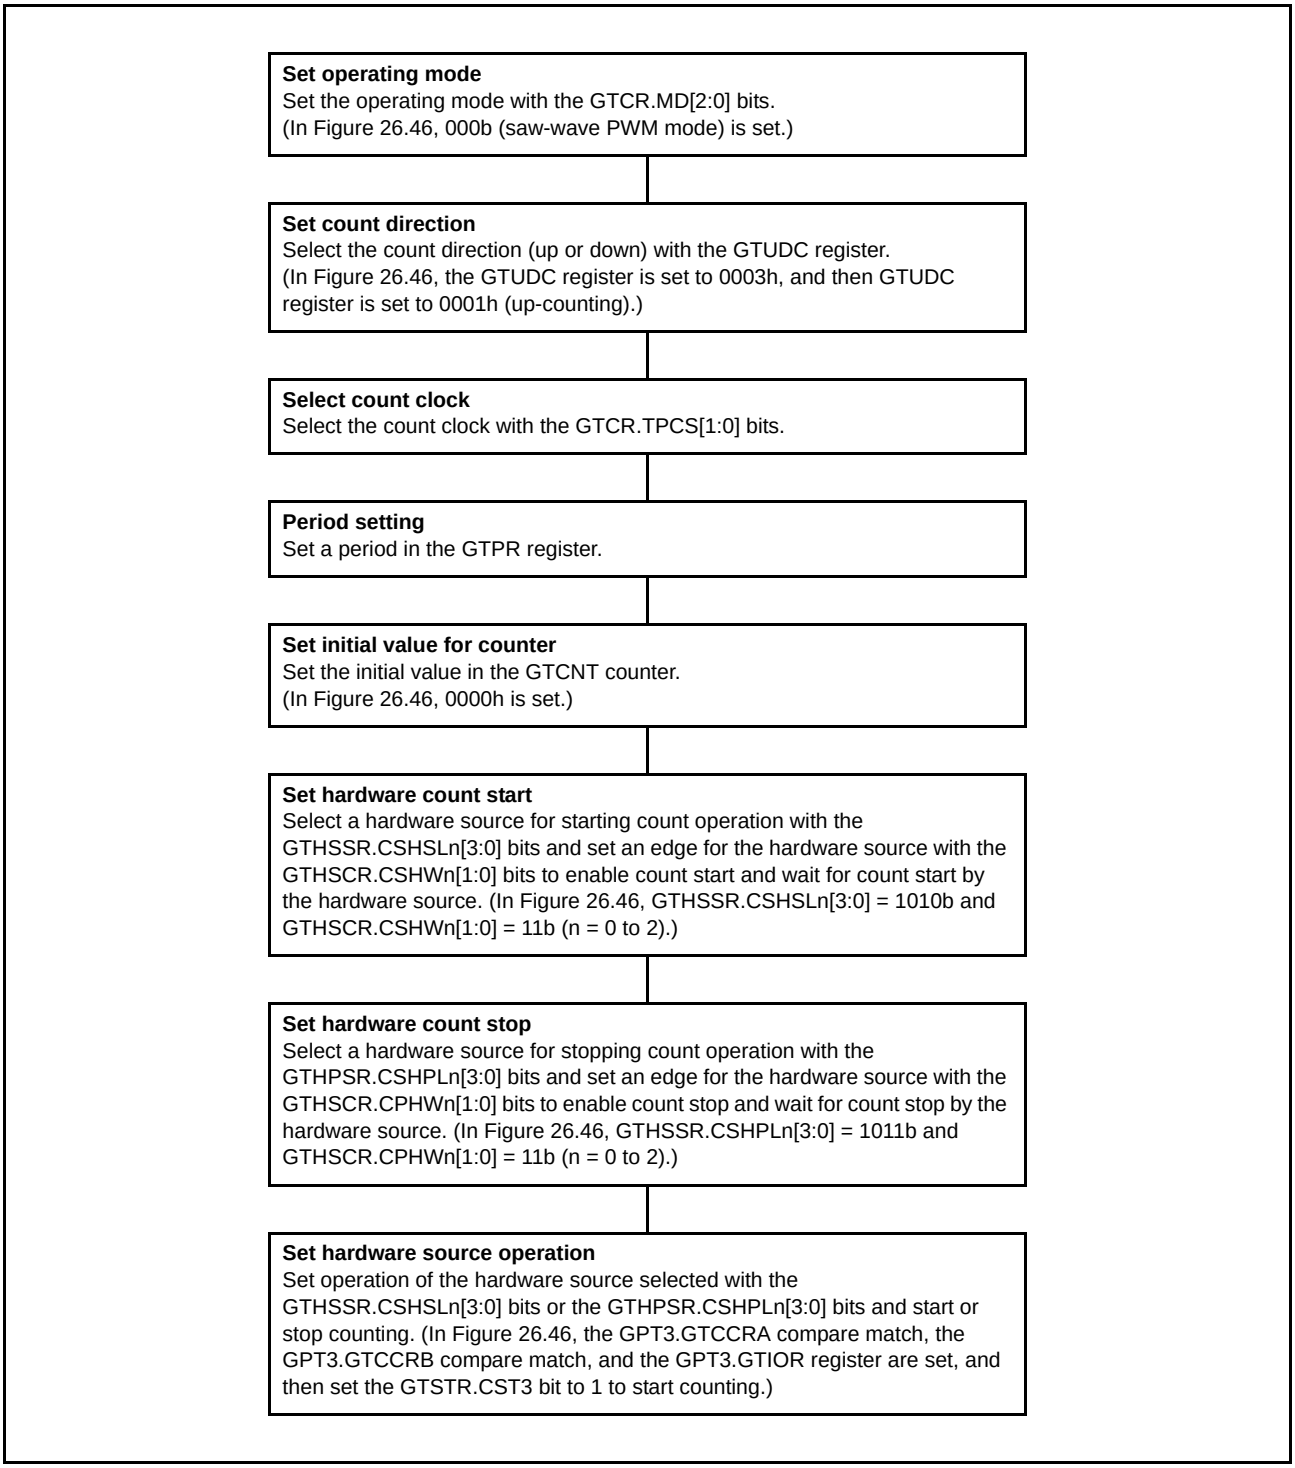

Figure 26.47 Example for Setting Count Stop Operation by Hardware Source

Figure 26.48 shows an example of count start/stop operation by a hardware source. Figure 26.49 shows the setting example. In this example, the counter operates during the high-level periods of the external trigger input GTETRG.

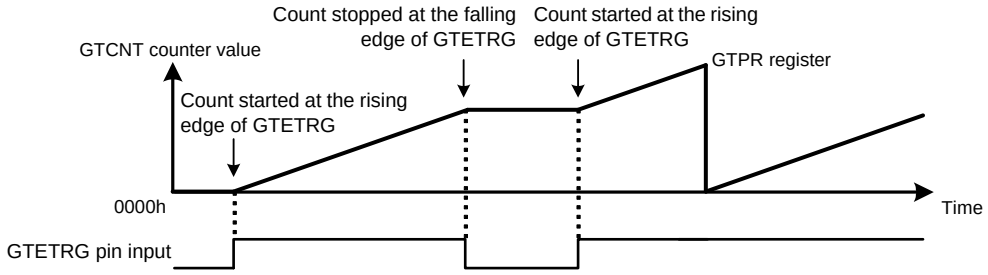

Figure 26.48 Example of Count Start/Stop Operation by Hardware Source (Started at Rising Edge of GTETRG Pin Input, Stopped at Falling Edge of GTETRG Pin Input)

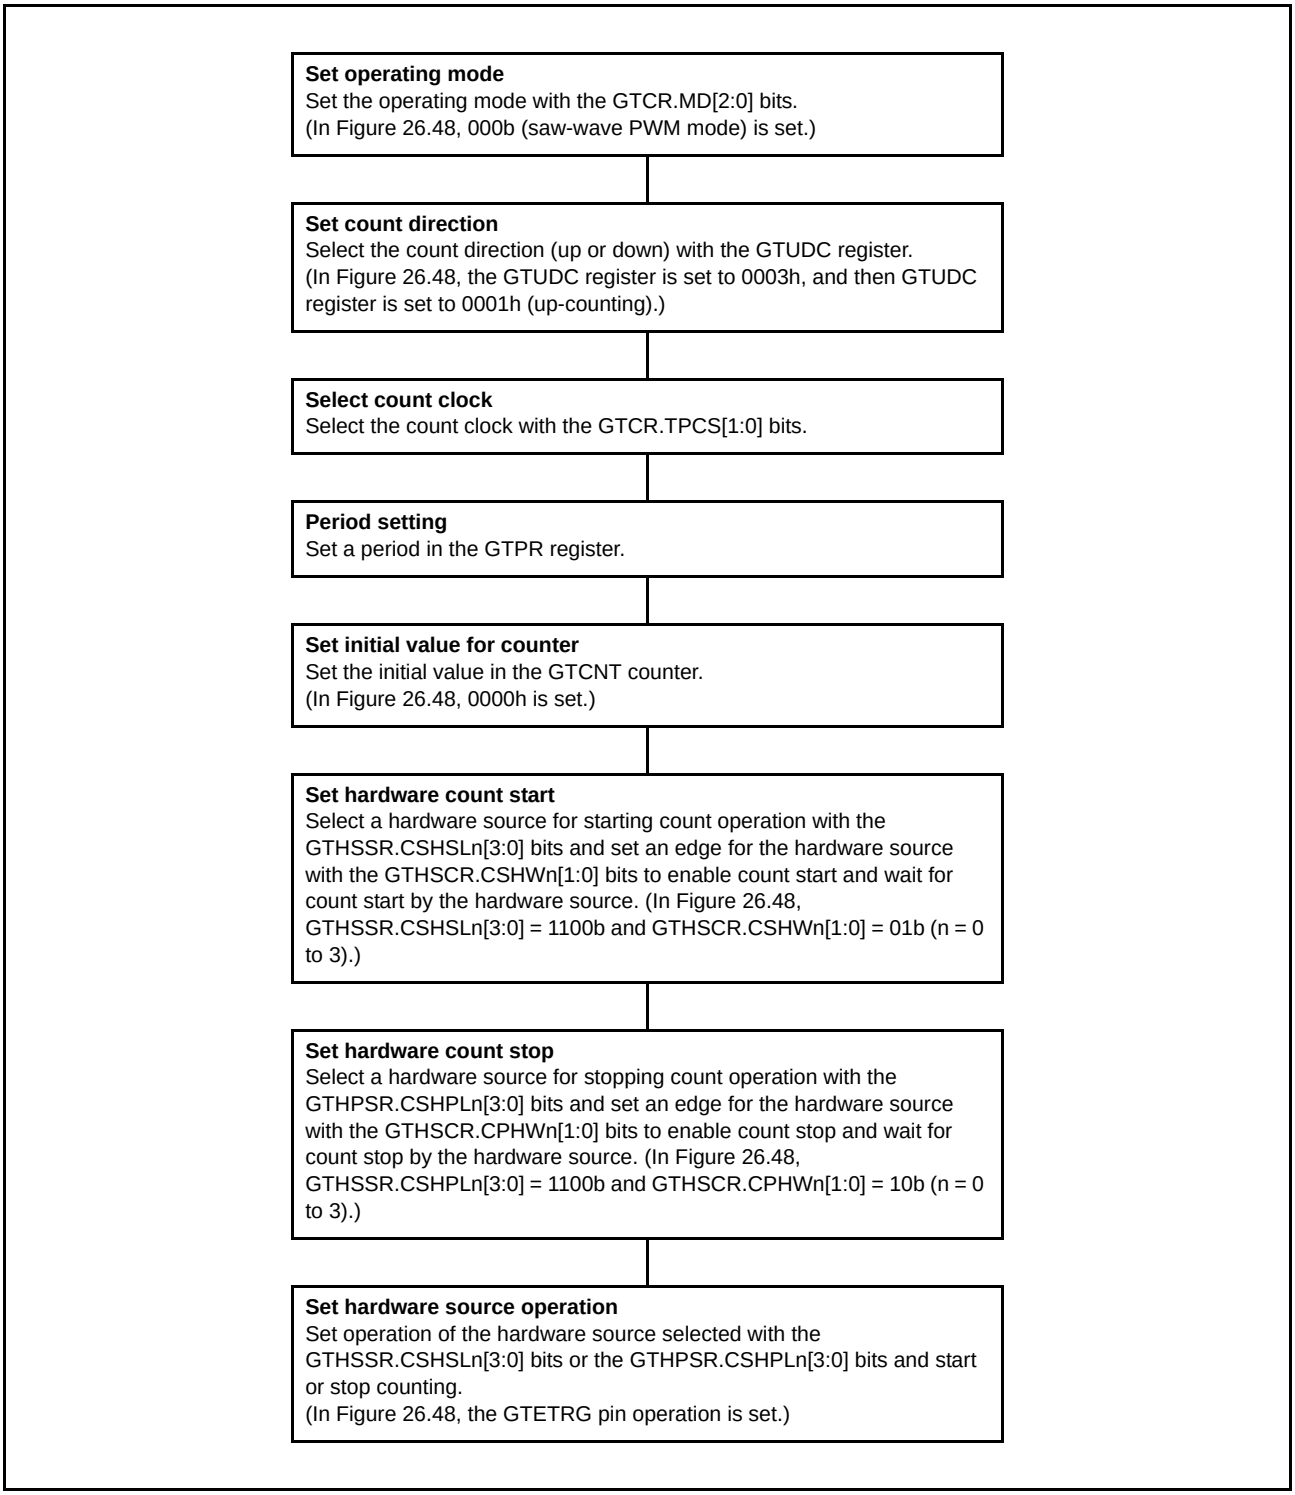

Figure 26.49 Example for Setting Count Start/Stop Operation by Hardware Source

26.3.6.3 Hardware Clear Operation

The GTCNT counter can be cleared by a hardware source. Select a hardware source to clear the counter using the GTHPSR.CSHPLn[3:0] bits (n = 0 to 3), set the edge polarity for the hardware source with the GTHCCR.CCHWn[1:0] bits, and enable clearing the counter.

The GTCNT counter can also be cleared by a GTCCRA or GTCCRB input capture by setting the GTCR.CCLR[1:0] bits.

When the count direction is down-counting (GTST.TUCF flag is 0) in saw-wave mode, the GTCNT counter is set to the value set in the GTPR register. In other cases, the GTCNT counter is set to 0000h when count clearing is executed.

Note that the GTCIV/GTCIU interrupt (overflow/underflow interrupt) is not generated when the GTCNT counter is cleared by a hardware source or by software.

Figure 26.50 and Figure 26.51 show examples of the GTCNT counter clearing operation by a hardware source. Figure 26.52 shows the setting example. Figure 26.53 shows the relationship between counter clearing by a hardware source and the GTCIV/GTCIU interrupt. In this example, the GTCNT counter is started at both edges of the GTIOC3A pin, and the counter is stopped/cleared at both edges of the GTOC3B pin input.

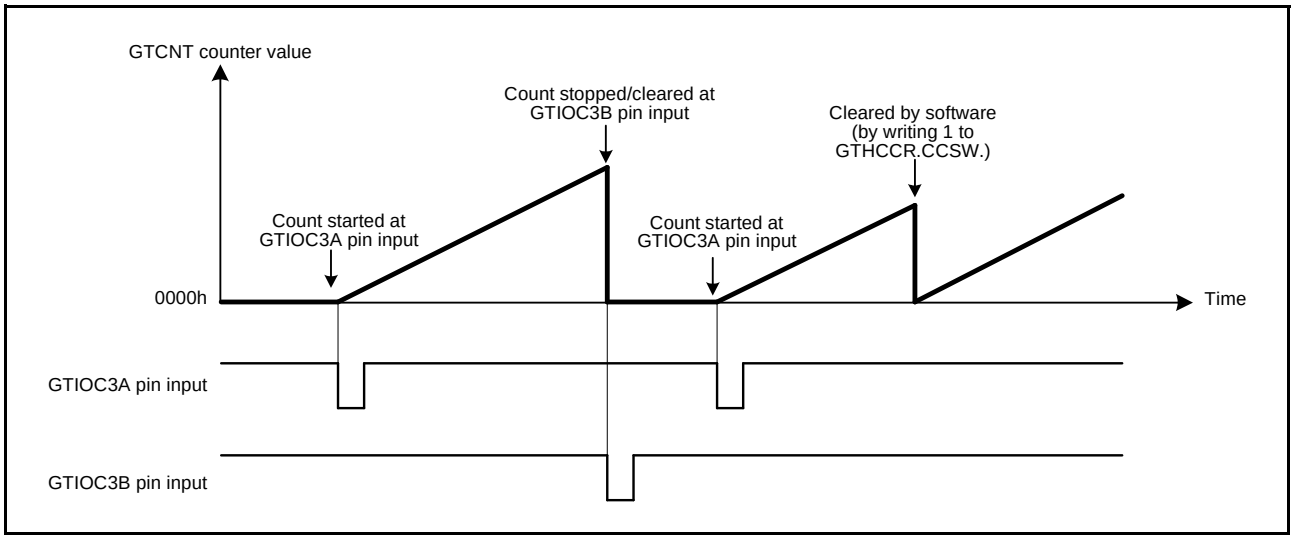

Figure 26.50 Examples of Count Clearing Operation by Hardware Source (Saw-Wave Up-Counting, Started at GTIOC3A Pin Input, Count Stopped/Count Cleared at GTIOC3B Pin Input)

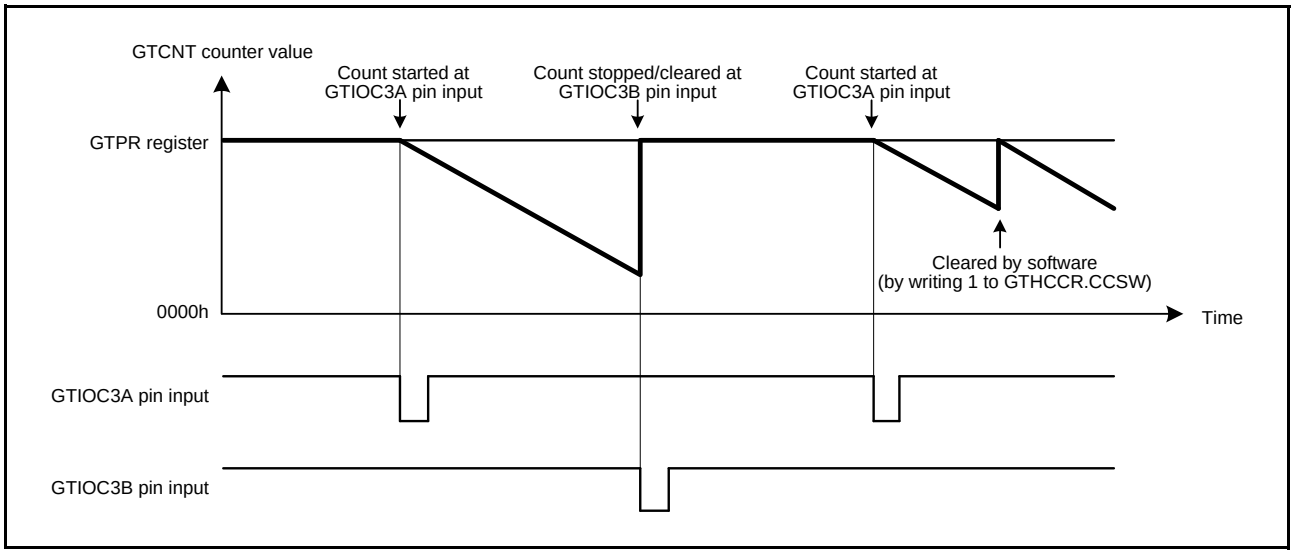

Figure 26.51 Examples of Count Clearing Operation by Hardware Source (Saw-Wave Down-Counting, Started at GTIOC3A Pin Input, Count Stopped/Count Cleared at GTIOC3B Pin Input)

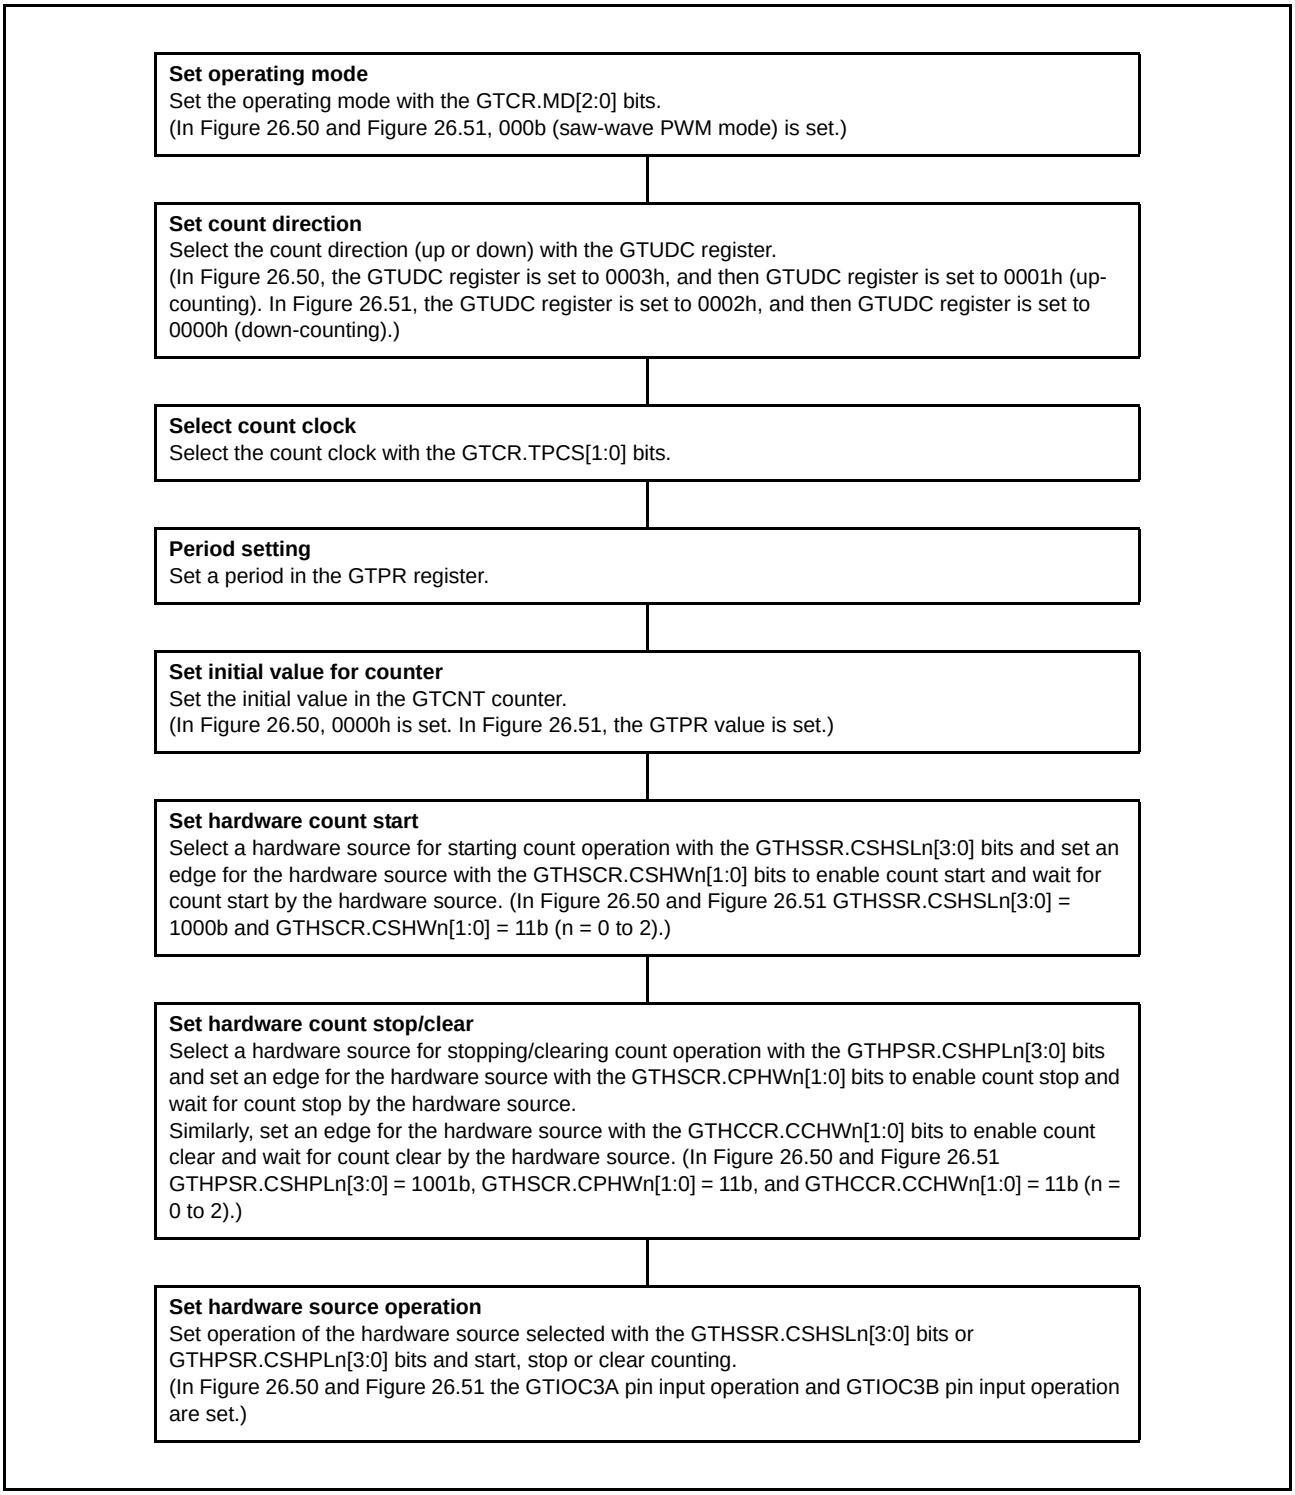

Figure 26.52 Example for Setting Count Clearing Operation by Hardware Source

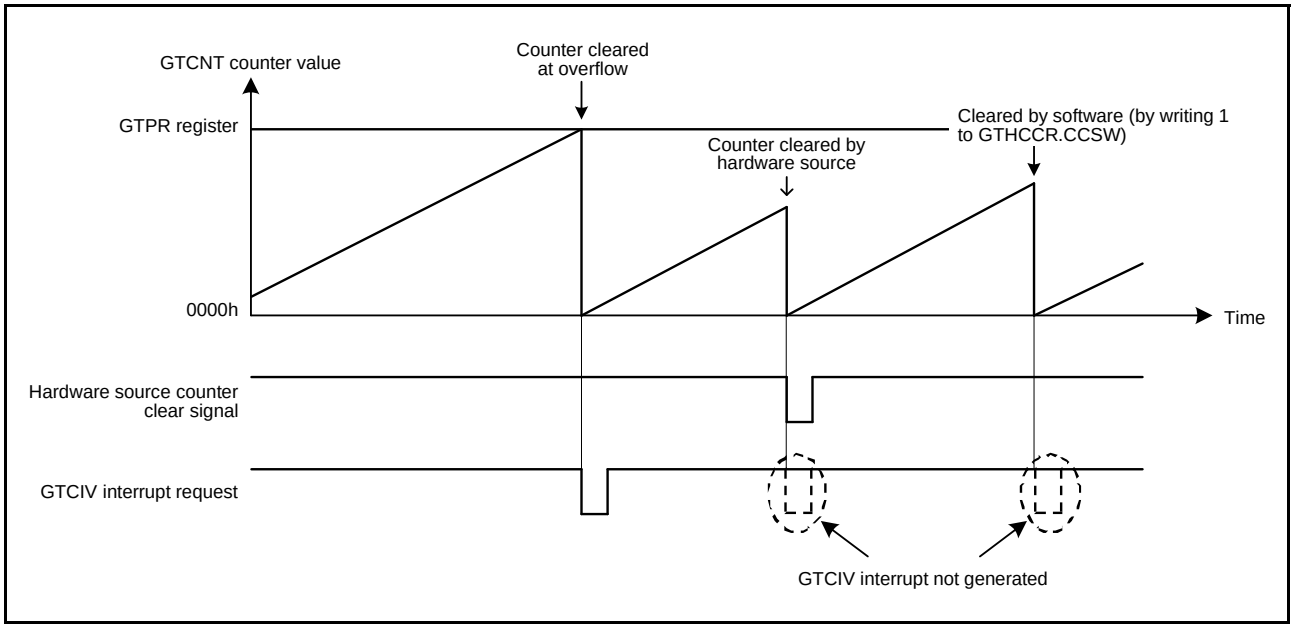

Figure 26.53 Relationship between Counter Clearing by Hardware Source and GTCIV Interrupt

26.3.7 Synchronous Operation

Synchronous operation on channels (synchronous clear operation, synchronous start operation) can be performed.

26.3.7.1 Synchronous Clear Operation

Synchronous clearing on channels can be controlled. Select which channels to be synchronously cleared by setting the GTCR.CCLR[1:0] bits of the pertinent channels to 11b and which channel clearing source to be used for synchronous clearing by setting the GTSYNC.SYNCn[1:0] bits (n = 0 to 3).

The sources used for synchronous clearing are a hardware source, software, event input, input capture, an overflow of saw waves (up-counting) and an underflow (down-counting).

Figure 26.54 shows an example of synchronous clear operation, and Figure 26.56 shows the setting example. In this example, the GPT1.GTCNT and GPT2.GTCNT counters are synchronously cleared by the GPT0.GTCNT clearing source (overflow).

Synchronous clearing of channels by a clear source does not cause synchronous clearing of another channel by the same clear source. (Synchronous clearing is not transmitted.)

Figure 26.55 shows an operation example in which two channels are synchronously cleared by the clear source of one of the channels and another channel is synchronously cleared by the clear source of the other one of the two channels.

Figure 26.56 shows the setting example. In this example, the GPT1.GTCNT counter is synchronously cleared by the GPT0.GTCNT counter clearing source (overflow), and the GPT2.GTCNT counter is synchronously cleared by the GPT1.GTCNT counter clearing source (overflow). Although the GPT1.GTCNT counter is synchronously cleared by the GPT0.GTCNT counter clearing source (overflow), the GPT2.GTCNT counter is not synchronously cleared when the GPT1.GTCNT counter is cleared by the GPT0.GTCNT counter clearing source.

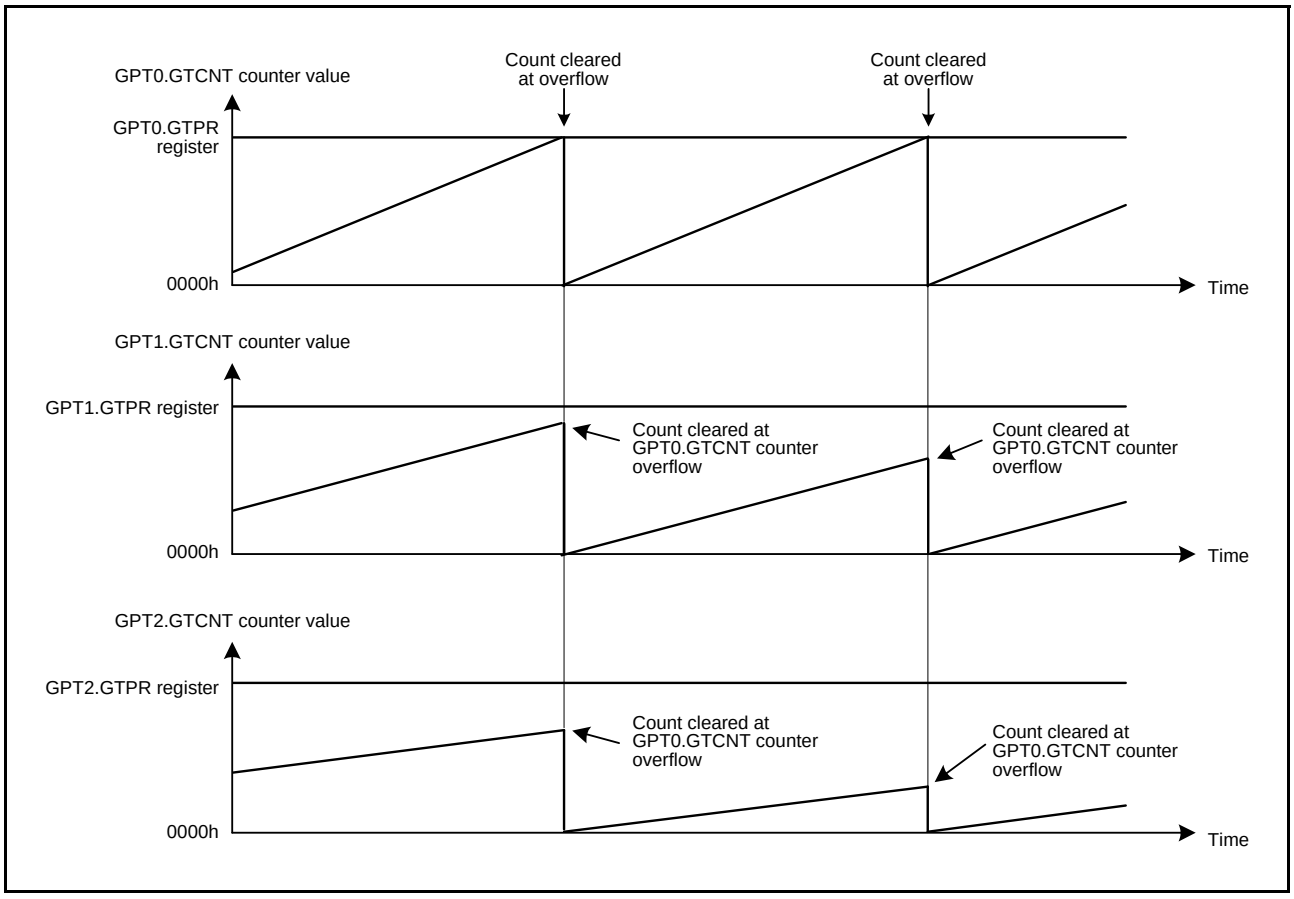

Figure 26.54 Example of Synchronous Clear Operation (GPT1.GTCNT and GPT2.GTCNT Counters are Synchronously Cleared by GPT0.GTCNT Counter Clearing Source)

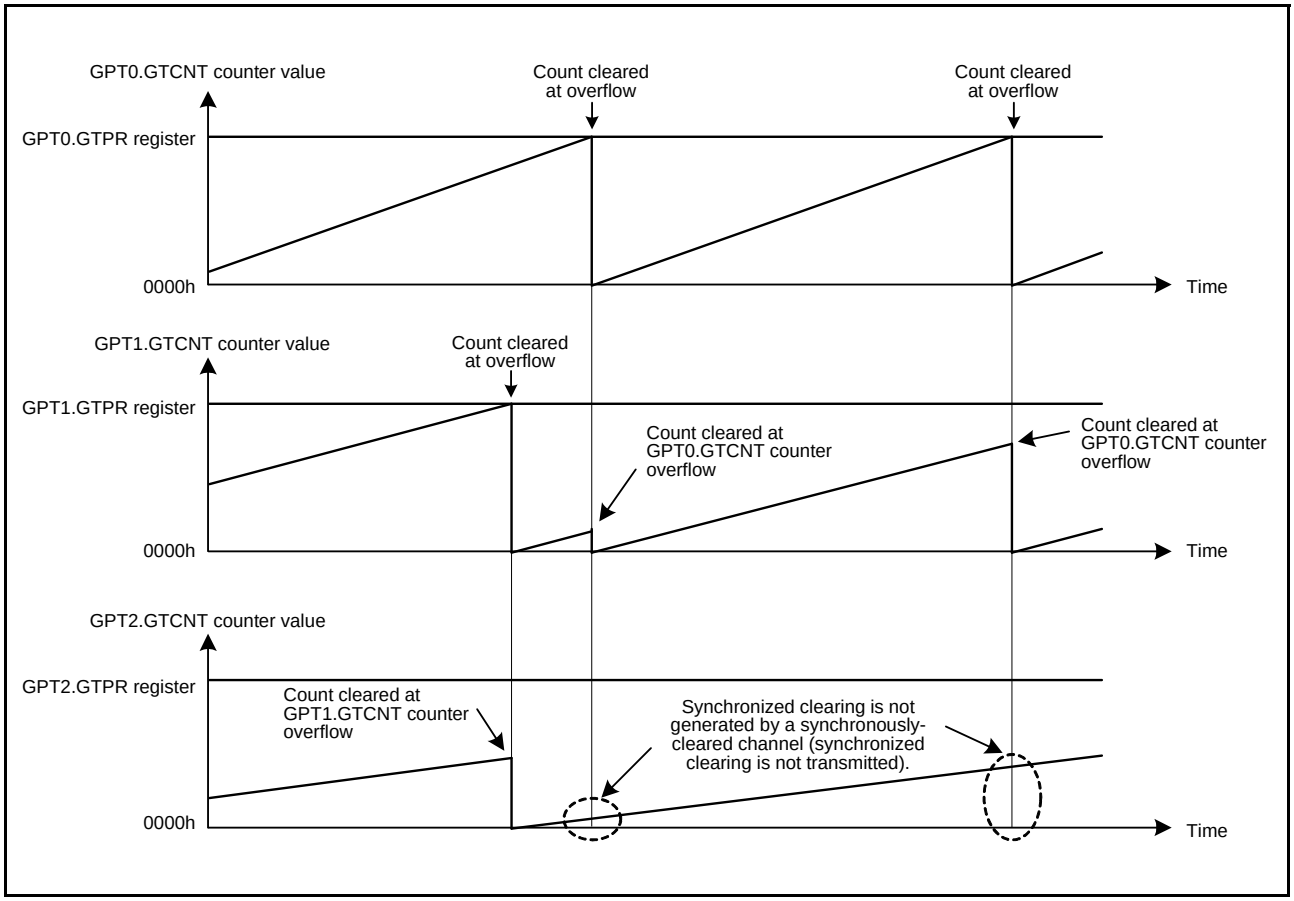

Figure 26.55 Example of Synchronous Clear Operation (GPT1.GTCNT Counter is Synchronously Cleared by GPT0.GTCNT Counter Clearing Source and GPT2.GTCNT Counter is Synchronously Cleared by GPT1.GTCNT Counter Clearing Source)

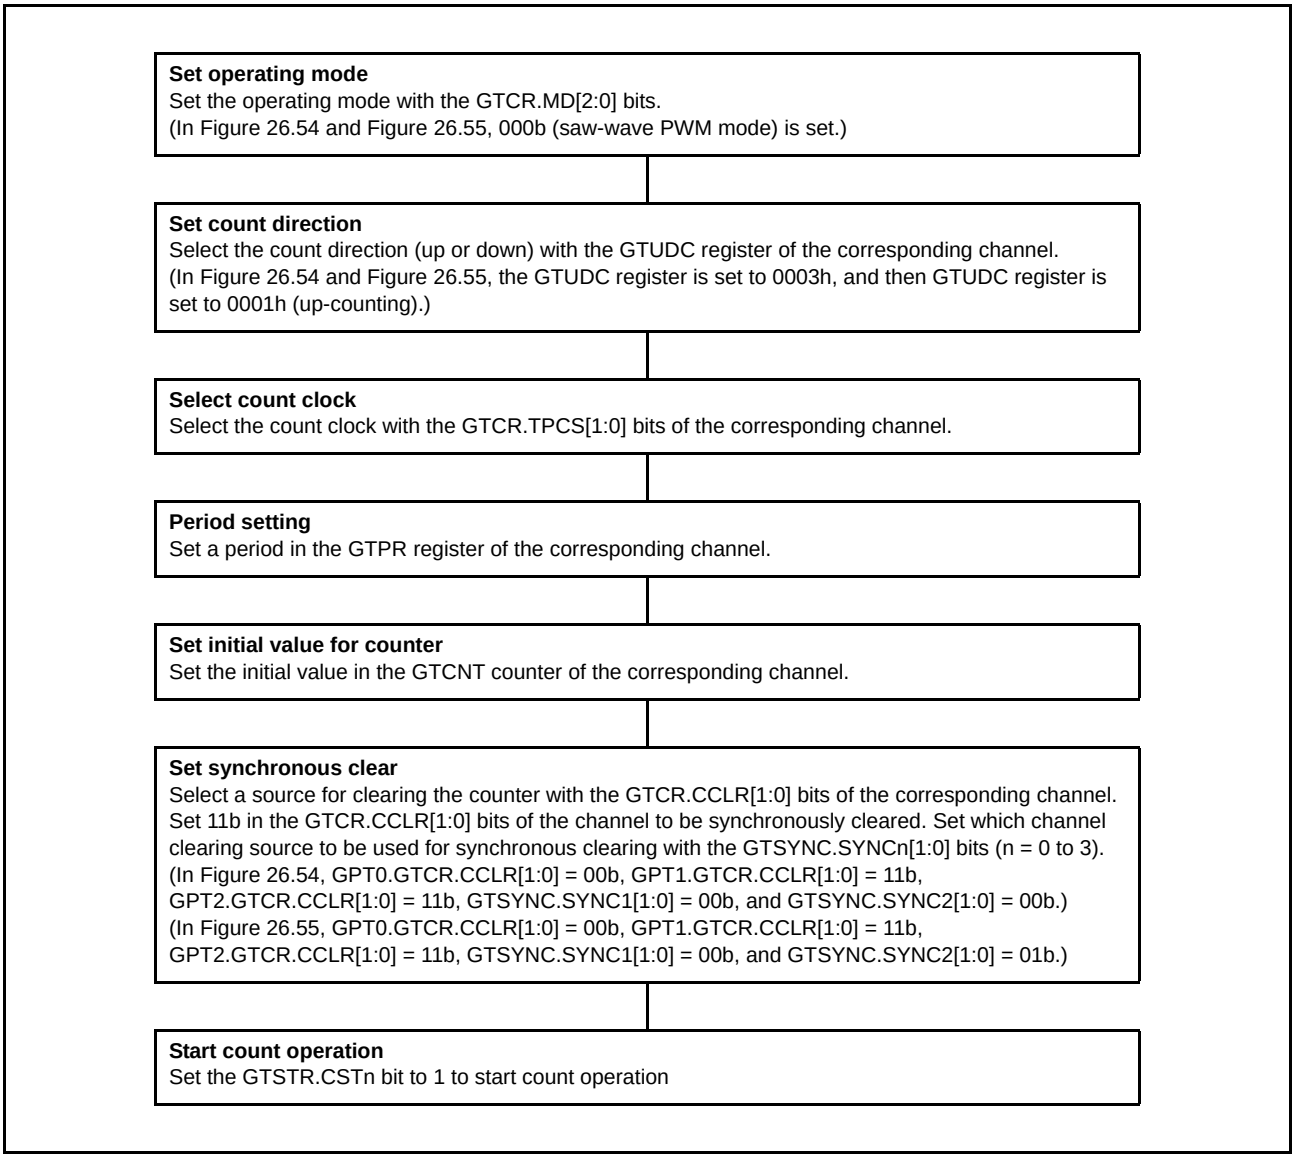

Figure 26.56 Example for Setting Synchronous Clear Operation

26.3.7.2 Synchronous Start Operation

(1) Simultaneous Start by Software

The GPTn.GTCNT counters can be started simultaneously on channels by simultaneously setting the GTSTR.CSTn bits which correspond to the channels to be started simultaneously to 1 (n = 0 to 3).
Figure 26.57 shows an example of simultaneous start by software.

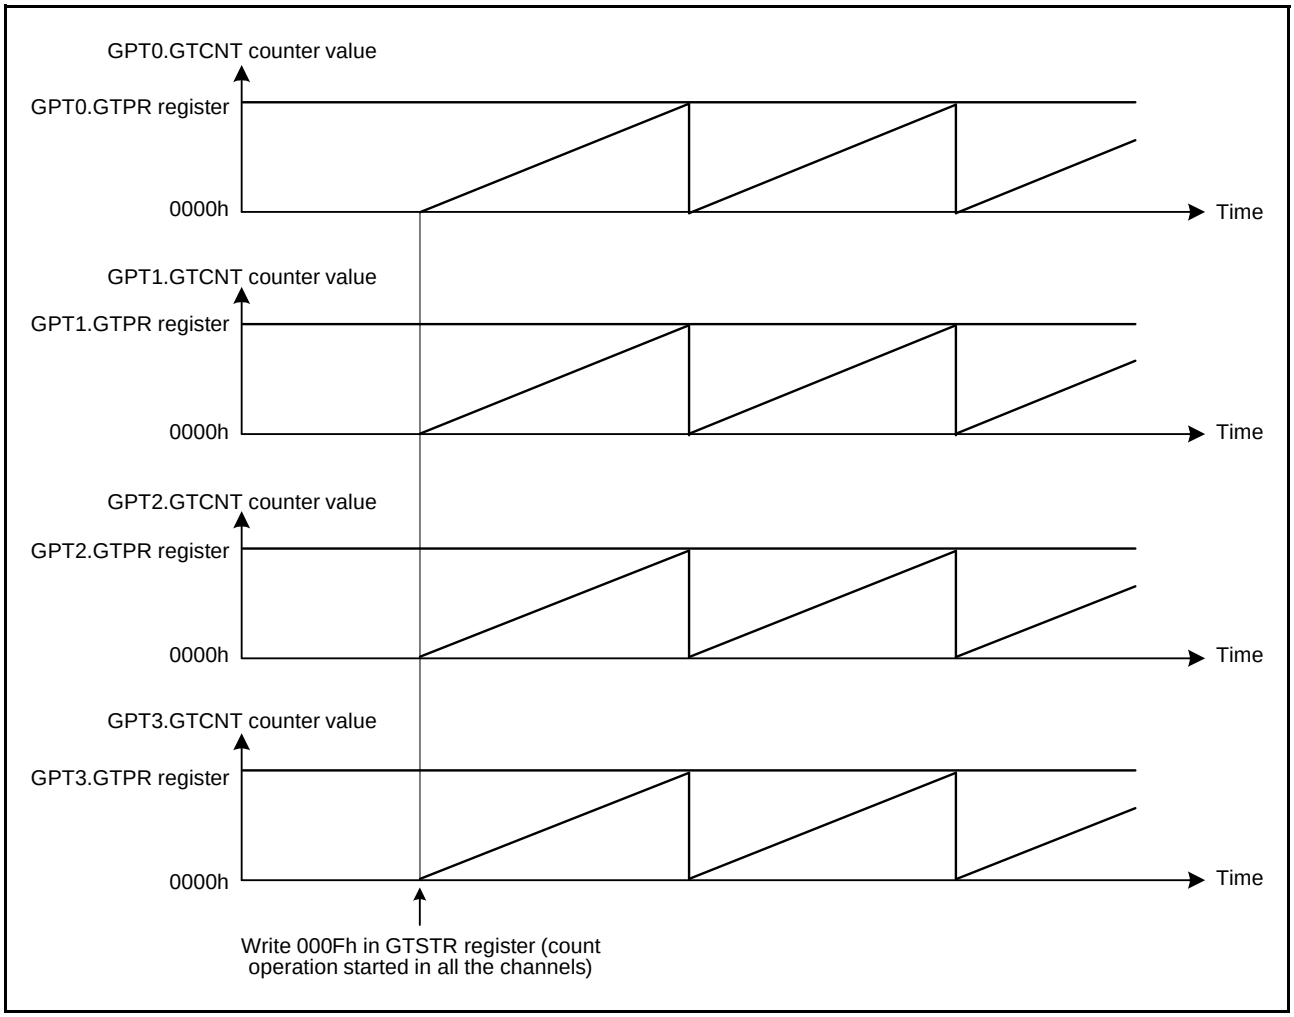

Figure 26.57 Example of Simultaneous Start by Software (with Same Count Period (GTPR Value))

(2) Phase Shift Start by Software

Count start with a phase difference is possible by setting the initial value in the GTCNT counter before counting starts and then simultaneously setting the GTSTR.CSTn bits which correspond to the channels to be started simultaneously to 1 (n = 0 to 3).

Figure 26.58 shows an example of phase shift start operation by software.

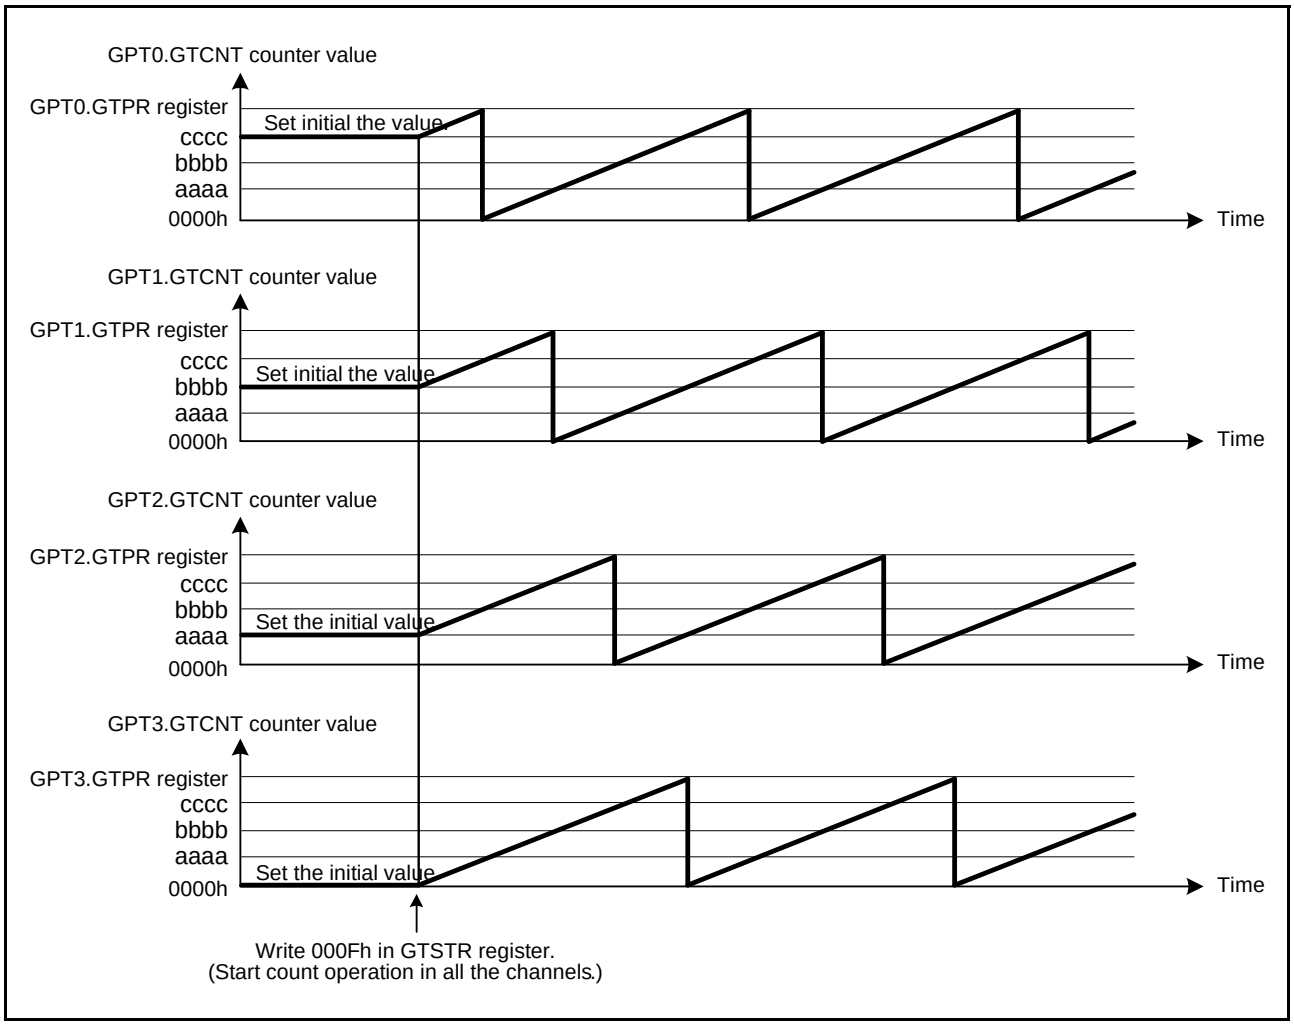

Figure 26.58 Example of Software Phase Shift Start (with Same Count Period (GTPR Register Value))

(3) Simultaneous Start by Hardware Source

The GPTn.GTCNT counters can be started simultaneously by following hardware sources: GTETRG pin input, GTIOC3A/GTIOC3B pin input, and GTIOC3A/GTIOC3B pin internal output (output compare) (n = 0 to 3). Figure 26.59 shows an example of simultaneous start operation by a hardware source and Figure 26.60 shows the setting example. In this example, count operation is started in all the channels by the input of a signal from the GTIOC3A pin.

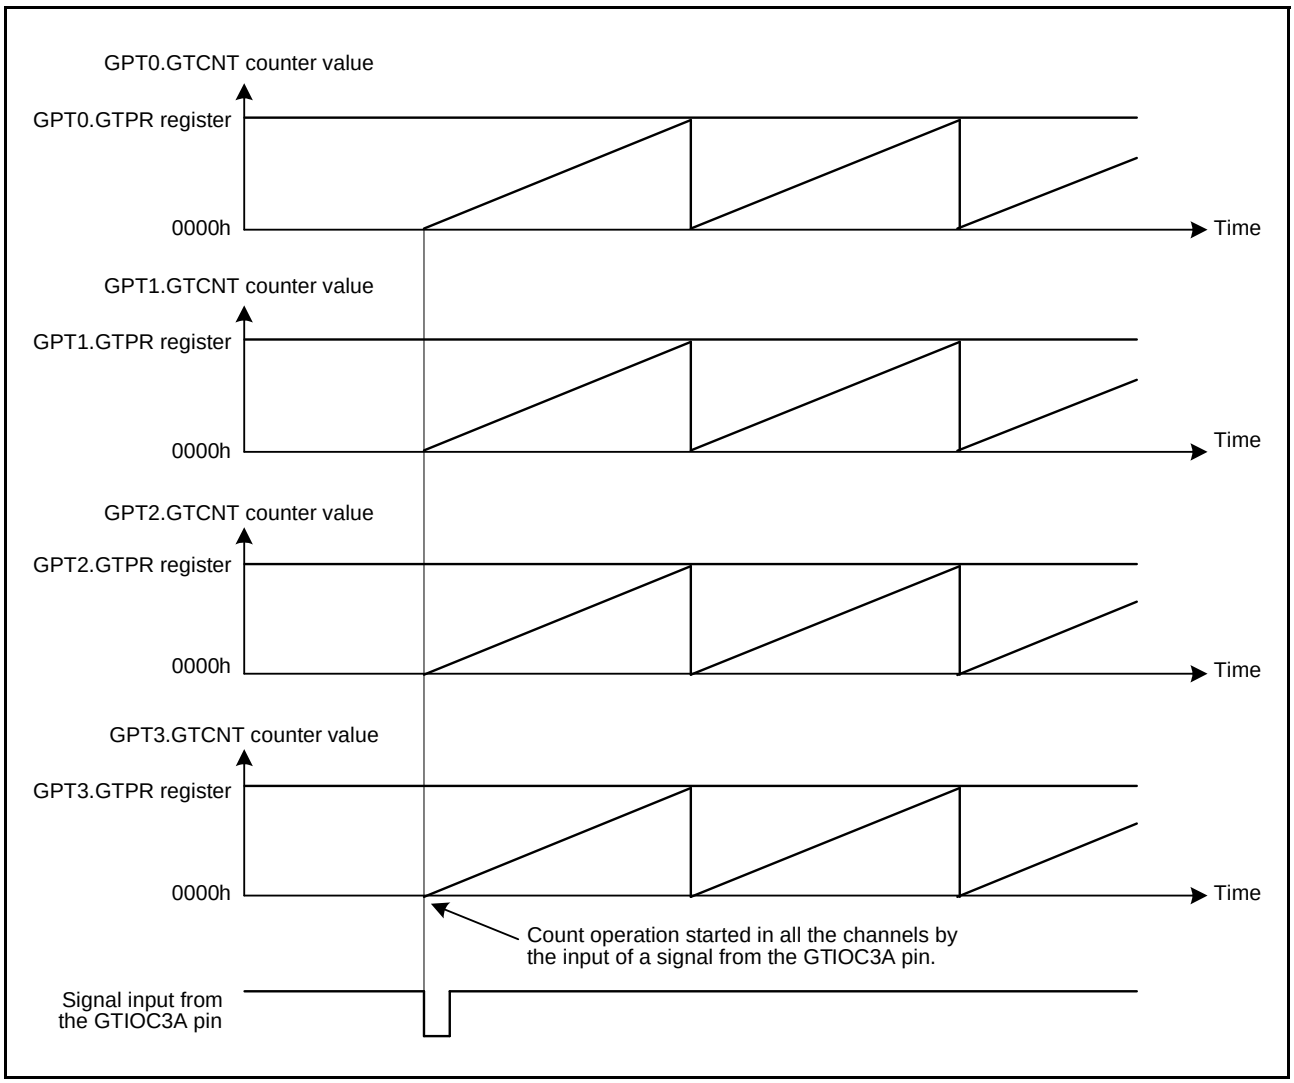

Figure 26.59 Example of Simultaneous Start Operation by Hardware Source (with Same Count Period (GTPR Value))

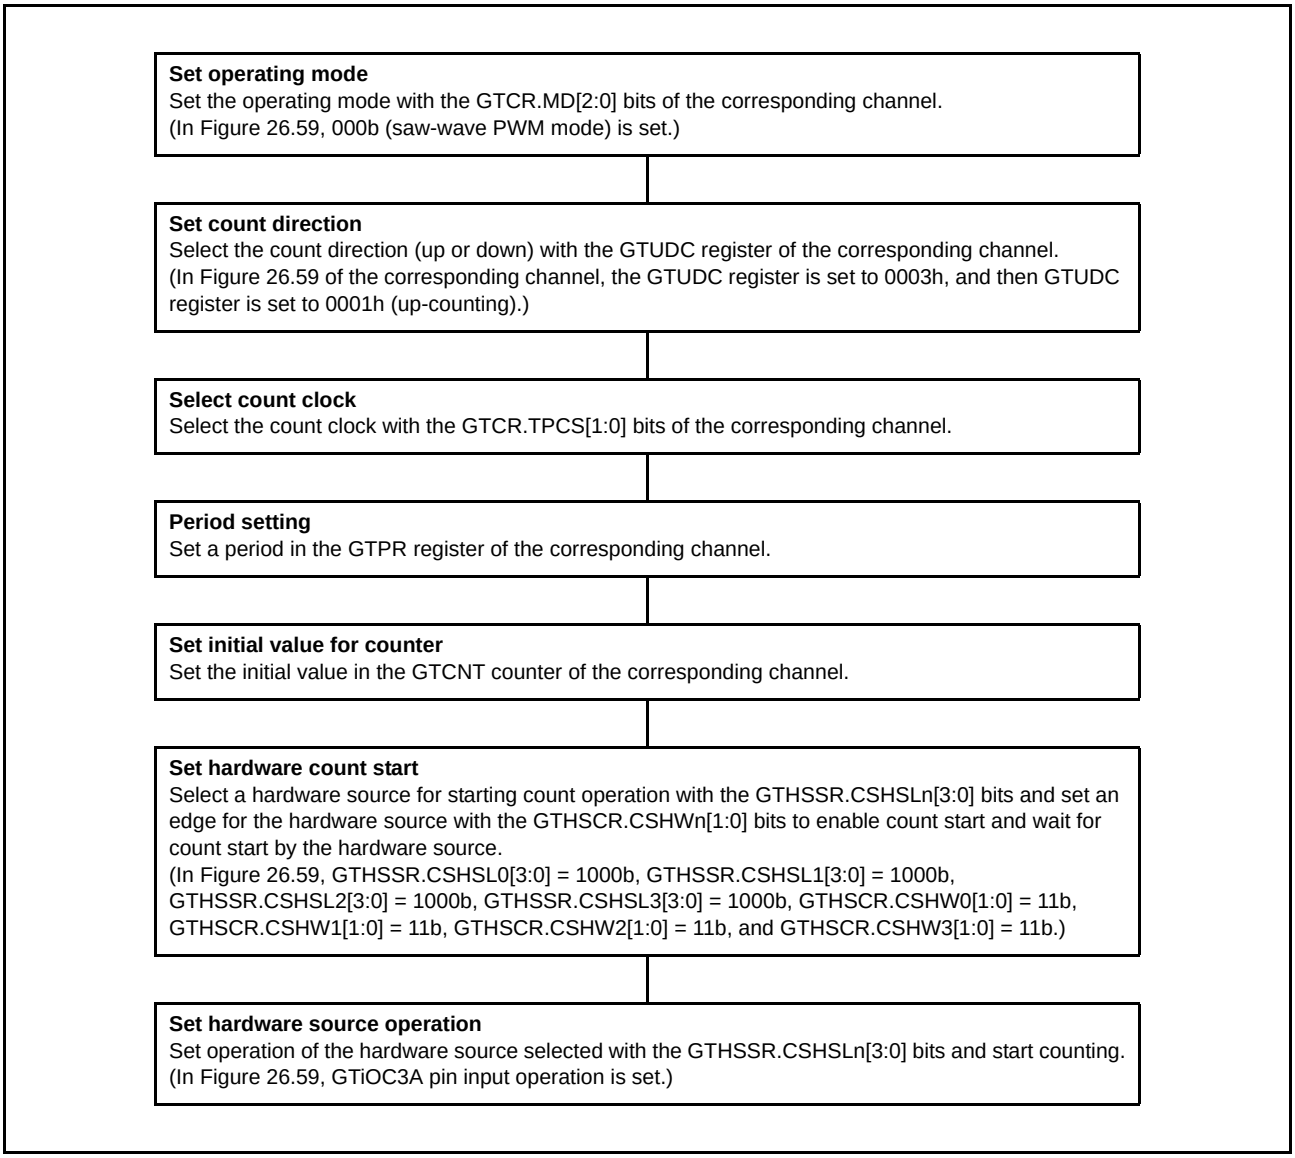

Figure 26.60 Example for Setting Simultaneous Start by Hardware Source

(4) Phase Shifting Start by Hardware Source

Count start with a phase difference is possible by following hardware sources: GTETRG pin input, GTIOC3A/GTIOC3B pin input, and GTIOC3A/GTIOC3B pin internal output (output compare).

Figure 26.61 shows an example of phase shifting start operation by a hardware source and Figure 26.62 shows the setting example. In this example, the GPT3.GTCNT and GPT0.GTCNT counters simultaneously start counting and the GPT1.GTCNT and GPT2.GTCNT counters start counting by the GTIOC3A and GTIOC3B pin internal outputs (output compare).

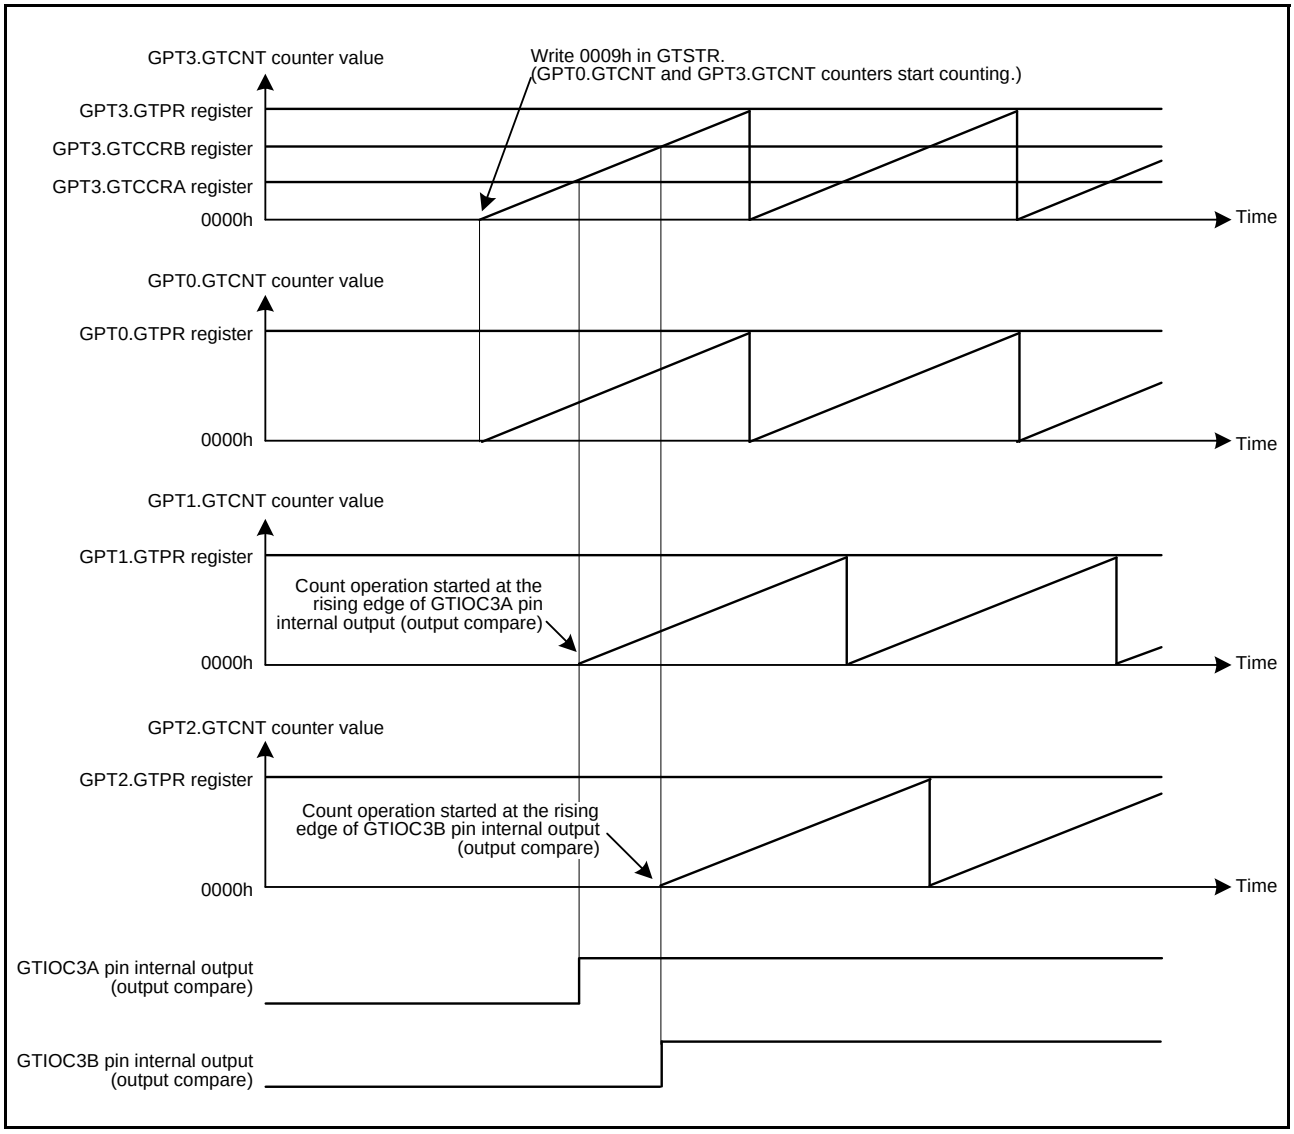

Figure 26.61 Example of Phase Shifting Start Operation by Hardware Source (with Same Count Period (GTPR Value))

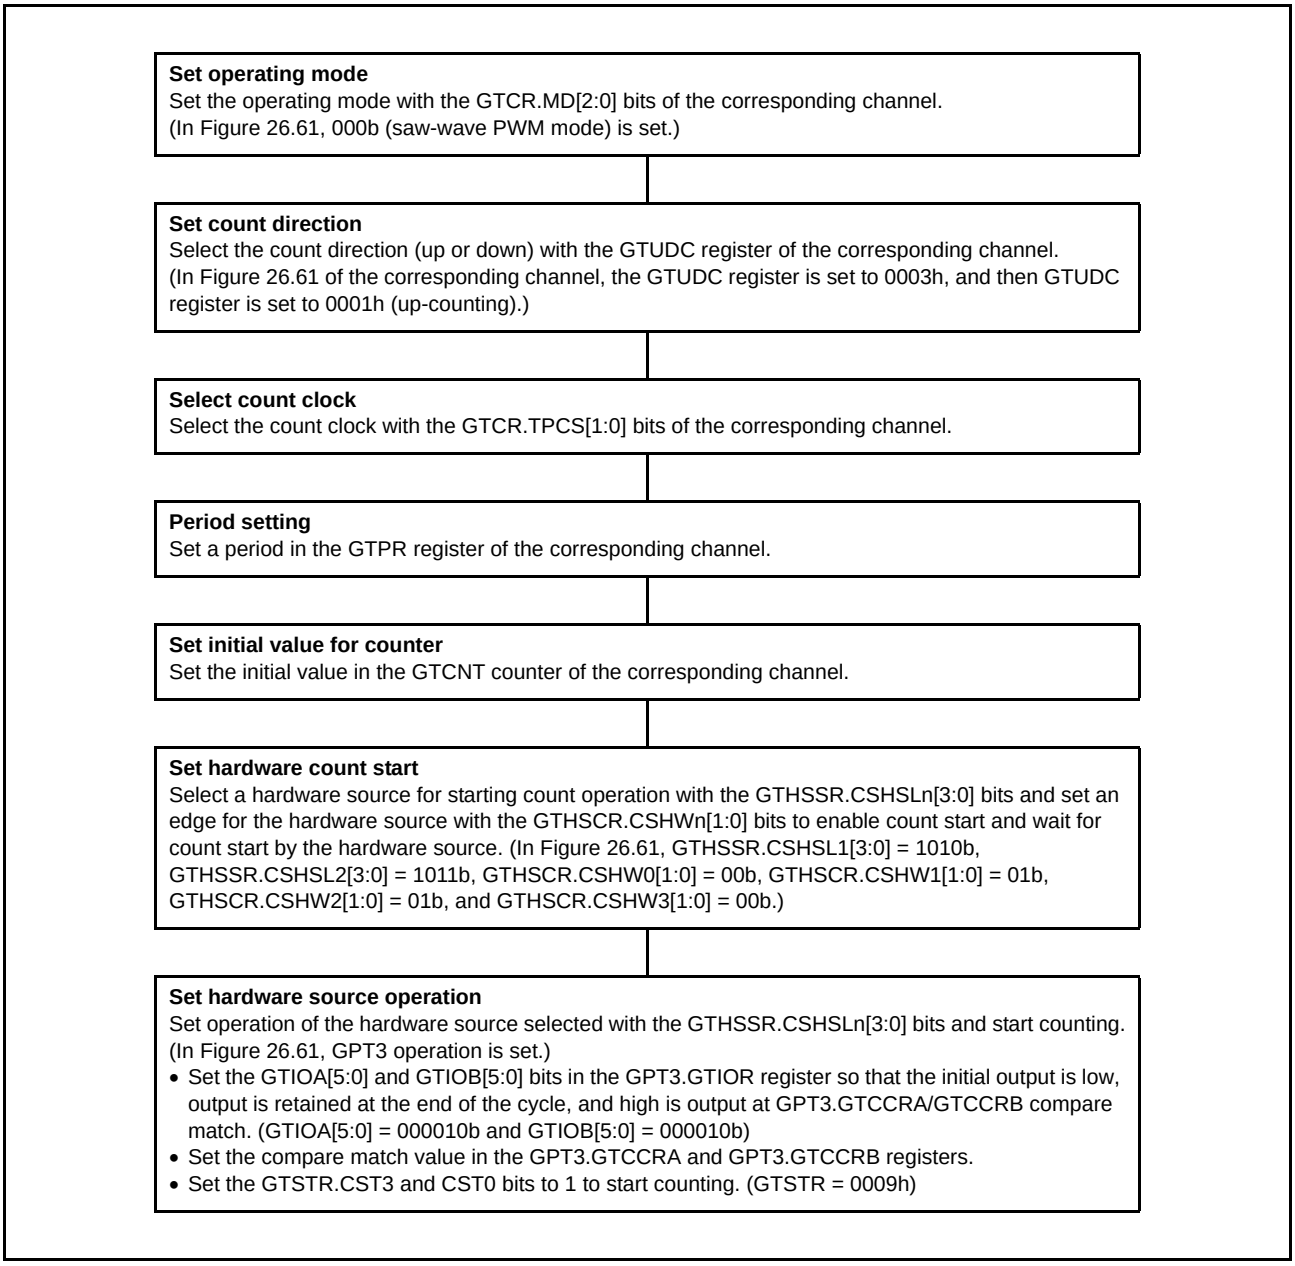

Figure 26.62 Example for Setting Phase Start by Hardware Source

26.3.8 PWM Output Operation Examples

(1) Synchronous PWM Output

The GPT can output eight phases of linked PWM waveforms for a maximum of four channels by synchronizing operation of the channels.

Figure 26.63 shows an example in which all the channels perform synchronous operation in saw-wave PWM mode and eight phases of PWM waveforms are output. The GTIOCnA pin is set so that it will output low as the initial output, high at a GTCCRA compare match, and low at the end of the cycle. The GTIOCnB pin is set so that it will output low as the initial output, high at a GTCCRB compare match, and low at the end of the cycle (n = 0 to 3).

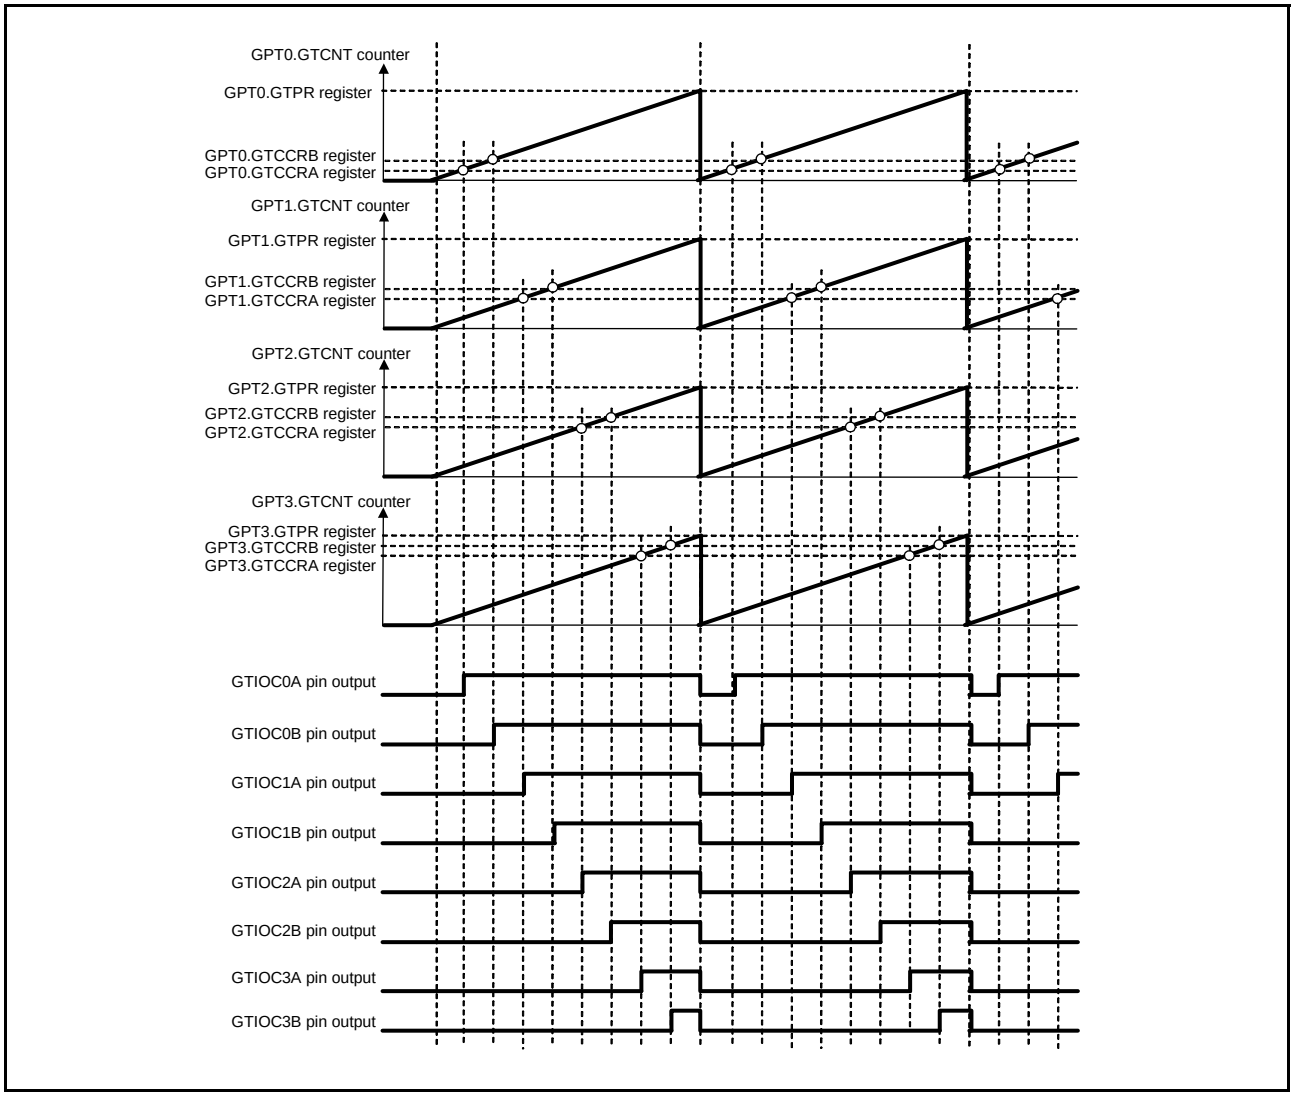

Figure 26.63 Example of Synchronous PWM Output

(2) Three-Phase Saw-Wave Complementary PWM Output

Figure 26.64 shows an example in which three channels perform synchronous operation in saw-wave PWM mode and three-phase complementary PWM waveforms are output. The GTIOCnA pin is set so that it will output low as the initial output, high at a GTCCRA compare match, and low at the end of the cycle. The GTIOCnB pin is set so that it will output high as the initial output, low at a GTCCRB compare match, and high at the end of the cycle.

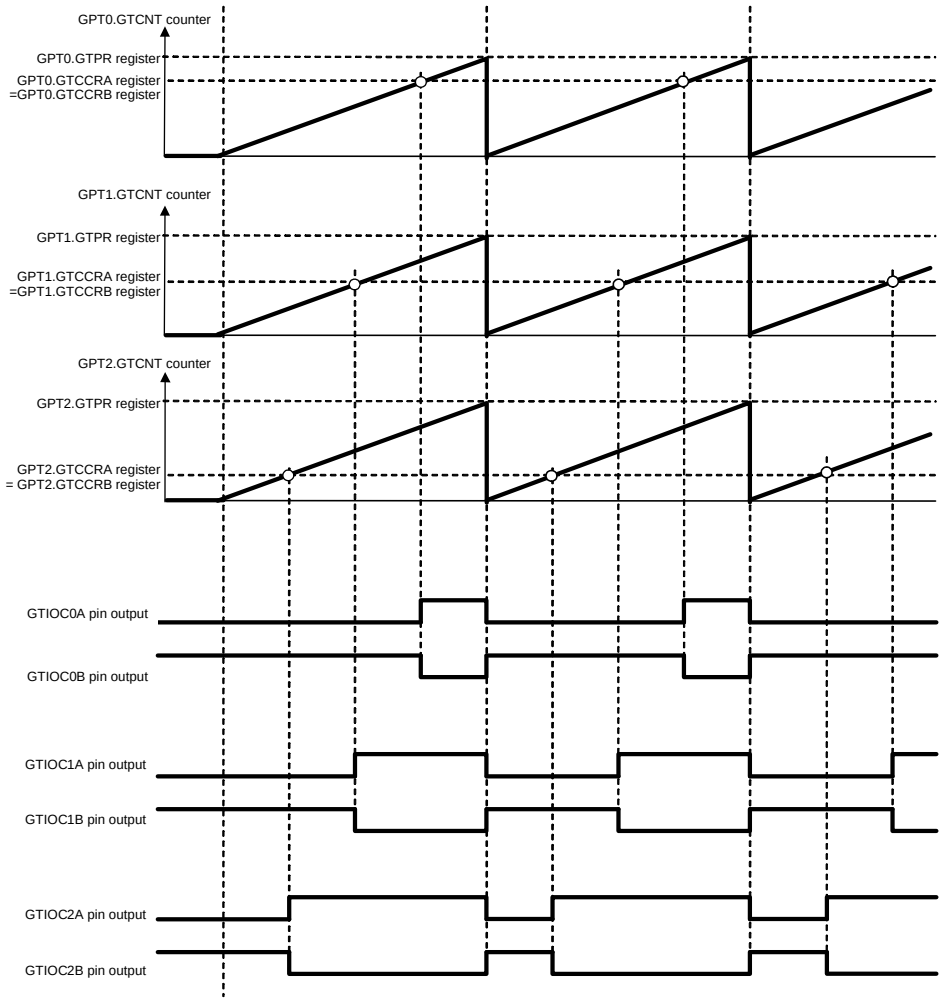

Figure 26.64 Example of Three-Phase Saw-Wave Complementary PWM Output

(3) Three-Phase Saw-Wave Complementary PWM Output with Automatic Dead Time Setting

Figure 26.65 shows an example in which three channels perform synchronous operation in saw-wave one-shot pulse mode with automatic dead time setting and three-phase complementary PWM waveforms are output. The GTIOCnA pin is set so that it will output low as the initial output, toggle the output at a GTCCRA compare match, and retain the output at the end of the cycle. The GTIOCnB pin is set so that it will output high as the initial output, toggle the output at a GTCCRB compare match, and retain the output at the end of the cycle.

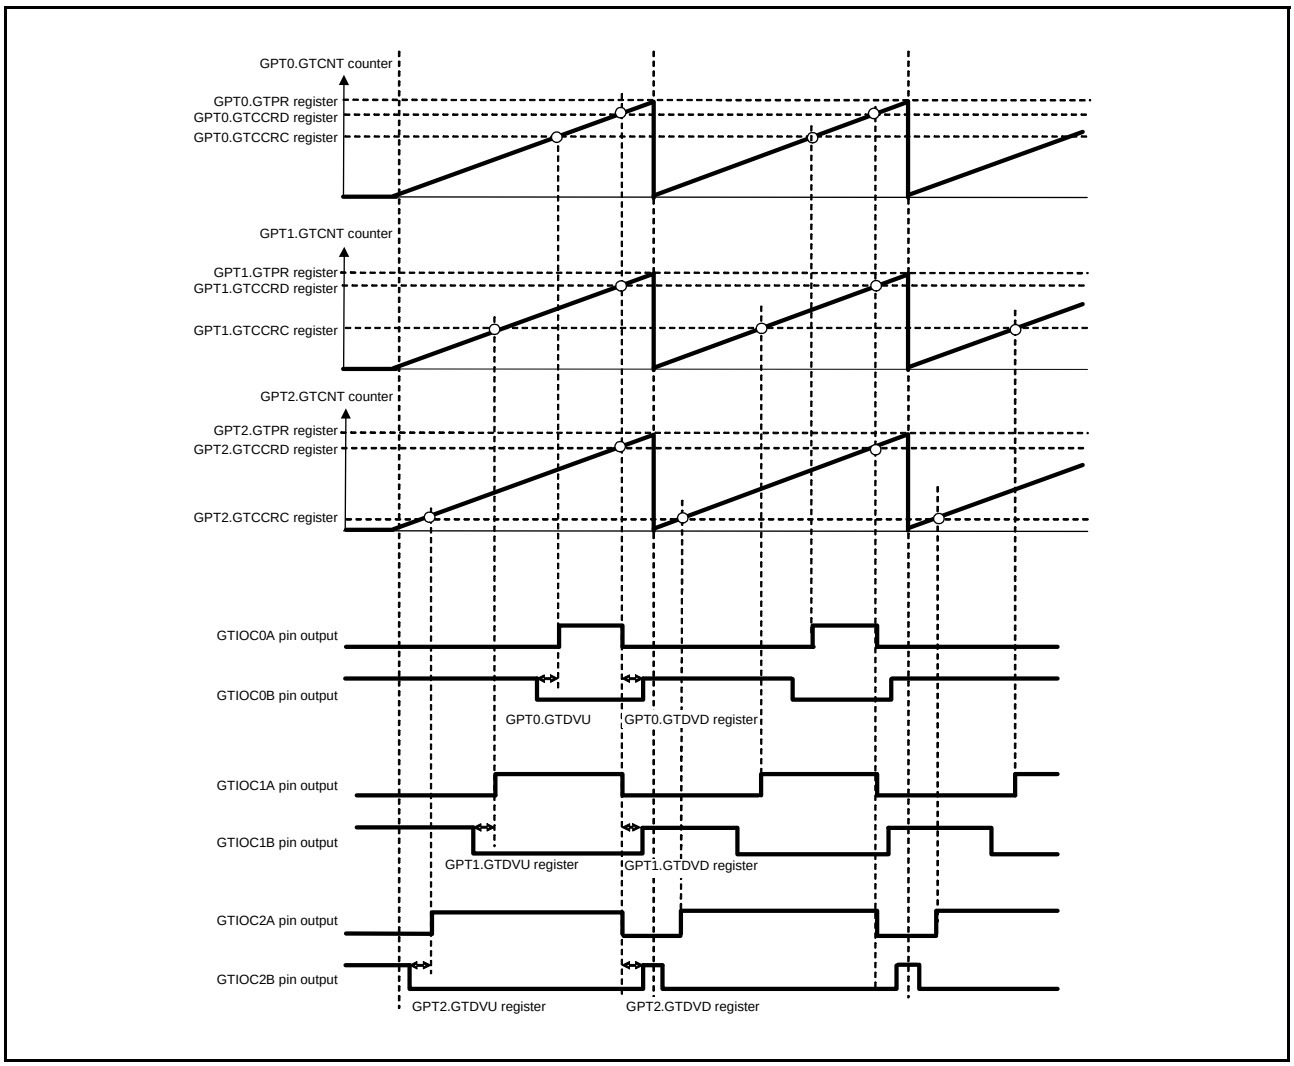

Figure 26.65 Example of Three-Phase Saw-Wave Complementary PWM Output with Automatic Dead Time Setting

(4) Three-Phase Triangle-Wave Complementary PWM Output

Figure 26.66 shows an example in which three channels perform synchronous operation in triangle-wave PWM mode 1 and three-phase complementary PWM waveforms are output. The GTIOCnA pin is set so that it will output low as the initial output, toggle the output at a GTCCRA compare match, and retain the output at the end of the cycle. The GTIOCnB pin is set so that it will output high as the initial output, toggle the output at a GTCCRB compare match, and retain the output at the end of the cycle.

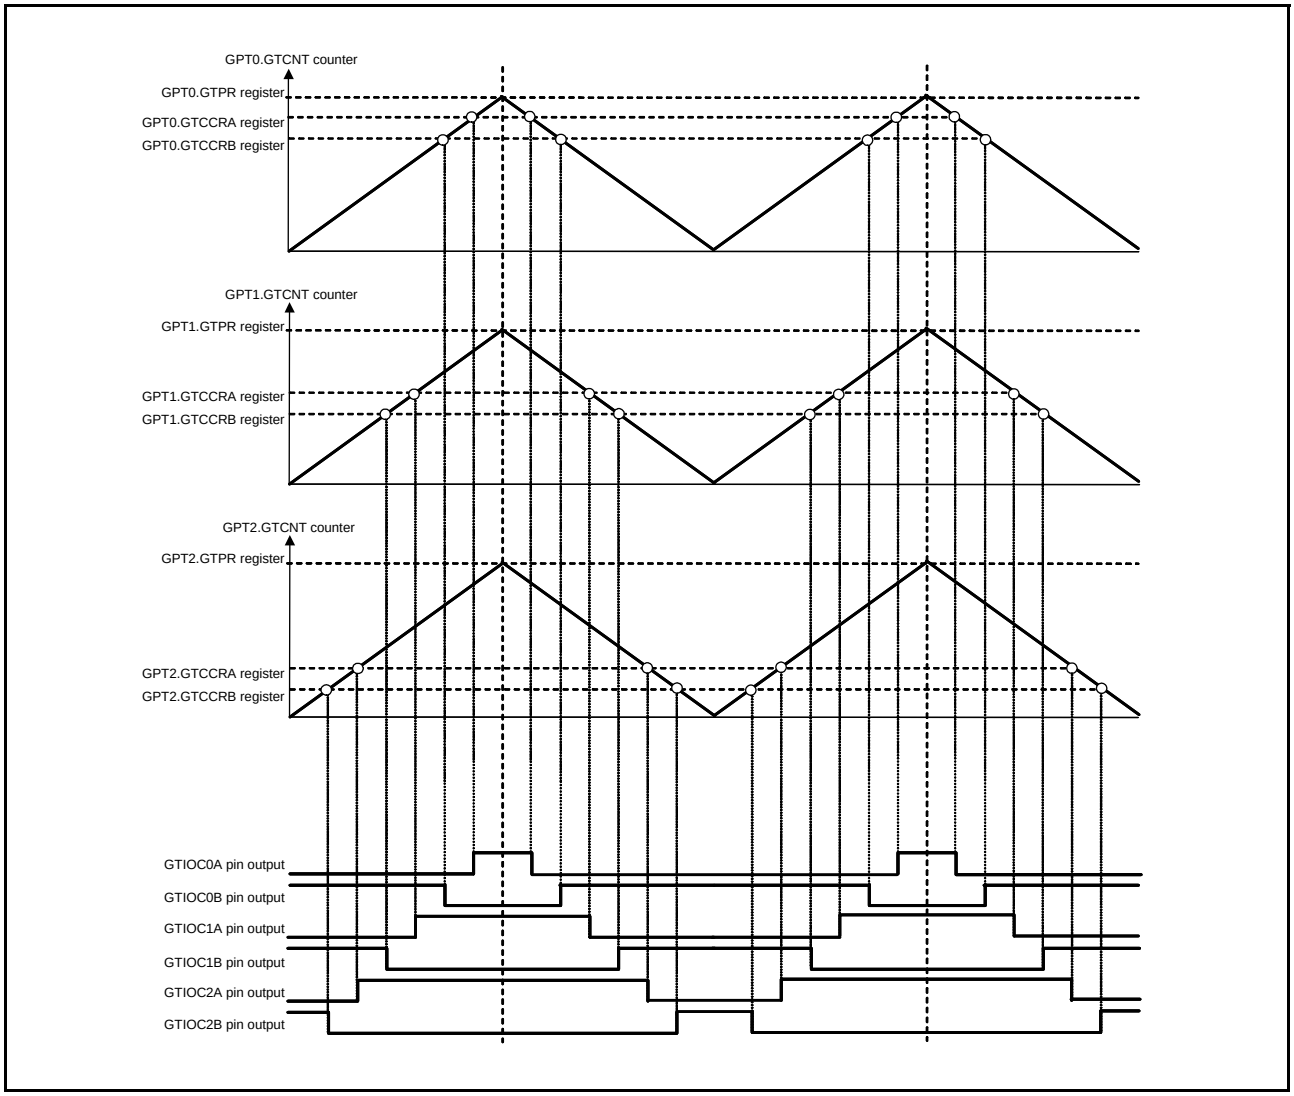

Figure 26.66 Example of Three-Phase Triangle-Wave Complementary PWM Output

(5) Three-Phase Triangle-Wave Complementary PWM Output with Automatic Dead Time Setting

Figure 26.67 shows an example in which three channels perform synchronous operation in triangle-wave PWM mode 1 with automatic dead time setting and three-phase complementary PWM waveforms are output. The GTIOCnA pin is set so that it will output low as the initial output, toggle the output at a GTCCRA compare match, and retain the output at the end of the cycle. The GTIOCnB pin is set so that it will output high as the initial output, toggle the output at a GTCCRB compare match, and retain the output at the end of the cycle.

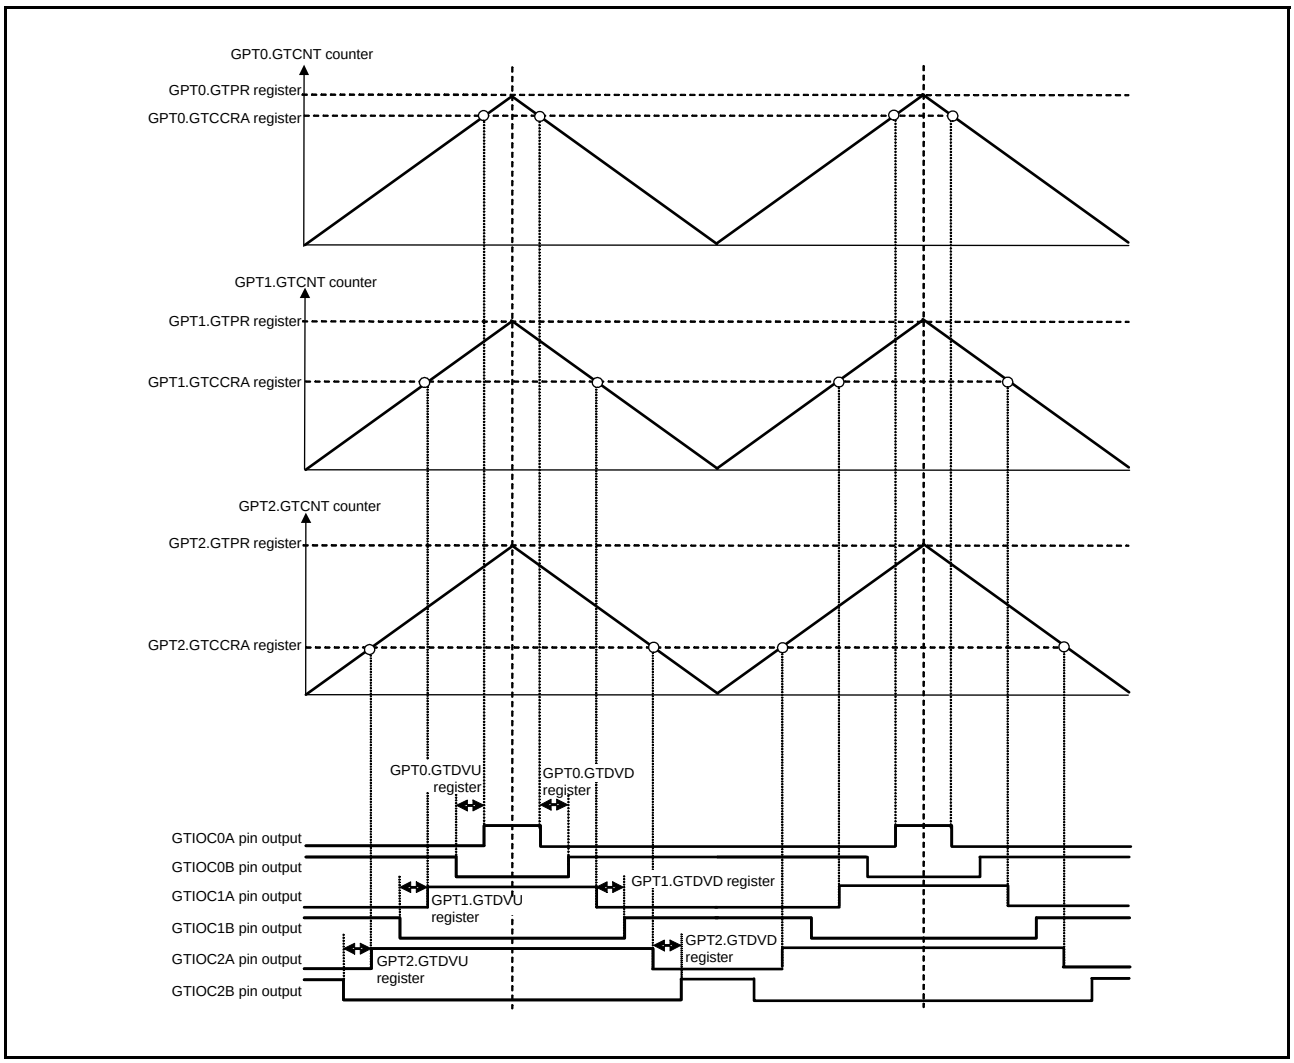

Figure 26.67 Example of Three-Phase Triangle-Wave Complementary PWM Output with Automatic Dead Time Setting

(6) Three-Phase Asymmetric Triangle-Wave Complementary PWM Output with Automatic Dead Time Setting

Figure 26.68 shows an example in which three channels perform synchronous operation in triangle-wave PWM mode 3 with automatic dead time setting and three-phase complementary PWM waveforms are output. The GTIOCnA is set so that it will output low as the initial output, toggle the output at a GTCCRA compare match, and retain the output at the end of the cycle. The GTIOCnB is set so that it will output high as the initial output, toggle the output at a GTCCRB compare match, and retain the output at the end of the cycle.

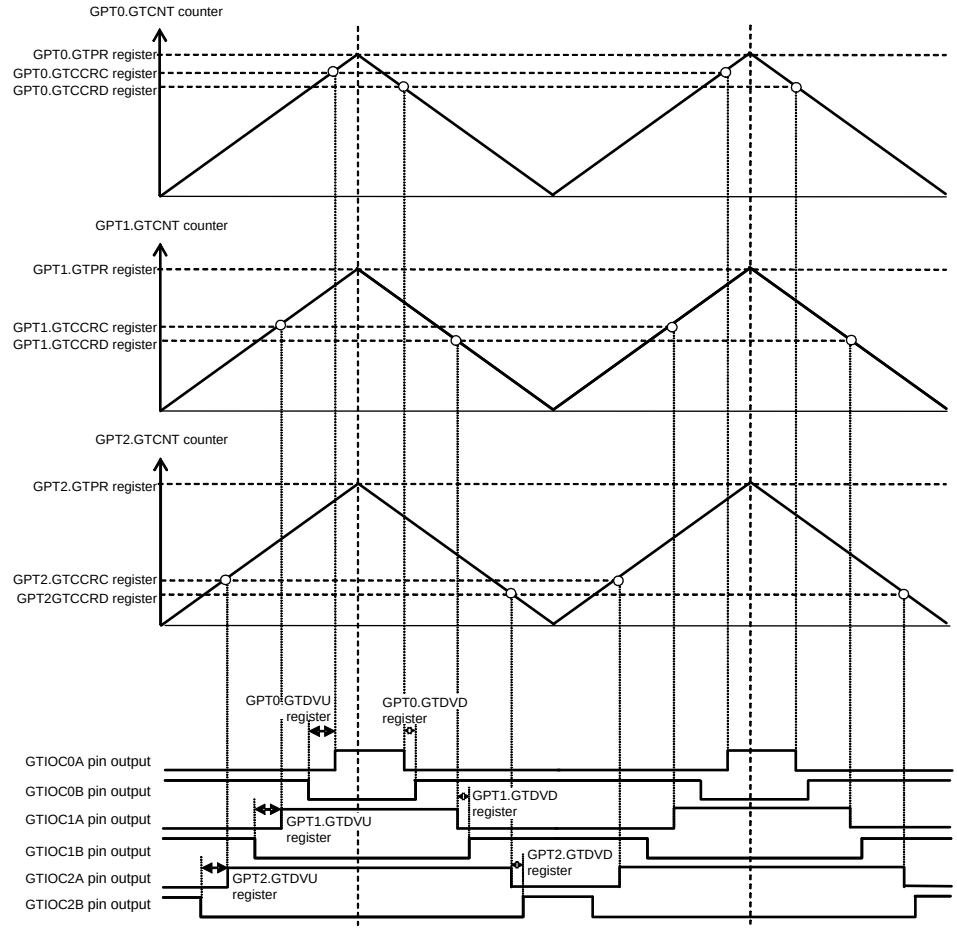

Figure 26.68 Example of Three-Phase Asymmetric Triangle-Wave Complementary PWM Output with Automatic Dead Time Setting

26.3.9 Noise Filter Function

Each pin for use in input capture and external trigger input to the GPT is equipped with a noise filter. The noise filter samples input signals at the sampling clock and removes the pulses of which length is less than three sampling periods. The noise filter functionality includes enabling and disabling of the noise filter for each pin and setting of the sampling clock for each channel. The NFCR register can be used to set the GTIOCnA and GTIOCnB pins. The GTETINT register can be used to set the GTETRG pin.

Figure 26.69 shows the timing of noise filtering.

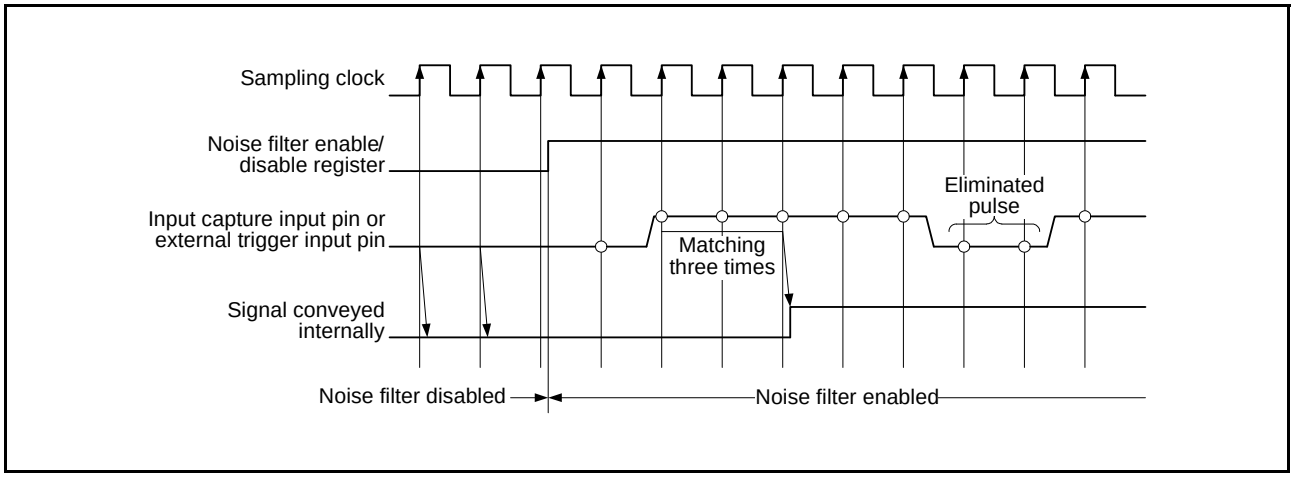

Figure 26.69 Timing of Noise Filtering

If noise filtering is enabled, input capture operation or external trigger operation is performed on the edges of noise-filtered signal after a delay of (minimum sampling interval × 2 + PCLKA) due to noise filtering for the input capture input or external trigger operation.

26.4 Interrupt Sources

26.4.1 Interrupt Sources and Priorities

Table 26.5 lists the interrupt sources.

Each interrupt source has a control bit for the respective dedicated interrupt request generation and enables or disables the generation of interrupt request independently.

The priority of channels can be changed by the interrupt controller settings. For details, see section 15, Interrupt Controller (ICUA).

Table 26.5 GPT Interrupt Sources

Channel	Name	Interrupt Source	DMAC/DTC Activation
Common	ETGIN	External trigger falling input	Possible
	ETGIP	External trigger rising input	Possible
GPT0	GTCIA0	GPT0.GTCCRA input capture/compare match	Possible
	GTCIB0	GPT0.GTCCRB input capture/compare match	Possible
	GTCIC0	GPT0.GTCCRC compare match	Possible
	GTCID0	GPT0.GTCCRD compare match	Possible
	GDTE0	Dead time error	Possible
	GTCIE0	GPT0.GTCCRE compare match	Possible
	GTCIF0	GPT0.GTCCRF compare match	Possible
	GTCIV0	GPT0.GTCNT overflow (GPT0.GTPR compare match)	Possible
	GTCIU0	GPT0.GTCNT underflow	Possible
GPT1	GTCIA1	GPT1.GTCCRA input capture/compare match	Possible
	GTCIB1	GPT1.GTCCRB input capture/compare match	Possible
	GTCIC1	GPT1.GTCCRC compare match	Possible
	GTCID1	GPT1.GTCCRD compare match	Possible
	GDTE1	Dead time error	Possible
	GTCIE1	GPT1.GTCCRE compare match	Possible
	GTCIF1	GPT1.GTCCRF compare match	Possible
	GTCIV1	GPT1.GTCNT overflow (GPT1.GTPR compare match)	Possible
	GTCIU1	GPT1.GTCNT underflow	Possible
GPT2	GTCIA2	GPT2.GTCCRA input capture/compare match	Possible
	GTCIB2	GPT2.GTCCRB input capture/compare match	Possible
	GTCIC2	GPT2.GTCCRC compare match	Possible
	GTCID2	GPT2.GTCCRD compare match	Possible
	GDTE2	Dead time error	Possible
	GTCIE2	GPT2.GTCCRE compare match	Possible
	GTCIF2	GPT2.GTCCRF compare match	Possible
	GTCIV2	GPT2.GTCNT overflow (GPT2.GTPR compare match)	Possible
	GTCIU2	GPT2.GTCNT underflow	Possible
GPT3	GTCIA3	GPT3.GTCCRA input capture/compare match	Possible
	GTCIB3	GPT3.GTCCRB input capture/compare match	Possible
	GTCIC3	GPT3.GTCCRC compare match	Possible
	GTCID3	GPT3.GTCCRD compare match	Possible
	GDTE3	Dead time error	Possible
	GTCIE3	GPT3.GTCCRE compare match	Possible
	GTCIF3	GPT3.GTCCRF compare match	Possible
	GTCIV3	GPT3.GTCNT overflow (GPT3.GTPR compare match)	Possible
	GTCIU3	GPT3.GTCNT underflow	Possible

(1) GTCIAn interrupt (n = 0 to 3)

When the GTINTAD.GTINTA bit is 1, an interrupt request is generated under the following conditions.

- When the GTCCRA register functions as a compare match register, the GTCNT counter value matches with the GTCCRA register.
- When the GTCCRA register functions as an input capture register, the input-capture signal has caused transfer of the GTCNT counter value to the GTCCRA register.

(2) GTCIBn interrupt (n = 0 to 3)

When the GTINTAD.GTINTB bit is 1, an interrupt request is generated under the following conditions.

- When the GTCCRB register functions as a compare match register, the GTCNT counter value matches with the GTCCRB register.
- When the GTCCRB register functions as an input capture register, the input-capture signal has caused transfer of the GTCNT counter value to the GTCCRB register.

(3) GTCICn interrupt (n = 0 to 3)

When the GTINTAD.GTINTC bit is 1, an interrupt request is generated under the following condition.

- When the GTCCRC register functions as a compare match register, the GTCNT counter value matches with the GTCCRC register.

A compare match is not performed and thus interrupt is not requested under the following conditions.

- GTCR.MD[2:0] = 001b (saw-wave one-shot pulse mode)
- GTCR.MD[2:0] = 110b (triangle-wave PWM mode 3)
- GTBER.CCRA[1:0] = 01b, 10b, 11b (buffer operation with the GTCCRC register)

(4) GTCIDn interrupt (n = 0 to 3)

When the GTINTAD.GTINTD bit is 1, an interrupt request is generated under the following condition.

- When the GTCCRD register functions as a compare match register, the GTCNT counter value matches with the GTCCRD register.

A compare match is not performed and thus interrupt is not requested under the following conditions.

- GTCR.MD[2:0] = 001b (saw-wave one-shot pulse mode)
- GTCR.MD[2:0] = 110b (triangle-wave PWM mode 3)
- GTBER.CCRA[1:0] = 10b, 11b (buffer operation with the GTCCRD register)

(5) GTCIEn interrupt (n = 0 to 3)

When the GTINTAD.GTINTE bit is 1, an interrupt request is generated under the following condition.

- When the GTCCRE register functions as a compare match register, the GTCNT counter value matches with the GTCCRE register.

A compare match is not performed and thus interrupt is not requested under the following conditions.

- GTCR.MD[2:0] = 001b (saw-wave one-shot pulse mode)
- GTCR.MD[2:0] = 110b (triangle-wave PWM mode 3)
- GTBER.CCRB[1:0] = 01b, 10b, 11b (buffer operation with the GTCCRE register)

(6) GTCIFn interrupt (n = 0 to 3)

When the GTINTAD.GTINTF bit is 1, an interrupt request is generated under the following condition.

- When the GTCCRF register functions as a compare match register, the GTCNT counter value matches with the GTCCRF register.

A compare match is not performed and thus interrupt is not requested under the following conditions.

- GTCR.MD[2:0] = 001b (saw-wave one-shot pulse mode)
- GTCR.MD[2:0] = 110b (triangle-wave PWM mode 3)
- GTBER.CCRB[1:0] = 10b, 11b (buffer operation with the GTCCRF register)

(7) GTCIVn interrupt (n = 0 to 3)

When the GTINTAD.GTINTPR[0] bit is 1, an interrupt request is generated under the following conditions.

- In saw-wave mode, interrupt requests are enabled at overflows (GTCNT counter value changes from GTPR register value to 0000h during up-counting).
- In triangle-wave mode, interrupt requests are enabled at crests (GTCNT counter value changes from GTPR register value to GTPR register value minus 1).

(8) GTCIUn interrupt (n = 0 to 3)

When the GTINTAD.GTINTPR[1] bit is 1, an interrupt request is generated under the following conditions.

- In saw-wave mode, interrupt requests are enabled at underflows (GTCNT counter value changes from 0000h to GTPR register value during down-counting).
- In triangle-wave mode, interrupt requests are enabled at troughs (GTCNT counter value changes from 0000h to 0001h).

(9) ETGIP interrupt

When the GTETINT.ETIPEN bit is 1, an interrupt request is generated under the following condition.

- When the rising edge of an external trigger input is detected

(10) ETGIN interrupt

When the GTETINT.ETINEN bit is 1, an interrupt request is generated under the following condition.

- When the falling edge of an external trigger input is detected

(11) GDTEn interrupt (n = 0 to 3)

When automatic dead time setting has been made, the GTST.DTEF flag becomes 1 when the timer output toggle point with dead time added exceeds the count period. If GTINTAD.EINT is 1 at this time, a dead time error interrupt request (GDTE) is generated.
In addition, when the timer output toggle point with dead time added is back within the count period, the GTST.DTEF flag changes from 1 to 0.

26.4.2 DMAC/DTC Activation

The DMAC and DTC can be triggered by the interrupt request in each channel. For details, see section 15, Interrupt Controller (ICUA), section 18, DMA Controller (DMACAa), and section 20, Data Transfer Controller (DTCa).

26.4.3 Interrupt and A/D Conversion Request Skipping Function

By setting the GTITC register, the GTCNT counter overflow (GTPR compare match) interrupt (GTCIV) and underflow interrupt (GTCIU) can be skipped. Other interrupts and A/D converter start request signals can be skipped in coordination with the GTCIV/GTCIU skipping function. However, the dead time error interrupts cannot be linked with the GTCIV/GTCIU skipping function.

When both troughs and crests are counted and skipped in triangle-wave mode, if the number of times of skipping is odd, GTCIV/GTCIU interrupt requests cannot be generated at troughs only or at crests only depending on the skipping counter start timing. Therefore, in order to count both troughs and crests and generate the GTCIV/GTCIU interrupts at troughs only or crests only in triangle-wave mode, the number of times of skipping should be even.

Similarly, in saw-wave mode, when both overflows and underflows are counted and skipped with the count direction changed, GTCIV/GTCIU interrupt requests cannot be generated at overflows only or at underflows only. Therefore, in order to count both overflows and underflows with the count direction changed and generate the GTCIV/GTCIU interrupts at overflows only or underflows only in saw wave mode, the skipping state should be carefully checked before using.

When changing the skipping count, be sure to release the skipping count setting (GTITC.IVTC[1:0] bits = 00b).

Figure 26.70 to Figure 26.75 show examples of skipping function operation.

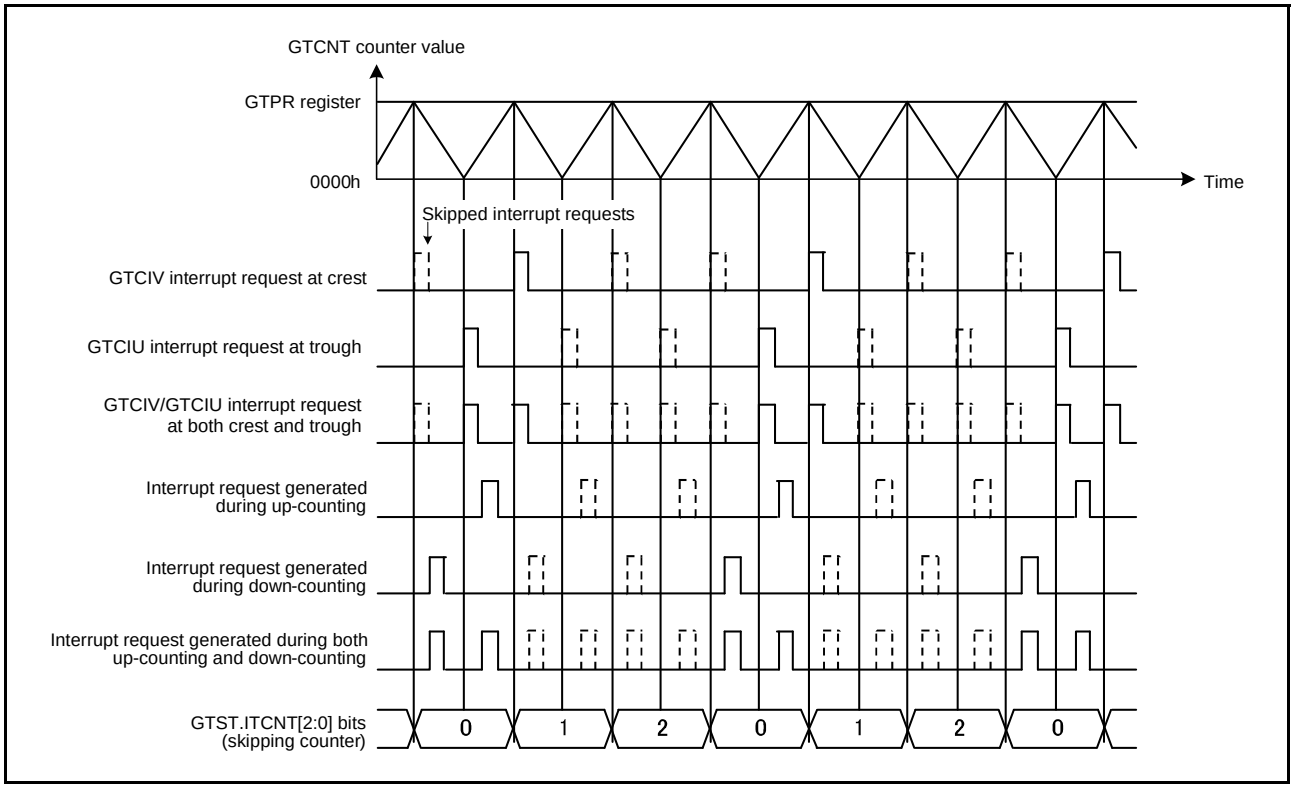

Figure 26.70 Example of Interrupt Skipping Function Operation (Triangle Waves, Counting and Skipping Crests, Skipping Count: 2)

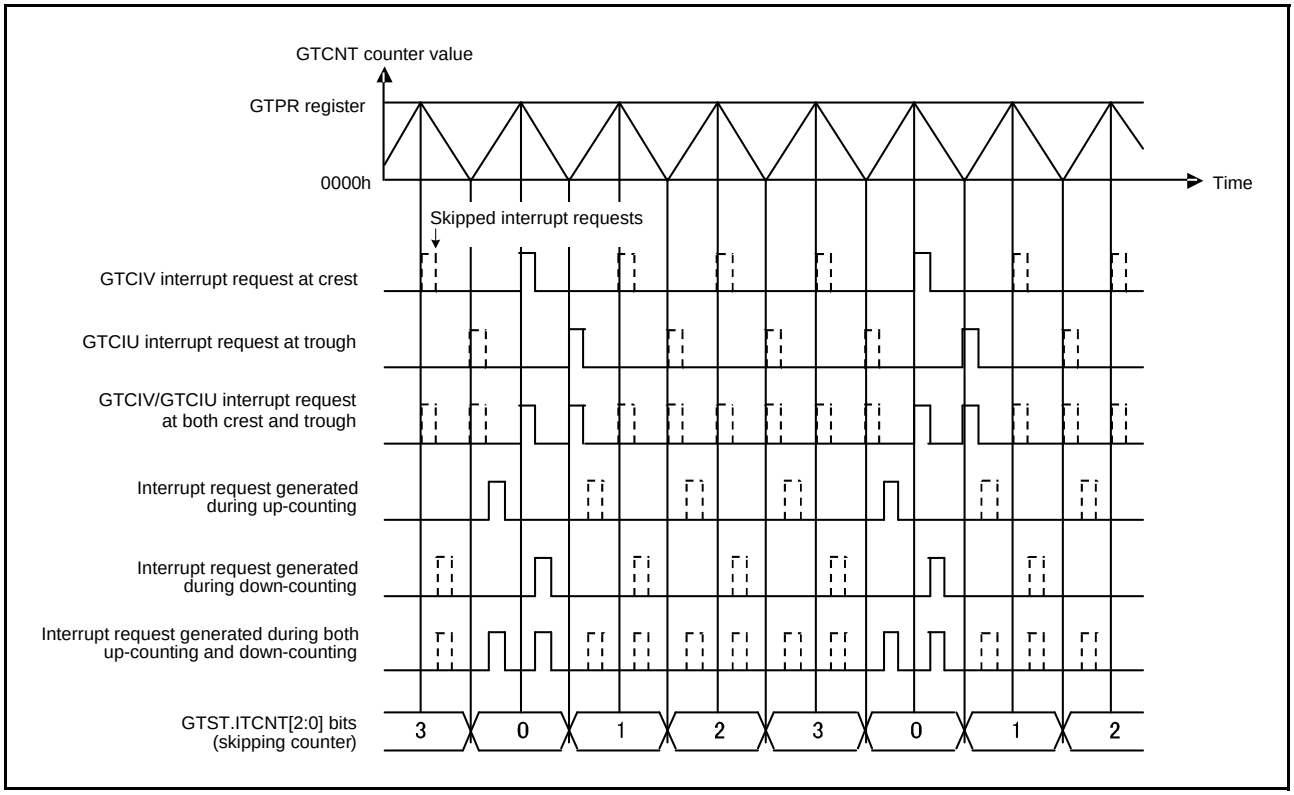

Figure 26.71 Example of Interrupt Skipping Function Operation (Triangle Waves, Counting and Skipping Troughs, Skipping Count: 3)

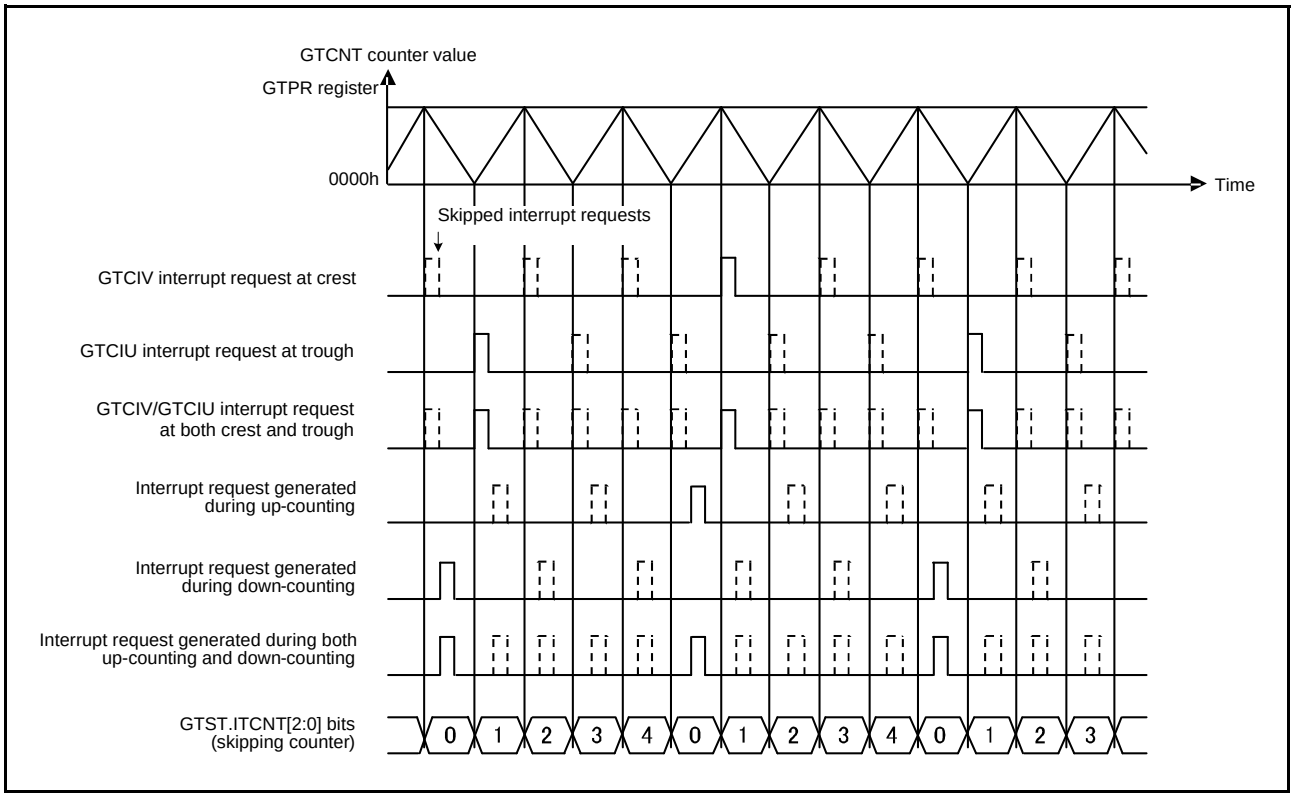

Figure 26.72 Example of Interrupt Skipping Function Operation (Triangle Waves, Counting and Skipping Both Troughs and Crests, Skipping Count: 4)

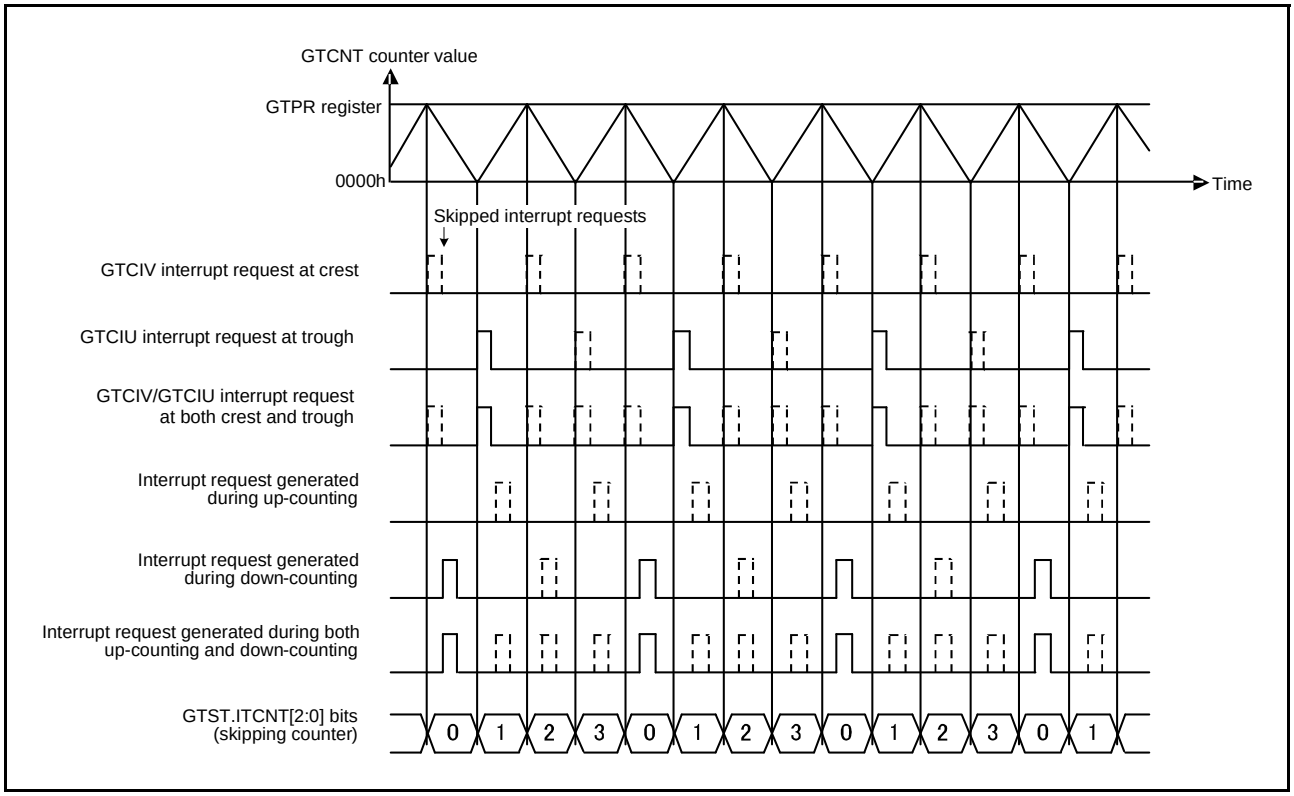

Figure 26.73 Example of Interrupt Skipping Function Operation (Triangle Waves, Counting and Skipping Both Troughs and Crests, Skipping Count: 3, Skipping Started at Up-Counting)

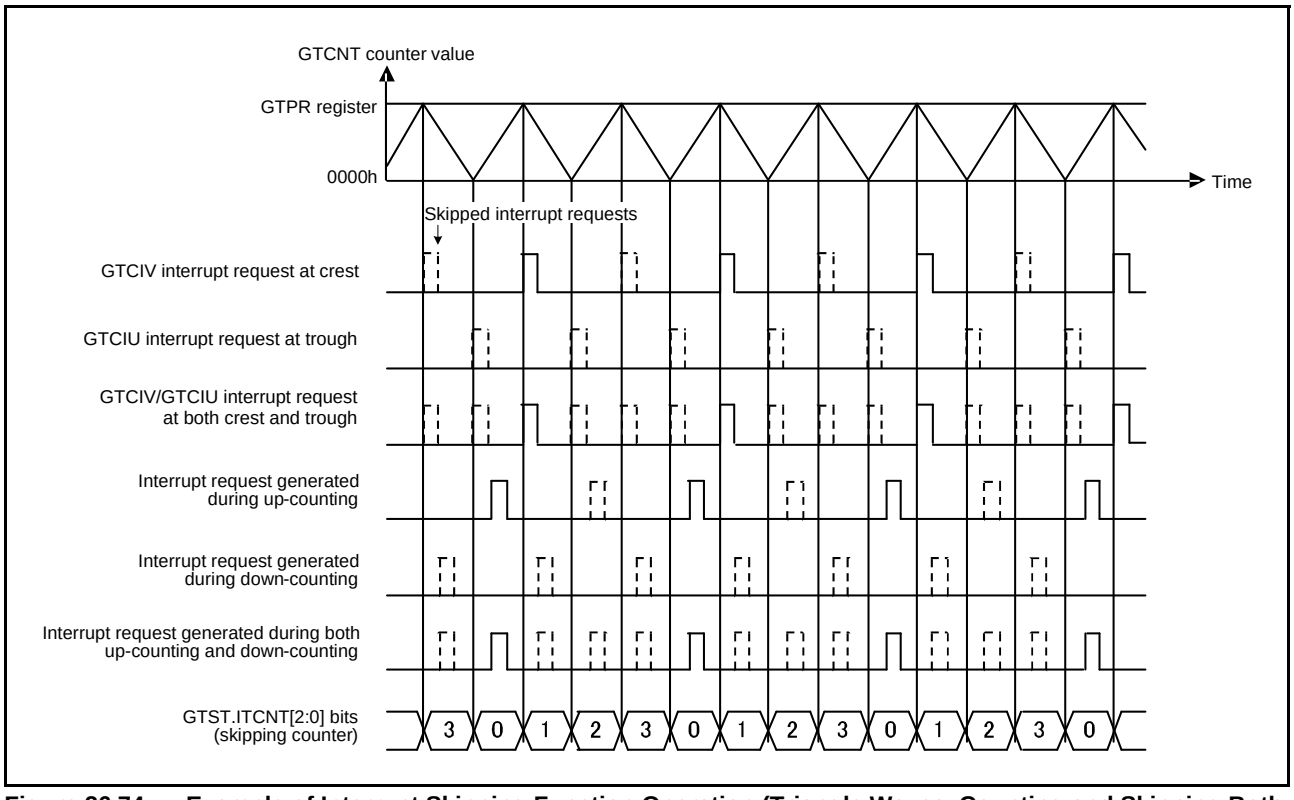

Figure 26.74 Example of Interrupt Skipping Function Operation (Triangle Waves, Counting and Skipping Both Troughs and Crests, Skipping Count: 3, Skipping Started at Down-Counting)

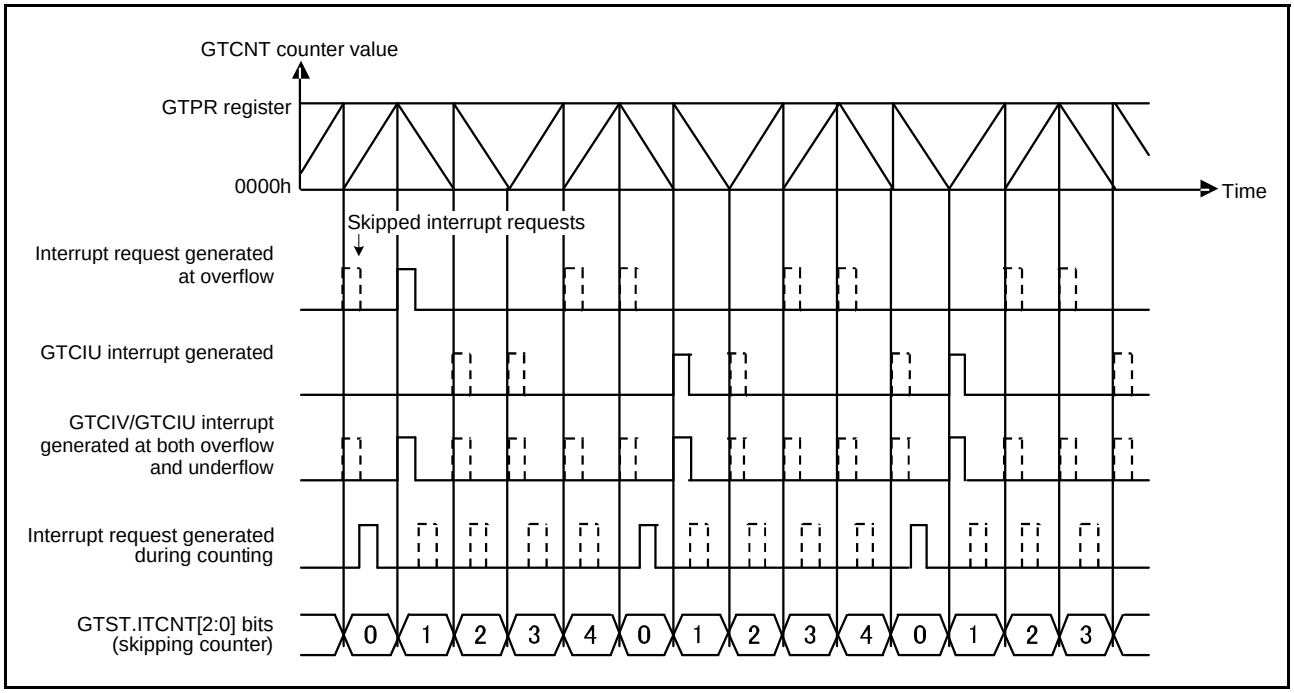

Figure 26.75 Example of Interrupt Skipping Function Operation (Saw Waves, Operation with Count Direction Changed, Counting and Skipping Both Overflows and Underflows, Skipping Count: 4)

26.5 A/D Converter Start Request

An A/D converter start request can be issued at a compare match between the GTCNT counter and the GTADTRA or GTADTRB register, up-counting only, down-counting only, or both up-counting and down-counting can be specified by setting the GTINTAD register.

The GTADTRA and GTADTRB registers each has two buffer registers. Buffer operation with the GTADTRA register used together with the GTADTBRA and GTADTDBRA registers, and buffer operation with the GTADTRB register used together with the GTADTBRB and GTADTDBRB registers can be performed.

Figure 26.76 shows an example of A/D converter start request operation, and Figure 26.77 shows an example for setting A/D converter start request operation.

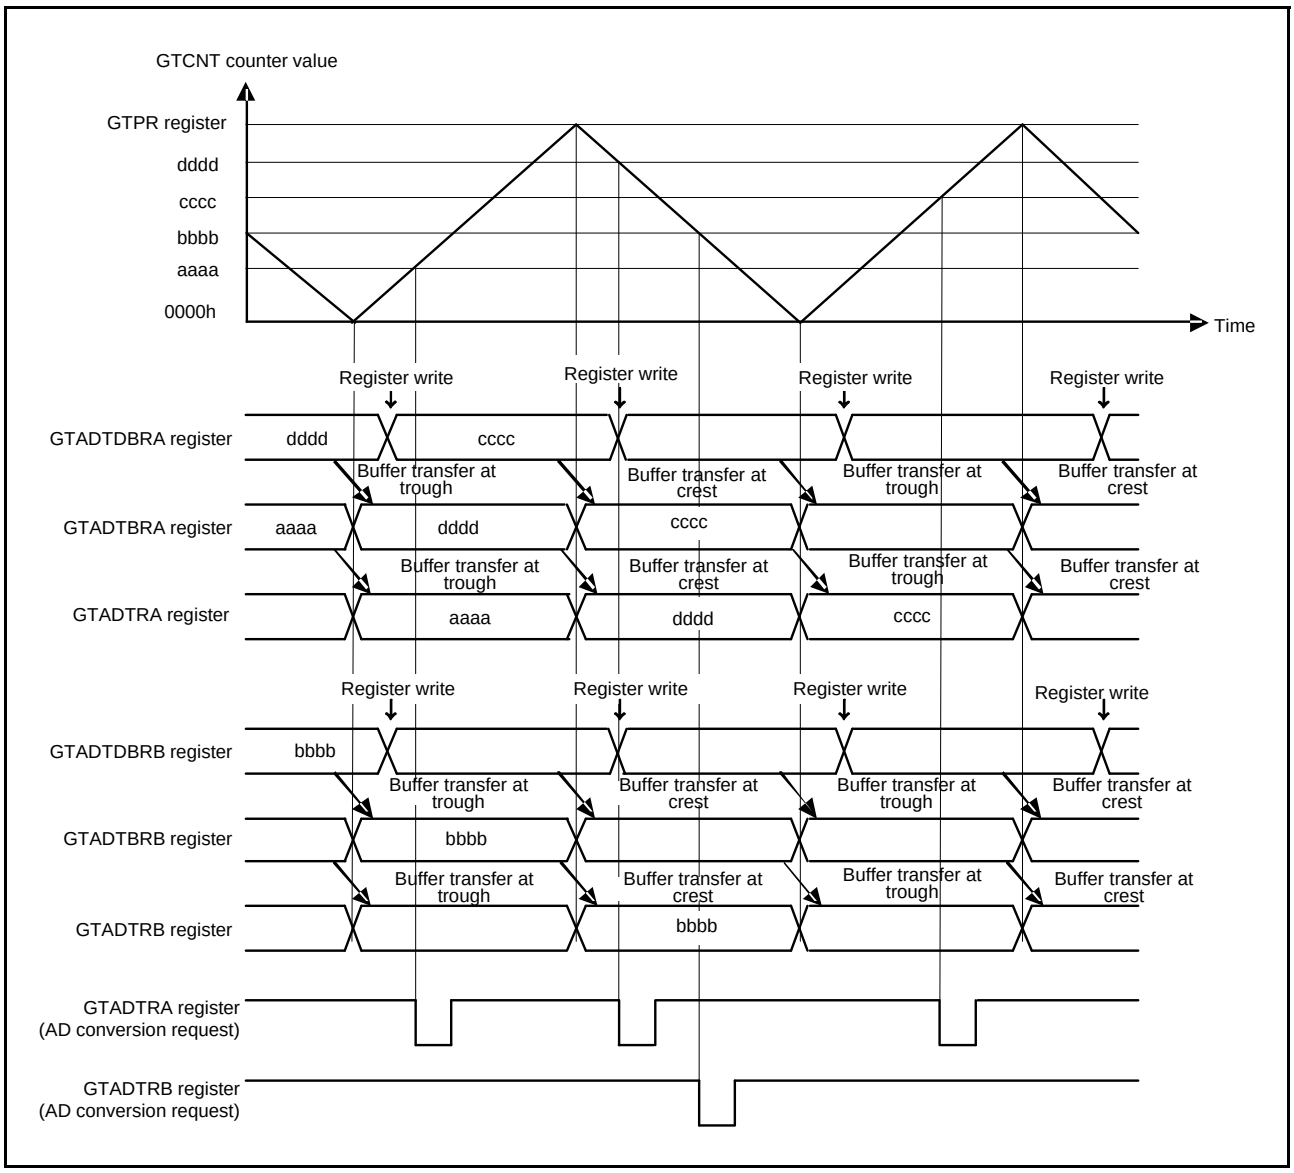

Figure 26.76 Example of A/D Converter Start Request Timing Operation (Triangle Waves, Double Buffer Operation, Buffer Transfer at Both Troughs and Crests, A/D Converter Start Requested by GTADTRA0 at Both Up-Counting and Down-Counting, A/D Converter Start Requested by GTADTRB0 at Down-Counting)

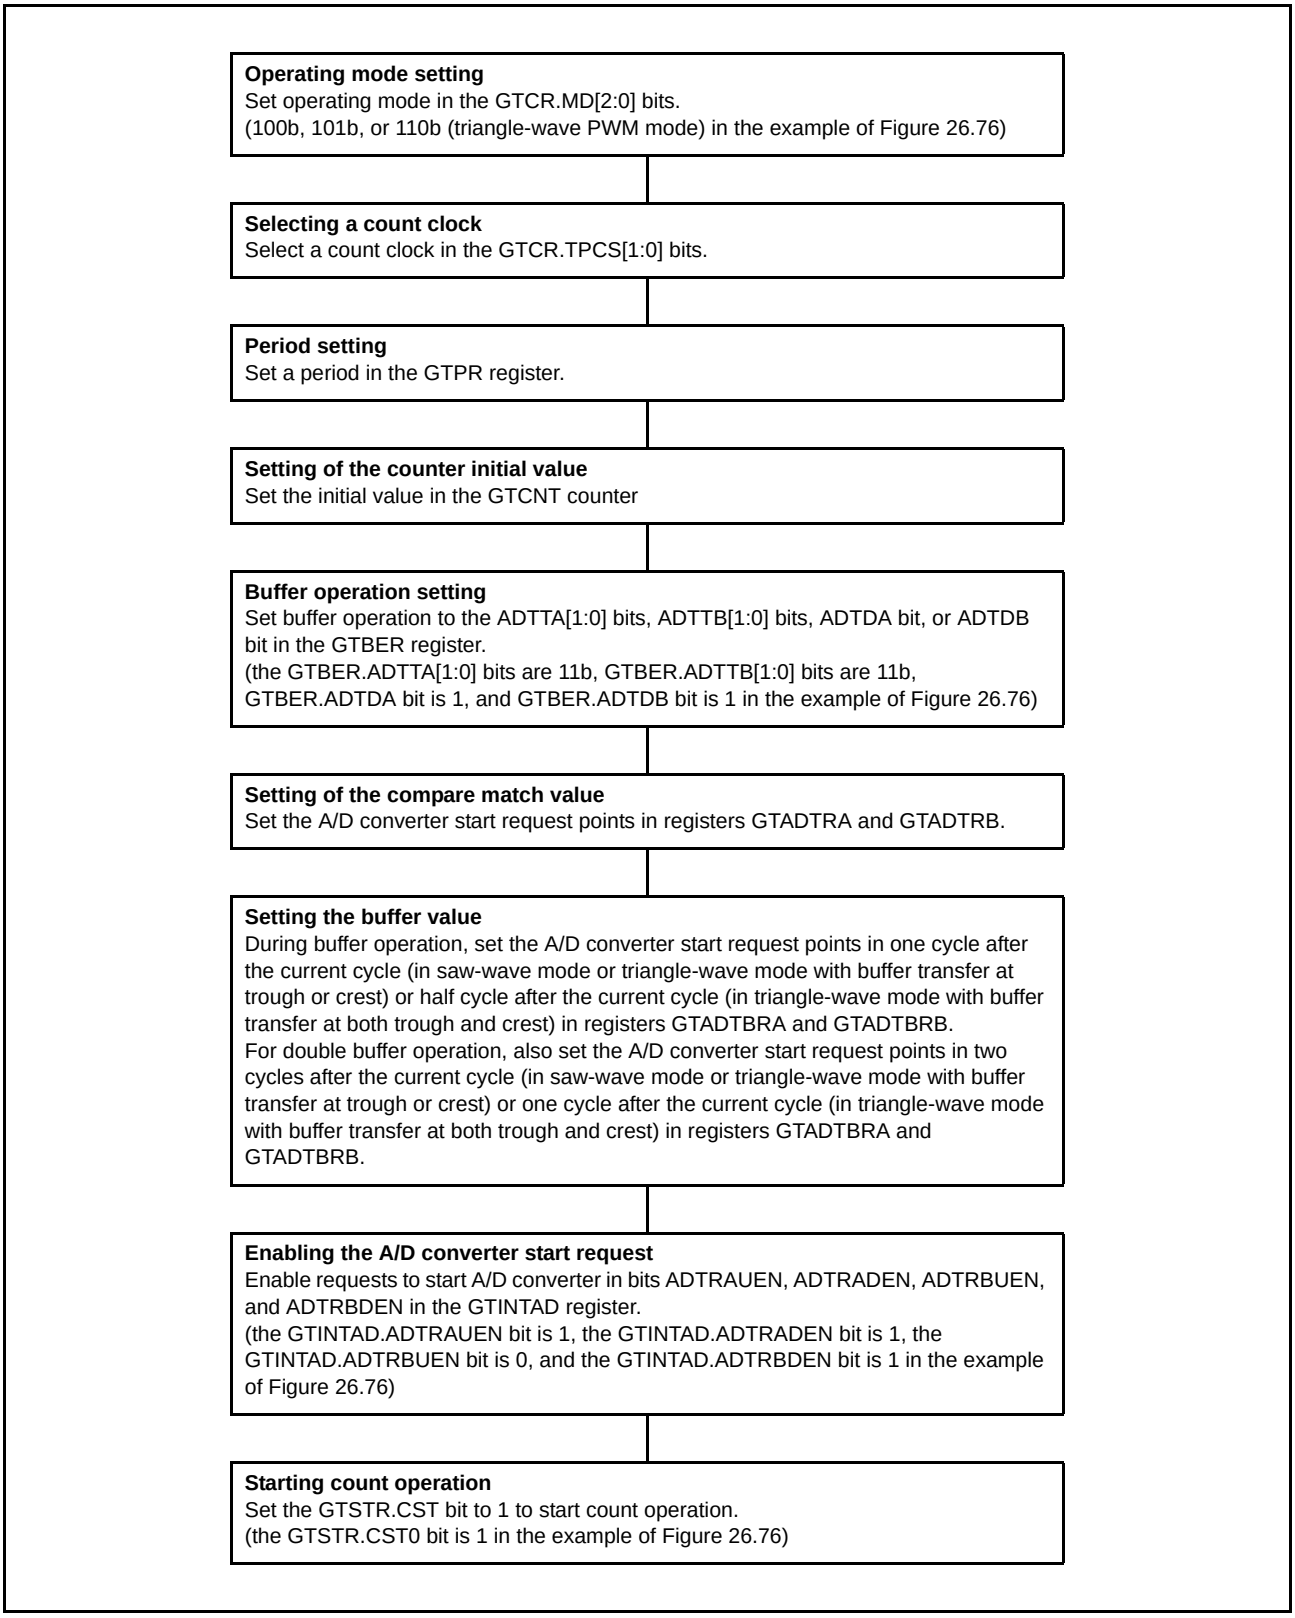

Figure 26.77 Example for Setting A/D Converter Start Request Timing Operation

26.6 Operations Linked by the ELC

26.6.1 Event Signal Output to the ELC

GPT is capable of operation linked with another module set in advance when its interrupt request signal is used as an event signal by the event link controller (ELC).
GPT outputs the following event signal: compare match A, compare match B, compare match C, compare match D, overflow, and underflow.
The event signal can be output regardless of the settings of the corresponding interrupt request enabling bits.
For details, refer to section 21, Event Link Controller (ELC).

26.6.2 GPT Operations in Response to Receiving Event Signals from the ELC

The GPT can perform the following operations in response to the event set in advance in the ELSRn register of the event link controller (ELC).

(1) Start Counting

Counting by the GPT starts in response to the event when this is selected by the setting of the ELOPI or ELOPJ register of the ELC. The ELOPI register handles control for GPT0 and GPT1, and the ELOPJ register controls for GPT2 and GPT3. When the event specified in the ELSRn register occurs, the GTSTR.CSTn bit shown in Table 26.6 is set to 1, and the GPT counter starts.
However, when the specified event is generated while the GTSTR.CSTn bit has already been set to 1, the event has no effect. Table 26.6 lists the GTSTR register bits used for each channel.

Table 26.6 General PWM Timer Software Start Registers for Linked Operation with the ELC

Channel No.	GTSTR register (timer start register)
GPT0	GTSTR.CST0 bit
GPT1	GTSTR.CST1 bit
GPT2	GTSTR.CST2 bit
GPT3	GTSTR.CST3 bit

(2) Input Capture Operation

Input capture by the GPT proceeds when this is selected by the setting of the ELOPI or ELOPJ register of the ELC. The ELOPI register handles control for GPT0 and GPT1, and the ELOPJ register controls for GPT2 and GPT3. When the event specified in the ELSRn register occurs, the GTCCRm register (general PWM timer compare capture register) captures the value of the GTCNT counter (timer counter register). When using input capture in response to an event, the corresponding bit of the GTIOR register (general PWM timer I/O control register) in the GPT should be set for input capture and the GTSTR.CSTn bit should be set to 1 to start counting by the counter.
In this case, the GTIOCnA pin (input capture pin) input has no effect.
Table 26.7 lists the GTCCRm and GTIOR registers used for each channel in input capture operation in response to the ELC.

Table 26.7 Registers Used in the Input Capture Operation by ELC

Channel No.	Timer General Register Name	Timer I/O Control Register
GPT0	GPT0.GTCCRA register	GPT0.GTIOR.GTIOA[5:0] bit
GPT1	GPT1.GTCCRA register	GPT1.GTIOR.GTIOA[5:0] bit
GPT2	GPT2.GTCCRA register	GPT2.GTIOR.GTIOA[5:0] bit
GPT3	GPT3.GTCCRA register	GPT3.GTIOR.GTIOA[5:0] bit

(3) Restart Counting

The counter is cleared in response to the event when the ELOPI or ELOPJ register of the ELC is set for “restart counting” as the operation for the GPT. The ELOPI register handles control for GPT0 and GPT1, and the ELOPJ register controls for GPT2 and GPT3. When the event specified in the ELSRn register occurs, the GTCNT counter (timer counter register) is returned to its initial value. If the corresponding GTSTR.CSTn bit is set to 1, counting will continue. For the GTSTR.CSTn bit, see Table 26.6.

(4) Stop Counting

The counter is cleared in response to the event when the ELOPI or ELOPJ register of the ELC is set for “stop counting” as the operation for the GPT. The ELOPI register handles control for GPT0 and GPT1, and the ELOPJ register controls for GPT2 and GPT3. When the event specified in the ELSRn register occurs, the corresponding GTSTR.CSTn bit is set to 0 and the GPT counter stops.
If an event occurs while the GTSTR.CSTn bit is 0, the event is ignored.

26.6.3 Usage Notes on GPT Operation by Event Signal Reception from ELC

The following notes on usage apply when the GPT is used in event link operation.

(1) Start Counting

If the event specified in the ELSRn register occurs during a cycle of writing to a GTSTR.CSTn bit, writing to the GTSTR.CSTn bit takes priority.

(2) Stop Counting

If the event specified in the ELSRn register occurs during a cycle of writing to the GTCNT counter (timer counter register), writing to the GTCNT counter takes priority.

(3) Restart Counting

When the counter is restarted, the compare match function is disabled.

26.7 Protection Function

26.7.1 Write-Protection for Registers

Registers can be write-protected per channel by setting the GTWP.WPn bit (n = 0 to 3) to prevent the values of the registers of each channel from being accidentally modified.
The write-protection can be set for the following registers:

Table 26.8 List of Write-Protected Registers

Register Symbol	Register Name
GTIOR	General PWM timer I/O control register
GTINTAD	General PWM timer interrupt output register
GTCR	General PWM timer control register
GTBER	General PWM timer buffer enable register
GTUDC	General PWM timer count direction register
GTITC	General PWM timer interrupt and A/D converter start request skipping setting register
GTST	General PWM timer status register
GTCNT	General PWM timer counter
GTCCRA to GTCCRF	General PWM timer compare capture registers A to F
GTPR	General PWM timer period setting register
GTPBR	General PWM timer period setting buffer register
GTPDBR	General PWM timer period setting double-buffer register
GTADTRA, GTADTRB	A/D converter start request timing registers A and B
GTADTBRA, GTADTBRB	A/D converter start request timing buffer registers A and B
GTADTDBRA, GTADTDBRB	A/D converter start request timing double-buffer registers A and B
GTONCR	General PWM timer output negate control register
GTDTCR	General PWM timer dead time control register
GTDVU, GTDVD	General PWM timer dead time value registers U and D
GTDBU, GTDBD	General PWM timer dead time buffer registers U and D
GTSOTR	General PWM timer output protection function temporary release register

26.7.2 Disabling of Buffer Operation

If the timing of buffer register write is too late for the buffer transfer timing, buffer operation can be suspended with the GTBDR setting. Specifically, buffer transfer can be temporarily disabled, even though a buffer transfer condition is generated during buffer register write, by setting the corresponding GTBDR bit to 1 (buffer operation disabled) before buffer register write and setting the bit to 0 (buffer operation enabled) after completion of writing to all the buffer registers.
Figure 26.78 shows an example of operation for disabling buffer operation

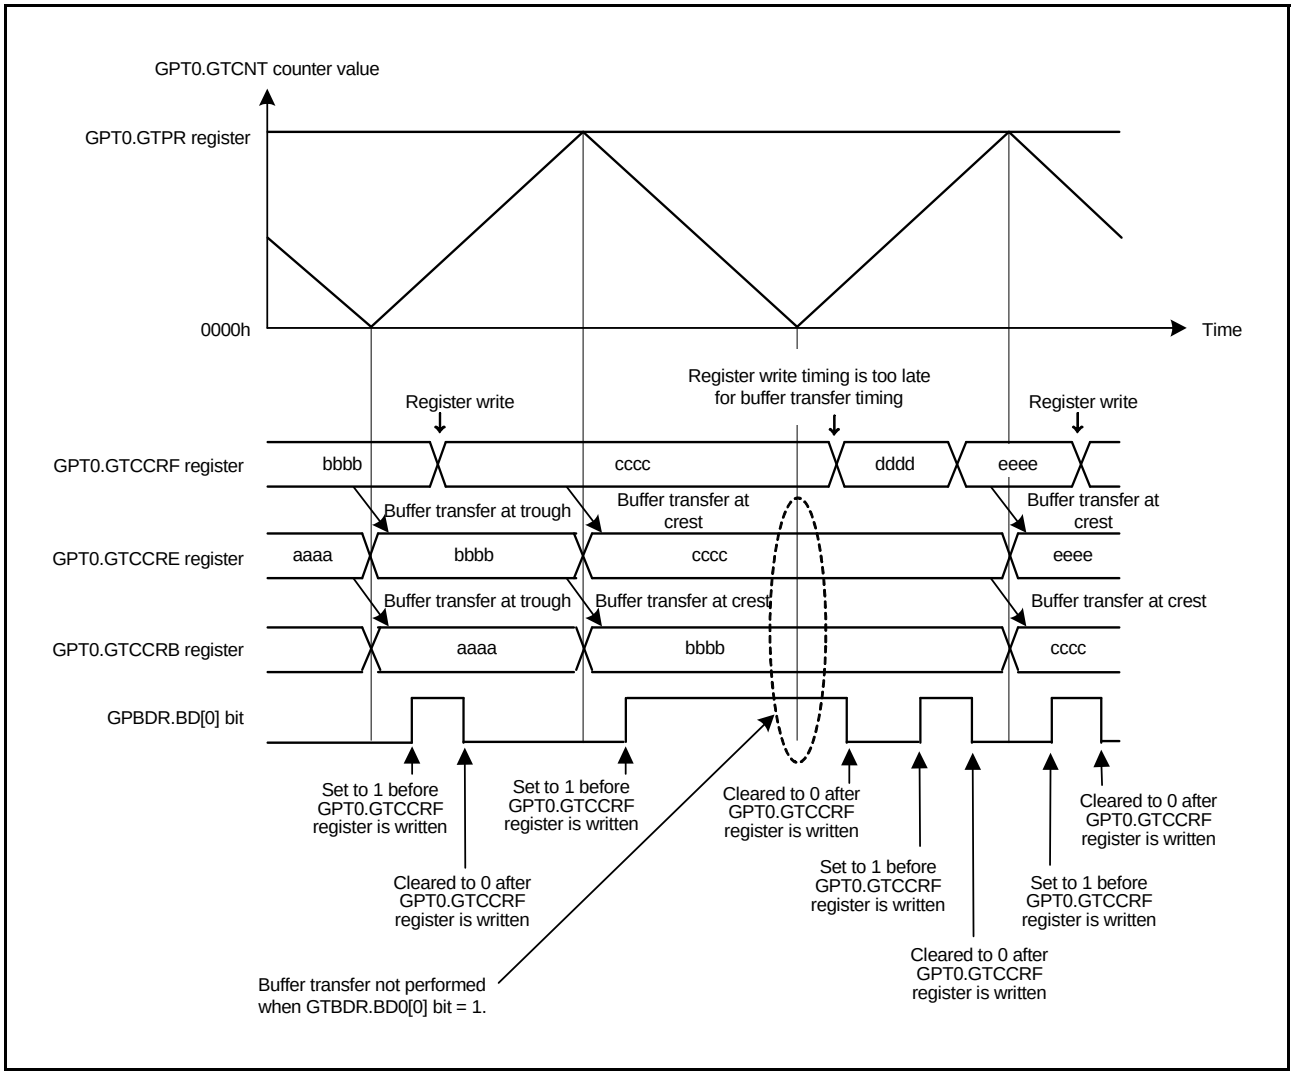

Figure 26.78 Example of Operation for Disabling Buffer Operation (Triangle Waves, Double Buffer Operation, Buffer Transfer at Both Troughs and Crests)

26.7.3 GTIOC Pin Output Negate Control

For protection from system failure, the negate control (deactivating the output level) is provided for GTIOC pin output. There are two negate control sources:GTETRG pin input, and writing to the GTONCR.SWN bit.

The negate control source can be selected by the GTONCR.NFS[3:0] bits, and the polarity of the negate source by the GTONCR.NFV bits. The inactive level to be output can be selected by the GTONCR.NVA and NAB bits.

When negate control is enabled by the GTONCR.NEA and NAB NEB bits, the inactive level selected by the GTONCR.NVA and NAB bits is output from the GTIOC pin.

Figure 26.79 shows an example of the GTIOC pin output negate control operation (when the GTONCR.NFV bit is set to 1 and the GTONCR.NVA bit is set to 0).

Note that once the negate control is performed, the negate control will not be released in the same cycle if the negate condition is no longer satisfied. The negate control is released in the next cycle.

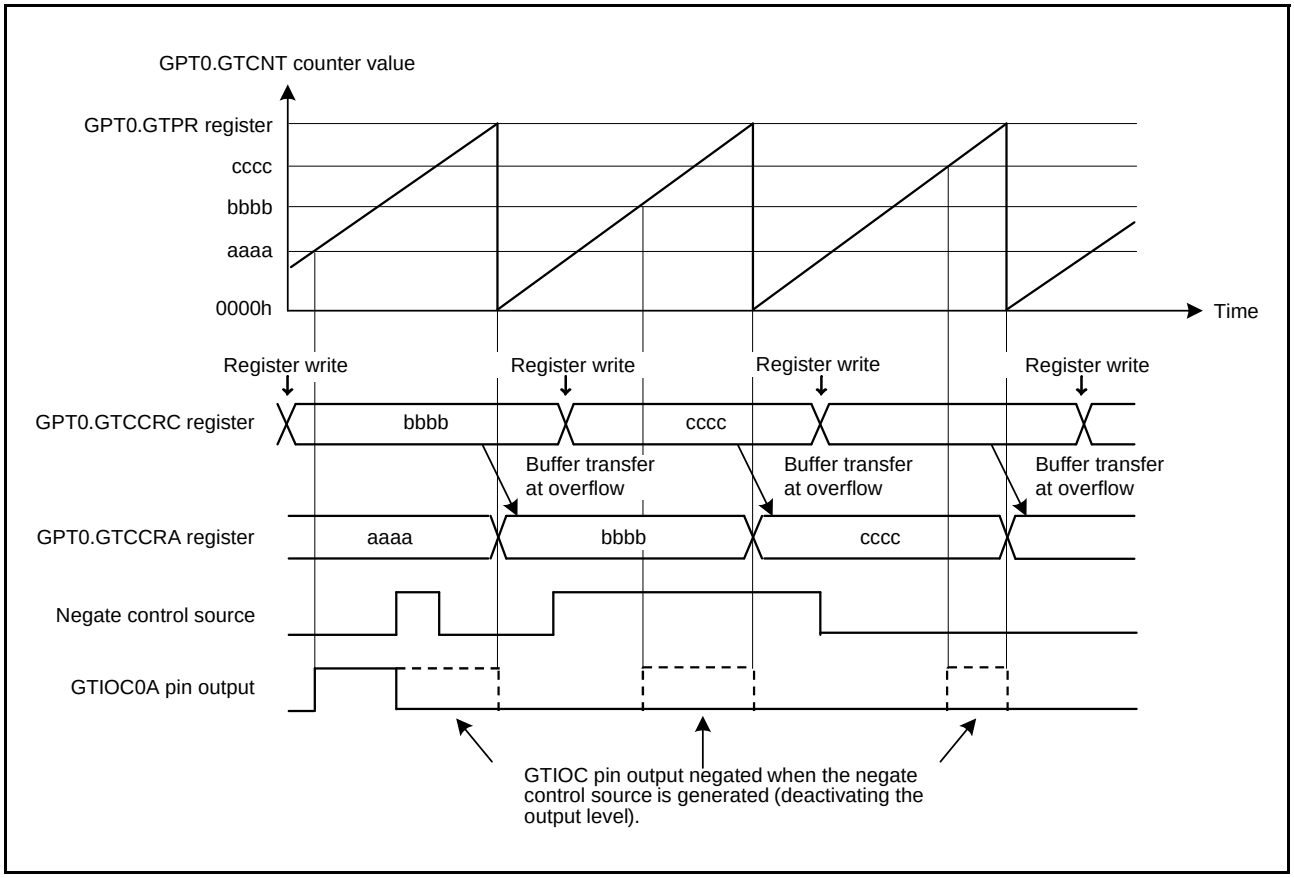

Figure 26.79 Example of GTIOC Pin Output Negate Control Operation (Saw-Wave Up-Counting, Buffer Operation, Active Level: 1, High Output at GTCCRA Compare Match, Low Output at the End of the Cycle)

26.7.4 Output Protection Function for GTIOC Pin Output

Under the automatic dead time setting (GTDTCR.TDE bit = 1) in triangle-wave PWM mode, if an incorrect value (0000h or a value greater than or equal to the GTPR value) is set in the GTCCRA register, the output protection function for the GTIOC pin output (disabling function) is activated.

The status of the output protection function can be read from the GTSOS.SOS[1:0] bits.

The output protection for the GTIOCnB pin can temporarily be released by setting the GTSOTR.SOTR bit to 1 only when an incorrect value (greater than or equal to the GTPR setting value) during buffer transfer at troughs is transferred to the GTCCRA register and output protection (disabling) is activated (the GTSOS.SOS[1:0] bits are 10b). After setting the GTSOTR.SOTR bit to 1, the output protection function is released from the first trough. When setting the GTSOTR.SOTR bit to 0 while the output protection function is released, the output protection function operates from the first trough.

Figure 26.80 shows the output protection function state transition.

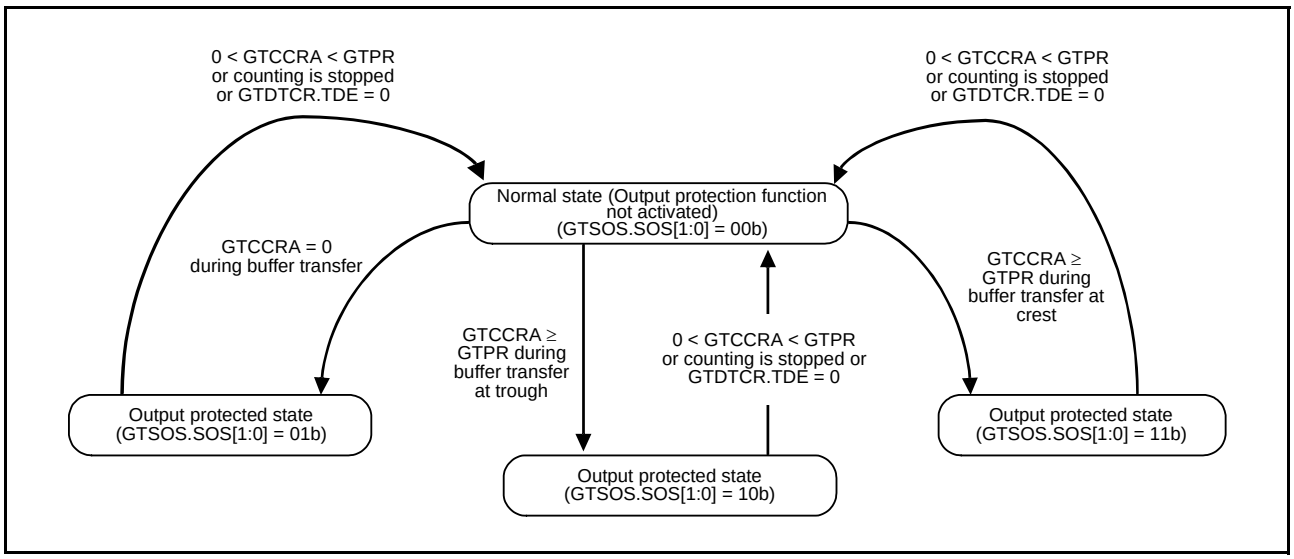

Figure 26.80 Output Protection Function

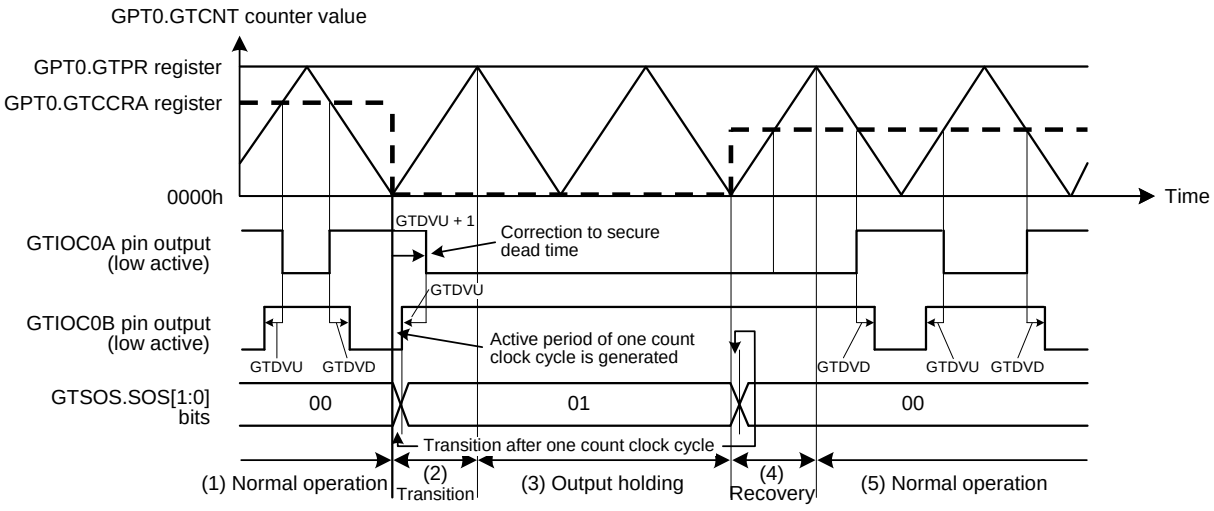
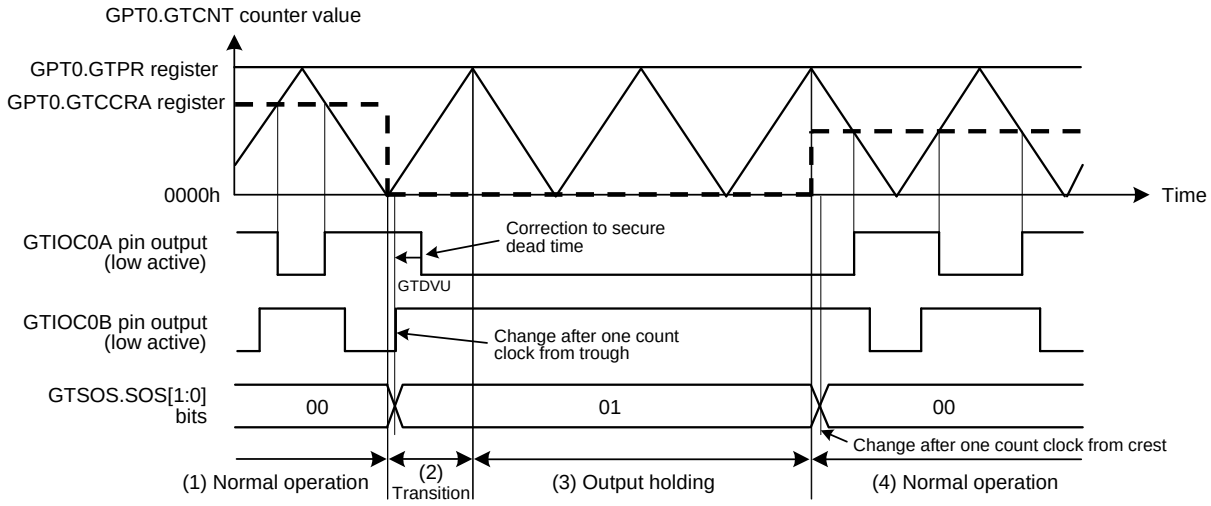
(1) Output Protection Function When the GTCCRA Register is Set to 0000h during Buffer Transfer

Figure 26.81 and Figure 26.82 show examples of output protection function operation when the GTCCRA register is set to 0000h during buffer transfer at troughs, and Figure 26.83 and Figure 26.84 show examples when the GTCCRA register is set to 0000h during buffer transfer at crests.



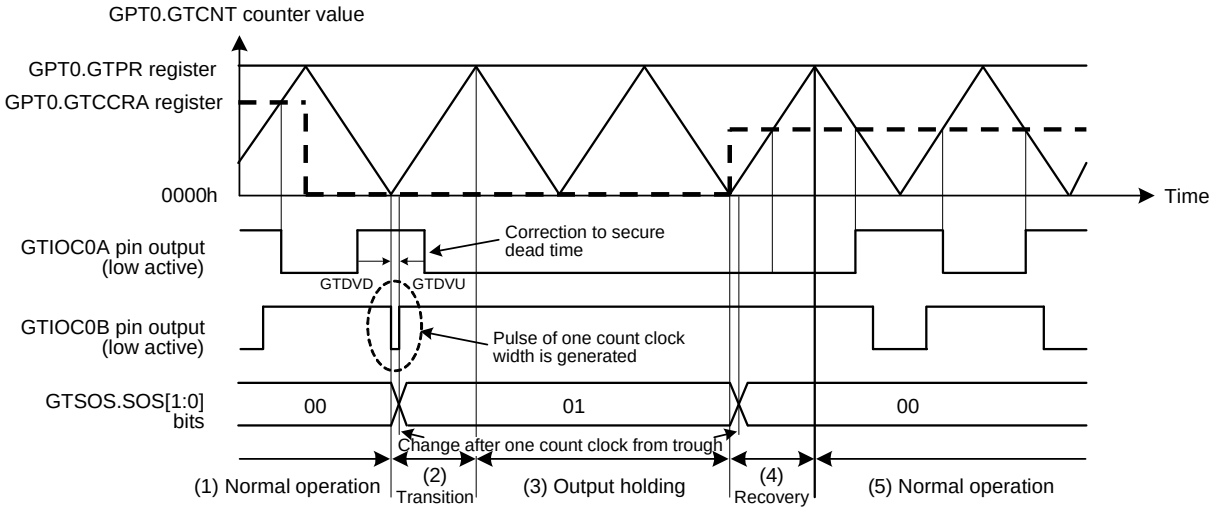
(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Transition period: When GTCCRA register = 0 is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 01b, and toggle output is continued up to the next crest.
(3) Output holding period: The output is held while GTCCRA register = 0.
(4) Recovery period: When 0 < GTCCRA register < GTPR register is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 00b, and holding output is maintained up to the next crest.
(5) Normal operation period: Toggle output due to a compare match is performed normally.

Figure 26.81 Example of Output Protection Function Operation When the GTCCRA Register is Set to 0000h during Buffer Transfer at Troughs (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Troughs, Active Level: Low)



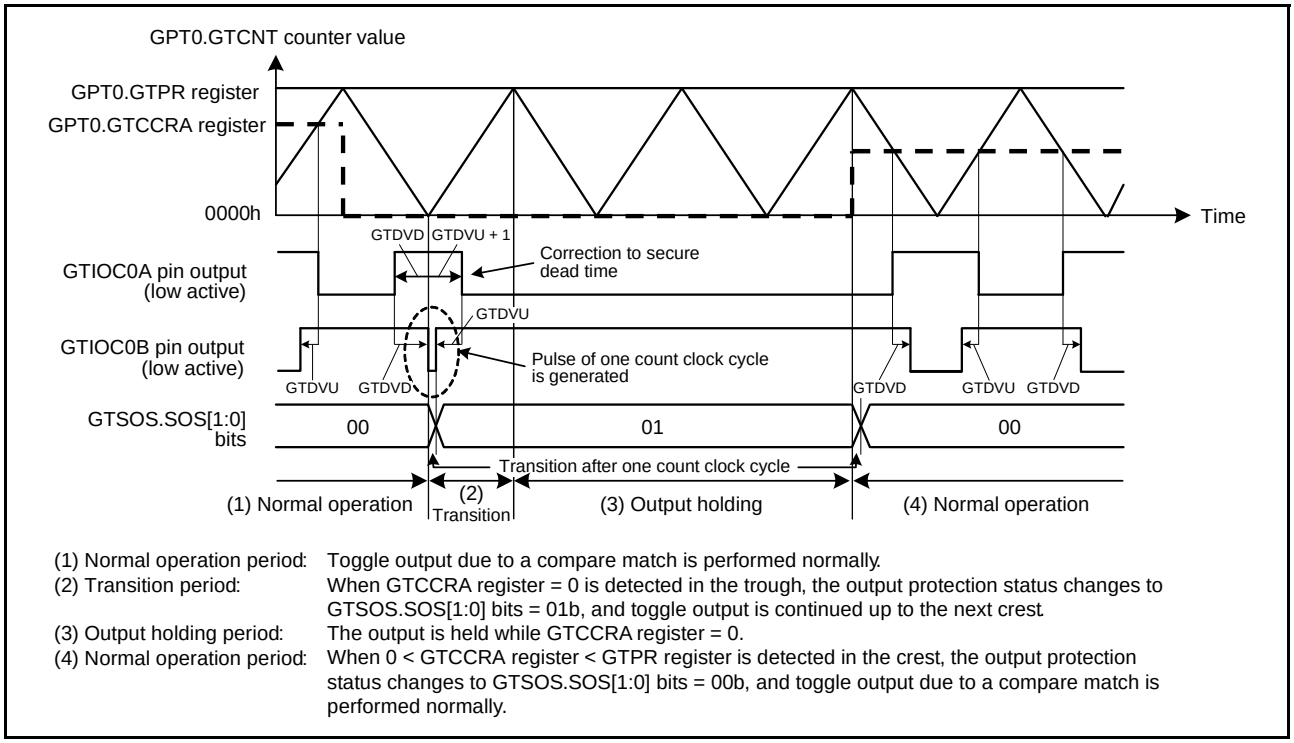
(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Transition period: When GTCCRA register = 0 is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 01b, and toggle output is continued up to the next crest.
(3) Output holding period: The output is held while GTCCRA register = 0.
(4) Normal operation period: When 0 < GTCCRA register < GTPR register is detected in the crest, the output protection status changes to GTSOS.SOS[1:0] bits = 00b, and toggle output due to a compare match is performed normally.

Figure 26.82 Example of Output Protection Function Operation When the GTCCRA Register is Set to 0000h during Buffer Transfer at Troughs (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Crests, Active Level: Low)



(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Transition period: When GTCCRA register = 0 is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 01b, and toggle output is continued up to the next crest.
(3) Output holding period: The output is held while GTCCRA register = 0.
(4) Recovery period: When 0 < GTCCRA register < GTPR register is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 00b, and holding output is maintained up to the next crest.
(5) Normal operation period: Toggle output due to a compare match is performed normally.

Figure 26.83 Example of Output Protection Function Operation When the GTCCRA Register is Set to 0000h during Buffer Transfer at Crests (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Troughs, Active Level: Low)

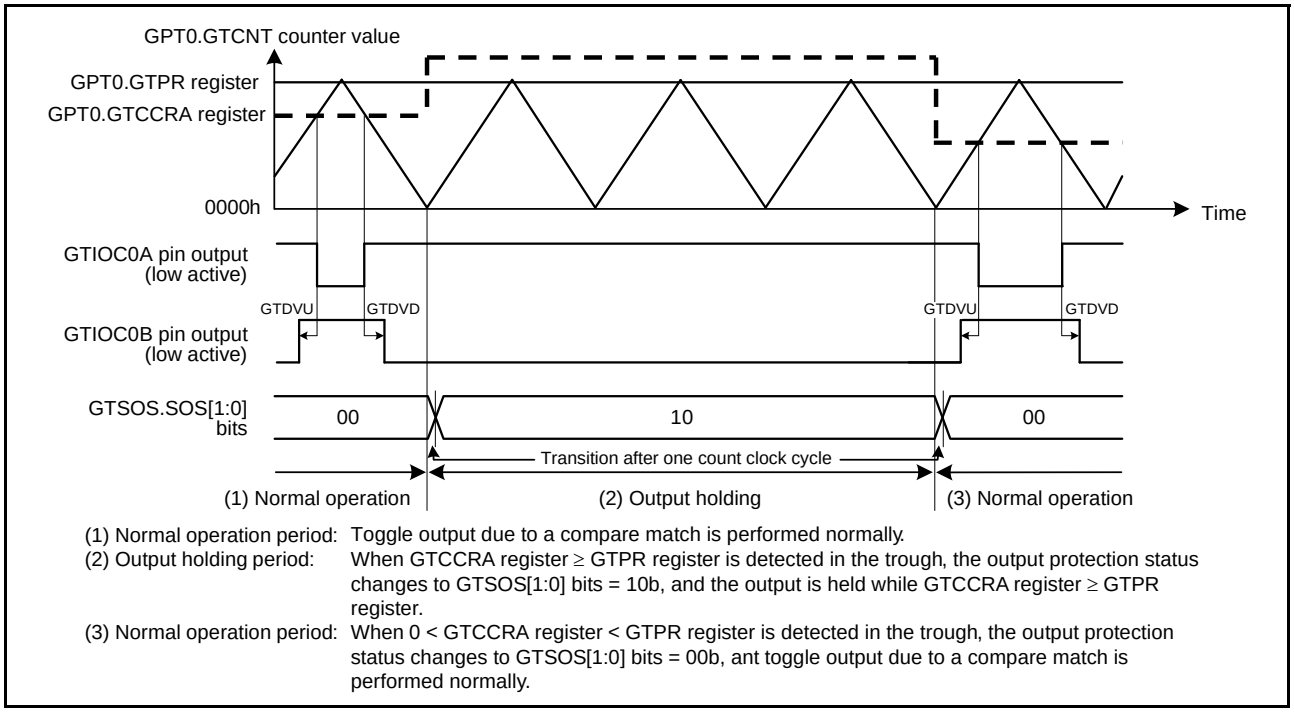


(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Transition period: When GTCCRA register = 0 is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 01b, and toggle output is continued up to the next crest.
(3) Output holding period: The output is held while GTCCRA register = 0.
(4) Normal operation period: When 0 < GTCCRA register < GTPR register is detected in the crest, the output protection status changes to GTSOS.SOS[1:0] bits = 00b, and toggle output due to a compare match is performed normally.

Figure 26.84 Example of Output Protection Function Operation When the GTCCRA Register is Set to 0000h during Buffer Transfer at Crests (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Crests, Active Level: Low)

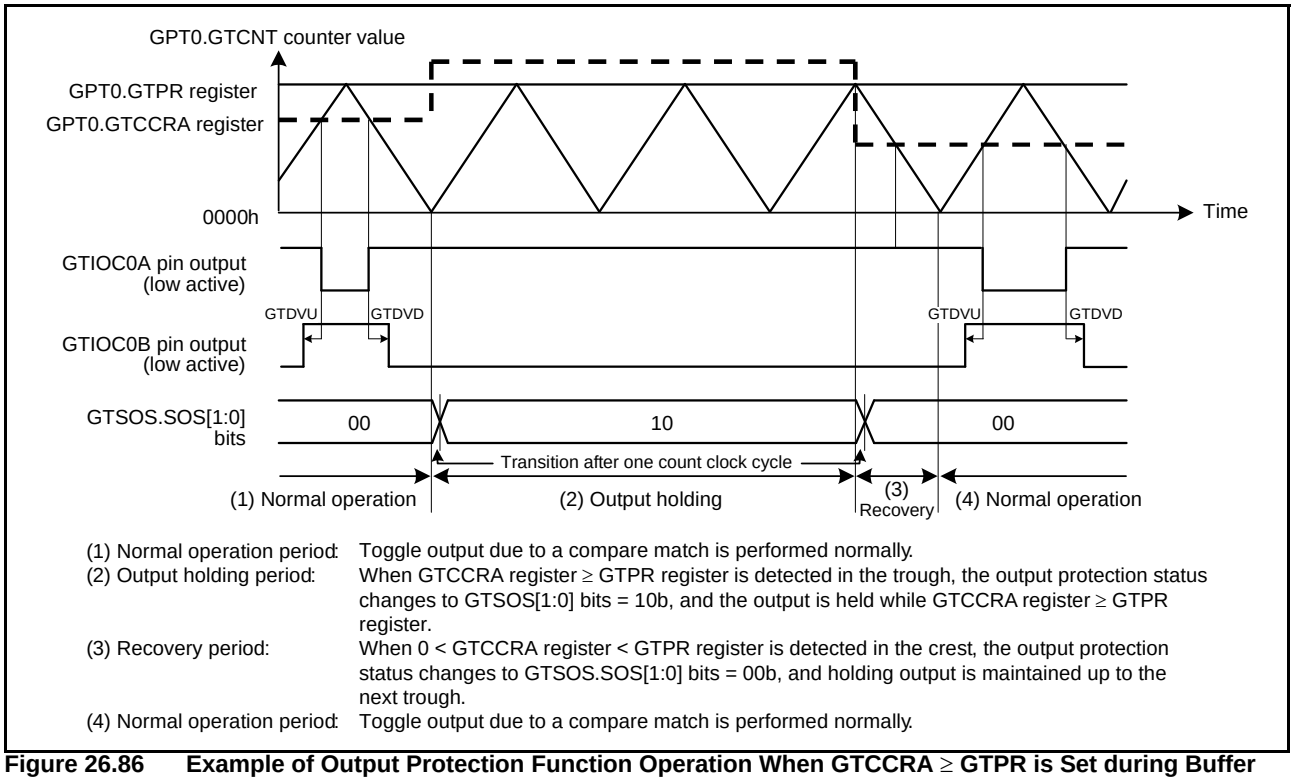
(2) Output Protection Function When GTCCRA ≥ GTPR is Set during Buffer Transfer at Troughs

Figure 26.85 and Figure 26.86 show examples of output protection function operation when GTCCRA ≥ GTPR is set during buffer transfer at troughs.



(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Output holding period: When GTCCRA register ≥ GTPR register is detected in the trough, the output protection status changes to GTSOS[1:0] bits = 10b, and the output is held while GTCCRA register ≥ GTPR register.
(3) Normal operation period: When 0 < GTCCRA register < GTPR register is detected in the trough, the output protection status changes to GTSOS[1:0] bits = 00b, ant toggle output due to a compare match is performed normally.

Figure 26.85 Example of Output Protection Function Operation When GTCCRA ≥ GTPR is set during Buffer Transfer at Troughs (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Troughs, Active Level: Low)

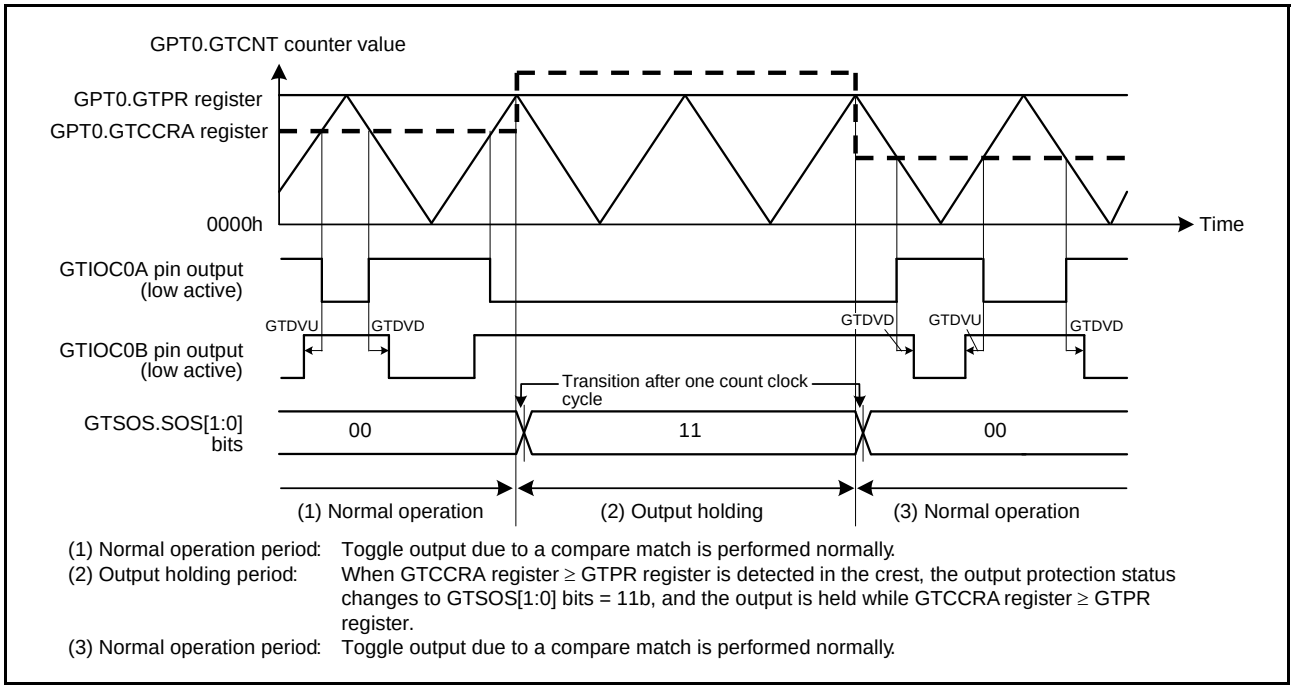


(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Output holding period: When GTCCRA register ≥ GTPR register is detected in the trough, the output protection status changes to GTSOS[1:0] bits = 10b, and the output is held while GTCCRA register ≥ GTPR register.
(3) Recovery period: When 0 < GTCCRA register < GTPR register is detected in the crest, the output protection status changes to GTSOS.SOS[1:0] bits = 00b, and holding output is maintained up to the next trough.
(4) Normal operation period: Toggle output due to a compare match is performed normally.

Figure 26.86 Example of Output Protection Function Operation When GTCCRA ≥ GTPR is Set during Buffer Transfer at Troughs (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Crests, Active Level: Low)

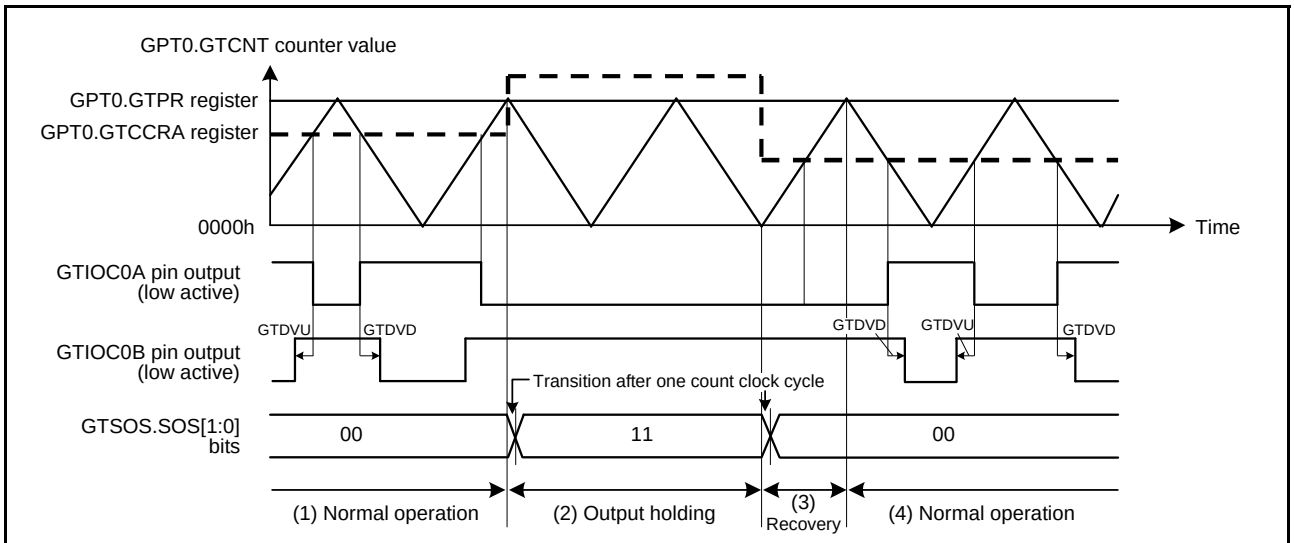
(3) Output Protection Function When GTCCRA ≥ GTPR is Set during Buffer Transfer at Crests

Figure 26.87 and Figure 26.88 show examples of output protection function operation when GTCCRA ≥ GTPR is set during buffer transfer at crests.



(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Output holding period: When GTCCRA register ≥ GTPR register is detected in the crest, the output protection status changes to GTSOS[1:0] bits = 11b, and the output is held while GTCCRA register ≥ GTPR register.
(3) Normal operation period: Toggle output due to a compare match is performed normally.

Figure 26.87 Example of Output Protection Function Operation When GTCCRA ≥ GTPR is Set during Buffer Transfer at Crests (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Crests, Active Level: Low)



(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Output holding period: When GTCCRA register ≥ GTPR register is detected in the crest, the output protection status changes to GTSOS.SOS[1:0] bits = 11b, and the output is held while GTCCRA register ≥ GTPR register.
(3) Recovery period: When 0 < GTCCRA register < GTPR register is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 00b, and holding output is maintained up to the next crest.
(4) Normal operation period: Toggle output due to a compare match is performed normally.

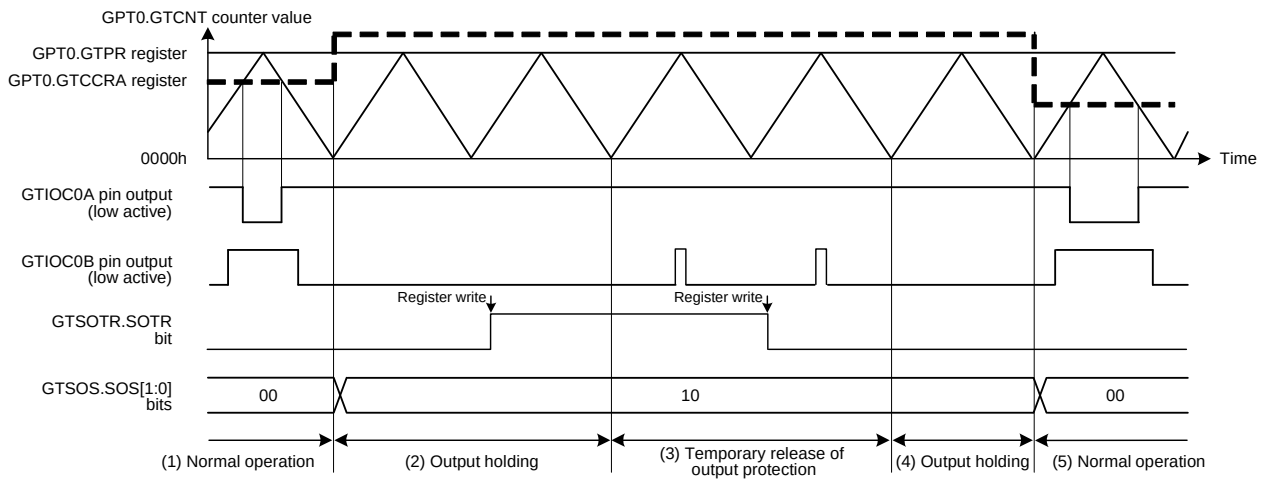
Figure 26.88 Example of Output Protection Function Operation When GTCCRA ≥ GTPR is Set during Buffer Transfer at Crests (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Troughs, Active Level: Low)

(4) Restricted Specification of Output Protection Function

When the GTCCRA value is greater than 0000h, and less than the setting value of the GTPR register, start count operation.
Even if an incorrect value (0000h or a value greater than or equal to the GTPR value) is set in the GTCCRA register during count operation, the output protection functions in a specific way such that one of the positive- and negative-phase outputs becomes non-active. However, when count operation is started while an incorrect value is set in the GTCCRA register, the output protection does not operate normally.

(5) Temporary Release of Output Protection Function

When the GTSOS.SOS[1:0] bits = 10b (protected state in which GTCCRA ≥ GTPR has occurred during transfer at trough), the protected state of the GTIOCnBF pin output can be temporarily released by setting the GTSOTR.SOTR bit to 1. The GTSOS.SOS[1:0] bits retain 10b even if the output protection function is released.
When the SOTR bit is set to 0, the GTIOCnB pin output protection can be restarted.
Figure 26.89 shows an example of output protection function operation when GTCCRA ≥ GTPR is set during buffer transfer at troughs.



(1) Normal operation period:	Toggle output due to a compare match is performed normally.
(2) Output holding period:	When GTCCRA register ≥ GTPR register is detected in the trough, the output protection status changes to GTSOS[1:0] bits = 10b, and the output is held while GTCCRA register ≥ GTPR register.
(3) Output protection temporary release period:	Even when the GTSOTR.SOTR bit is set to 1, the GTIOCOB pin output is held until the first trough.
(4) Output holding period:	After the GTSOTR.SOTR bit is set to 1, the GTIOCOB pin output is performed normally from the first trough. The output is held until 0 < GTCCRA register < GTPR register is detected in the tough.
(5) Normal operation period:	When 0 < GTCCRA register < GTPR register is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 00b, and toggle output due to a compare match is performed normally.

Figure 26.89 Example of Output Protection Function Operation When GTCCRA ≥ GTPR is Set during Buffer Transfer at Troughs (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Troughs, Active Level: Low)

26.7.5 High-Impedance Control of GTIOC Pin Output by POE Function

For protection from system failure, the high-impedance state of the GTIOC pin output can be controlled by the port output enable (POE) function.
For details, see section 25, Port Output Enable 3 (POE3a).

26.8 Initialization Method of Output Pins

26.8.1 Pin Settings after Reset

The GPT registers are initialized at a reset. Start counting after selecting the port mode (PMR and PmnPFS), setting the GTIOR register and the OAE and OBE bits in the GTONCR register and outputting the GPT function to external pins.

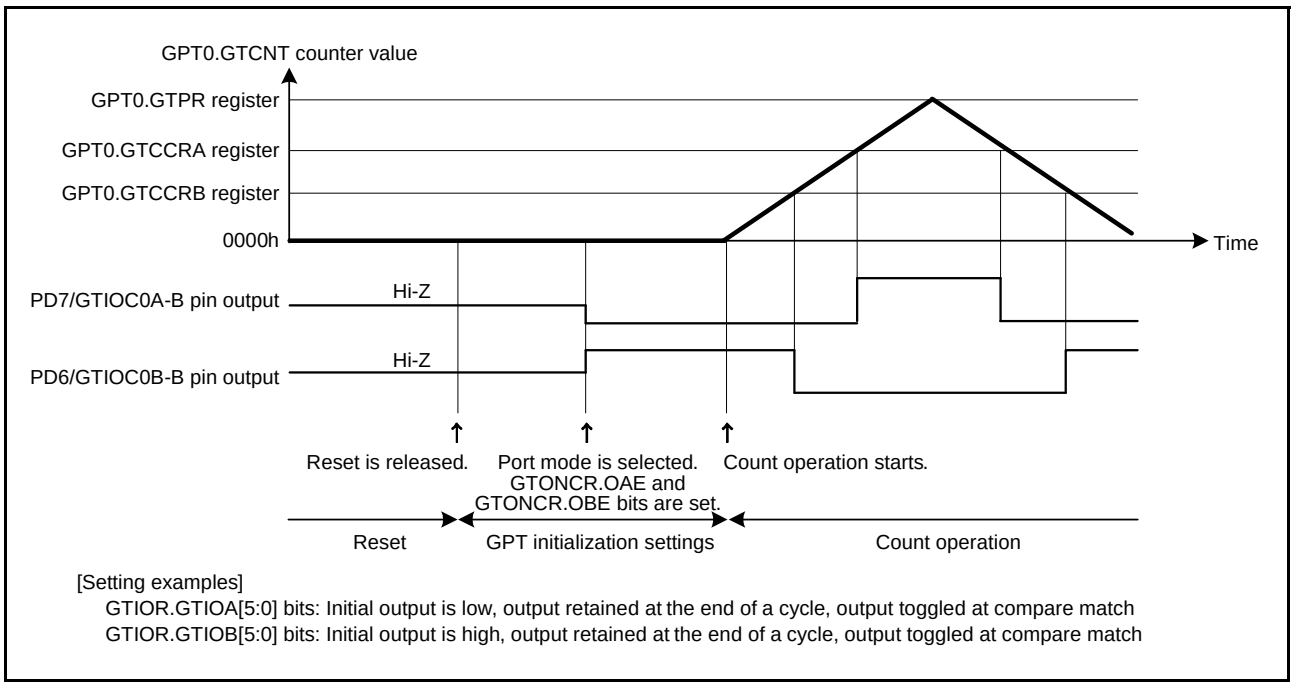


Figure 26.90 Example of Pin Settings after Reset

26.8.2 Pin Initialization Due to Error during Operation

If an error occurs during GPT operation, the following four types of pin processing can be performed before pin initialization.

(1) Set OAHLD and OBHLD bits in the GTIOR register to 1 and retain the outputs at count stop.

(2) Set OAHLD and OBHLD bits in the GTIOR register to 0, specify arbitrary output values at OADFLT and OBDFLT in the GTIOR register, and output the arbitrary values at count stop.

(3) Set the pin to output an arbitrary value as a general output port by setting the PDR, PODR, and PMR registers of the I/O port in advance. Set the OAE and OBE bits in the GTONCR register to 0 and the control bit in PMR that corresponds to the pin to 0 to allow the arbitrary values to be output from the pin set as a general output port when an error occurs.

(4) Drive the output to a high impedance state using the POE function.

When automatic dead time setting has been made, set the GTDTCR.TDE bit to 0 once after counting is stopped.

When counting is stopped, only the values of registers that are changed by a GPT external source will change. If counting is resumed, operation will carry on from where it was stopped.
If counting was stopped, registers should be initialized before counting is started.

26.9 Usage Notes

26.9.1 Module Stop Function Setting

Operation of the GPT can be disabled or enabled by the module stop control register. The initial setting is for operation of the GPT to be halted. Register access is enabled by clearing module stop state. For details, see section 11, Low Power Consumption.

26.9.2 Settings of the GTCCRm Register during Compare Match Operation (m = A to F)

(1) When automatic dead time setting has been made in triangle-wave PWM mode

The GTCCRA register should satisfy the following conditions:

GTCCRA > GTDVU,
GTCCRA > GTDVD, and
GTCCRA < GTPR.

When the GTCCRA register is set to 0000h or a value greater than or equal to the GTPR value during count operation, the output protection function is activated.
When the GTCCRA value is greater than 0000h, and less than the setting value of the GTPR register, start count operation. If count operation is started while 0000h or a value greater than or equal to the GTPR value is set in the GTCCRA register, the output protection does not operate normally.
For details, refer to section 26.7.4, Output Protection Function for GTIOC Pin Output.

(2) When automatic dead time setting has not been made in triangle-wave PWM mode

Set a value greater than 0000h, and less than the setting value of the GTPR register in the GTCCRA register. When 0000h or the same value as that of the GTPR register is set in the GTCCRA register, compare match is generated in one cycle only when [GTCCRA = 0000h] or [GTCCRA = GTPR] is met. Furthermore, a value exceeding the setting value of the GTPR register is set in the GTCCRA register, compare match does not occur.
Similarly, set a value greater than 0000h, and less than the setting value of the GTPR register in the GTCCRB register. When 0000h or the same value as that of the GTPR register is set in the GTCCRB register, compare match is generated in one cycle only when [GTCCRB = 0000h] or [GTCCRB = GTPR] is met. Furthermore, a value exceeding the setting value of the GTPR register is set in the GTCCRB register, compare match does not occur.

(3) When automatic dead time setting has been made in saw-wave one-shot pulse mode

The GTCCRC and GTCCRD registers should be set to satisfy the following restrictions. If the restrictions are not satisfied, correct output waveforms with secured dead time may not be obtained.

- In up-counting:
  GTCCRC < GTCCRD
  GTCCRC > GTDVU
  GTCCRD < GTPR – GTDVD
- In down-counting:
  GTCCRC > GTCCRD
  GTCCRC < GTPR – GTDVU
  GTCCRD > GTDVD

(4) When automatic dead time setting has not been made in saw-wave one-shot pulse mode

The GTCCRC and GTCCRD registers should be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting: 0 < GTCCRC < GTCCRD < GTPR
- In down-counting: GTPR > GTCCRC > GTCCRD > 0

Similarly, GTCCRE and GTCCRF should be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting: 0 < GTCCRE < GTCCRF < GTPR
- In down-counting: GTPR > GTCCRE > GTCCRF > 0

(5) In saw-wave PWM mode

The GTCCRA register should be set with the range of 0 < GTCCRA < GTPR. If GTCCRA = 0000h or GTCCRA = GTPR is set, a compare match occurs within the cycle only when GTCCRA = 0000h or GTCCRA = GTPR is satisfied. If GTCCRA > GTPR is set, no compare match occurs.
Similarly, GTCCRB should be set with the range of 0 < GTCCRB < GTPR. If GTCCRB = 0000h or GTCCRB = GTPR is set, a compare match occurs within the cycle only when GTCCRB = 0000h or GTCCRB = GTPR is satisfied. If GTCCRB > GTPR is set, no compare match occurs.

26.9.3 Stopping the Timer in the Safe Way

When the timer stopping by the GTSTR register writing and the GPT compare match interrupt conflict, an interrupt may be generated after the GTSTR register writing.
Therefore, stop the timer in the following order. Then, a compare match interrupt is not generated after the timer has been stopped, and the timer can be stopped in the safe way.

(1) Disable the GPT interrupt request by the IER register of the ICU.
(2) Disable the interrupt request by the GTINTAD register.
(3) Set the GTSTR.CSTn bit to 0.

26.9.4 Order of Priority in Event Counter Operation

(1) Contention between writing to and clearing of the GTCNT counter

If the counter clearing signal is generated during a cycle of writing to the GTCNT counter, writing to the GTCNT counter takes priority over clearing of the GTCNT counter.

(2) Contention between writing to the GTSTR.CSTn bit and a hardware source/event signal

If a hardware source or event signal from the ELC is generated in a cycle of writing to the GTSTR.CSTn bit (n = 0 to 3), writing to the CSTn bit takes priority over an automatic set or reset of the CSTn bit due to the hardware source.

(3) Contention between a set and a reset by a hardware source to the GTSTR.CSTn bit or event signal

When a set and a reset by a hardware source to the GTSTR.CSTn bit (n = 0 to 3) or event signal from the ELC occurs at the same time, an automatic set takes priority.

(4) Contention between access to the GTCCRm register and input capture/buffer transfer

In case of contention between the writing to the GTCCRm register (m = A to F) and input capture or buffer transfer, writing to the GTCCRm register takes priority over input capture or buffer transfer.
If reading from the GTCCRm register and input capture or buffer transfer are in contention, the data before an update is read.

(5) Contention between access to the GTPR register and buffer transfer

If writing to the GTPR register and buffer transfer are in contention, writing to the GTPR register takes priority over buffer transfer.

If reading from the GTPR register and buffer transfer are in contention, the data before an update is read.

(6) Contention between access to the GTADTRm register and buffer transfer

If writing to the GTADTRm register (m = A, B) and buffer transfer are in contention, writing to the GTADTRm register takes priority over the buffer transfer.
If reading from the GTADTRm register and buffer transfer are in contention, the data before an update is read.

(7) Contention between access to the GTDVm register and buffer transfer

If writing to the GTDVm register (m = U, D) and buffer transfer are in contention, writing to the GTDVm register takes priority over the buffer transfer.
If reading from the GTDVm register and buffer transfer are in contention, the data before an update is read.

27. 16-Bit Timer Pulse Unit (TPUa)

This MCU has on-chip 16-bit timer pulse units (TPU) comprising six-channel 16-bit timers.
In this section, “PCLK” is used to refer to PCLKB.

27.1 Overview

Specifications of the TPU are listed in Table 27.1. Functions of TPU are listed in Table 27.2.
Figure 27.1 shows a block diagram of TPU.

Table 27.1 Specifications of TPU

Item	Description
Pulse input/output	Maximum 16
Count clocks	Seven or eight types are provided for each channel.
Settable operations	• Waveform output at compare match • Input capture function (noise filters can be set) • Counter clear operation • Simultaneous writing to multiple timer counters (TCNT) • Simultaneous clearing by compare match and input capture • Synchronous input/output for registers by counter synchronous operation • Maximum of 15-phase PWM output by combination with synchronous operation • Cascaded operation
TPU0 and TPU3	Buffer operation can be set.
TPU1, TPU2, TPU4, and TPU5	Phase counting mode can be set.
Interrupt sources	26 sources
Buffer operation	Automatic transfer of register data
Generation of trigger	Programmable pulse generator (PPG) output trigger can be generated.
	Conversion start trigger for the A/D converter can be generated.
Event linking (output)	• Six types of event signal can be output to the ELC. Compare match A (TPU0 to TPU3) Compare match B (TPU0 to TPU3) Compare match C (TPU0, TPU3) Compare match D (TPU0, TPU3) Overflow (TPU0 to TPU3) Underflow (TPU1, TPU2)
Event linking (input)	• Any of the three operations in response to event input is possible. Starting counts (TPU0 to TPU3) Restarting counts (TPU0 to TPU3) Input capture operation (TPU0 to TPU3)
Low power consumption function	Module stop state can be set.

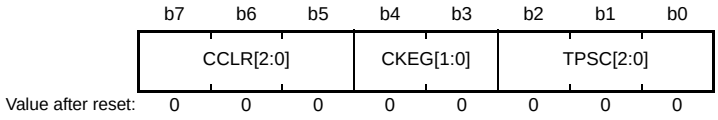
27.2 Register Descriptions

27.2.1 Timer Control Register (TCR)

Address(es): TPU0.TCR 0008 8110h, TPU1.TCR 0008 8120h, TPU2.TCR 0008 8130h, TPU3.TCR 0008 8140h, TPU4.TCR 0008 8150h, TPU5.TCR 0008 8160h



Bit	Symbol	Bit Name	Description	R/W
b2 to b0	TPSC[2:0]	Timer Prescaler Select	See Table 27.4 to Table 27.9.	R/W
b4, b3	CKEG[1:0]	Input Clock Edge Select	See Table 27.10.	R/W
b7 to b5	CCLR[2:0]*1	Counter Clear Source Select	See Table 27.11 and Table 27.12.	R/W

Note 1. Bit 7 in TCR of TPU1, TPU2, TPU4, and TPU5 are reserved. These bits are read as 0. The write value should be 0.

TPUm.TCR settings should be made while TPUm.TCNT operation is stopped.

TPSC[2:0] Bits (Timer Prescaler Select)

These bits select the TCNT clock. The clock source can be selected independently for each channel.
To select the external clock as the clock source, set the bit in the port direction register (PDR) for the corresponding pin to 0 (input port), and set the bit in the port mode register (PMR) to 1 (uses the pin as an I/O port for peripheral functions). For details, see section 22, I/O Ports.

CKEG[1:0] Bits (Input Clock Edge Select)

These bits select the input clock edge.
When the internal clock is counted using both edges, the input clock period is halved (e.g. Both edges of PCLK/4 = PCLK/2 rising edge).
Internal clock edge selection is valid when the input clock is PCLK/4 or slower. This setting is ignored if the input clock is PCLK/1, or when overflow/underflow of another channel is selected.

Table 27.4 Bits TPSC[2:0] (TPU0)

Channel	Bits TPSC[2:0]			Description
	b2	b1	b0	
TPU0	0	0	0	Internal clock: counts on PCLK/1
	0	0	1	Internal clock: counts on PCLK/4
	0	1	0	Internal clock: counts on PCLK/16
	0	1	1	Internal clock: counts on PCLK/64
	1	0	0	External clock: counts on TCLKA pin input
	1	0	1	External clock: counts on TCLKB pin input
	1	1	0	External clock: counts on TCLKC pin input
	1	1	1	External clock: counts on TCLKD pin input

Table 27.5 Bits TPSC[2:0] (TPU1)

Channel	Bits TPSC[2:0]			Description
	b2	b1	b0	
TPU1	0	0	0	Internal clock: counts on PCLK/1
	0	0	1	Internal clock: counts on PCLK/4
	0	1	0	Internal clock: counts on PCLK/16
	0	1	1	Internal clock: counts on PCLK/64
	1	0	0	External clock: counts on TCLKA pin input
	1	0	1	External clock: counts on TCLKB pin input
	1	1	0	Internal clock: counts on PCLK/256
	1	1	1	Counts on TPU2.TCNT overflow/underflow

Note: This setting is invalid when TPU1 is in phase counting mode.

Table 27.6 Bits TPSC[2:0] (TPU2)

Channel	Bits TPSC[2:0]			Description
	b2	b1	b0	
TPU2	0	0	0	Internal clock: counts on PCLK/1
	0	0	1	Internal clock: counts on PCLK/4
	0	1	0	Internal clock: counts on PCLK/16
	0	1	1	Internal clock: counts on PCLK/64
	1	0	0	External clock: counts on TCLKA pin input
	1	0	1	External clock: counts on TCLKB pin input
	1	1	0	External clock: counts on TCLKC pin input
	1	1	1	Internal clock: counts on PCLK/1024

Note: This setting is invalid when TPU2 is in phase counting mode.

Table 27.7 Bits TPSC[2:0] (TPU3)

Channel	Bits TPSC[2:0]			Description
	b2	b1	b0	
TPU3	0	0	0	Internal clock: counts on PCLK/1
	0	0	1	Internal clock: counts on PCLK/4
	0	1	0	Internal clock: counts on PCLK/16
	0	1	1	Internal clock: counts on PCLK/64
	1	0	0	External clock: counts on TCLKA pin input
	1	0	1	Internal clock: counts on PCLK/1024
	1	1	0	Internal clock: counts on PCLK/256
	1	1	1	Internal clock: counts on PCLK/4096

Table 27.8 Bits TPSC[2:0] (TPU4)

Channel	Bits TPSC[2:0]			Description
	b2	b1	b0	
TPU4	0	0	0	Internal clock: counts on PCLK/1
	0	0	1	Internal clock: counts on PCLK/4
	0	1	0	Internal clock: counts on PCLK/16
	0	1	1	Internal clock: counts on PCLK/64
	1	0	0	External clock: counts on TCLKA pin input
	1	0	1	External clock: counts on TCLKC pin input
	1	1	0	Internal clock: counts on PCLK/1024
	1	1	1	Counts on TPU5.TCNT overflow/underflow

Note: This setting is invalid when TPU4 is in phase counting mode.

Table 27.9 Bits TPSC[2:0] (TPU5)

Channel	Bits TPSC[2:0]			Description
	b2	b1	b0	
TPU5	0	0	0	Internal clock: counts on PCLK/1
	0	0	1	Internal clock: counts on PCLK/4
	0	1	0	Internal clock: counts on PCLK/16
	0	1	1	Internal clock: counts on PCLK/64
	1	0	0	External clock: counts on TCLKA pin input
	1	0	1	External clock: counts on TCLKC pin input
	1	1	0	Internal clock: counts on PCLK/256
	1	1	1	External clock: counts on TCLKD pin input

Note: This setting is invalid when TPU5 is in phase counting mode.

Table 27.10 Bits CKEG[1:0]

Bits CKEG[1:0]		Input Clock	
b4	b3	Internal Clock	External clock
0	0	Counted at falling edge	Counted at rising edge
0	1	Counted at rising edge	Counted at falling edge
1	0	Counted at both edges	Counted at both edges
1	1	Counted at both edges	Counted at both edges

Table 27.11 Bits CCLR[2:0] (TPU0, TPU3)

Channel	Bits CCLR[2:0]			Description
	b7	b6	b5	
TPU0, TPU3	0	0	0	TCNT clearing disabled
	0	0	1	TCNT cleared by TGRA compare match/input capture
	0	1	0	TCNT cleared by TGRB compare match/input capture
	0	1	1	TCNT cleared by counter clearing for another channel performing synchronous clearing/ synchronous operation*2
	1	0	0	TCNT clearing disabled
	1	0	1	TCNT cleared by TGRC compare match/input capture*1
	1	1	0	TCNT cleared by TGRD compare match/input capture*1
	1	1	1	TCNT cleared by counter clearing for another channel performing synchronous clearing/ synchronous operation*2

Note 1. When TGRC or TGRD is used as a buffer register, TCNT is not cleared because the buffer register setting has priority, and compare match/input capture does not occur.
Note 2. Synchronous operation is selected by setting the TPUA.TSYR.SYNCj bit (j = 0, 3) to 1.

Table 27.12 Bits CCLR[2:0] (TPU1, TPU2, TPU4, TPU5)

Channel	Bits CCLR[2:0]*1			Description
	b7	b6	b5	
TPU1, TPU2, TPU4, TPU5	0	0	0	TCNT clearing disabled
	0	0	1	TCNT cleared by TGRA compare match/input capture
	0	1	0	TCNT cleared by TGRB compare match/input capture
	0	1	1	TCNT cleared by counter clearing for another channel performing synchronous clearing/ synchronous operation*2
	1	0	0	Setting prohibited
	1	0	1	Setting prohibited
	1	1	0	Setting prohibited
	1	1	1	Setting prohibited

Note 1. Bit 7 in TCR of TPU1, TPU2, TPU4, and TPU5 are reserved. These bits are read as 0. The write value should be 0.
Note 2. Synchronous operation is selected by setting the TPUA.TSYR.SYNCj bit (j = 1, 2, 4, 5) to 1.

27.2.2 Timer Mode Register (TMDR)

Address(es): TPU0.TMDR 0008 8111h, TPU1.TMDR 0008 8121h, TPU2.TMDR 0008 8131h, TPU3.TMDR 0008 8141h, TPU4.TMDR 0008 8151h, TPU5.TMDR 0008 8161h

	b7	b6	b5	b4	b3	b2	b1	b0
	ICSELD	ICSELB	BFB	BFA	MD[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	MD[3:0]	Mode Select	b3 b0 0 0 0 0: Normal operation 0 0 0 1: Setting prohibited 0 0 1 0: PWM mode 1 0 0 1 1: PWM mode 2 0 1 0 0: Phase counting mode 1*1 0 1 0 1: Phase counting mode 2*1 0 1 1 0: Phase counting mode 3*1 0 1 1 1: Phase counting mode 4*1 Settings other than above are prohibited.	R/W
b4	BFA*2	Buffer Operation A	0: TPUm.TGRA operates normally 1: TPUm.TGRA and TPUm.TGRC used together for buffer operation (m = 0, 3)	R/W
b5	BFB*3	Buffer Operation B	0: TPUm.TGRB operates normally 1: TPUm.TGRB and TPUm.TGRD used together for buffer operation (m = 0, 3)	R/W
b6	ICSELB	TGRB Input Capture Input Select	0: Input capture input source is TIOCBn pin 1: Input capture input source is TIOCAn pin (n = 0 to 5)	R/W
b7	ICSELD*3	TGRD Input Capture Input Select	0: Input capture input source is TIOCDn pin 1: Input capture input source is TIOCCn pin (n = 0, 3)	R/W

Note 1. Phase counting mode cannot be set for TPU0 and TPU3. A 0 should be written to bit 2 for them.
Note 2. Bit 4 of TPU1, TPU2, TPU4, and TPU5 that do not have TGRC is reserved. This bit is read as 0. The write value should be 0.
Note 3. Bits 5 and 7 of TPU1, TPU2, TPU4, and TPU5 that do not have TGRD are reserved. These bits are read as 0. The write value should be 0.

TPUm.TMDR settings should be made while TPUm.TCNT operation is stopped.

BFA Bit (Buffer Operation A)

Specifies whether TPUm.TGRA (m = 0, 3) is to normally operate, or TPUm.TGRA and TPUm.TGRC (m = 0, 3) are to be used together for buffer operation.

When TGRC is used as a buffer register, TGRC input capture/output compare is not generated.

BFB Bit (Buffer Operation B)

Specifies whether TPUm.TGRB (m = 0, 3) is to normally operate, or TPUm.TGRB and TPUm.TGRD (m = 0, 3) are to be used together for buffer operation.

When TGRD is used as a buffer register, TGRD input capture/output compare is not generated.

ICSELB Bit (TGRB Input Capture Input Select)

Selects the input capture input for TPUm.TGRB (m = 0 to 5).

This function allows measurement of high-level width and period of the input pulse on a TIOCAn input pin.

ICSELD Bit (TGRD Input Capture Input Select)

Selects the input capture input for TPUm.TGRD (m = 0, 3).

This function allows measurement of high-level width and period of the input pulse on a TIOCCn input pin.

27.2.3 Timer I/O Control Register (TIORH, TIORL, TIOR)

- TPU0.TIORH, TPU1.TIOR, TPU2.TIOR, TPU3.TIORH, TPU4.TIOR, TPU5.TIOR

Address(es): TPU0.TIORH 0008 8112h, TPU1.TIOR 0008 8122h, TPU2.TIOR 0008 8132h, TPU3.TIORH 0008 8142h, TPU4.TIOR 0008 8152h, TPU5.TIOR 0008 8162h

	b7	b6	b5	b4	b3	b2	b1	b0
	IOB[3:0]				IOA[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	IOA[3:0]	TGRA Control	See Table 27.13 to Table 27.18.*1	R/W
b7 to b4	IOB[3:0]	TGRB Control	See Table 27.13 to Table 27.18.*1	R/W

Note 1. If the IOn[3:0] bit (n = A, B) values are changed to output disabled (0000b or 0100b) during low/high/toggle output on compare match, the TIOCAn/TIOCBn pin (n = 0 to 5) is placed in high impedance state.

- TPU0.TIORL, TPU3.TIORL

Address(es): TPU0.TIORL 0008 8113h, TPU3.TIORL 0008 8143h

	b7	b6	b5	b4	b3	b2	b1	b0
	IOD[3:0]				IOC[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	IOC[3:0]	TGRC Control	See Table 27.19 and Table 27.20.*1	R/W
b7 to b4	IOD[3:0]	TGRD Control	See Table 27.19 and Table 27.20.*1	R/W

Note 1. If the IOn[3:0] bit (n = C, D) values are changed to output disabled (0000b or 0100b) during low/high/toggle output on compare match, the TIOCCn/TIOCDn pin (n = 0, 3) is placed in high impedance state.

TPU has two TIORH registers, one for TPU0 and TPU3, and two TIORL registers, one for TPU0 and TPU3, and also has four TIOR registers, one for TPU1, TPU2, TPU4, and TPU5. Thus the TPU has eight timer I/O control registers in total.

TIORH, TIORL, and TIOR control registers TGRA, TGRB, TGRC, and TGRD.

Note that TIORH, TIORL, and TIOR are affected by the TMDR setting. For details, see Table 27.13 to Table 27.20.

The initial output specified by TIORH, TIORL, and TIOR is valid when the counter is stopped (the TPUA.TSTR.CSTj bit (j = 0 to 5) is cleared to 0). In PWM mode 2, the output at the time when the TCNT is cleared to 0 is specified as the initial output.

When buffer operation has been selected for register TGRC or TGRD, the settings of the IOC[3:0] or IOD[3:0] bits become ineffective, and the TGRC or TGRD register simply operates as a buffer.

To specify the input capture pin in TIORH, TIORL, or TIOR, set the bit in the port direction register (PDR) for the corresponding pin to 0 (input port), and set the bit in the port mode register (PMR) to 1 (uses the pin as an I/O port for peripheral functions). For details, see section 22, I/O Ports.

IOA[3:0] Bits (TGRA Control)

Select the function of TPUm.TGRA (m = 0 to 5).

IOB[3:0] Bits (TGRB Control)

Select the function of TPUm.TGRB (m = 0 to 5).

IOC[3:0] Bits (TGRC Control)

Select the function of TPUm.TGRC (m = 0, 3).

IOD[3:0] Bits (TGRD Control)

Select the function of TPUm.TGRD (m = 0, 3).

Table 27.13 TPU0.TIORH

Bits IOA[3:0]				Description	
b3	b2	b1	b0	TPU0.TGRA Function	TIOCA0 Pin Function and Related Issue
0	0	0	0	Output compare register	Output disabled
0	0	0	1		Initial output is low output; low output at compare match
0	0	1	0		Initial output is low output; high output at compare match
0	0	1	1		Initial output is low output; toggle output at compare match
0	1	0	0		Output disabled
0	1	0	1		Initial output is high output; low output at compare match
0	1	1	0		Initial output is high output; high output at compare match
0	1	1	1		Initial output is high output; toggle output at compare match
1	0	0	0	Input capture register	Capture input source is TIOCA0 pin; input capture at rising edge
1	0	0	1		Capture input source is TIOCA0 pin; input capture at falling edge
1	0	1	x		Capture input source is TIOCA0 pin; input capture at both edges
1	1	x	x		Capture input source is TPU1 count clock; input capture at TPU1.TCNT count-up/ count-down*1

Bits IOB[3:0]				Description	
b7	b6	b5	b4	TPU0.TGRB Function	TIOCB0 Pin Function and Related Issue
0	0	0	0	Output compare register	Output disabled
0	0	0	1		Initial output is low output; low output at compare match
0	0	1	0		Initial output is low output; high output at compare match
0	0	1	1		Initial output is low output; toggle output at compare match
0	1	0	0		Output disabled
0	1	0	1		Initial output is high output; low output at compare match
0	1	1	0		Initial output is high output; high output at compare match
0	1	1	1		Initial output is high output; toggle output at compare match
1	0	0	0	Input capture register	Capture input source is TIOCB0 or TIOCA0 pin*2; input capture at rising edge
1	0	0	1		Capture input source is TIOCB0 or TIOCA0 pin*2; input capture at falling edge
1	0	1	x		Capture input source is TIOCB0 or TIOCA0 pin*2; input capture at both edges
1	1	x	x		Capture input source is TPU1 count clock; input capture at TPU1.TCNT count-up/ count-down*1

x: Don't care

Note 1. When the TPSC[2:0] bits in TPU1.TCR are set to 000b and PCLK/1 is used as the TPU1.TCNT count clock, this setting is invalid and input capture is not generated.

Note 2. Selected by the ICSELB bit in TPU0.TMDR.

Table 27.14 TPU1.TIOR

Bits IOA[3:0]				Description	
b3	**b2**	**b1**	**b0**	**TPU1.TGRA Function**	**TIOCA1 Pin Function and Related Issue**
0	0	0	0	Output compare register	Output disabled
0	0	0	1		Initial output is low output; low output at compare match
0	0	1	0		Initial output is low output; high output at compare match
0	0	1	1		Initial output is low output; toggle output at compare match
0	1	0	0		Output disabled
0	1	0	1		Initial output is high output; low output at compare match
0	1	1	0		Initial output is high output; high output at compare match
0	1	1	1		Initial output is high output; toggle output at compare match
1	0	0	0	Input capture register	Capture input source is TIOCA1 pin; input capture at rising edge
1	0	0	1		Capture input source is TIOCA1 pin; input capture at falling edge
1	0	1	x		Capture input source is TIOCA1 pin; input capture at both edges
1	1	x	x		Capture input source is TPU0.TGRA compare match/input capture; input capture at generation of TPU0.TGRA compare match/input capture

Bits IOB[3:0]				Description	
b7	**b6**	**b5**	**b4**	**TPU1.TGRB Function**	**TIOCB1 Pin Function and Related Issue**
0	0	0	0	Output compare register	Output disabled
0	0	0	1		Initial output is low output; low output at compare match
0	0	1	0		Initial output is low output; high output at compare match
0	0	1	1		Initial output is low output; toggle output at compare match
0	1	0	0		Output disabled

1	x	0	0	Input capture register	Capture input source is TIOCB5 or TIOCA5 pin*1; input capture at rising edge
1	x	0	1		Capture input source is TIOCB5 or TIOCA5 pin*1; input capture at falling edge
1	x	1	x		Capture input source is TIOCB5 or TIOCA5 pin*1; input capture at both edges

x: Don't care

Note 1. Selected by the ICSELB bit in TPU5.TMDR.

Table 27.19 TPU0.TIORL

Bits IOC[3:0]				Description	
b3	b2	b1	b0	TPU0.TGRC Function	TIOCC0 Pin Function and Related Issue
0	0	0	0	Output compare register*1	Output disabled
0	0	0	1		Initial output is low output; low output at compare match
0	0	1	0		Initial output is low output; high output at compare match
0	0	1	1		Initial output is low output; toggle output at compare match
0	1	0	0		Output disabled
0	1	0	1		Initial output is high output; low output at compare match
0	1	1	0		Initial output is high output; high output at compare match
0	1	1	1		Initial output is high output; toggle output at compare match
1	0	0	0	Input capture register*1	Capture input source is TIOCC0 pin; input capture at rising edge
1	0	0	1		Capture input source is TIOCC0 pin; input capture at falling edge
1	0	1	x		Capture input source is TIOCC0 pin; input capture at both edges
1	1	x	x		Capture input source is TPU1 count clock; input capture at TPU1.TCNT count-up/ count-down*3

Bits IOD[3:0]				Description	
b7	b6	b5	b4	TPU0.TGRD Function	TIOCD0 Pin Function and Related Issue
0	0	0	0	Output compare register*2	Output disabled
0	0	0	1		Initial output is low output; low output at compare match
0	0	1	0		Initial output is low output; high output at compare match
0	0	1	1		Initial output is low output; toggle output at compare match
0	1	0	0		Output disabled
0	1	0	1		Initial output is high output; low output at compare match
0	1	1	0		Initial output is high output; high output at compare match
0	1	1	1		Initial output is high output; toggle output at compare match
1	0	0	0	Input capture register*2	Capture input source is TIOCD0 or TIOCC0 pin*4; input capture at rising edge
1	0	0	1		Capture input source is TIOCD0 or TIOCC0 pin*4; input capture at falling edge
1	0	1	x		Capture input source is TIOCD0 or TIOCC0 pin*4; input capture at both edges
1	1	x	x		Capture input source is TPU1 count clock; input capture at TPU1.TCNT count-up/ count-down*3

x: Don't care

Note 1. When the BFA bit in TPU0.TMDR is set to 1 (TPU0.TGRA and TPU0.TGRC are used for buffer operation) and TPU0.TGRC is used as a buffer register, this setting is invalid and input capture/output compare is not generated.

Note 2. When the BFB bit in TPU0.TMDR is set to 1 (TPU0.TGRB and TPU0.TGRD are used for buffer operation) and TPU0.TGRD is used as a buffer register, this setting is invalid and input capture/output compare is not generated.

Note 3. When the TPSC[2:0] bits in TPU1.TCR are set to 000b and PCLK/1 is used as the TPU0.TCNT count clock, this setting is invalid and input capture is not generated.

Note 4. Selected by the ICSELD bit in TPU0.TMDR.

Table 27.20 TPU3.TIORL

Bits IOC[3:0]				Description	
b3	b2	b1	b0	TPU3.TGRC Function	TIOCC3 Pin Function and Related Issue
0	0	0	0	Output compare register*1	Output disabled
0	0	0	1		Initial output is low output; low output at compare match

0	0	0	0	Output compare register*2	Output disabled
0	0	0	1		Initial output is low output; low output at compare match
0	0	1	0		Initial output is low output; high output at compare match
0	0	1	1		Initial output is low output; toggle output at compare match
0	1	0	0		Output disabled
0	1	0	1		Initial output is high output; low output at compare match
0	1	1	0		Initial output is high output; high output at compare match
0	1	1	1		Initial output is high output; toggle output at compare match
1	0	0	0	Input capture register*2	Capture input source is TIOCD3 or TIOCC3 pin*4; input capture at rising edge
1	0	0	1		Capture input source is TIOCD3 or TIOCC3 pin*4; input capture at falling edge
1	0	1	x		Capture input source is TIOCD3 or TIOCC3 pin*4; input capture at both edges
1	1	X	x		Capture input source is TPU4 count clock; input capture at TPU4.TCNT count-up/ count-down*3

x: Don't care

Note 1. When the BFA bit in TPU3.TMDR is set to 1 (TPU3.TGRA and TPU3.TGRC are used for buffer operation) and TPU3.TGRC is used as a buffer register, this setting is invalid and input capture/output compare is not generated.

Note 2. When the BFB bit in TPU3.TMDR is set to 1 (TPU3.TGRB and TPU3.TGRD are used for buffer operation) and TPU3.TGRD is used as a buffer register, this setting is invalid and input capture/output compare is not generated.

Note 3. When the TPSC[2:0] bits in TPU4.TCR are set to 000b and PCLK/1 is used as the TPU3.TCNT count clock, this setting is invalid and input capture is not generated.

Note 4. Selected by the ICSELD bit in TPU3.TMDR.

27.2.4 Timer Interrupt Enable Register (TIER)

Address(es): TPU0.TIER 0008 8114h, TPU1.TIER 0008 8124h, TPU2.TIER 0008 8134h, TPU3.TIER 0008 8144h, TPU4.TIER 0008 8154h, TPU5.TIER 0008 8164h

	b7	b6	b5	b4	b3	b2	b1	b0
	TTGE	—	TCIEU	TCIEV	TGIED	TGIEC	TGIEB	TGIEA
Value after reset:	0	1	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TGIEA	TGRA Interrupt Enable	0: Interrupt requests (TGImA) disabled 1: Interrupt requests (TGImA) enabled (m = 0 to 5)	R/W
b1	TGIEB	TGRB Interrupt Enable	0: Interrupt requests (TGImB) disabled 1: Interrupt requests (TGImB) enabled (m = 0 to 5)	R/W
b2	TGIEC*1	TGRC Interrupt Enable	0: Interrupt requests (TGImC) disabled 1: Interrupt requests (TGImC) enabled (m = 0, 3)	R/W
b3	TGIED*1	TGRD Interrupt Enable	0: Interrupt requests (TGImD) disabled 1: Interrupt requests (TGImD) enabled (m = 0, 3)	R/W
b4	TCIEV	Overflow Interrupt Enable	0: Interrupt requests (TCImV) disabled 1: Interrupt requests (TCImV) enabled (m = 0 to 5)	R/W
b5	TCIEU*2	Underflow Interrupt Enable	0: Interrupt requests (TCImU) disabled 1: Interrupt requests (TCImU) enabled (m = 1, 2, 4, 5)	R/W
b6	—	Reserved	This bit is read as 1. The write value should be 1.	R/W
b7	TTGE*3	A/D Conversion Start Request Enable	0: A/D conversion start request generation disabled 1: A/D conversion start request generation enabled	R/W

Note 1. Bits 3 and 2 in TIER of TPU1, TPU2, TPU4, and TPU5 are reserved. These bits are read as 0. The write value should be 0.
Note 2. Bit 5 in TIER of TPU0 and TPU3 is reserved. This bit is read as 0. The write value should be 0.
Note 3. Bit 7 in TIER of TPU5 is reserved. This bit is read as 0. The write value should be 0.

TTGE Bit (A/D Conversion Start Request Enable)

Enables/disables generation of A/D conversion start requests by TPUm.TGRA (m = 0 to 4) input capture/compare match.

27.2.5 Timer Status Register (TSR)

Address(es): TPU0.TSR 0008 8115h, TPU1.TSR 0008 8125h, TPU2.TSR 0008 8135h, TPU3.TSR 0008 8145h, TPU4.TSR 0008 8155h, TPU5.TSR 0008 8165h

	b7	b6	b5	b4	b3	b2	b1	b0
	TCFD	—	TCFU	TCFV	TGFD	TGFC	TGFB	TGFA
Value after reset:	1	1	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TGFA	Input Capture/Output Compare Flag A	0: Input capture to TPUm.TGRA or compare match with TPUm.TGRA has not occurred. 1: Input capture to TPUm.TGRA or compare match with TPUm.TGRA has occurred. (m = 0 to 5)	R/W*2
b1	TGFB	Input Capture/Output Compare Flag B	0: Input capture to TPUm.TGRB or compare match with TPUm.TGRB has not occurred. 1: Input capture to TPUm.TGRB or compare match with TPUm.TGRB has occurred. (m = 0 to 5)	R/W*2
b2	TGFC*4	Input Capture/Output Compare Flag C	0: Input capture to TPUm.TGRC or compare match with TPUm.TGRC has not occurred. 1: Input capture to TPUm.TGRC or compare match with TPUm.TGRC has occurred. (m = 0, 3)	R/W*2
b3	TGFD*4	Input Capture/Output Compare Flag D	0: Input capture to TPUm.TGRD or compare match with TPUm.TGRD has not occurred. 1: Input capture to TPUm.TGRD or compare match with TPUm.TGRD has occurred. (m = 0, 3)	R/W*2
b4	TCFV	Overflow Flag	0: TPUm.TCNT has not overflowed. 1: TPUm.TCNT has overflowed. (m = 0 to 5)	R/W*2
b5	TCFU*3	Underflow Flag	0: TPUm.TCNT has not underflowed. 1: TPUm.TCNT has underflowed. (m = 1, 2, 4, 5)	R/W*2
b6	—	Reserved	This bit is read as 1. The write value should be 1.	R/W
b7	TCFD*1	Counting Direction Flag	0: TPUm.TCNT counts down. 1: TPUm.TCNT counts up. (m = 1, 2, 4, 5)	R

Note 1. Bit 7 of registers TPU0.TSR and TPU3.TSR is reserved. The bit is read as 1. The write value should be 1.
Note 2. Only writing 0 to this bit is possible; this clears the flag.
Note 3. Bit 5 of registers TPU0.TSR and TPU3.TSR is reserved. The bit is read as 0. The write value should be 0.
Note 4. Bits 2 and 3 of registers TPU1.TSR, TPU2.TSR, TPU4.TSR and TPU5.TSR are reserved. The bits are read as 0. The write value should be 0.

TGFA Flag (Input Capture/Output Compare Flag A)

This status flag indicates that input capture to TPUm.TGRA or compare match with TPUm.TGRA (m = 0 to 5) has occurred.

[Setting conditions]

- When TPUm.TGRA holds the value for comparison in output-compare operations, TPUm.TCNT matches TPUm.TGRA.
- When TPUm.TGRA is serving as an input-capture register, the input-capture signal has caused transfer of the value in TPUm.TCNT to TPUm.TGRA.

[Clearing conditions]

- Activation of the DTC by the TGImA interrupt and clearing of the DTC.MRB.DISEL bit.
- Writing 0 to TGFA after reading its value as 1.

TGFB Flag (Input Capture/Output Compare Flag B)

This status flag indicates that input capture to TPUm.TGRB or compare match with TPUm.TGRB (m = 0 to 5) has occurred.

[Setting conditions]

- When TPUm.TGRB holds the value for comparison in output-compare operations, TPUm.TCNT matches TPUm.TGRB.
- When TPUm.TGRB is serving as an input-capture register, the input-capture signal has caused transfer of the value in TPUm.TCNT to TPUm.TGRB.

[Clearing conditions]

- Activation of the DTC by the TGImB interrupt and clearing of the DTC.MRB.DISEL bit.
- Writing 0 to TGFB after reading its value as 1.

TGFC Flag (Input Capture/Output Compare Flag C)

This status flag indicates that input capture to TPUm.TGRC or compare match with TPUm.TGRC (m = 0, 3) has occurred.

[Setting conditions]

- When TPUm.TGRC holds the value for comparison in output-compare operations, TPUm.TCNT matches TPUm.TGRC.
- When TPUm.TGRC is serving as an input-capture register, the input-capture signal has caused transfer of the value in TPUm.TCNT to TPUm.TGRC.

[Clearing conditions]

- Activation of the DTC by the TGImC interrupt and clearing of the DTC.MRB.DISEL bit.
- Writing 0 to TGFC after reading its value as 1.

TGFD Flag (Input Capture/Output Compare Flag D)

This status flag indicates that input capture to TPUm.TGRD or compare match with TPUm.TGRD (m = 0, 3) has occurred.

[Setting conditions]

- When TPUm.TGRD holds the value for comparison in output-compare operations, TPUm.TCNT matches TPUm.TGRD.
- When TPUm.TGRD is serving as an input-capture register, the input-capture signal has caused transfer of the value in TPUm.TCNT to TPUm.TGRD.

[Clearing conditions]

- Activation of the DTC by the TGImD interrupt and clearing of the DTC.MRB.DISEL bit.
- Writing 0 to TGFD after reading its value as 1.

TCFV Flag (Overflow Flag)

This status flag indicates an overflow of TPUm.TCNT (m = 0 to 5).

[Setting condition]

- Overflow of the value in TPUm.TCNT (TCNT counted from FFFFh to 0000h).

[Clearing condition]

- Writing 0 to TCFV after reading its value as 1.

TCFU Flag (Underflow Flag)

This status flag indicates an underflow of TPUm.TCNT (m = 1, 2, 4, 5).

[Setting condition]

- Underflow of the value in TPUm.TCNT (TCNT counted from 0000h to FFFFh).

[Clearing condition]

- Writing 0 to TCFU after reading its value as 1.

27.2.6 Timer Counter (TCNT)

Address(es): TPU0.TCNT 0008 8116h, TPU1.TCNT 0008 8126h, TPU2.TCNT 0008 8136h, TPU3.TCNT 0008 8146h, TPU4.TCNT 0008 8156h, TPU5.TCNT 0008 8166h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

TPUm.TCNT is a readable/writable counter that counts the internal clock or external events.

27.2.7 Timer General Register A (TGRA)
Timer General Register B (TGRB)
Timer General Register C (TGRC)
Timer General Register D (TGRD)

Address(es): TPU0.TGRA 0008 8118h, TPU0.TGRB 0008 811Ah, TPU0.TGRC 0008 811Ch, TPU0.TGRD 0008 811Eh, TPU1.TGRA 0008 8128h, TPU1.TGRB 0008 812Ah, TPU2.TGRA 0008 8138h, TPU2.TGRB 0008 813Ah, TPU3.TGRA 0008 8148h, TPU3.TGRB 0008 814Ah, TPU3.TGRC 0008 814Ch, TPU3.TGRD 0008 814Eh, TPU4.TGRA 0008 8158h, TPU4.TGRB 0008 815Ah, TPU5.TGRA 0008 8168h, TPU5.TGRB 0008 816Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

TPU has 16 TGR registers in total, four each for TPU0 and TPU3, and two each for TPU1, TPU2, TPU4, and TPU5. TPUm.TGRA (m = 0 to 5), TPUm.TGRB (m = 0 to 5), TPUm.TGRC (m = 0, 3), and TPUm.TGRD (m = 0, 3) are readable/writable registers with a dual function as output compare and input capture registers.
TPUm.TGRC and TPUm.TGRD can also be specified for operation as buffer registers. Register combinations during buffer operations are TPUm.TGRA—TPUm.TGRC and TPUm.TGRB—TPUm.TGRD.

27.2.8 Timer Start Register (TSTR)

Address(es): TPUA.TSTR 0008 8100h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	CST5	CST4	CST3	CST2	CST1	CST0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CST0	Counter Start 0	0: TCNT count operation is stopped 1: TCNT performs count operation	R/W
b1	CST1	Counter Start 1		R/W
b2	CST2	Counter Start 2		R/W
b3	CST3	Counter Start 3		R/W
b4	CST4	Counter Start 4		R/W
b5	CST5	Counter Start 5		R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

TPUA.TSTR starts or stops TCNT operation for TPU0 to TPU5.
Before setting the operating mode in TPUm.TMDR or setting the TPUm.TCNT count clock in TPUm.TCR, stop the TPUm.TCNT operation.

CSTn Bit (Counter Start n) (n = 0 to 5)

This bit starts or stop the TCNT.
When the CSTn bit is cleared to 0 with CSTn = 1 and the corresponding TIOCyn pin (y = A to D; n = 0 to 5) specified for output, count operation stops but the output compare output level of the corresponding TIOCyn pin is retained.
If TIORH, TIORL, or TIOR is written to when the CSTn bit is 0, the pin output level will be changed to the set initial output value.

27.2.9 Timer Synchronous Register (TSYR)

Address(es): TPUA.TSYR 0008 8101h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	SYNC5	SYNC4	SYNC3	SYNC2	SYNC1	SYNC0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SYNC0	Timer Synchronization 0	0: TCNT operates independently (TCNT setting/clearing is unrelated to other channels) 1: TCNT performs synchronous operation*1 (TCNT synchronous setting/synchronous clearing is possible)	R/W
b1	SYNC1	Timer Synchronization 1		R/W
b2	SYNC2	Timer Synchronization 2		R/W
b3	SYNC3	Timer Synchronization 3		R/W
b4	SYNC4	Timer Synchronization 4		R/W
b5	SYNC5	Timer Synchronization 5		R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. To set synchronous operation, the SYNCn bit (n = 0 to 5) for at least two channels must be set to 1. To set synchronous clearing, the TCNT clearing source must also be set by the TCR.CCLR[2:0] bits in addition to the SYNCn bit.

TPUA.TSYR selects independent operation or synchronous operation for TCNT of TPU0 to TPU5.

SYNCn Bit (Timer Synchronization n) (n = 0 to 5)

This bit selects whether the TCNT operation is independent of or synchronized with TCNT of other channels. When synchronous operation is selected, synchronous setting of multiple TCNT and synchronous clearing through counter clearing on another channel are possible.

27.2.10 Noise Filter Control Register (NFCR)

Address(es): TPU0.NFCR 0008 8108h, TPU1.NFCR 0008 8109h, TPU2.NFCR 0008 810Ah, TPU3.NFCR 0008 810Bh, TPU4.NFCR 0008 810Ch, TPU5.NFCR 0008 810Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	NFCS[1:0]		NFDEN	NFCEN	NFBEN	NFAEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	NFAEN	Noise Filter Enable A	0: The noise filter for TIOCAm is disabled. 1: The noise filter for TIOCAm is enabled. (m = 0 to 5)	R/W
b1	NFBEN	Noise Filter Enable B	0: The noise filter for TIOCBm is disabled. 1: The noise filter for TIOCBm is enabled. (m = 0 to 5)	R/W
b2	NFCEN*1	Noise Filter Enable C	0: The noise filter for TIOCCm is disabled. 1: The noise filter for TIOCCm is enabled. (m = 0, 3)	R/W
b3	NFDEN*1	Noise Filter Enable D	0: The noise filter for TIOCDm is disabled. 1: The noise filter for TIOCDm is enabled. (m = 0, 3)	R/W
b5, b4	NFCS[1:0]	Noise Filter Clock Select	00: PCLK/1 01: PCLK/8 10: PCLK/32 11: Clock source that drives counting	R/W
b7, b6	—	Reserved	These bits are read as 0. Writing to these bits is not possible.	R

Note 1. Bits 2 and 3 of TPU1.NFCR, TPU2.NFCR, TPU4.NFCR, and TPU5.NFCR are reserved. The bits are read as 0. Writing to these bits is not possible.

Only set the TPUm.NFCR registers while the TPUm.TCNT is stopped.

NFAEN Bit (Noise Filter Enable A)

This bit disables or enables the noise filter for the TIOCAm pin (m = 0 to 5).

Since unexpected edges may be internally generated when the value of NFAEN is changed, select the output compare function in the timer I/O control register before changing the NFAEN value.

NFBEN Bit (Noise Filter Enable B)

This bit disables or enables the noise filter for the TIOCBm pin (m = 0 to 5).

Since unexpected edges may be internally generated when the value of NFBEN is changed, select the output compare function in the timer I/O control register before changing the NFBEN value.

NFCEN Bit (Noise Filter Enable C)

This bit disables or enables the noise filter for the TIOCCm pin (m = 0, 3).

Since unexpected edges may be internally generated when the value of NFCEN is changed, select the output compare function in the timer I/O control register before changing the NFCEN value.

NFDEN Bit (Noise Filter Enable D)

This bit disables or enables the noise filter for the TIOCDm pin (m = 0, 3).

Since unexpected edges may be internally generated when the value of NFDEN is changed, select the output compare function in the timer I/O control register before changing the NFDEN value.

NFCS[1:0] Bits (Noise Filter Clock Select)

These bits select the sampling clock for the noise filter.

When the count source is selected with NFCS[1:0] bits set to 11b, the clock that can be used as sampling clock are the internal clocks other than PCLK/1 specified with the TPSC[2:0] bits and the external clock. To select the PCLK/1 as both the count clock and the sampling clock, set the NFCS[1:0] bits to 00b.

The input-capture signal is sampled on rising edges of the selected clock signal. If the sampled levels match three times in a row, the given level is passed through as the input-capture signal. If the levels do not match, the existing value is retained.

After setting the NFCS[1:0] bits, wait for two selected sampling periods before setting the input capture function.

27.3 Operation

27.3.1 Basic Functions

Each channel has a TPUm.TCNT and a TPUm.TGRy register (y = A to D).
TCNT is a 16-bit up-counter, which can function as a free-running counter, periodic counter, or event counter.
TGRy can be used as an input capture register or output compare register.

(1) Counter Operation

When the CSTj bit (j = 0 to 5) in TPUA.TSTR is set to 1, the TCNT for the corresponding channel starts counting.

(a) Example of count operation setting procedure

Figure 27.2 shows an example of the count operation setting procedure.

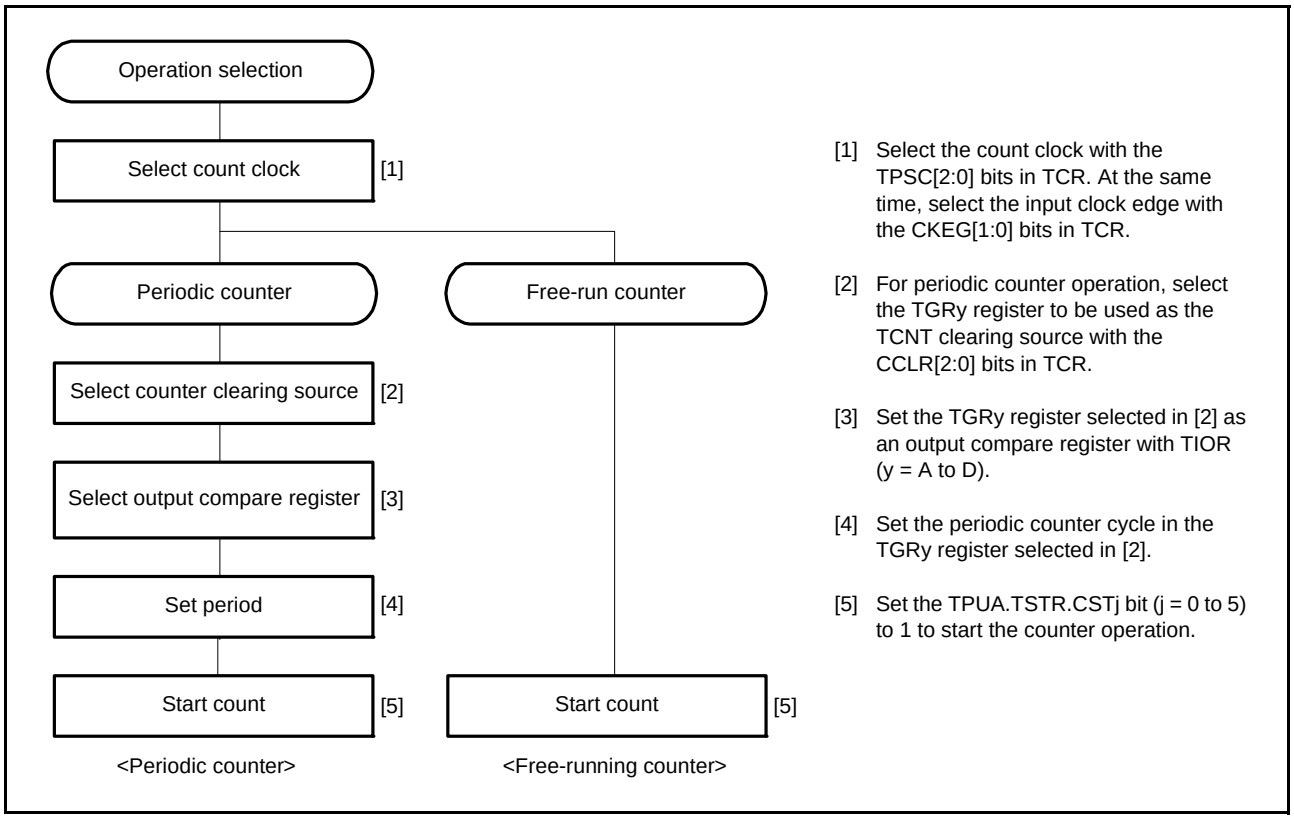

Figure 27.2 Example of Counter Operation Setting Procedure

(b) Free-running count operation and periodic count operation

Immediately after a reset, TPUm.TCNT are all set as free-running counters. When the relevant bit in TPUA.TSTR is set to 1, the corresponding TCNT starts up-count operation as a free-running counter. When TCNT overflows (changes from FFFFh to 0000h), the TPU requests an interrupt. After an overflow, TCNT restarts counting up from 0000h.
Figure 27.3 shows free-running counter operation.

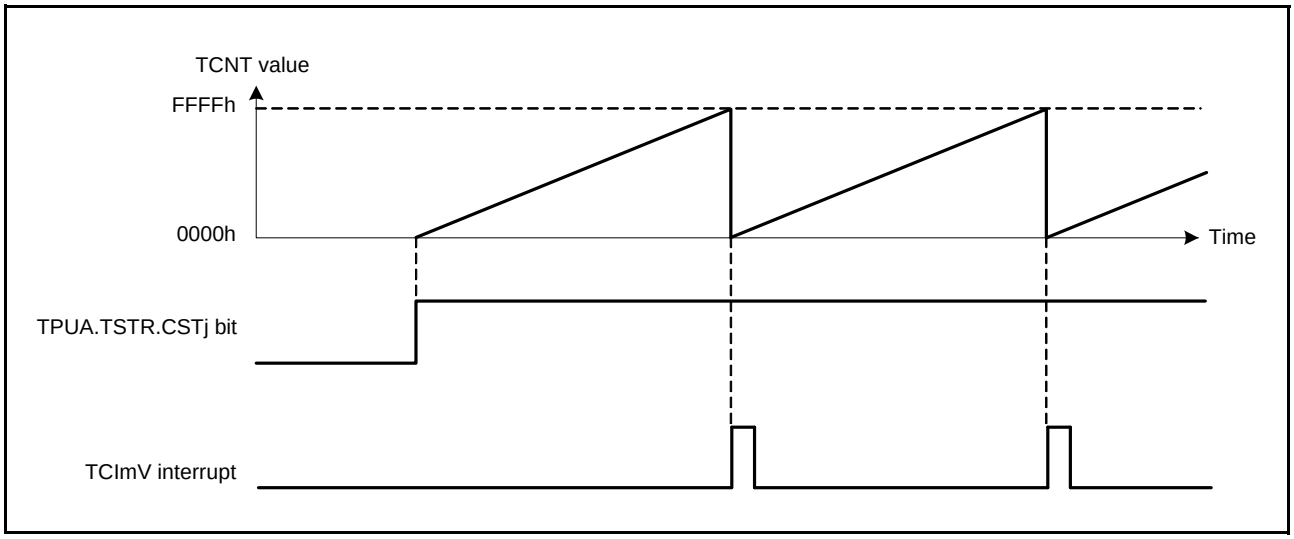

Figure 27.3 Free-Running Counter Operation

When compare match is selected as the TCNT clearing source, the TCNT for the relevant channel performs periodic count operation. The TPUm.TGRy for setting the period is set as an output compare register, and counter clearing by compare match is selected by the TPUm.TCR.CCLR[2:0] bits. After the settings have been made, TCNT starts count-up operation as a periodic counter when the corresponding bit in TPUA.TSTR is set to 1. When the count value matches the TGRy value, TCNT is cleared to 0000h.
At this time, the TPU requests an interrupt. After a compare match, TCNT restarts counting up from 0000h.
Figure 27.4 shows periodic counter operation.

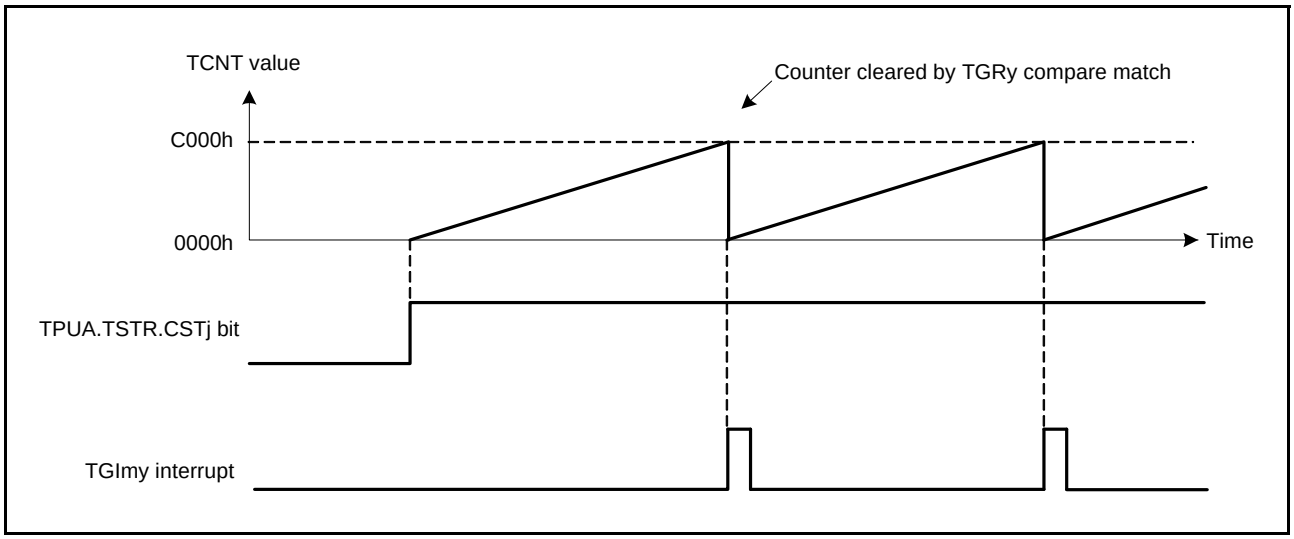

Figure 27.4 Periodic Counter Operation

(2) Waveform Output by Compare Match

The TPU can perform low, high, or toggle output from the corresponding output pin using a compare match.

(a) Example of setting procedure for waveform output by compare match

Figure 27.5 shows an example of the setting procedure for waveform output by a compare match.

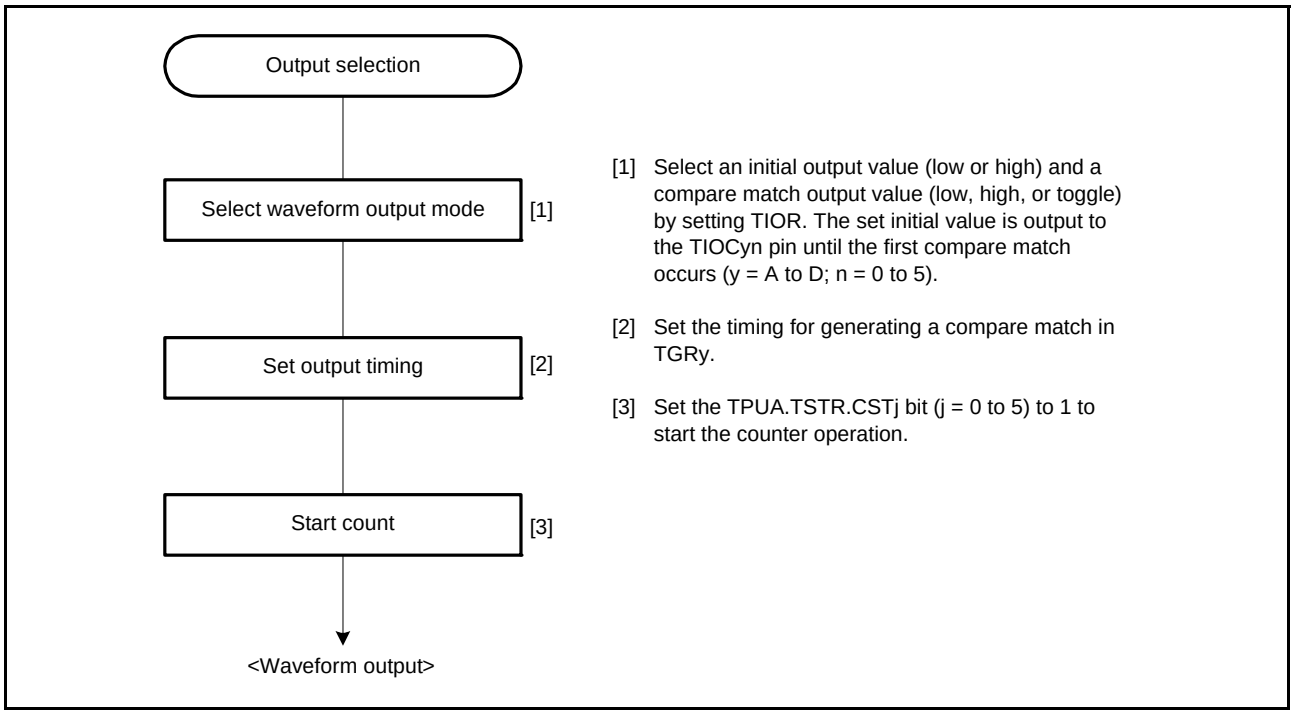

Figure 27.5 Example of Setting Procedure for Waveform Output by Compare Match

(b) Examples of waveform output operation

Figure 27.6 shows an example of low output/high output.

In this example, TPUm.TCNT has been set as a free-running counter, and settings have been made so that high is output by compare match A and low is output by compare match B. When the set level and the pin level match, the pin level does not change.

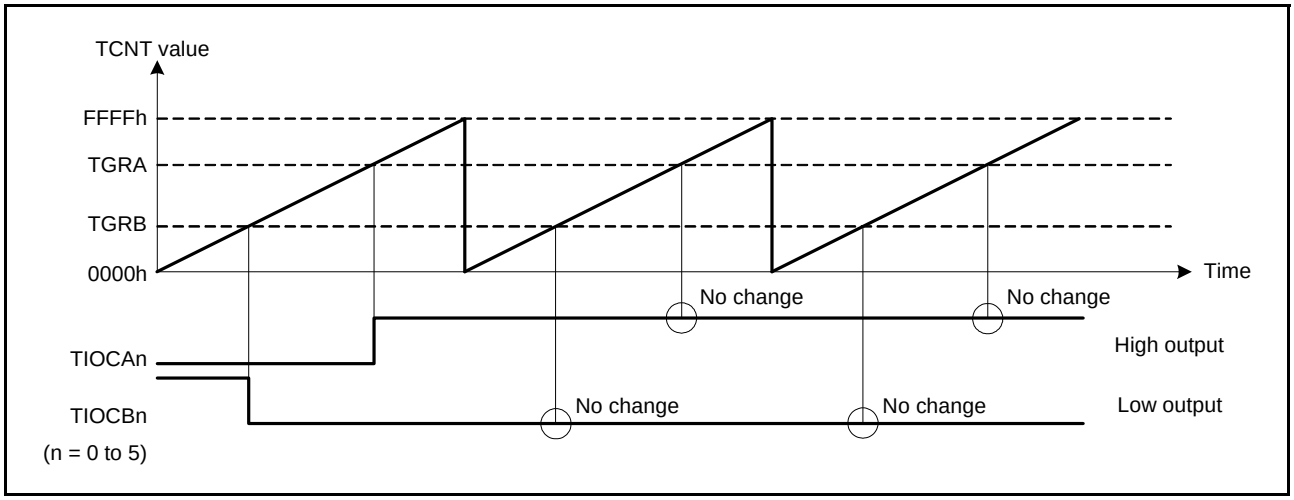

Figure 27.6 Example of Low-Output/High-Output Operation

Figure 27.7 shows an example of toggle output.
In this example, TPUm.TCNT has been set as a periodic counter (with counter clearing performed by compare match B), and settings have been made so that output is toggled by both compare match A and compare match B.

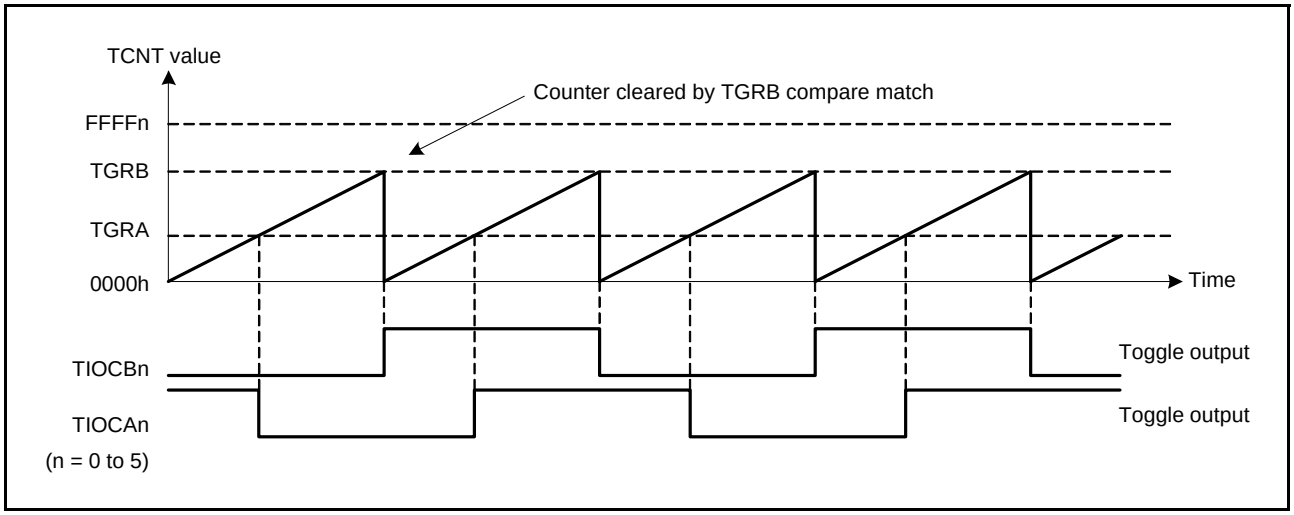

Figure 27.7 Example of Toggle Output Operation

(3) Input Capture Function

The TPUm.TCNT value can be transferred to TPUm.TGRy on detection of the TIOCyn pin (y = A to D; n = 0 to 5) input edge.
The rising edge, the falling edge, or both edges can be selected as the detection edge. It is also possible to specify the count clock or compare match signal of TPU0, TPU1, TPU3, and TPU4 as the input capture source. Noise filtering can be applied to the input capture input.

Note: Even if the counter is halted, an input capture is generated, and flag and interrupt signals are generated.
Note: When another channel's count clock is used as the input capture input for TPU0 and TPU3, PCLK/1 should not be selected as the count clock used for input capture input. Input capture will not be generated if PCLK/1 is selected.

(a) Example of setting procedure for input capture operation

Figure 27.8 shows an example of the setting procedure for input capture operation.

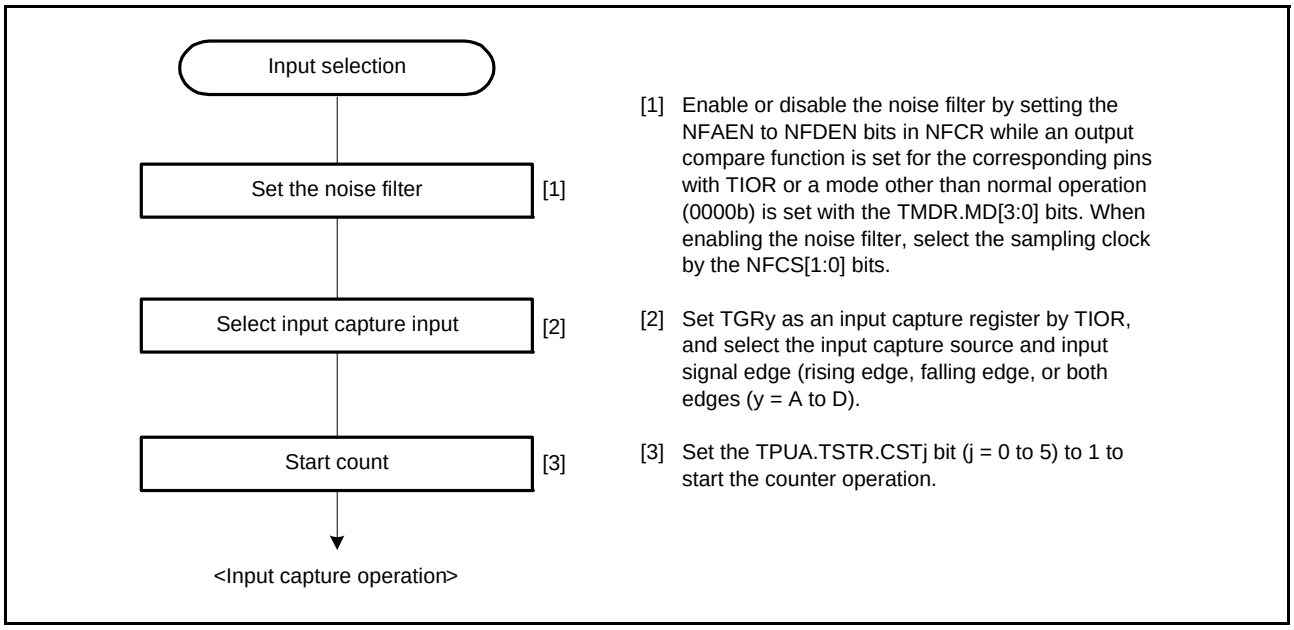

Figure 27.8 Example of Setting Procedure for Input Capture Operation

(b) Example of input capture operation

Figure 27.9 shows an example of input capture operation when the noise filter is stopped.
In this example, both rising and falling edges have been selected as the TIOCAn pin input capture input edge, the falling edge has been selected as the TIOCBn pin input capture input edge, and counter clearing by TPUm.TGRB input capture has been set for TPUm.TCNT.

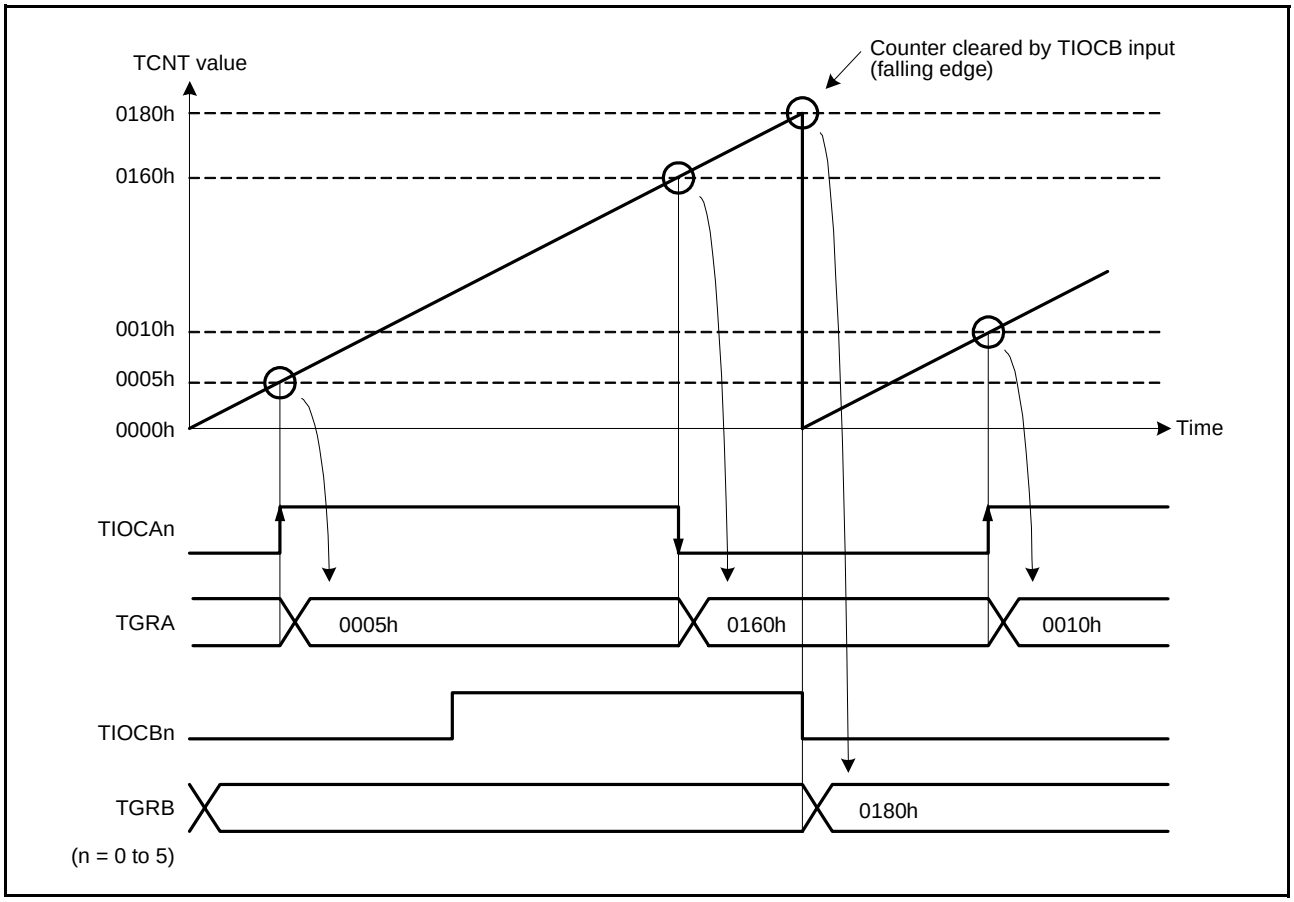

Figure 27.9 Example of Input Capture Operation (with Noise Filter Stopped)

When noise filtering is enabled, see Figure 27.30.

27.3.2 Synchronous Operation

In synchronous operation, the values in multiple TPUm.TCNT can be rewritten simultaneously (synchronous setting). Also, multiple TCNT can be cleared simultaneously (synchronous clearing) by making the appropriate setting in TPUm.TCR.
Synchronous operation enables TPUm.TGRy to be incremented with respect to a single time base.
TPU0 to TPU5 can all be set for synchronous operation.

(1) Example of Synchronous Operation Setting Procedure

Figure 27.10 shows an example of the synchronous operation setting procedure.

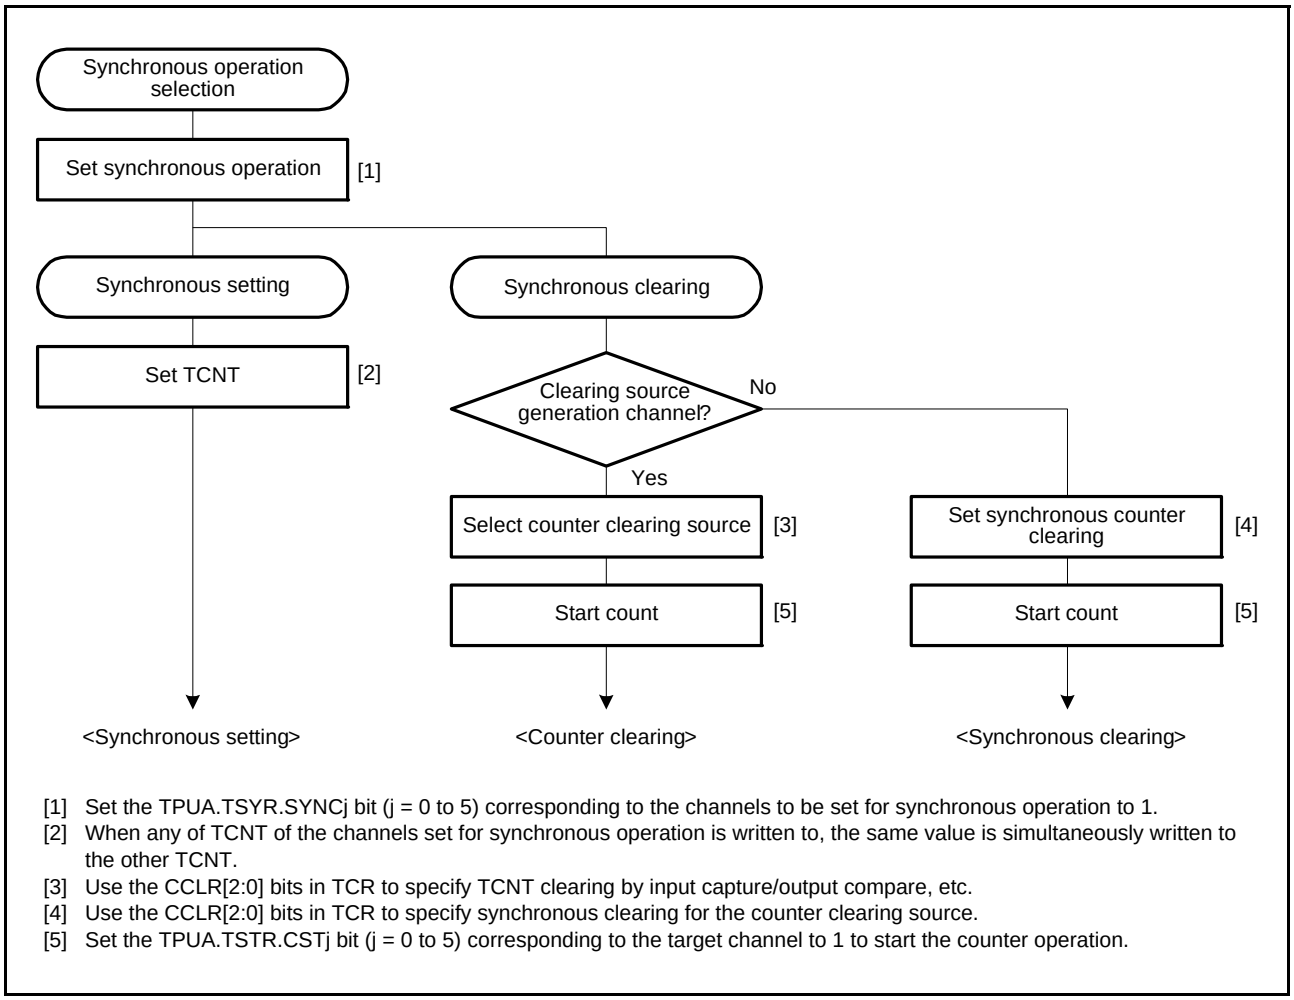

Figure 27.10 Example of Synchronous Operation Setting Procedure

(2) Example of Synchronous Operation

Figure 27.11 shows an example of synchronous operation.
In this example, synchronous operation and PWM mode 1 have been set for TPU0 to TPU2, TPU0.TGRB compare match has been set as the TPU0 counter clearing source, and synchronous clearing has been set for the TPU1 and TPU2 counter clearing source.
Three-phase PWM waveforms are output from pins TIOCA0, TIOCA1, and TIOCA2. At this time, synchronous setting and synchronous clearing by TPU0.TGRB compare match are performed for TPUm.TCNT of TPU0 to TPU2, and the data set in TPU0.TGRB is used as the PWM cycle.
For details on PWM modes, see section 27.3.5, PWM Modes.

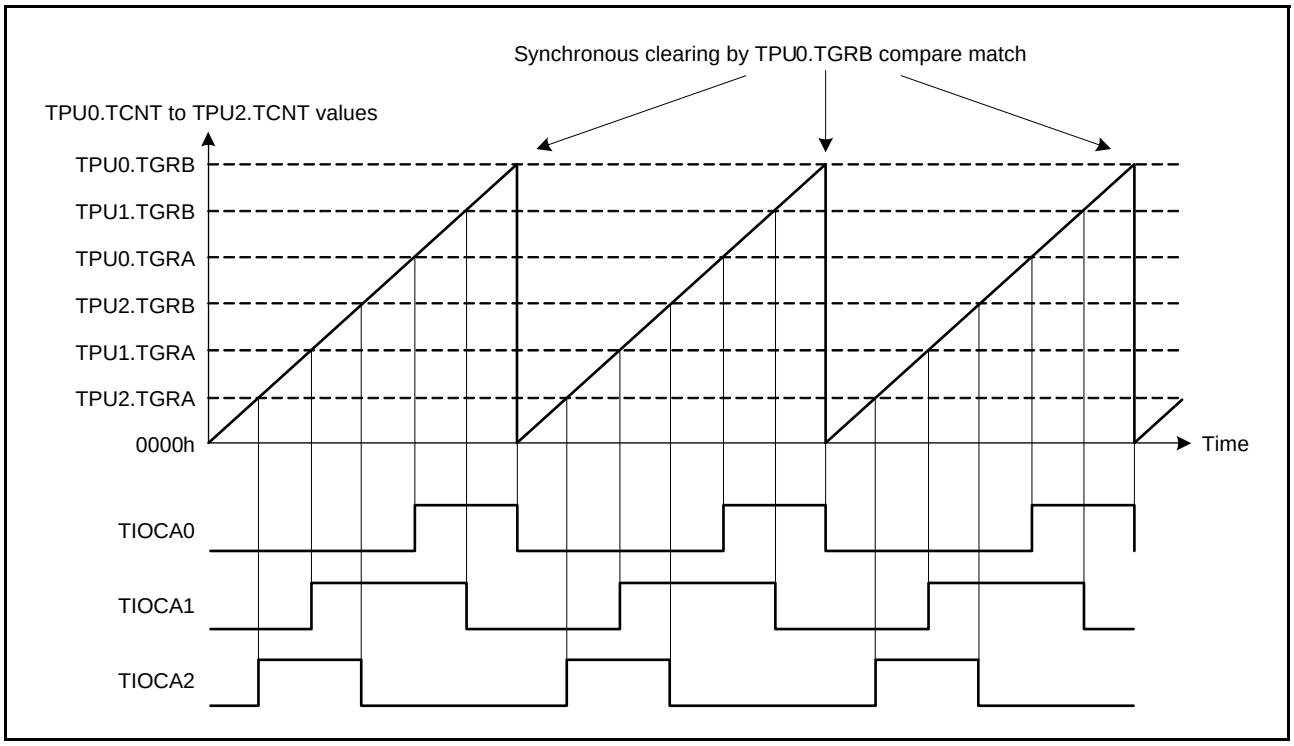

Figure 27.11 Example of Synchronous Operation

27.3.3 Buffer Operation

Buffer operation, provided for TPU0 and TPU3, enables TPUm.TGRC and TPUm.TGRD to be used as buffer registers. Buffer operation differs depending on whether TPUm.TGRy has been set as an input capture register or a compare match register.

Table 27.21 lists the register combinations used in buffer operation.

Table 27.21 Register Combinations

Channel	Timer General Register	Buffer Register
TPU0	TPU0.TGRA	TPU0.TGRC
	TPU0.TGRB	TPU0.TGRD
TPU3	TPU3.TGRA	TPU3.TGRC
	TPU3.TGRB	TPU3.TGRD

- When TPUm.TGRy is an output compare register

When a compare match occurs, the value in the buffer register for the corresponding channel is transferred to the timer general register.

This operation is shown in Figure 27.12.

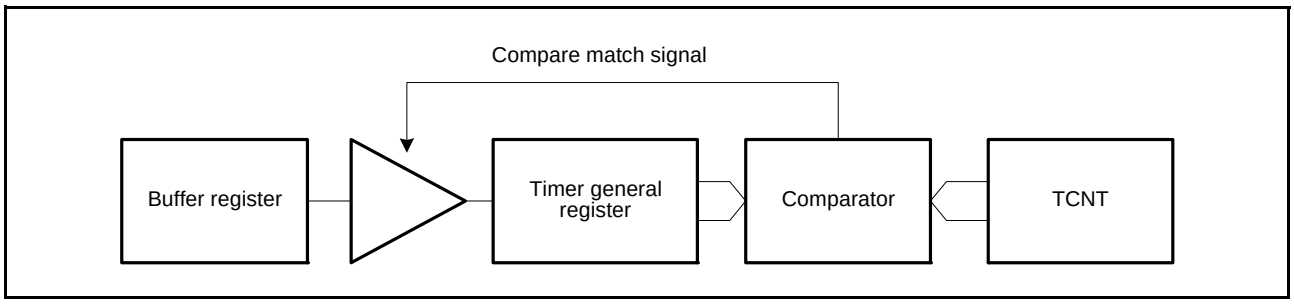

Figure 27.12 Compare Match Buffer Operation

- When TPUm.TGRy is an input capture register

When input capture occurs, the value in TPUm.TCNT is transferred to TGRy and the value previously held in TGRy is simultaneously transferred to the buffer register.

This operation is shown in Figure 27.13.

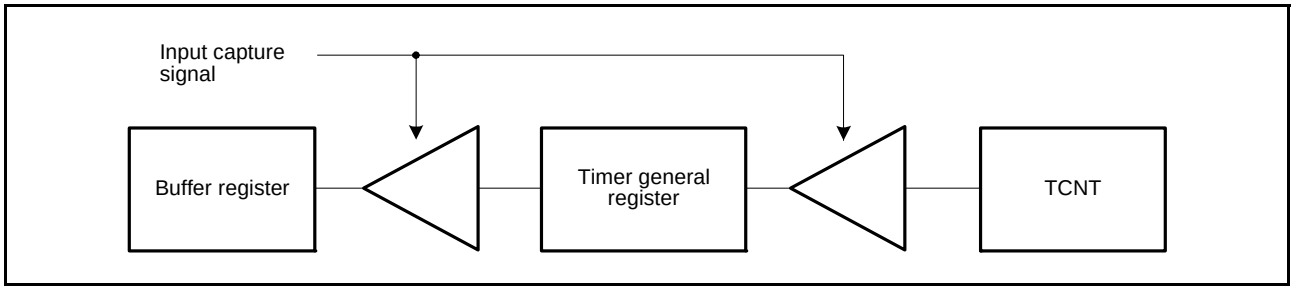

Figure 27.13 Input Capture Buffer Operation

(1) Example of Buffer Operation Setting Procedure

Figure 27.14 shows an example of the buffer operation setting procedure.

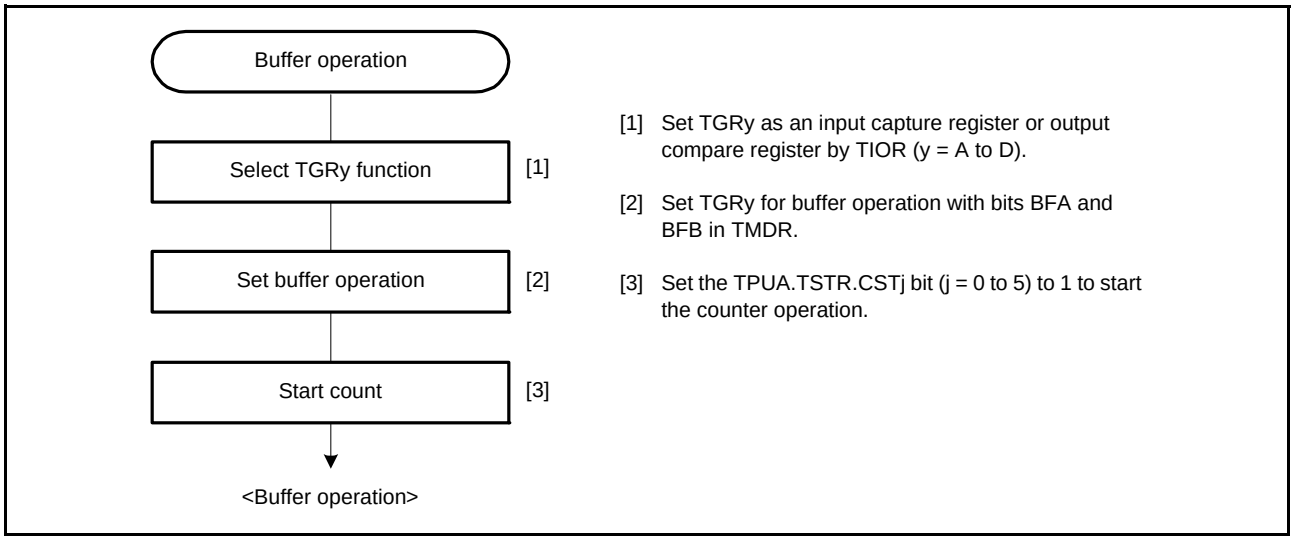

Figure 27.14 Example of Buffer Operation Setting Procedure

(2) Examples of Buffer Operation

(a) When TPUm.TGRy is an output compare register

Figure 27.15 shows an operation example in which PWM mode 1 has been set for TPU0, and buffer operation has been set for TPU0.TGRA and TPU0.TGRC. The settings used in this example are TPU0.TCNT clearing by compare match B, high output at compare match A, and low output at compare match B.

As buffer operation has been set, when compare match A occurs, the output changes and the TPU0.TGRC value is simultaneously transferred to TPU0.TGRA. This operation is repeated each time compare match A occurs.

For details on PWM modes, see section 27.3.5, PWM Modes.

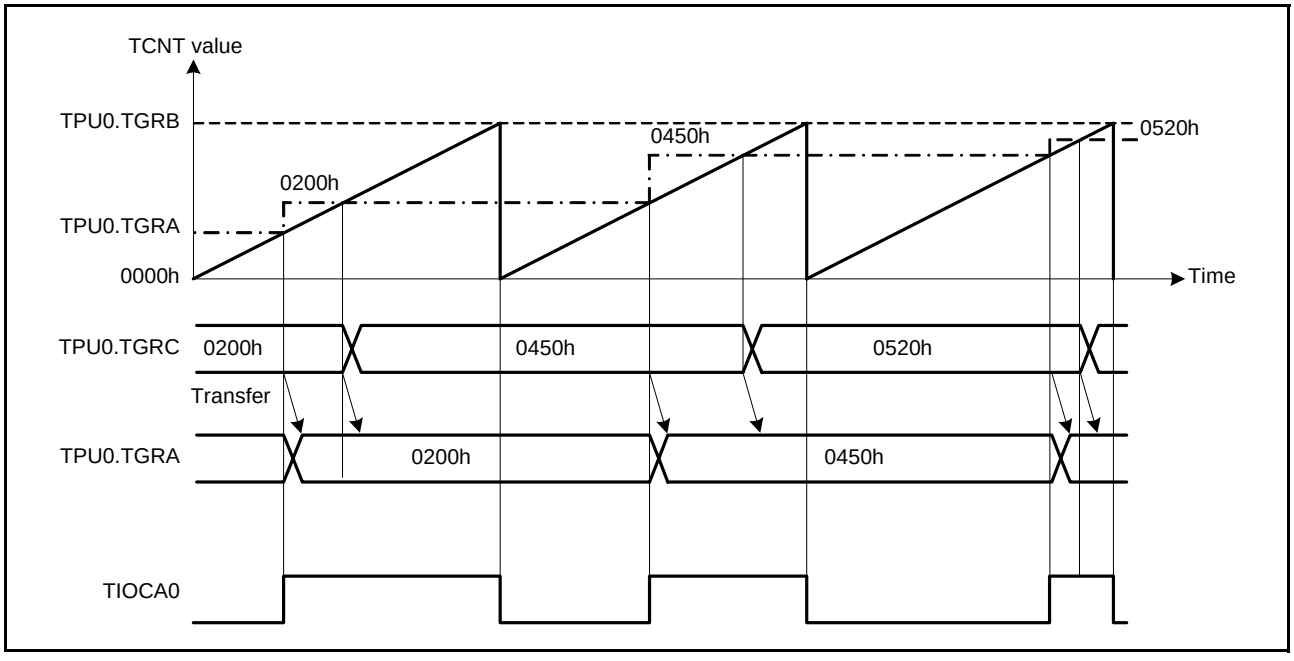

Figure 27.15 Example of Buffer Operation (1)

(b) When TPUm.TGRy is an input capture register

Figure 27.16 shows an operation example in which TPUm.TGRA has been set as an input capture register, and buffer operation has been set for the TGRA register and TPUm.TGRC.
Counter clearing by TGRA input capture has been set for TPUm.TCNT, and both rising and falling edges have been selected as the TIOCAn pin input capture input edge.
As buffer operation has been set, when the TCNT value is stored in TGRA upon occurrence of input capture A, the value previously stored in TGRA is simultaneously transferred to TGRC.

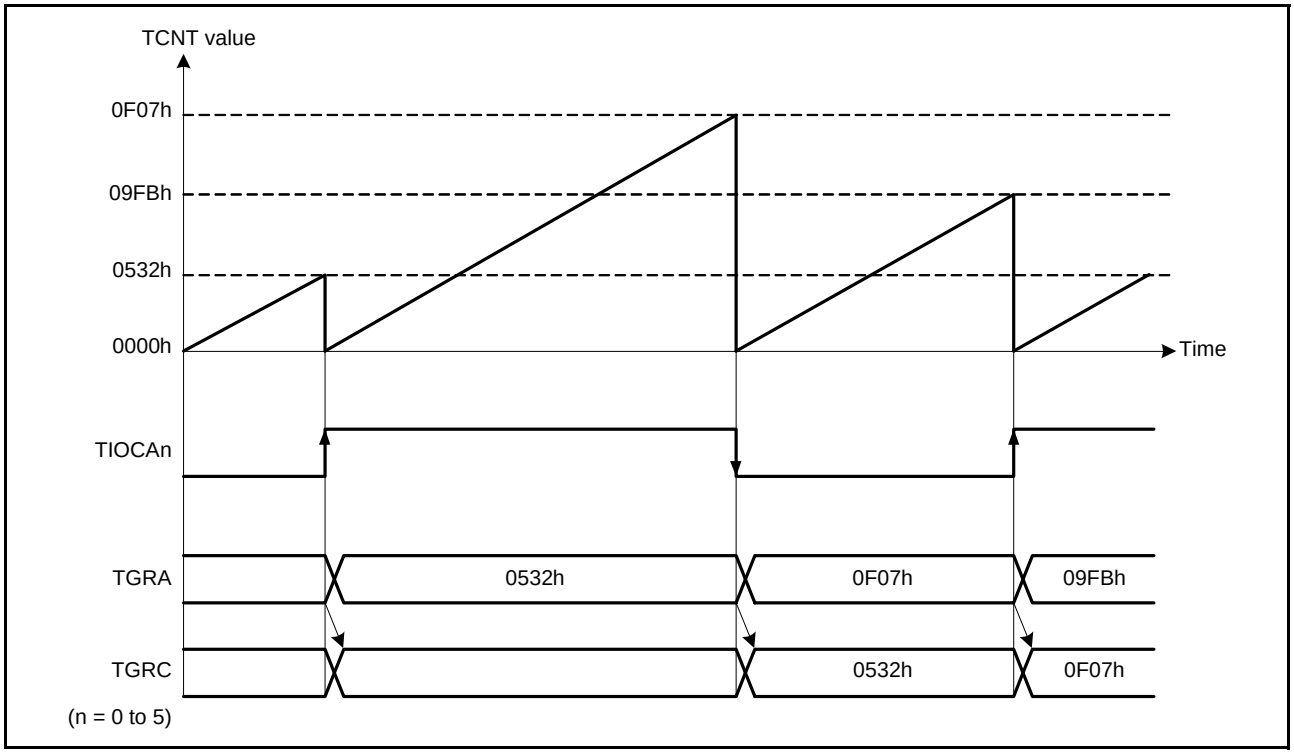

Figure 27.16 Example of Buffer Operation (2)

27.3.4 Cascaded Operation

In cascaded operation, two 16-bit counters for different channels are used together as a 32-bit counter.
This function works by counting the TPU1 (TPU4) count clock at overflow/underflow of TPU2.TCNT (TPU5.TCNT) as set by the TPSC[2:0] bits in TPU1.TCR (TPSC[2:0] bits in TPU4.TCR).
Underflow occurs only when the lower 16-bit TPUm.TCNT is in phase counting mode.
Table 27.22 lists the register combinations used in cascaded operation.

Note: When phase counting mode is set for TPU1 or TPU4, the count clock setting is invalid and the counter operates independently in phase counting mode.

Table 27.22 Cascaded Combinations

Combination	Upper 16 Bits	Lower 16 Bits
TPU1 and TPU2	TPU1.TCNT	TPU2.TCNT
TPU4 and TPU5	TPU4.TCNT	TPU5.TCNT

(1) Example of Cascaded Operation Setting Procedure

Figure 27.17 shows an example of the setting procedure for cascaded operation.

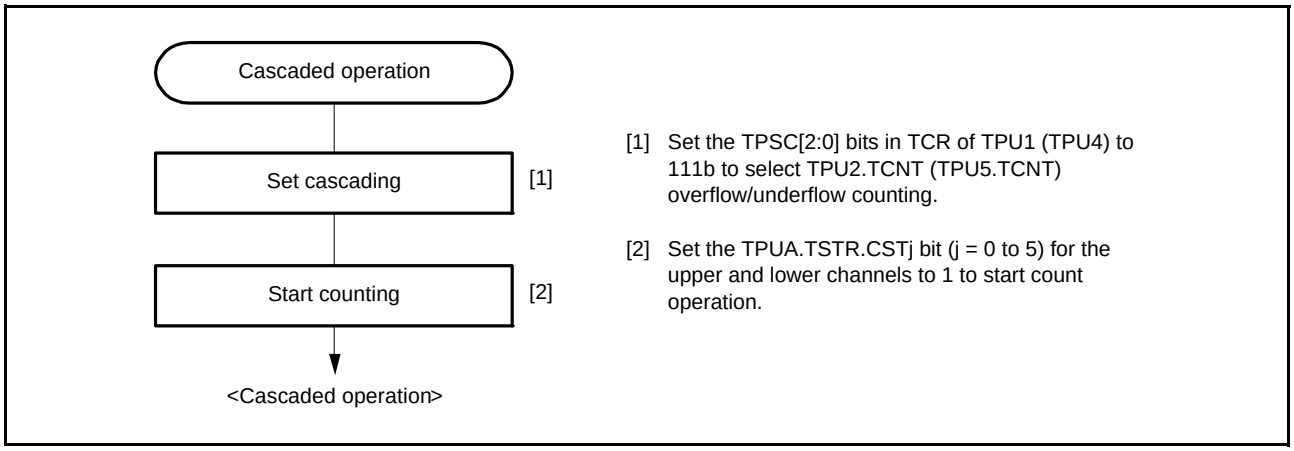

Figure 27.17 Cascaded Operation Setting Procedure

(2) Examples of Cascaded Operation

Figure 27.18 shows the operation when counting upon TPU2.TCNT overflow/underflow has been set for TPU1.TCNT, TPU1.TGRA and TPU2.TGRA have been set as input capture registers, and the rising edge of the TIOCA1 and TIOCA2 pins has been selected.

When a rising edge is input to the TIOCA1 and TIOCA2 pins simultaneously, the upper 16 bits of the 32-bit data are transferred to TPU1.TGRA, and the lower 16 bits to TPU2.TGRA.

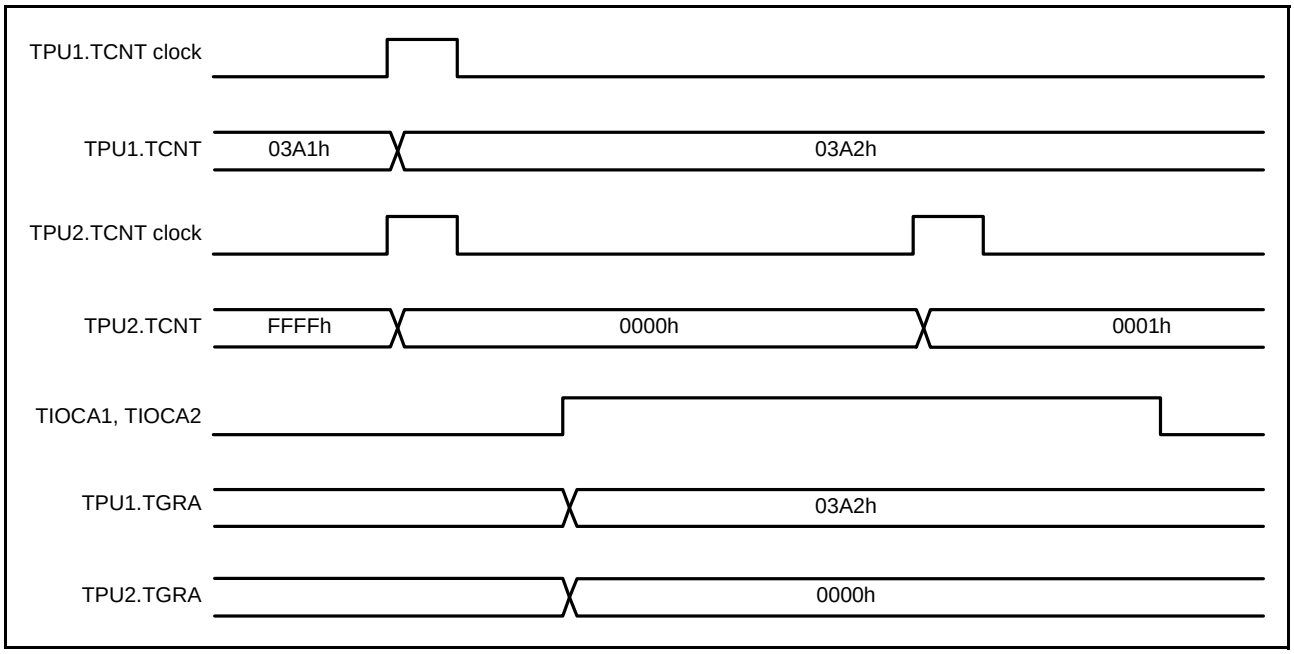

Figure 27.18 Example of Cascaded Operation (1)

Figure 27.19 shows the operation when counting upon TPU2.TCNT overflow/underflow has been set for TPU1.TCNT, and phase counting mode 1 has been specified for TPU2.

TPU1.TCNT is incremented by TPU2.TCNT overflow and decremented by TPU2.TCNT underflow.

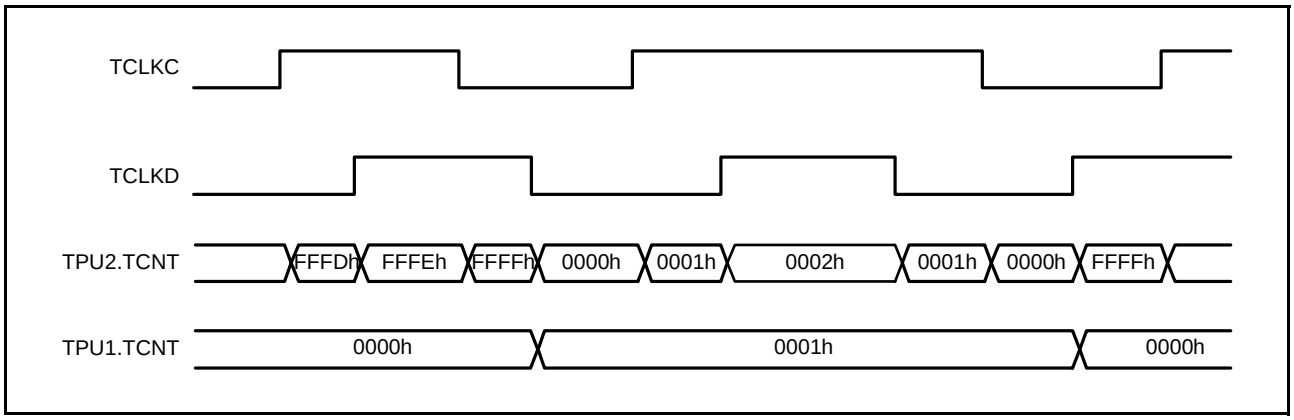

Figure 27.19 Example of Cascaded Operation (2)

27.3.5 PWM Modes

In PWM mode, PWM waveforms are output from the output pins. low, high, or toggle output can be selected as the output level in response to compare match of each TPUm.TGRy.

Settings of TGRy registers can output a PWM waveform in the range of 0% to 100% duty cycle.

Specifying TGRy compare match as the counter clearing source enables the cycle to be set in that register. All channels can be set for PWM mode independently. Synchronous operation is also possible.

There are two PWM modes, as described below.

1. PWM mode 1

   PWM waveform is generated from the TIOCAn and TIOCCn pins by pairing TPUm.TGRA with TPUm.TGRB and TPUm.TGRC with TPUm.TGRD. The outputs specified by the IOA[3:0] bits in TPUm.TIOR(H) and IOC[3:0] bits in TPUm.TIORL are output from the TIOCAn and TIOCCn pins at compare matches A and C, respectively. The outputs specified by the IOB[3:0] bits in TPUm.TIOR(H) and IOD[3:0] bits in TPUm.TIORL are output from the TIOCAn and TIOCCn pins at compare matches B and D, respectively. The initial output value is the value set in TGRA or TGRC. If the set values of paired TGRy registers are identical, the output value does not change even when a compare match occurs.

   In PWM mode 1, a maximum 8-phase PWM output is possible.

2. PWM mode 2

   PWM waveform is generated by using one TPUm.TGRy as the cycle register and the others as duty cycle registers. The output specified in TPUm.TIORH, TPUm.TIORL, or TPUm.TIOR is performed by compare matches. Upon counter clearing by a synchronous register compare match, the output value of each pin is the initial value set in TIORH, TIORL, or TIOR. If the set values of the cycle register and duty cycle register are identical, the output value does not change even when a compare match occurs.

   In PWM mode 2, a maximum 15-phase PWM waveform is possible by combined use with synchronous operation.

The correspondence between PWM output pins and registers is listed in Table 27.23.

Table 27.23 PWM Output Registers and Output Pins

Channel	Register	Output Pin	
		PWM Mode 1	PWM Mode 2
TPU0	TPU0.TGRA	TIOCA0	TIOCA0
	TPU0.TGRB		TIOCB0
	TPU0.TGRC	TIOCC0	TIOCC0
	TPU0.TGRD		TIOCD0
TPU1	TPU1.TGRA	TIOCA1	TIOCA1
	TPU1.TGRB		TIOCB1
TPU2	TPU2.TGRA	TIOCA2	TIOCA2
	TPU2.TGRB		TIOCB2
TPU3	TPU3.TGRA	TIOCA3	TIOCA3
	TPU3.TGRB		TIOCB3
	TPU3.TGRC	TIOCC3	TIOCC3
	TPU3.TGRD		TIOCD3
TPU4	TPU4.TGRA	TIOCA4	TIOCA4
	TPU4.TGRB		TIOCB4
TPU5	TPU5.TGRA	TIOCA5	TIOCA5
	TPU5.TGRB		TIOCB5

Note: In PWM mode 2, PWM waveform output is not possible for the TPUm.TGRy register in which the cycle is set.

(1) Example of PWM Mode Setting Procedure

Figure 27.20 shows an example of the PWM mode setting procedure.

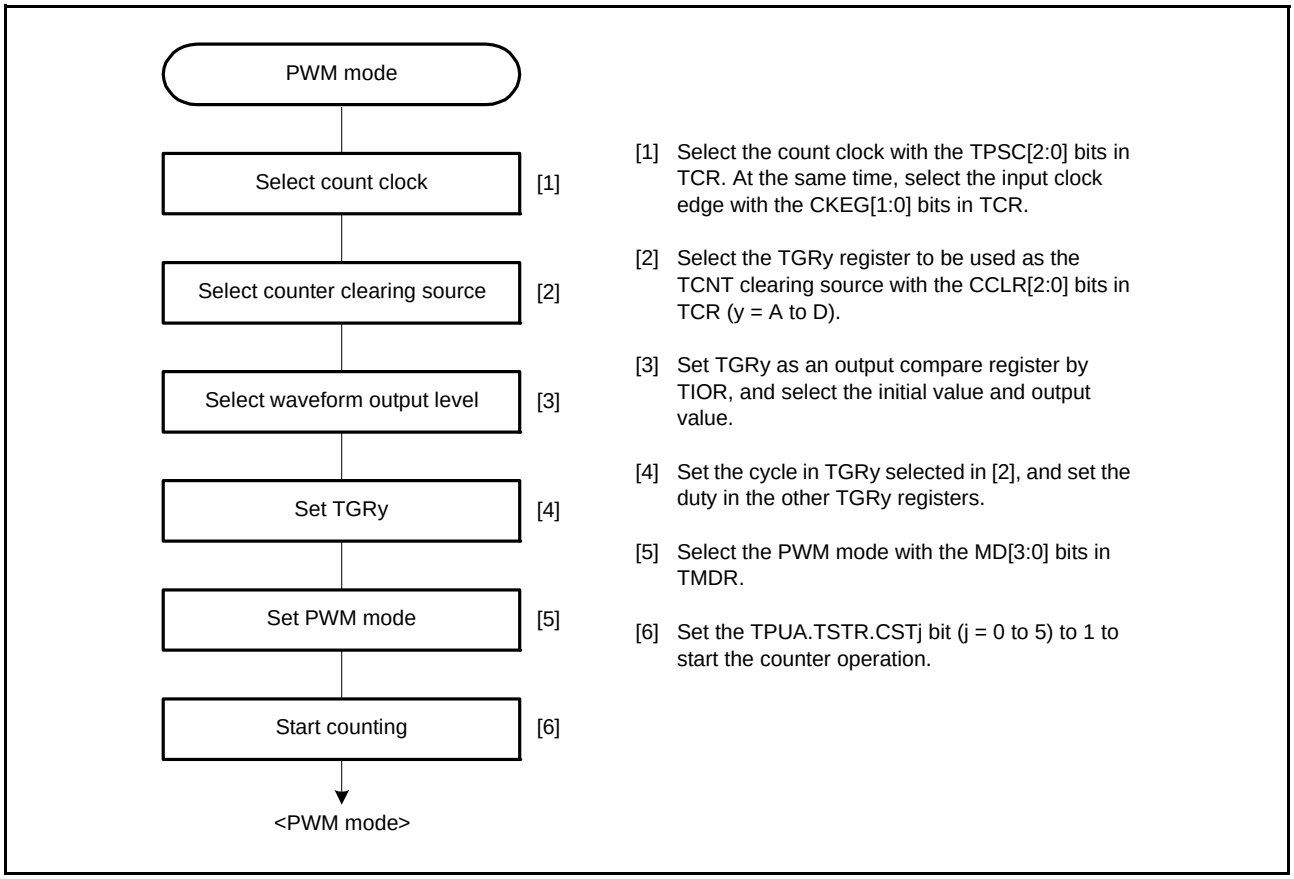

Figure 27.20 Example of PWM Mode Setting Procedure

(2) Examples of PWM Mode Operation

Figure 27.21 shows an example of PWM mode 1 operation.
In this example, TPUm.TGRA compare match is set as the TPUm.TCNT clearing source, low is set for the TGRA initial output value and output value, and high is set as the TPUm.TGRB output value.
In this case, the value set in TGRA is used as the cycle, and the value set in TGRB is used as the duty cycle.

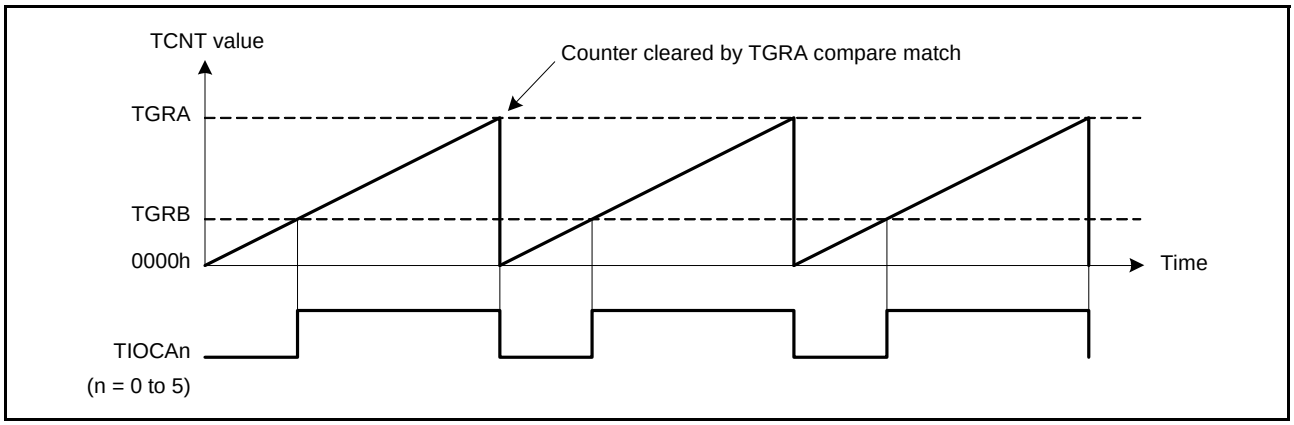

Figure 27.21 Example of PWM Mode Operation (1)

Figure 27.22 shows an example of PWM mode 2 operation.
In this example, synchronous operation is specified for TPU0 and TPU1, TPU1.TGRB compare match is set as the TPUm.TCNT clearing source, and low is set for the initial output value and high for the output value of the other TPUm.TGRy registers (TPU0.TGRA to TPU0.TGRD and TPU1.TGRA), to output a 5-phase PWM waveform.
In this case, the value set in TPU1.TGRB is used as the cycle, and the values set in the other TGRy registers are used as the duty cycle.

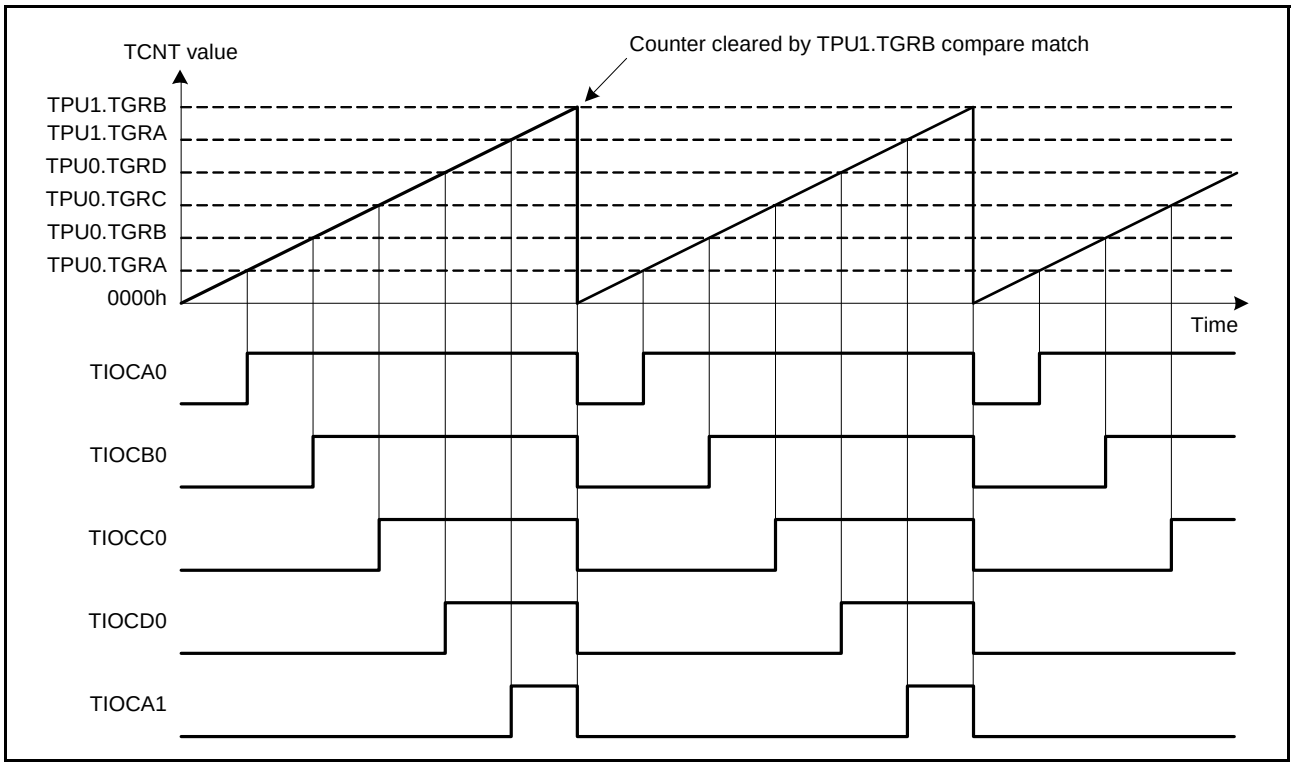

Figure 27.22 Example of PWM Mode Operation (2)

Figure 27.23 shows examples of PWM waveform output with 0% duty cycle and 100% duty cycle in PWM mode.

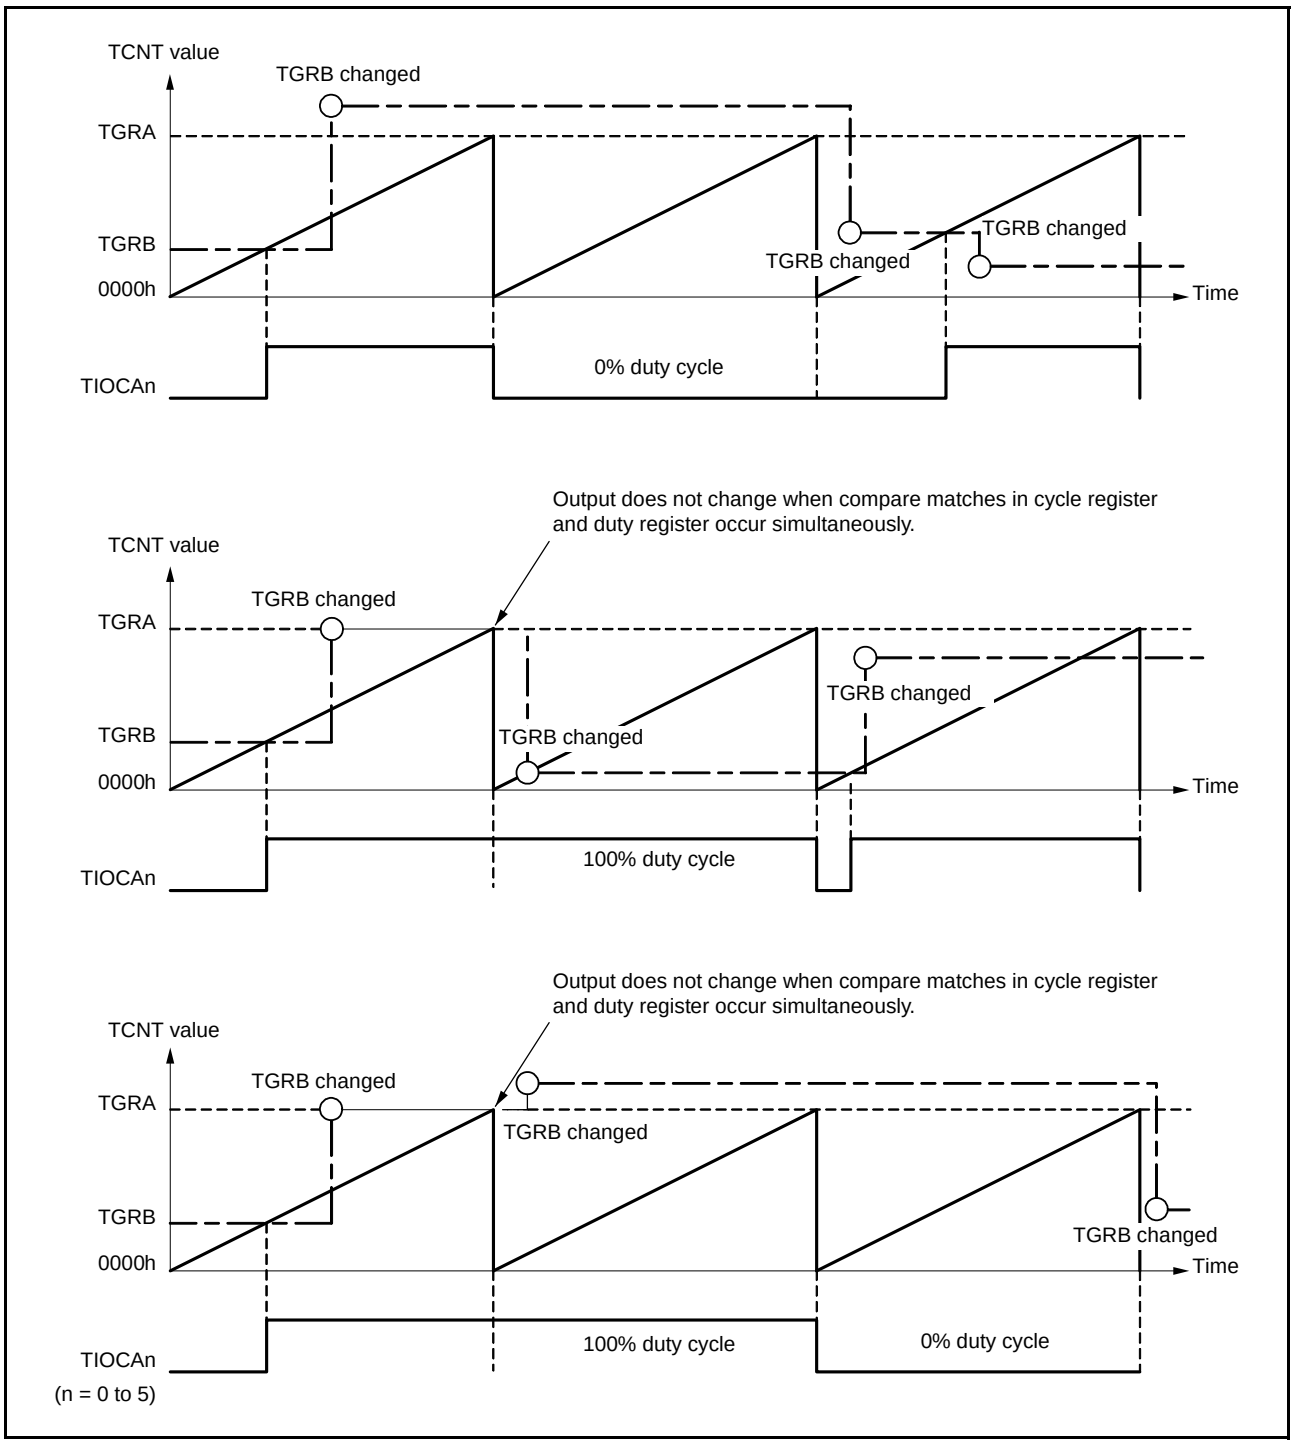

Figure 27.23 Example of PWM Mode Operation (3)

27.3.6 Phase Counting Mode

In phase counting mode, the phase difference between two external clock inputs is detected by the settings for channels 1, 2, 4, and 5, and TPUm.TCNT is incremented/decremented accordingly.
When phase counting mode is set, an external clock is selected as the count clock and TCNT operates as an up-/down-counter regardless of the setting of the TPSC[2:0] bits and CKEG[1:0] bits in TPUm.TCR. However, the lower 2 bits of the CCLR[2:0] bits in TPUm.TCR and the functions of TPUm.TIORH, TPUm.TIORL, TPUm.TIOR, TPUm.TIER, and TPUm.TGRy are valid, and therefore input capture/compare match and interrupt functions are available.
When an overflow occurs while TCNT is counting up, a TCIV interrupt request is generated; when an underflow occurs while TCNT is counting down, a TCIU interrupt request is generated. The TCFD bit in TPUm.TSR is the count direction flag. Reading the TCFD flag provides an indication of whether TCNT is counting up or down.
In phase counting mode, the external clock pins TCLKA, TCLKB, TCLKC, and TCLKD can be used as 2-phase encoder pulse input.
Table 27.24 lists the correspondence between external clock pins and channels.

Table 27.24 Clock Input Pins in Phase Counting Mode

	External Clock Pins	
Channel	**A-Phase**	**B-Phase**
When TPU1 or TPU5 is set to phase counting mode	TCLKA	TCLKB
When TPU2 or TPU4 is set to phase counting mode	TCLKC	TCLKD

(1) Example of Phase Counting Mode Setting Procedure

Figure 27.24 shows an example of the phase counting mode setting procedure.

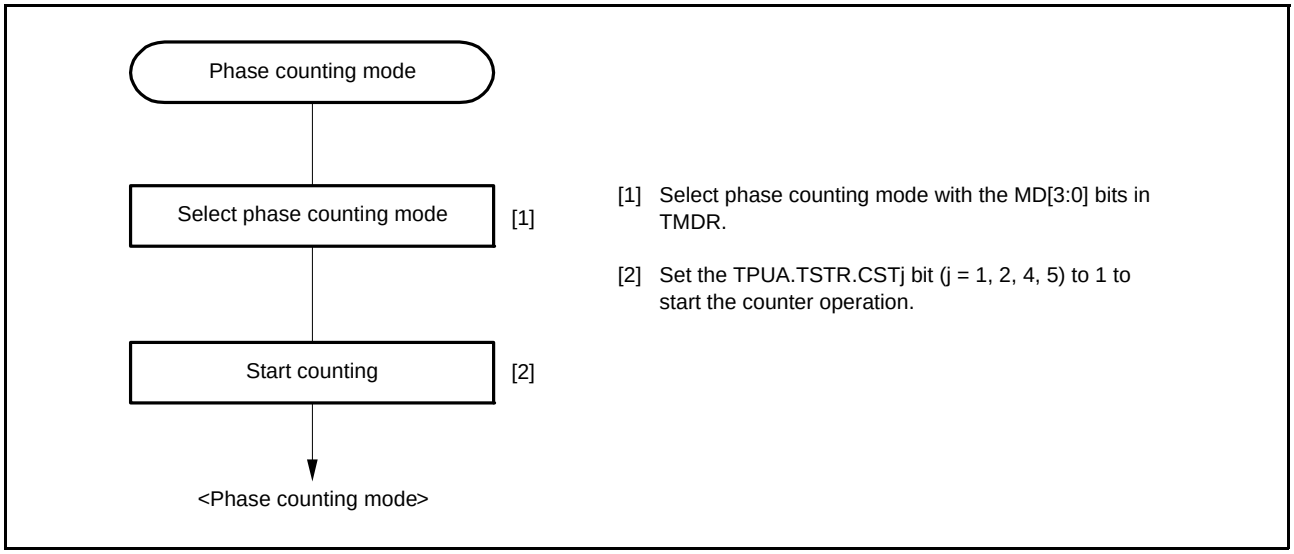

Figure 27.24 Example of Phase Counting Mode Setting Procedure

(2) Examples of Phase Counting Mode Operation

In phase counting mode, TPUm.TCNT counts up or down according to the phase difference between two external clocks. There are four modes, according to the count conditions.

(a) Phase counting mode 1

Figure 27.25 shows an example of phase counting mode 1 operation, and Table 27.25 lists the TPUm.TCNT up-/down-count conditions.

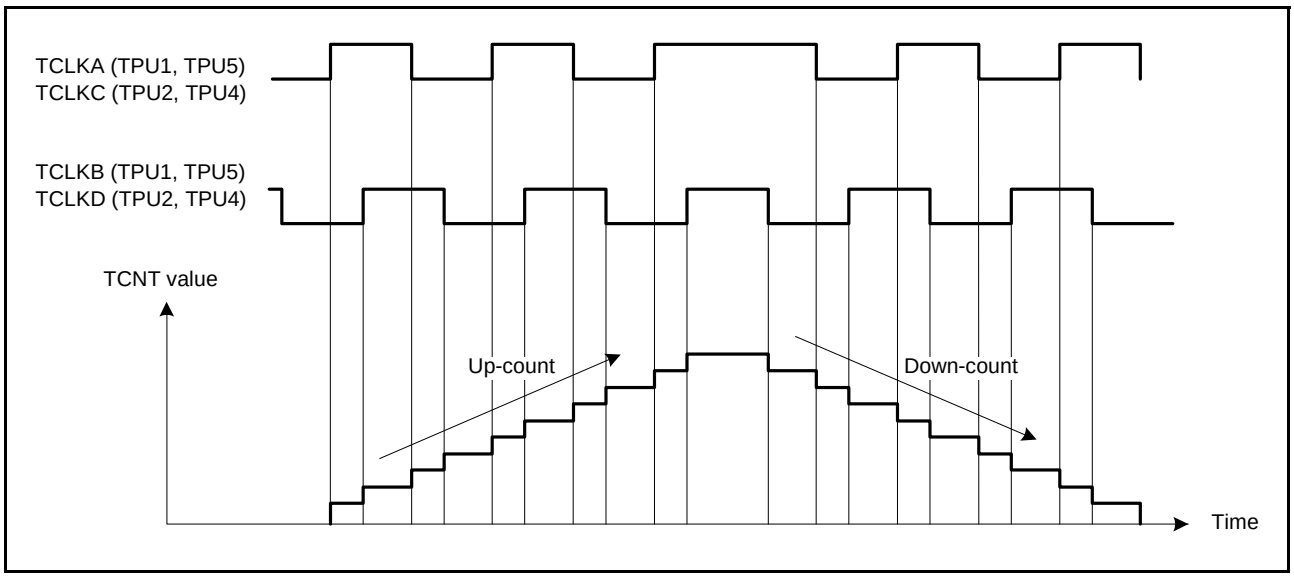

Figure 27.25 Example of Phase Counting Mode 1 Operation

Table 27.25 Up-/Down-Count Conditions in Phase Counting Mode 1

TCLKA (TPU1, TPU5) TCLKC (TPU2, TPU4)	TCLKB (TPU1, TPU5) TCLKD (TPU2, TPU4)	Operation
High	↑	Up-count
Low	↓	
↑	Low	
↓	High	
High	↓	Down-count
Low	↑	
↑	High	
↓	Low

27.3.6.1 Phase Counting Mode Application Example

Figure 27.29 shows an example in which phase counting mode is set for TPU1, and TPU1 is coupled with TPU0 to input servo motor 2-phase encoder pulses in order to detect the position or speed.

TPU1 is set to phase counting mode 1, and the encoder pulse A-phase and B-phase are input to the TCLKA and TCLKB pins.

TPU0 operates with TPU0.TCNT clearing by TPU0.TGRC compare match; TPU0.TGRA and TPU0.TGRC are used for the compare match function and are set with the speed control cycle and position control cycle. TPU0.TGRB is used for input capture, with TPU0.TGRB and TPU0.TGRD operating in buffer mode. The TPU1 count clock is specified as the TPU0.TGRB input capture source, and the pulse width of 2-phase encoder 4-multiplication pulses is detected.

TPU1.TGRA and TPU1.TGRB for TPU1 are specified for input capture, TPU0.TGRA and TPU0.TGRC compare matches are selected as the input capture source, and the up-/down-counter values for the control cycles are stored.

This procedure enables accurate position/speed detection to be achieved.

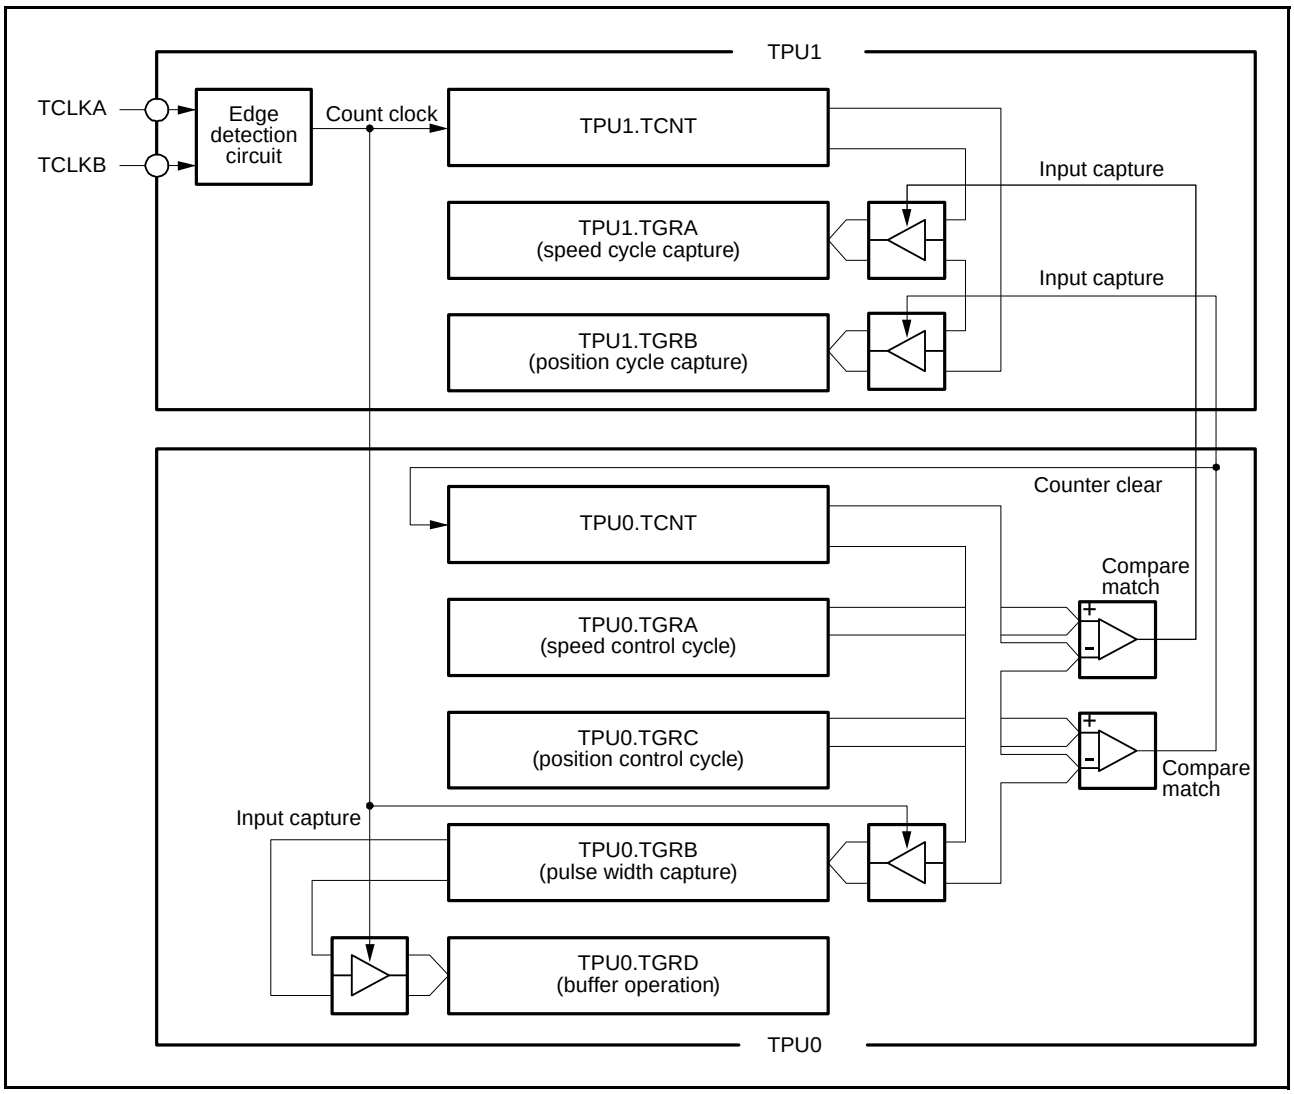

Figure 27.29 Phase Counting Mode Application Example

27.3.7 Noise Filters

Each pin for use in input capture by TPU is equipped with a noise filter. The noise filter samples the level on the pin three times at the selected sampling interval, conveys the level to the internal circuits if the samples match, and continues to convey that level until the other level is sampled from the pins three times in a row. The noise filter function can be enabled or disabled for each pin. Furthermore, sampling clock settings can be made for each channel.
Figure 27.30 is a timing chart for the noise filter.

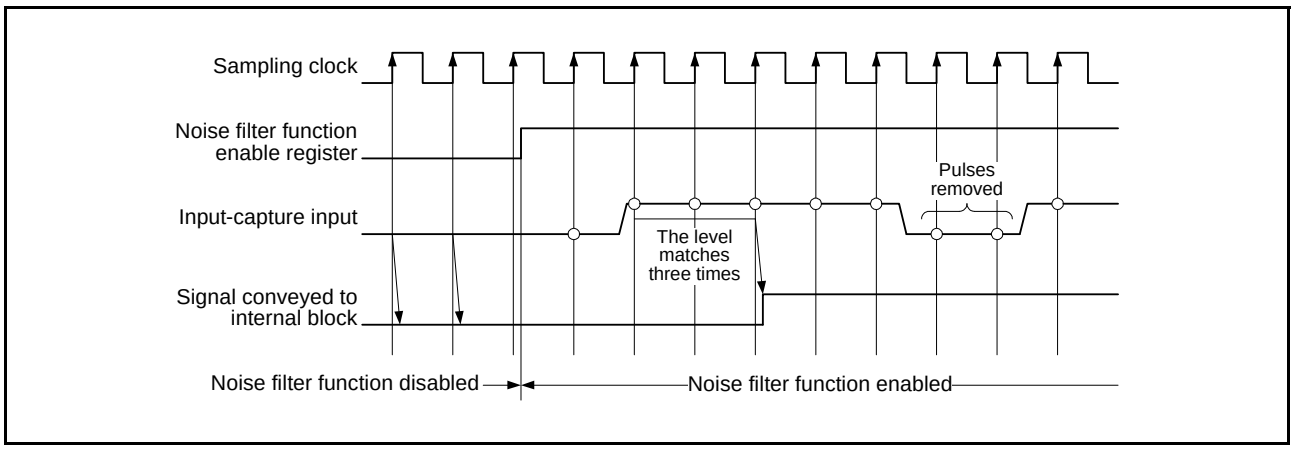

Figure 27.30 Timing Chart for the Noise Filter

If noise filtering is set, input capture operation is performed on the edges of noise-filtered signal after a minimum delay of (sampling interval × 2 + PCLK) due to noise filtering for the input capture input.

27.4 Interrupt Sources

There are three kinds of TPU interrupt sources: TPUm.TGRy input capture/compare match, TPUm.TCNT overflow, and TPUm.TCNT underflow.

Relative channel priority levels can be changed by the interrupt controller, but the priority within a channel is fixed. For details, see section 15, Interrupt Controller (ICUA).

Table 27.29 lists the TPU interrupt sources.

Table 27.29 TPU Interrupt Sources

Channel	Name	Interrupt Source	DTC Activation	DMAC Activation
TPU0	TGI0A	TPU0.TGRA input capture/compare match	Possible	Possible
	TGI0B	TPU0.TGRB input capture/compare match	Possible	Not possible
	TGI0C	TPU0.TGRC input capture/compare match	Possible	Not possible
	TGI0D	TPU0.TGRD input capture/compare match	Possible	Not possible
	TCI0V	TPU0.TCNT overflow	Not possible	Not possible
TPU1	TGI1A	TPU1.TGRA input capture/compare match	Possible	Possible
	TGI1B	TPU1.TGRB input capture/compare match	Possible	Not possible
	TCI1V	TPU1.TCNT overflow	Not possible	Not possible
	TCI1U	TPU1.TCNT underflow	Not possible	Not possible
TPU2	TGI2A	TPU2.TGRA input capture/compare match	Possible	Possible
	TGI2B	TPU2.TGRB input capture/compare match	Possible	Not possible
	TCI2V	TPU2.TCNT overflow	Not possible	Not possible
	TCI2U	TPU2.TCNT underflow	Not possible	Not possible
TPU3	TGI3A	TPU3.TGRA input capture/compare match	Possible	Possible
	TGI3B	TPU3.TGRB input capture/compare match	Possible	Not possible
	TGI3C	TPU3.TGRC input capture/compare match	Possible	Not possible
	TGI3D	TPU3.TGRD input capture/compare match	Possible	Not possible
	TCI3V	TPU3.TCNT overflow	Not possible	Not possible
TPU4	TGI4A	TPU4.TGRA input capture/compare match	Possible	Possible
	TGI4B	TPU4.TGRB input capture/compare match	Possible	Not possible
	TCI4V	TPU4.TCNT overflow	Not possible	Not possible
	TCI4U	TPU4.TCNT underflow	Not possible	Not possible
TPU5	TGI5A	TPU5.TGRA input capture/compare match	Possible	Possible
	TGI5B	TPU5.TGRB input capture/compare match	Possible	Not possible
	TCI5V	TPU5.TCNT overflow	Not possible	Not possible
	TCI5U	TPU5.TCNT underflow	Not possible	Not possible

Note: This table lists the initial state immediately after a reset. The relative channel priority levels can be changed by the interrupt controller.

(1) Input Capture/Compare Match Interrupt

An interrupt is requested when the TGIEy bit (y = A, B, C, D) in TPUm.TIER is set to 1 by the occurrence of a TPUm.TGRy input capture/compare match on a channel. The TPU has 16 input capture/compare match interrupts, four each for TPU0 and TPU3, and two each for TPU1, TPU2, TPU4, and TPU5.

(2) Overflow Interrupt

An interrupt is requested when the TCIEV bit in TPUm.TIER is set to 1 by the occurrence of a TPUm.TCNT overflow on a channel. The TPU has six overflow interrupts, one for each channel.

(3) Underflow Interrupt

An interrupt is requested when the TCIEU bit in TPUm.TIER is set to 1 by the occurrence of a TPUm.TCNT underflow on a channel. The TPU has four underflow interrupts, one each for TPU1, TPU2, TPU4, and TPU5.

27.5 DTC Activation

The DTC can be activated by the TPUm.TGRy input capture/compare match interrupt of each channel. For details, see section 20, Data Transfer Controller (DTCa).
A total of 16 input capture/compare match interrupts can be used as DTC activation sources, four each for TPU0 and TPU3, and two each for TPU1, TPU2, TPU4, and TPU5.

27.6 DMAC Activation

The DMAC can be activated by the TPUm.TGRA input capture/compare match interrupt of each channel. For details, see section 18, DMA Controller (DMACAa).
A total of six TPUm.TGRA input capture/compare match interrupts can be used as DMAC activation sources, one for each channel.

27.7 A/D Converter Activation

The TPU can activate the A/D converter by the TPUm.TGRA input capture/compare match for each channel.
When the TTGE bit in TPUm.TIER is set to 1, the TPU requests the A/D converter to start A/D conversion by the occurrence of a TPUm.TGRA input capture/compare match on a particular channel.

27.8 PPG Trigger

Input capture to or compare match with TGRA and TGRB in TPU0 to TPU3 can be made to act as a PPG1 waveform trigger. For details, see section 28, Programmable Pulse Generator (PPG).

27.9 Operation Timing

27.9.1 Input/Output Timing

(1) TPUm.TCNT Count Timing

Figure 27.31 shows TPUm.TCNT count timing in internal clock operation, and Figure 27.32 shows TCNT count timing in external clock operation.

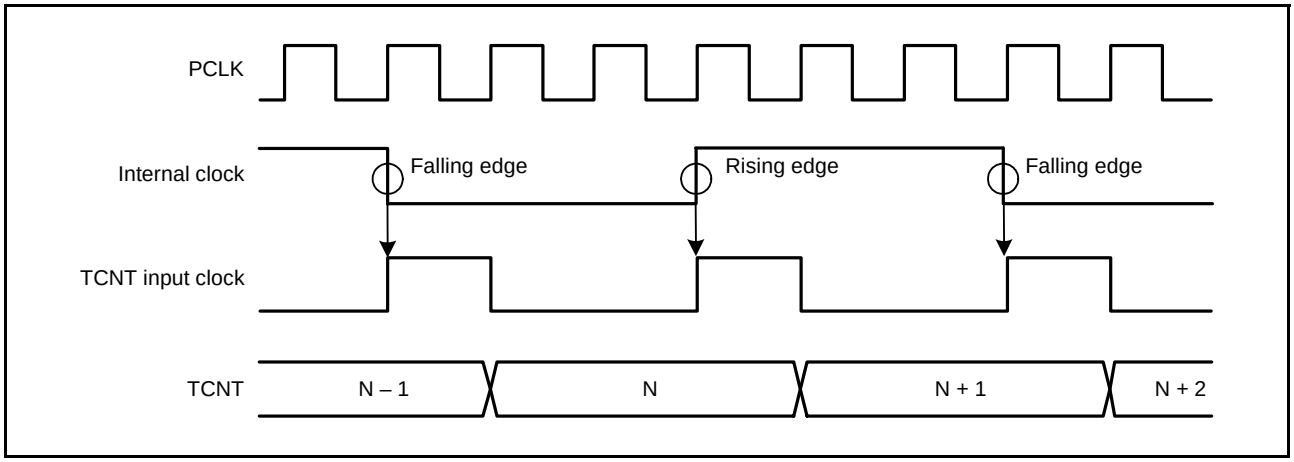

Figure 27.31 Count Timing in Internal Clock Operation

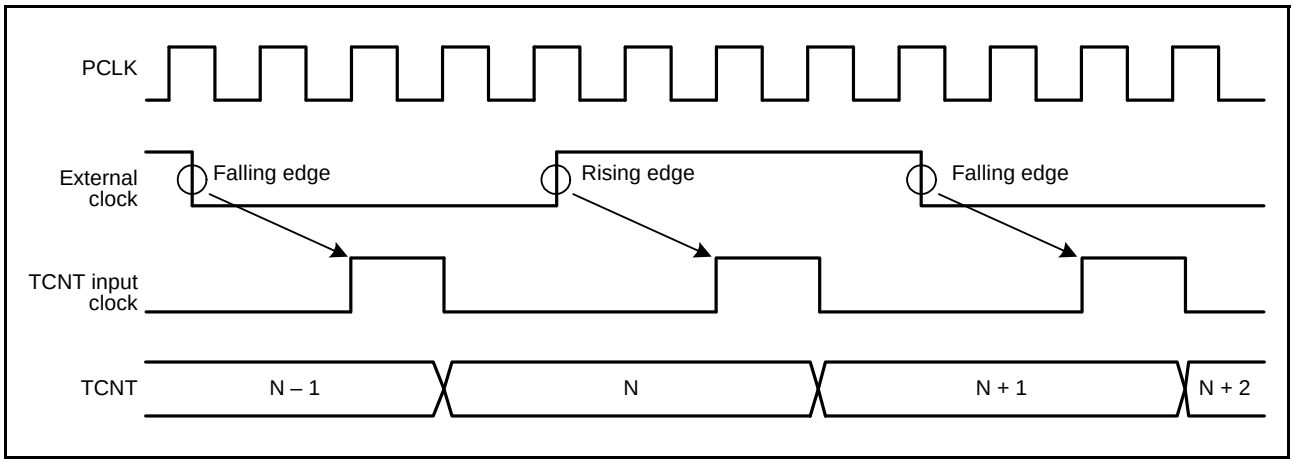

Figure 27.32 Count Timing in External Clock Operation

(2) Output Compare Output Timing

A compare match signal is generated in the final state in which TPUm.TCNT and TPUm.TGRy match (the point at which the count value matched by TCNT is updated). When a compare match signal is generated, the output value set in TPUm.TIORH, TPUm.TIORL, or TPUm.TIOR is output to the output compare output pin TIOCyn (y = A to D; n = 0 to 5). After a match between TCNT and TGRy, the compare match signal is not generated until the TCNT input clock is generated.

Figure 27.33 shows output compare output timing.

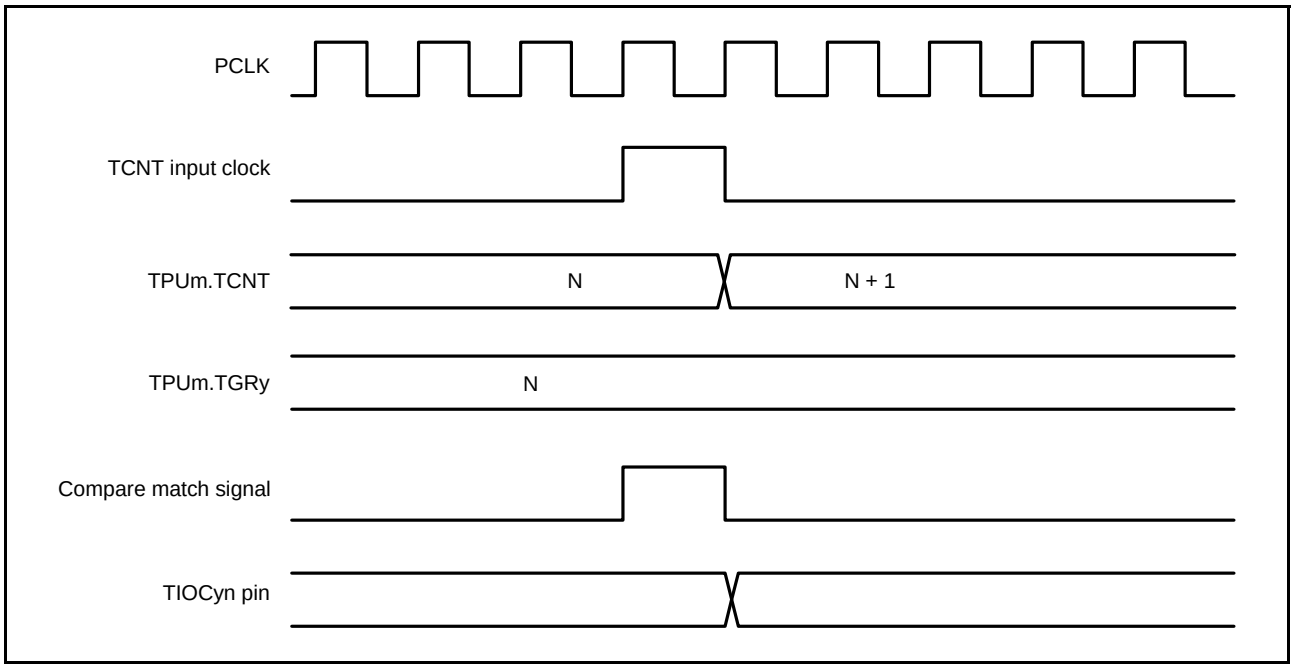

Figure 27.33 Output Compare Output Timing

(3) Input Capture Signal Timing

Figure 27.34 shows input capture signal timing.

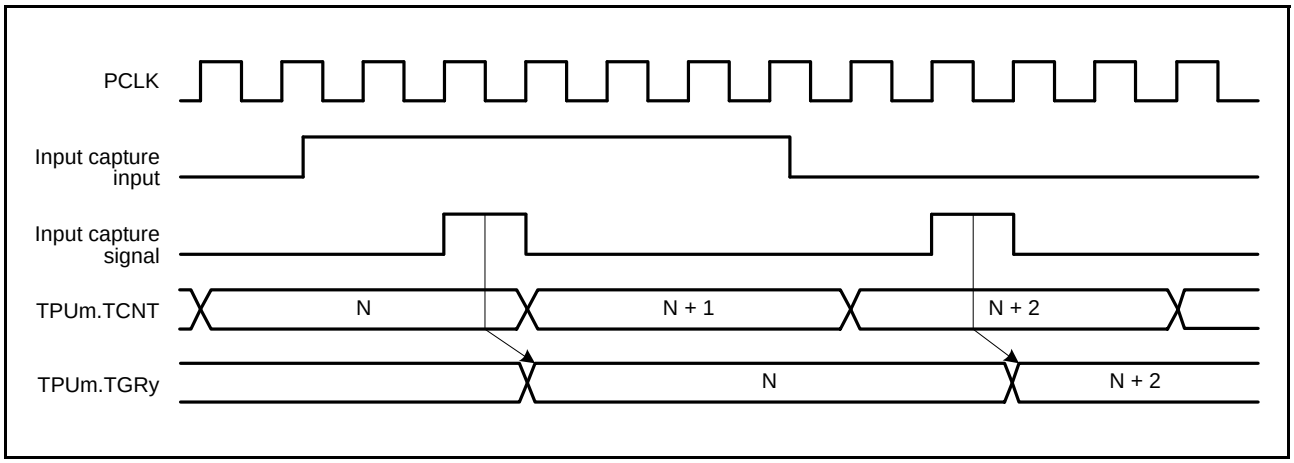

Figure 27.34 Input Capture Signal Timing

(4) Timing for Counter Clearing by Compare Match/Input Capture

Figure 27.35 shows the timing when counter clearing by compare match occurrence is specified, and Figure 27.36 shows the timing when counter clearing by input capture occurrence is specified.

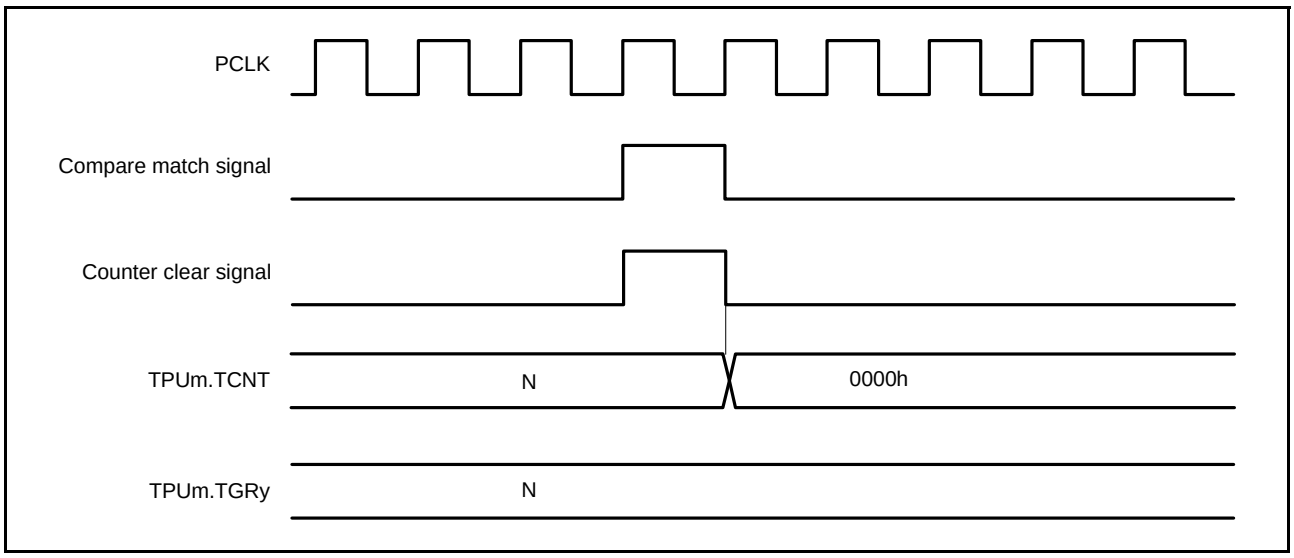

Figure 27.35 Counter Clear Timing (Compare Match)

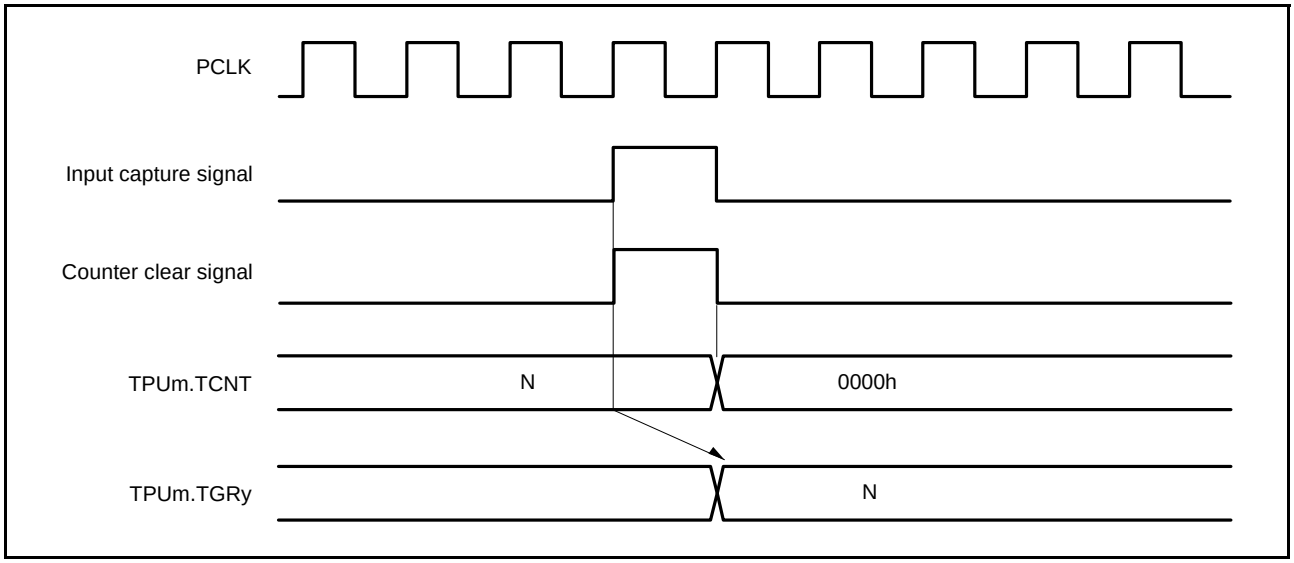

Figure 27.36 Counter Clear Timing (Input Capture)

(5) Buffer Operation Timing

Figure 27.37 and Figure 27.38 show the timings in buffer operation.

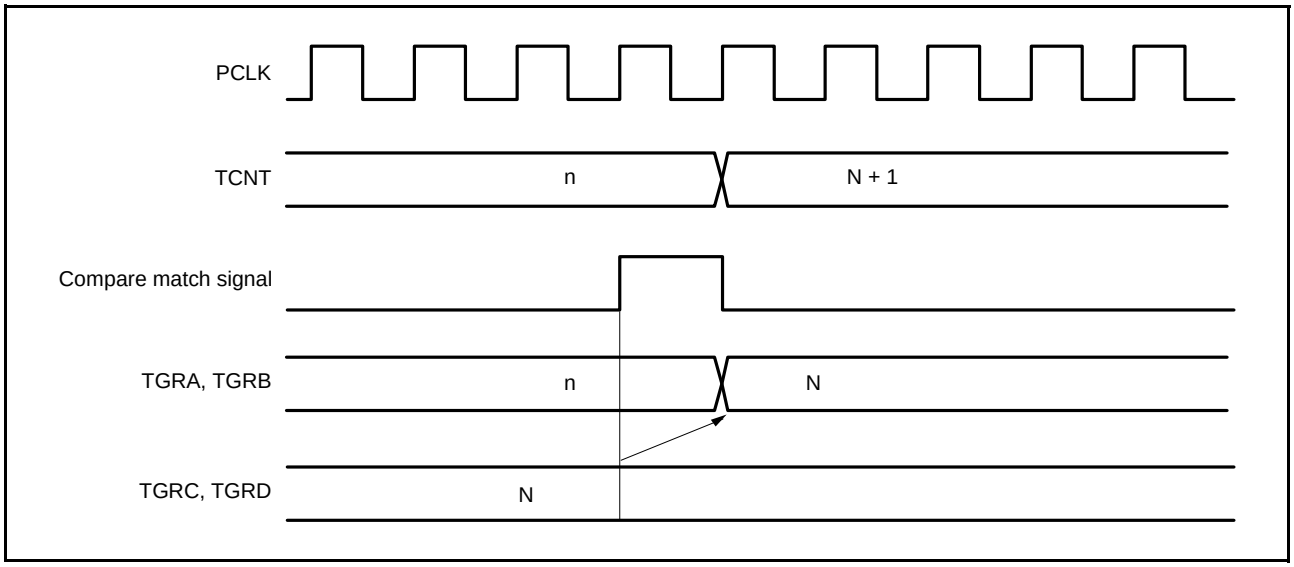

Figure 27.37 Buffer Operation Timing (Compare Match)

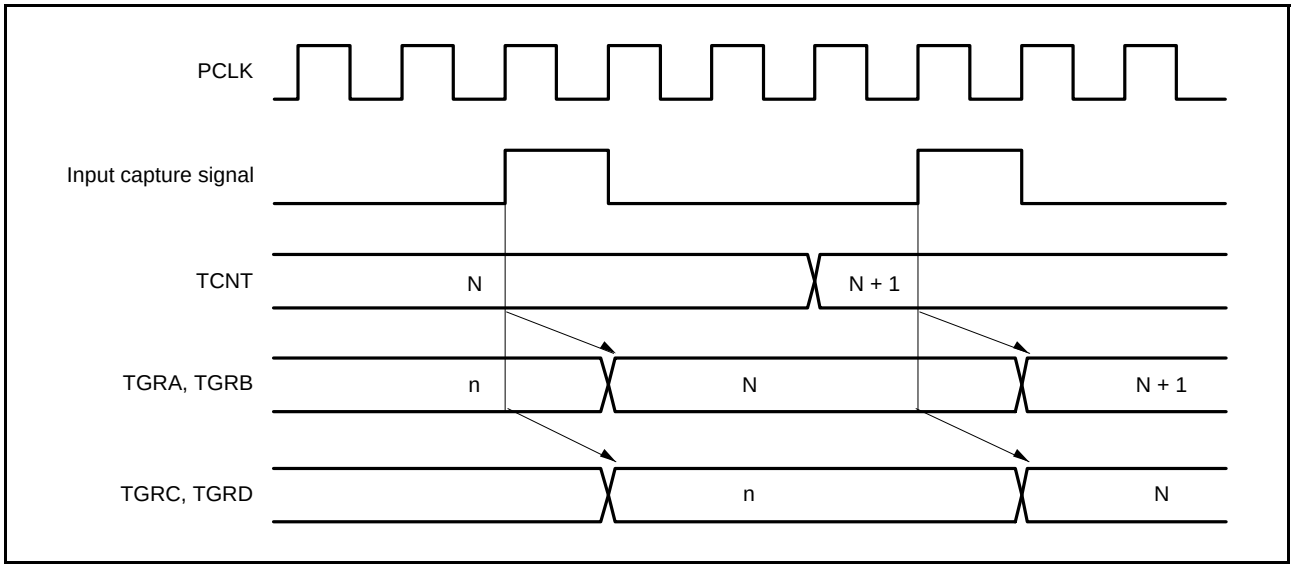

Figure 27.38 Buffer Operation Timing (Input Capture)

27.9.2 Interrupt Signal Timing

(1) Timing of Interrupt Signal Setting on Compare Match

Figure 27.39 shows the timing for setting the interrupt signal by compare match occurrence.

(2) Timing of Interrupt Signal Setting on Input Capture

Figure 27.40 shows the timing for setting the interrupt signal by input capture occurrence.

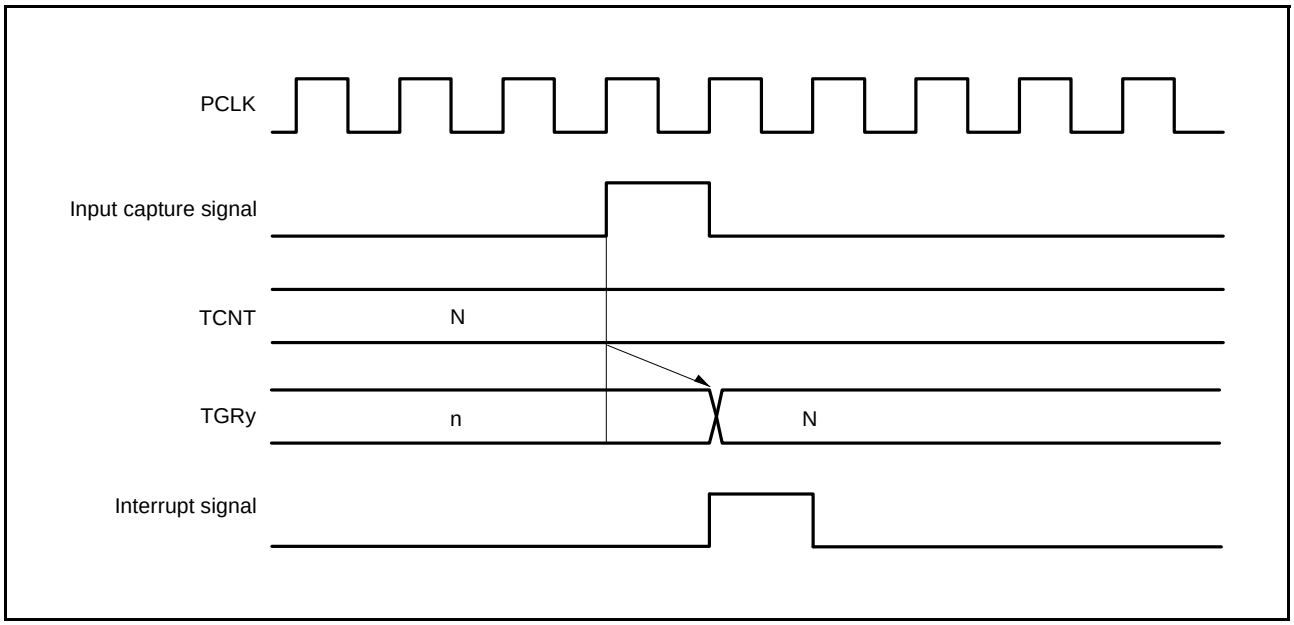

Figure 27.40 TGImy Interrupt Timing (Input Capture)

(3) Timing of TCImV/TCImU Interrupt Signal Setting

Figure 27.41 shows the timing for generating the TCImV interrupt signal by overflow occurrence.
Figure 27.42 shows the timing for generating the TCImU interrupt signal by underflow occurrence.

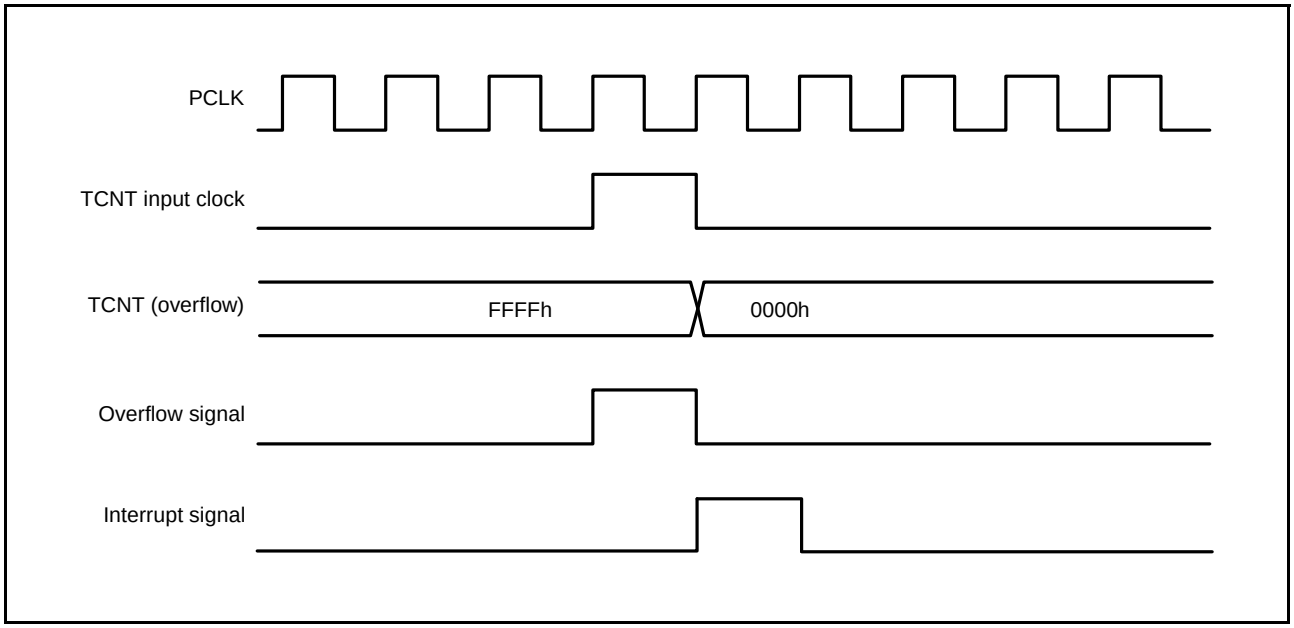

Figure 27.41 TCImV Interrupt Setting Timing

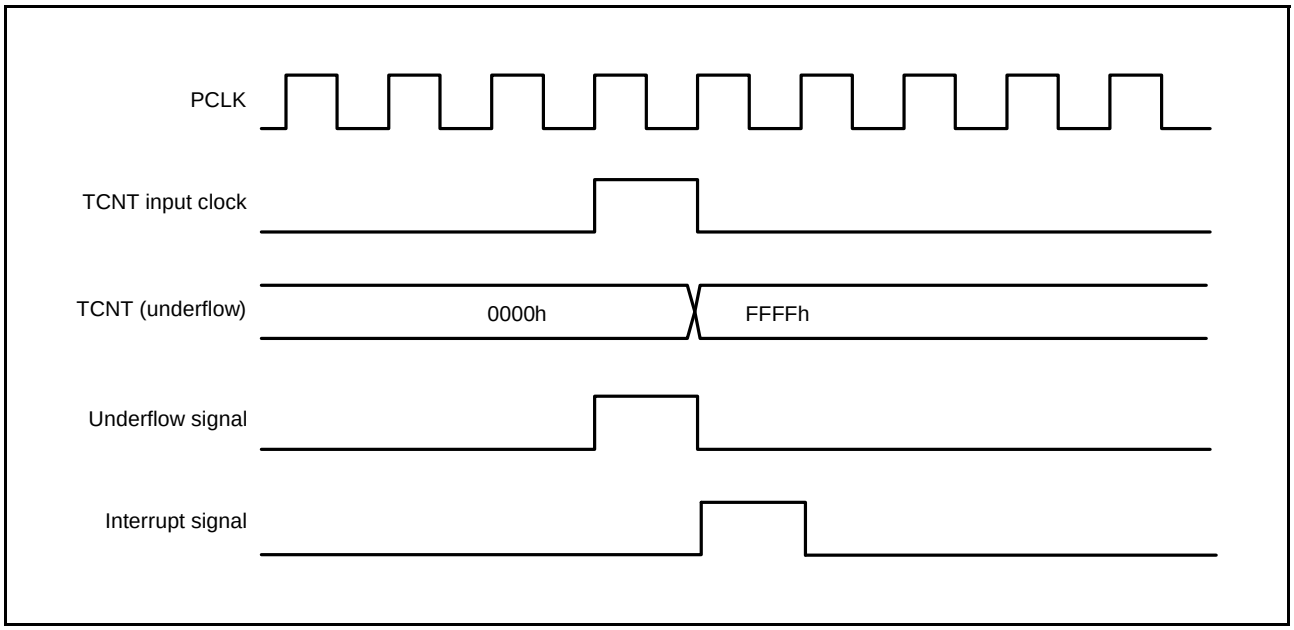

Figure 27.42 TCImU Interrupt Setting Timing

27.10 Usage Notes

27.10.1 Module Stop Function Setting

Operation of the TPU can be disabled or enabled using the module stop control register. The TPU does not operate with the initial setting. Register access is enabled by releasing the module stop state. For details, see section 11, Low Power Consumption.

27.10.2 Input Clock Restrictions

The input clock pulse width must be at least 1.5 PCLK cycles in the case of single-edge detection, and at least 2.5 PCLK cycles in the case of both-edge detection. The TPU will not operate properly with a narrower pulse width.
In phase counting mode, the phase difference and overlap between the two input clocks must be at least 1.5 PCLK cycles, and the pulse width must be at least 2.5 PCLK cycles. Figure 27.43 shows the input clock conditions in phase counting mode.

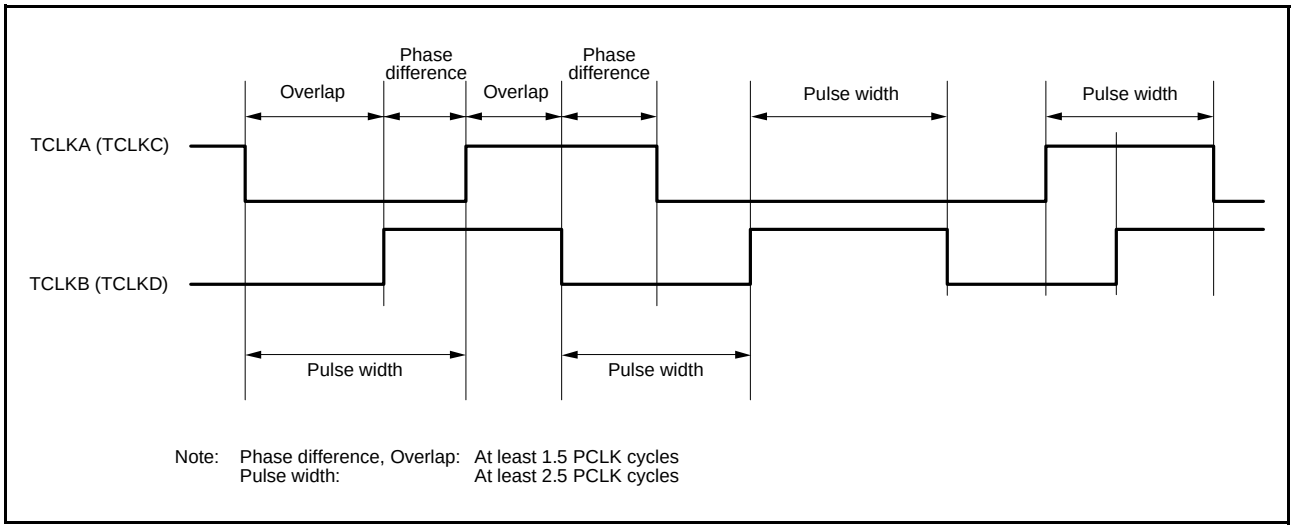

Figure 27.43 Phase Difference, Overlap, and Pulse Width in Phase Counting Mode

27.10.3 Notes on Cycle Setting

When counter clearing by compare match is set, TPUm.TCNT is cleared in the final state in which it matches the TPUm.TGRy value (the point at which the count value matched by TCNT is updated). Consequently, the actual counter frequency is given by the following formula:

$$f = \frac{f_{TCNT\_CLK}}{(N + 1)}$$

f: Counter frequency
f_{TCNT_CLK}: Count clock frequency
N: TGRy set value

27.10.4 Conflict between TPUm.TCNT Write and Clear Operations

If the counter clearing signal is generated in a TCNT write cycle, TCNT clearing takes precedence and the TCNT write is not performed. Figure 27.44 shows the timing in this case.

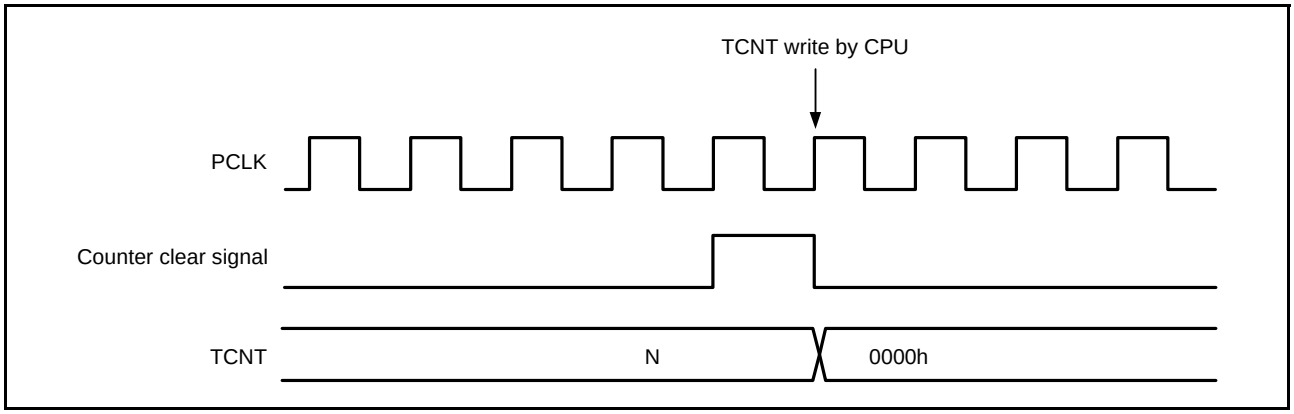

Figure 27.44 Conflict between TPUm.TCNT Write and Clear Operations

27.10.5 Conflict between TPUm.TCNT Write and Increment Operations

If incrementing occurs in a TCNT write cycle, the TCNT write takes precedence and TCNT is not incremented. Figure 27.45 shows the timing in this case.

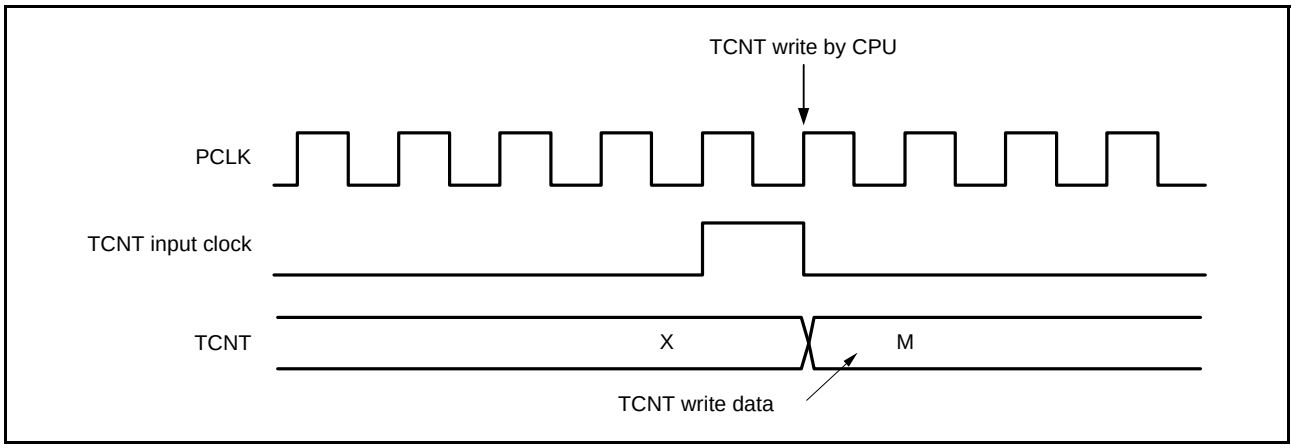

Figure 27.45 Conflict between TPUm.TCNT Write and Increment Operations

27.10.6 Conflict between TPUm.TGRy Write and Compare Match

If a compare match occurs in a TGRy write cycle, the TGRy write takes precedence and the compare match signal is disabled. A compare match also does not occur when the same value as before is written.
Figure 27.46 shows the timing in this case.

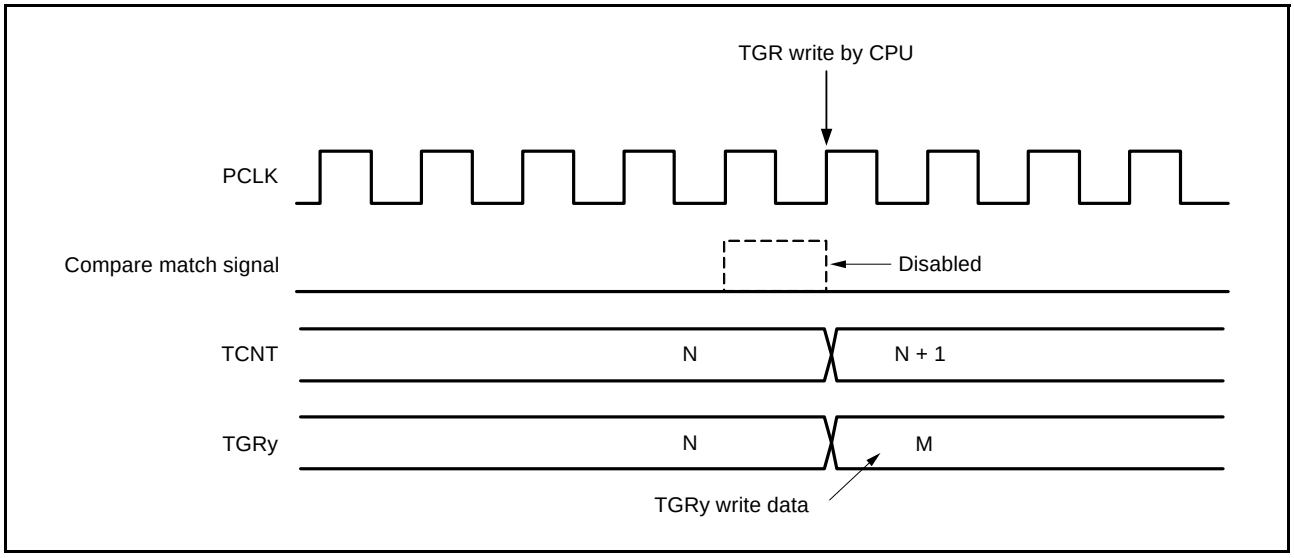

Figure 27.46 Conflict between TPUm.TGRy Write and Compare Match

27.10.7 Conflict between Buffer Register Write and Compare Match

If a compare match occurs in a TPUm.TGRy write cycle, the data transferred to TGRy by the buffer operation will be the data before writing.
Figure 27.47 shows the timing in this case.

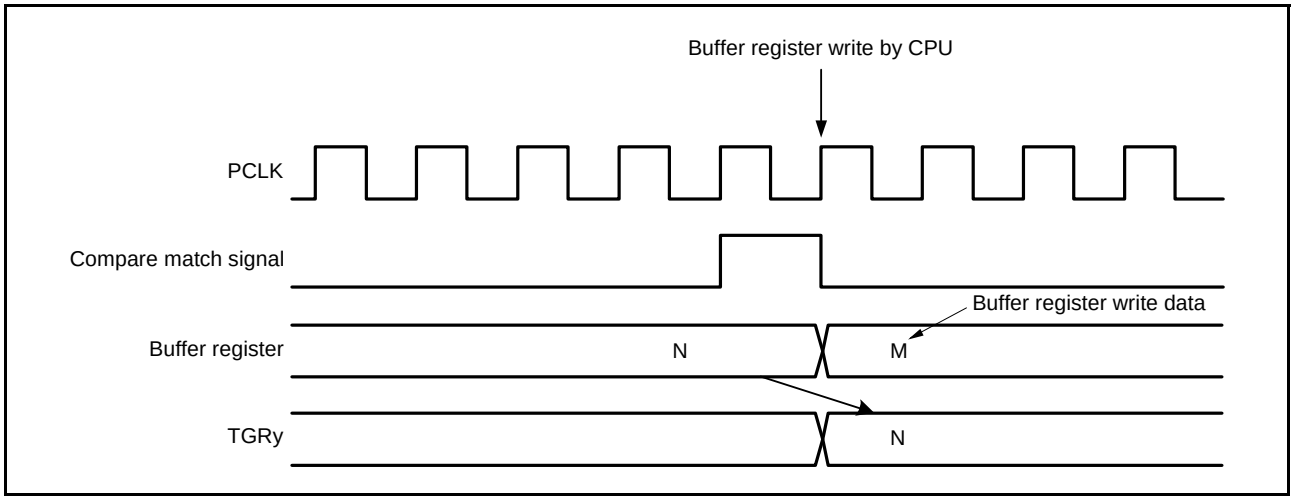

Figure 27.47 Conflict between Buffer Register Write and Compare Match

27.10.8 Conflict between TPUm.TGRy Read and Input Capture

If the input capture signal is generated in a TGRy read cycle, the data that is read will be the data before input capture transfer.

Figure 27.48 shows the timing in this case.

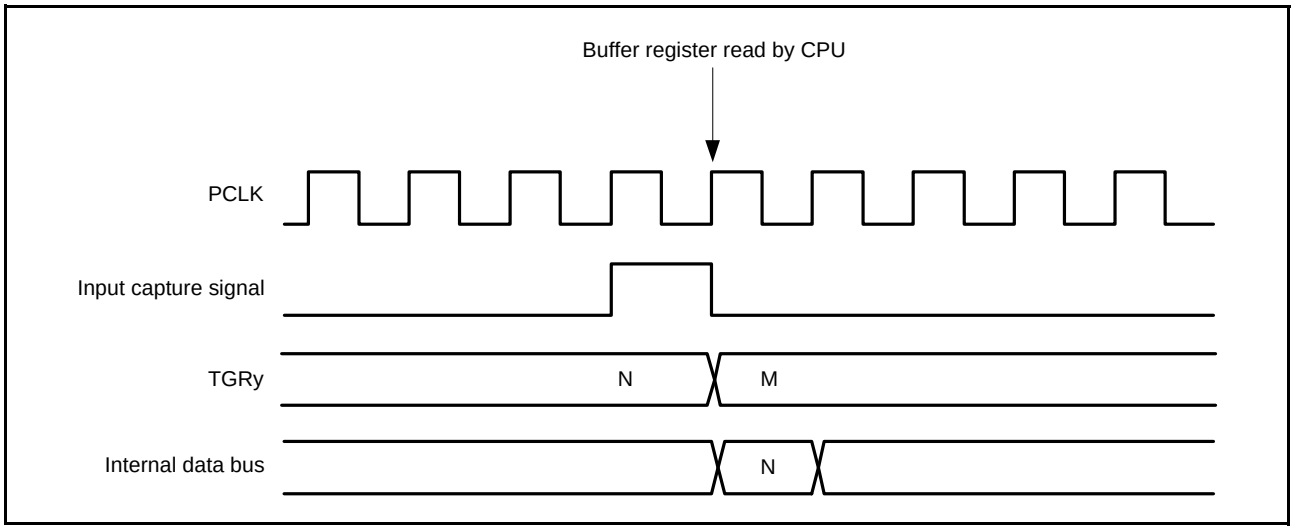

Figure 27.48 Conflict between TPUm.TGRy Read and Input Capture

27.10.9 Conflict between TPUm.TGRy Write and Input Capture

If the input capture signal is generated in a TGRy write cycle, the input capture operation takes precedence and the write to TGRy is not performed. Figure 27.49 shows the timing in this case.

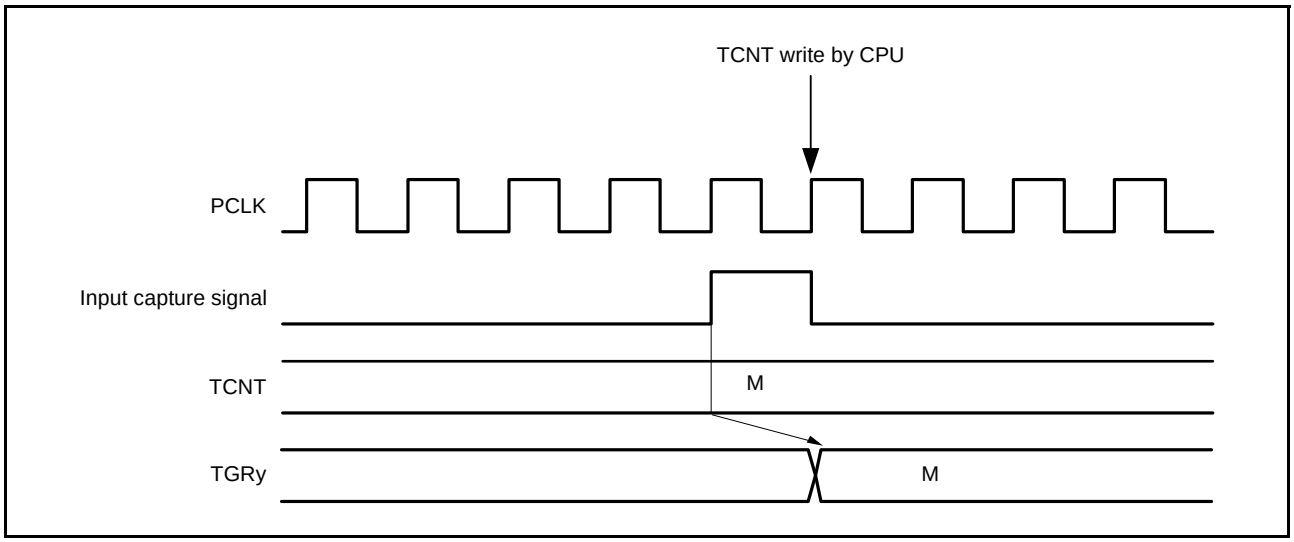

Figure 27.49 Conflict between TPUm.TGRy Write and Input Capture

27.10.10 Conflict between Buffer Register Write and Input Capture

If the input capture signal is generated in a buffer register write cycle, the buffer operation takes precedence and the write to the buffer register is not performed. Figure 27.50 shows the timing in this case.

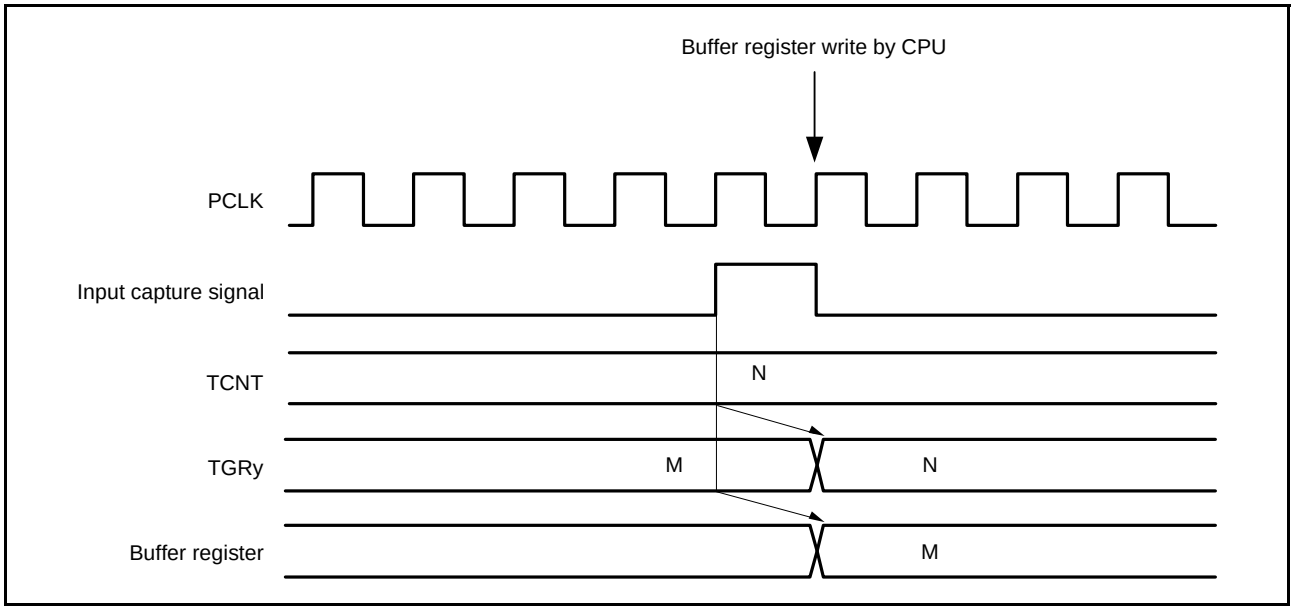

Figure 27.50 Conflict between Buffer Register Write and Input Capture

27.10.11 Conflict between Overflow/Underflow and Counter Clearing

If overflow/underflow and counter clearing*1 occur simultaneously, TPUm.TCNT is cleared with the generation of the compare match interrupt and an overflow interrupt is generated.

Figure 27.51 shows the operation timing when a TPUm.TGRy compare match is specified as the clearing source and FFFFh is set in TGRy.

Note 1. There are four counter clearing sources:
- Compare match
- Input capture
- Synchronous clearing
- Counter restart operation by an event signal

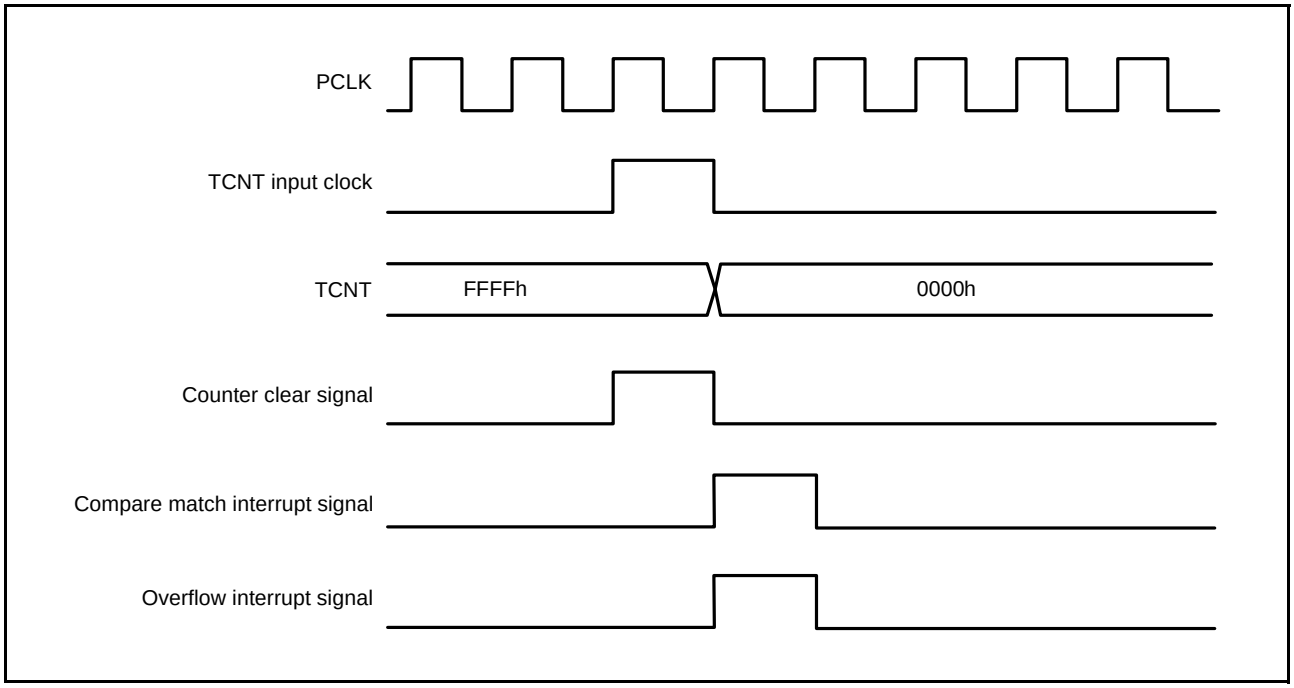

Figure 27.51 Conflict between Overflow and Counter Clearing

27.10.12 Conflict between TPUm.TCNT Write and Overflow/Underflow

If an overflow/underflow occurs due to increment/decrement in a TCNT write cycle, the TCNT write takes precedence. Figure 27.52 shows the operation timing when there is conflict between TCNT write and overflow.

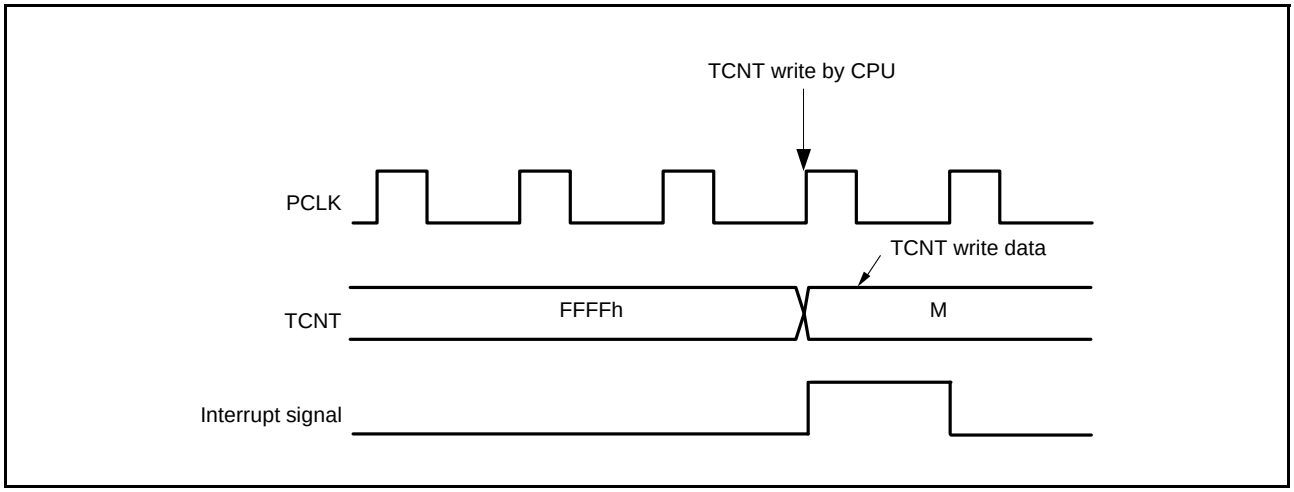

Figure 27.52 Conflict between TPUm.TCNT Write and Overflow

27.10.13 Multiplexing of I/O Pins

In this MCU, the TCLKA input pin is multiplexed with the TIOCB5 I/O pin, the TCLKB input pin with the TIOCB2 I/O pin, the TCLKC input pin with the TIOCB1 I/O pin, the TCLKD input pin with the TIOCB0 I/O pin, the TCLKB input pin with the TIOCD0 I/O pin, the TCLKC input pin with the TIOCC3 I/O pin, and the TCLKD input pin with the TIOCD3 I/O pin. When an external clock is input, compare match output should not be performed from a multiplexed pin.

27.10.14 Continuous Output of Compare-Match Pulse Interrupt Signal

When TGR is set to 0000h, PCLK/1 is set as the count clock, and compare match is set as the counter clear source, the TCNT remains 0000h and is not updated, and a compare-match pulse interrupt signal is output continuously to form a flat signal level.

When a pulse interrupt signal is used, the interrupt controller cannot detect the second and subsequent interrupts.

Figure 27.53 shows an operation timing when the compare-match pulse interrupt signal is continuously output.

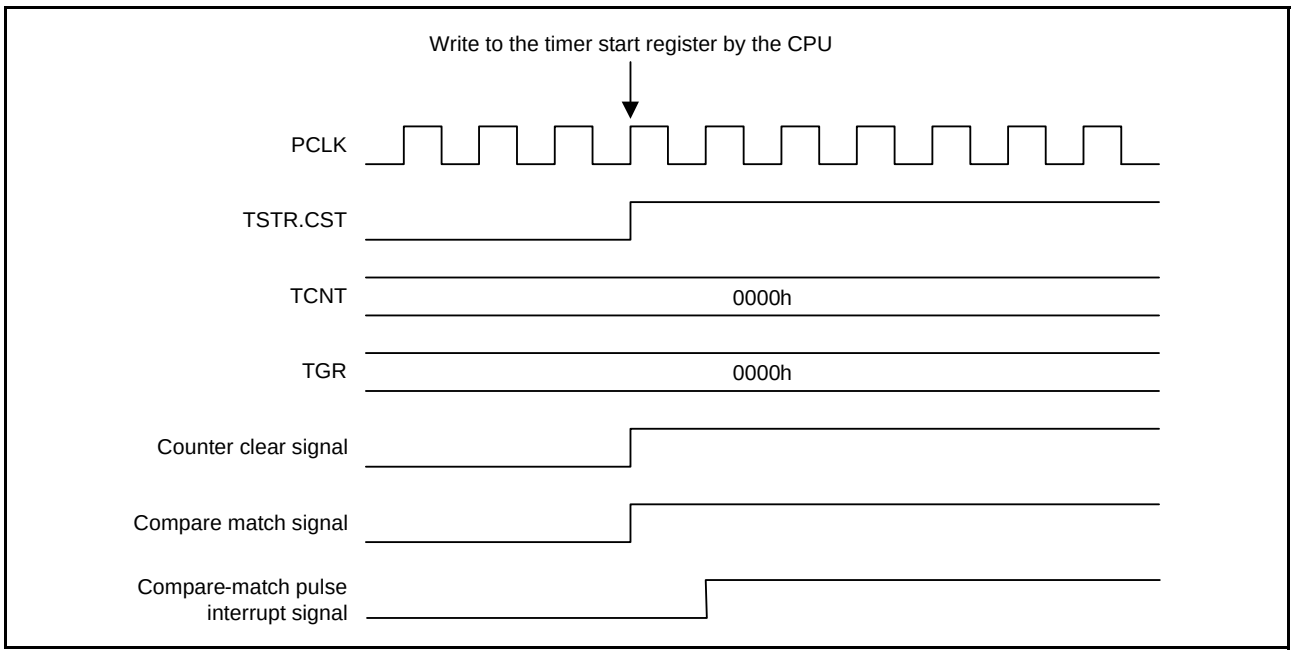

Figure 27.53 Continuous Output of Compare-Match Pulse Interrupt Signal

27.10.15 Continuous Output of Input-Capture Pulse Interrupt Signal

When input-capture signal is set on both edges and when the pulse width of the input-capture input equals to one PCLK cycle detected by internal sampling, input capture is generated continuously on the rising and falling edges. Therefore, an input-capture pulse interrupt signal is output continuously to form a flat signal level.
When a pulse interrupt signal is used, the interrupt controller cannot detect the second and subsequent interrupts.
Figure 27.54 shows an operation timing when the input-capture pulse interrupt signal is output continuously.

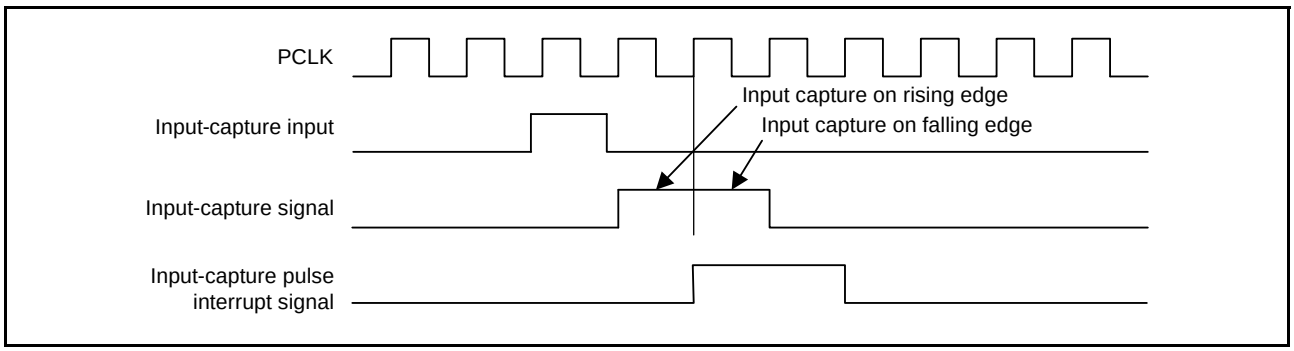

Figure 27.54 Continuous Output of Input-Capture Pulse Interrupt Signal

27.10.16 Continuous Output of Underflow Pulse Interrupt Signal

If two external clock signals' same direction edges to be phase counted are generated within two PCLK cycles in phase counting mode 1, with TGR being 0000h, and compare match set as the counter clear source, the TCNT remains 0000h and is not updated, and a compare-match pulse interrupt signal and an underflow interrupt signal are output continuously to form a flat signal level.

When a pulse interrupt signal is used, the interrupt controller cannot detect the second and subsequent interrupts.

Figure 27.55 shows an operation timing when the underflow pulse interrupt signal is output continuously.

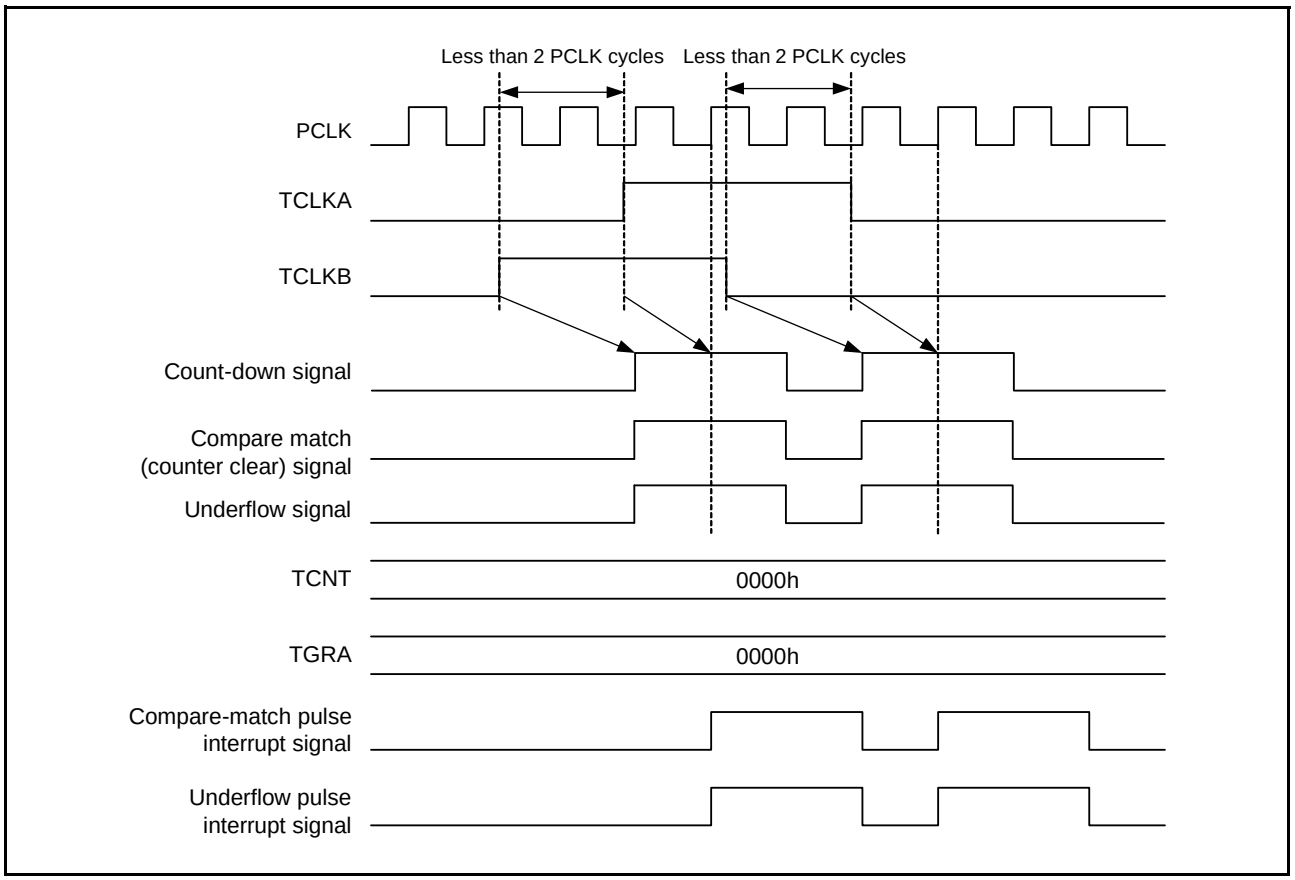

Figure 27.55 Continuous Output of Underflow Pulse Interrupt Signal

27.11 Event Link Operation

27.11.1 Event Signal Output to ELC

The TPU uses the ELC (event link controller) to perform link operation to the previously specified module using the interrupt request signal as the event signal.
The event signal can be output regardless of the setting of the corresponding interrupt request enable bits (TGIEA, TGIEB, TGIEC, or TGIED, and TCIEV, or TCIEU).

27.11.2 Event Signal Input from ELC

The TPU can perform any of the following three operations using the event link setting register of the ELC (event link controller).

(1) Start Counting

When an event signal is input while the TPU count start operation is selected, the CSTn bit in TSTRA register (the timer start register) is set to 1 and counting starts.
However, if this event is generated for the channels when the CSTn bit is set to 1, the event is ignored.
Table 27.30 lists the TSTRA.CSTn bit used for each channel.
Figure 27.56 shows the timing of the count start operation.

For details on the setting procedure to start counting, see section 27.3.1, (1) Counter Operation.

Table 27.30 Correspondence between Channels and TSTRA.CSTn bit

Channel No.	TSTRA.CSTn bit
TPU0	CST0
TPU1	CST1
TPU2	CST2
TPU3	CST3

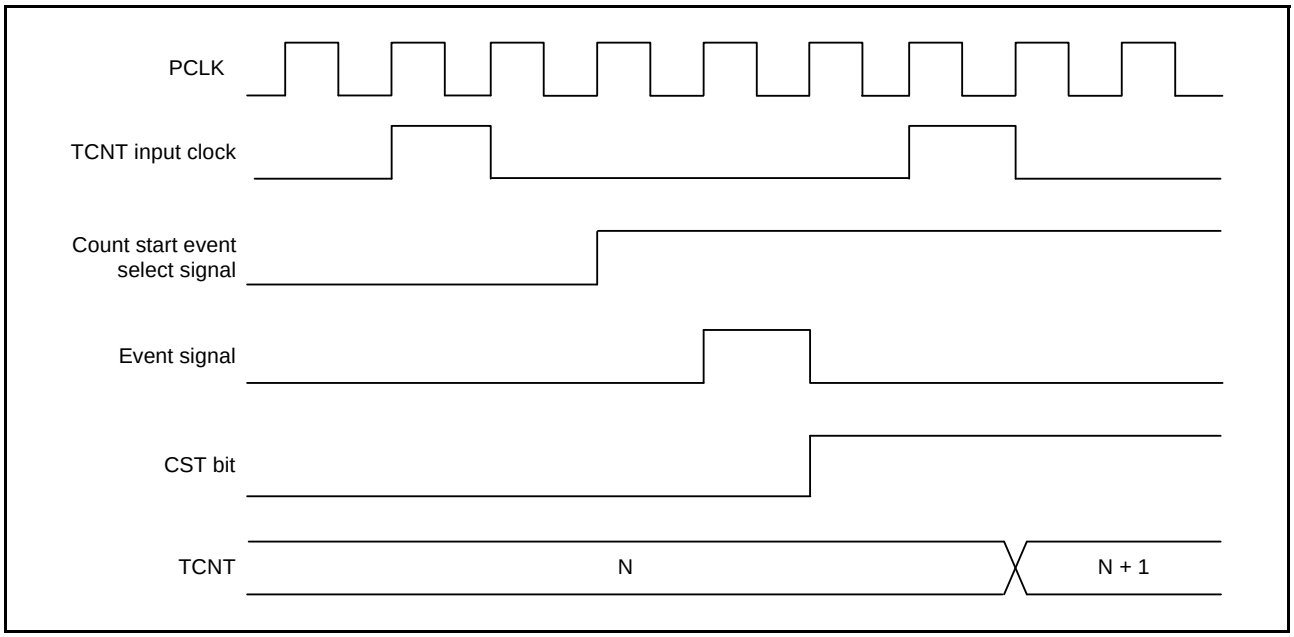

Figure 27.56 Start Counting on Input of the Event Signal

(2) Restart Counting

When an event signal is input while the TPU count restart operation is selected, the value of TCNTn counter (the timer start register) is returned to its initial value (0000h). If the CSTn bit in TSTRA register (the timer start register) is set to 1, however, counting operation will then continue.
Table 27.30 lists the TSTRA.CSTn bit used for each channel.
Figure 27.57 shows the timing of the count restart operation.

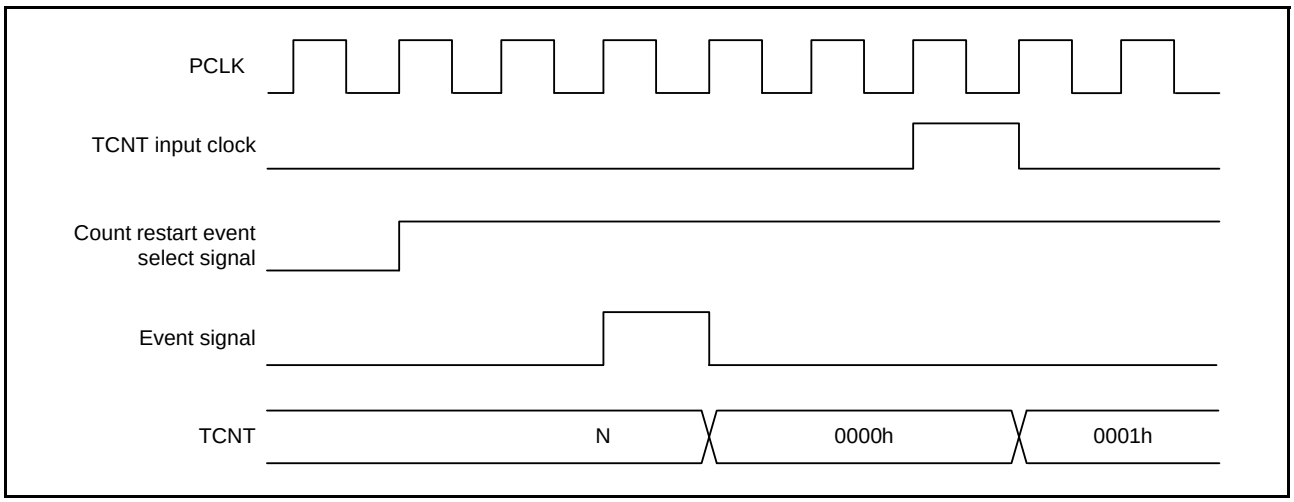

Figure 27.57 Restart Counting on Input of the Event Signal

(3) Input Capture Operation

When an event signal is input while the TPU input capture operation is selected, the value of TCNT counter (the timer count register) for the corresponding channel is captured in TGR register (the timer general register). When using input capture due to the event link, set the bit in TIOR (the timer I/O control register) to specify input capture, and then set the CSTn bit in TSTRA register (the timer start register) to 1 to start counting.
Table 27.31 lists TGR register and TIOR register bits used for each channel. For the TSTRA.CSTn bit used for each channel, see Table 27.30.
Figure 27.58 shows the timing of input capture operation.
When input capture operation by event linking is selected, the setting of TIOR register and the corresponding input capture (the linkage of the TIOCnA pin (input capture pin) input with the specific operation of other channels) are not effective (this also applies when the event select signal is set to 1 at the same time).

For details on the setting procedure for input capture, see section 27.3.1, (3) Input Capture Function.

Table 27.31 TGR and TIOR Used for Input Capture by ELC

Channel No.	Capture Destination Registers	Bits in TIOR
TPU0	TGRA register (channel 0)	IOA[3:0] bits (TIORH0)
TPU1	TGRA register (channel 1)	IOA[3:0] bits (TIOR1)
TPU2	TGRA register (channel 2)	IOA[3:0] bits (TIOR2)
TPU3	TGRA register (channel 3)	IOA[3:0] bits (TIORH3)

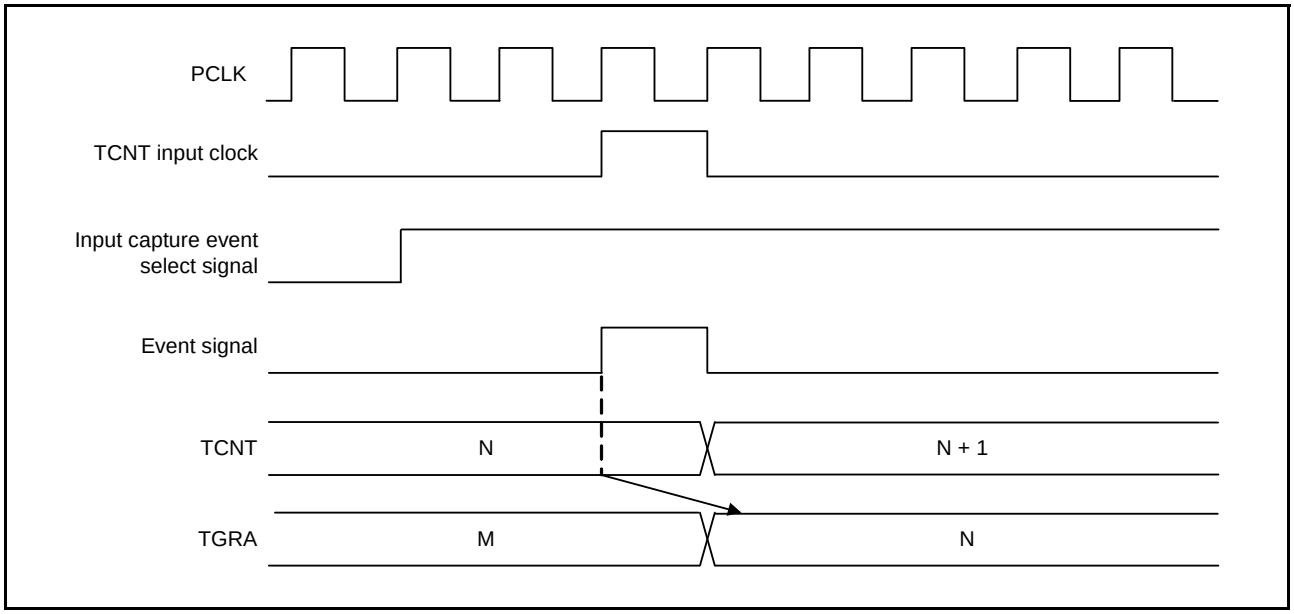

Figure 27.58 Input Capture on Input of the Event Signal

27.11.3 Usage Notes on Operation on Input of the Event Signal

The followings are the notes on using the TPU for event link operations.

(1) Start Counting

When writing to the TSTRA.CSTn bit (the timer start register) and a counting start are in contention, writing to the CSTn bit does not proceed since setting of the CSTn bit to 1 in response to the event takes priority.
Figure 27.59 shows the timing in this case.
Furthermore, even when a counting start due to the event link is selected, CPU writing to the TSTRA.CSTn bit proceeds if the event signal is low.

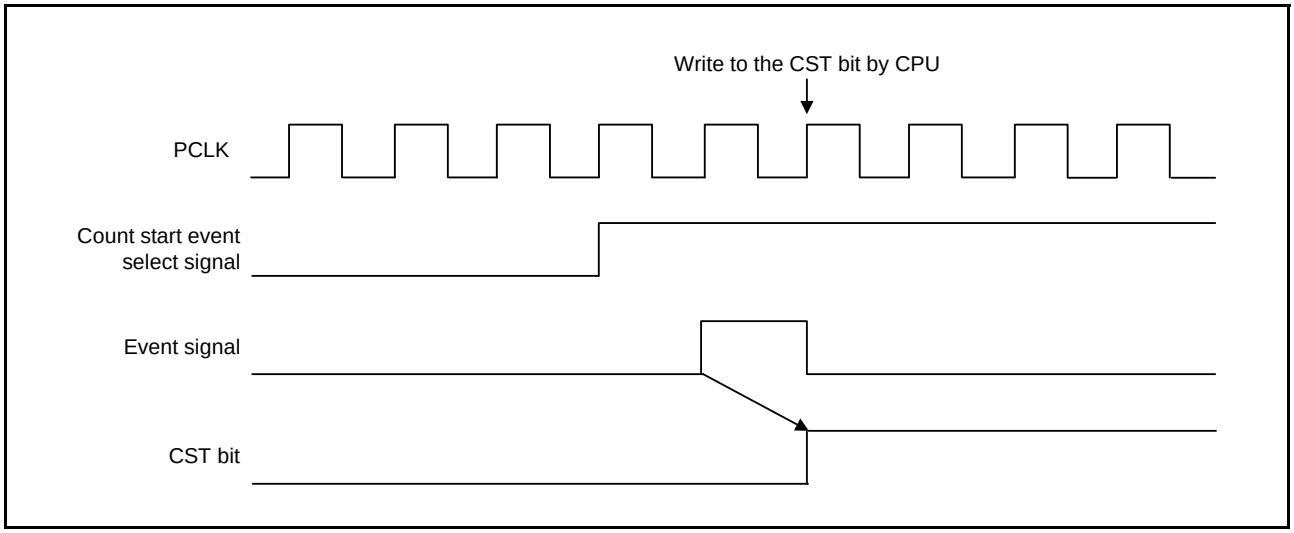

Figure 27.59 Conflict between Writing to the CSTn Bit and Counting Start

(2) Restart Counting

When a TCNTn counter (the timer count register) write cycle and a counting restart are in contention, writing to TCNTn counter does not proceed since the counter value initialization in response to the counting restart takes priority.
Figure 27.60 shows the timing in this case.
Furthermore, even when a counting restart due to the event link is selected, CPU writing to TCNTn counter proceeds if the event signal is low.

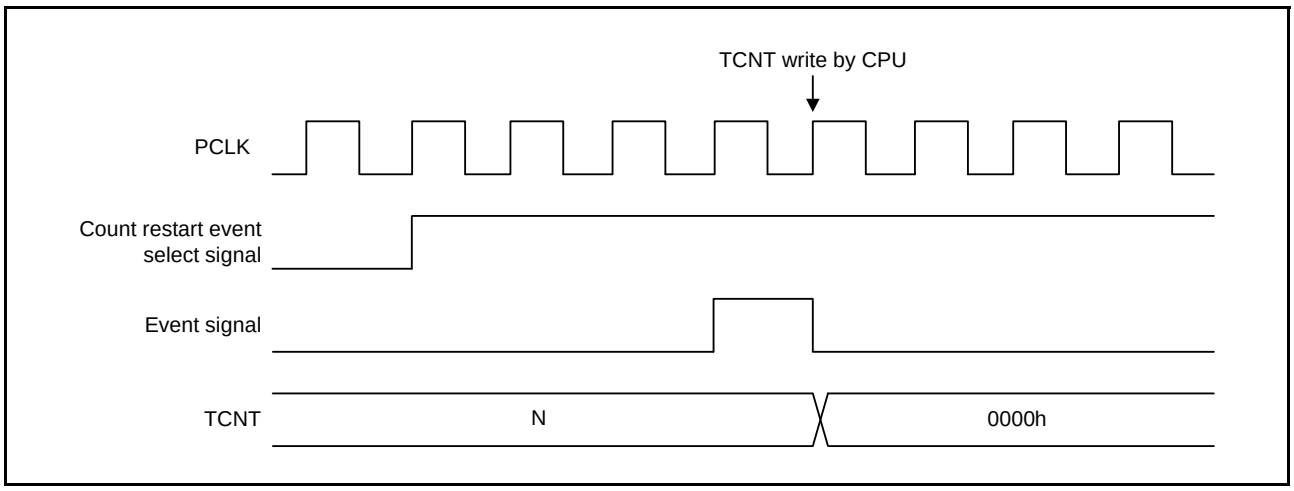

Figure 27.60 Conflict between TCNTn Write Cycle and Counting Restart

(3) Input Capture Operation

If a TGRA register (the timer general register) read/write cycle and input capture operation are in contention, operation proceeds as follows:

(a) Conflict between TGR Read Cycle and Input Capture

The internal data bus reads the data before input capture transfer.
Figure 27.61 shows the timing in this case.

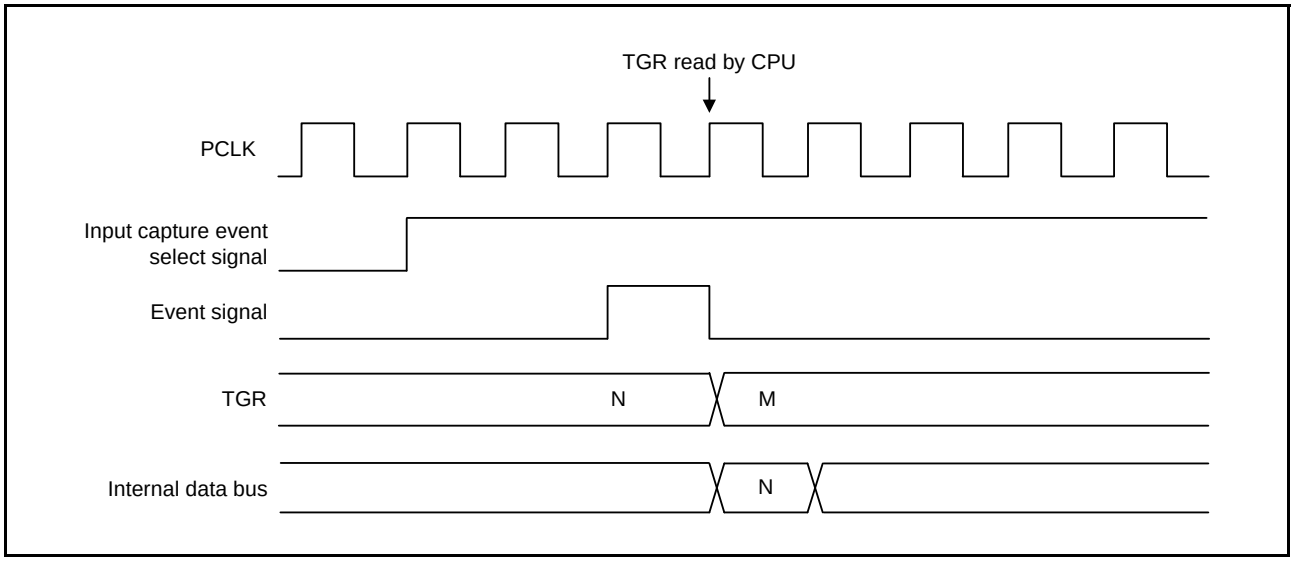

Figure 27.61 Conflict between TGR Read Cycle and Input Capture Operation

(b) Conflict between TGR Write Cycle and Input Capture

Writing to TGRA register does not proceed since input capture takes priority.

Figure 27.62 shows the timing in this case.

Furthermore, even when input capture operation due to the event link is selected, CPU writing to TGR proceeds if the event signal is low.

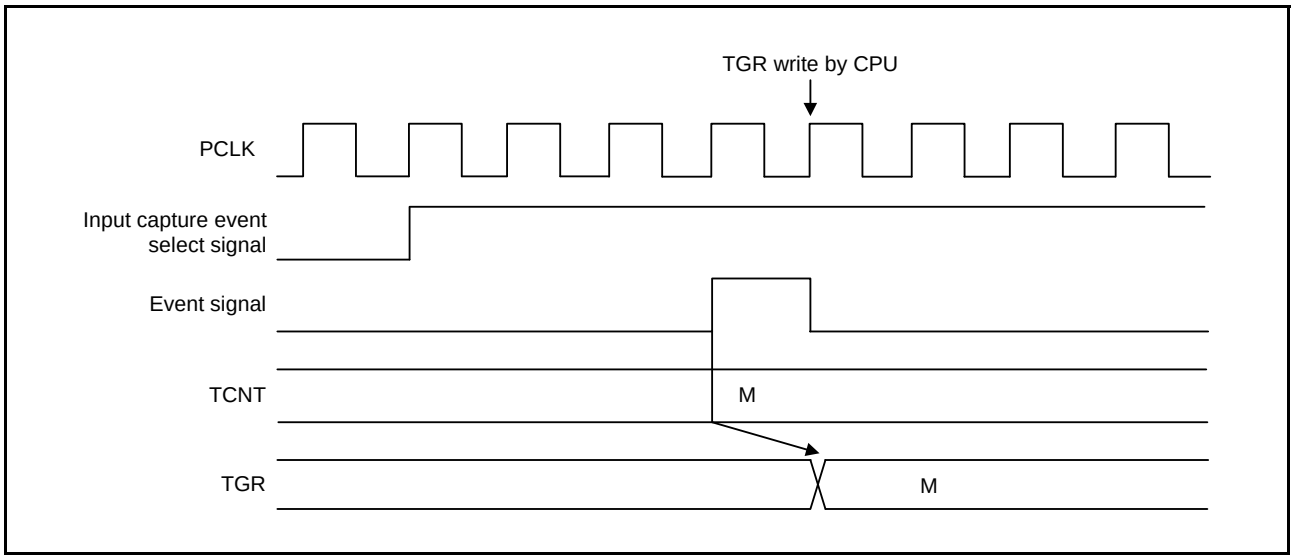

Figure 27.62 Conflict between TGR Write Cycle and Input Capture Operation

27.11.4 Notes on Output of the Event Signal

The followings are the notes on output of the event signal.

(1) Output of the Compare Match Event Signal

When the TGR register is set to 0000h, PCLK/1 is set as the counter clock, and compare match is set as the trigger for clearing of the counter clock (TCRn.TPSC[2:0] = 000b), the value of the TCNT remains 0000h, and the event output signal will be output continuously (i.e. its level will be flat) rather than output over a single cycle.
Figure 27.63 shows the timing for continuous output of the event output signal in response to a compare match.

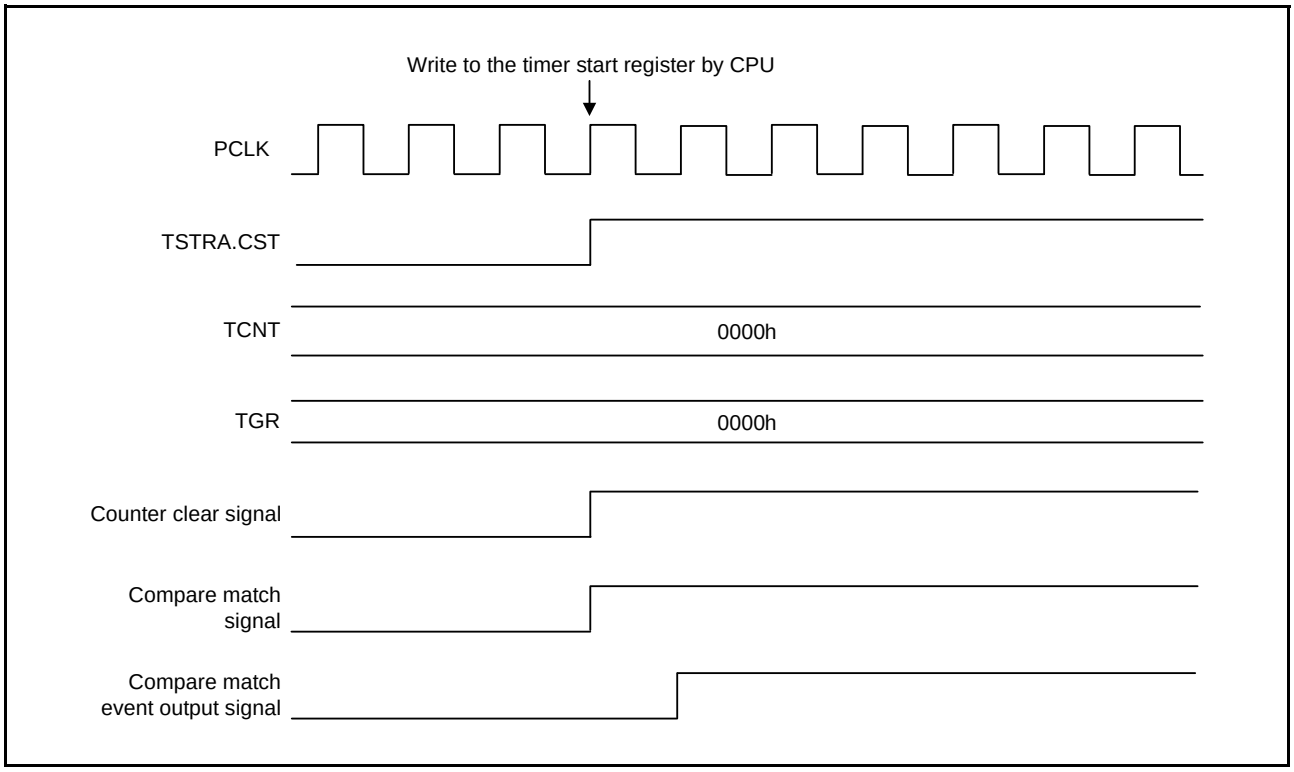

Figure 27.63 Continuous Output of the Compare Match Event Output Signal

(2) Output of the Underflow Event Signal

If two external clock signals' same direction edges to be phase counted are generated within two PCLK cycles in phase counting mode 1, with TGR being 0000h, and compare match set as the counter clear source, the TCNT counter remains 0000h, and a compare-match event signal and an underflow event signal are output continuously to form a flat signal level.

Figure 27.64 shows the timing for continuous output of the event output signal in response to underflow.

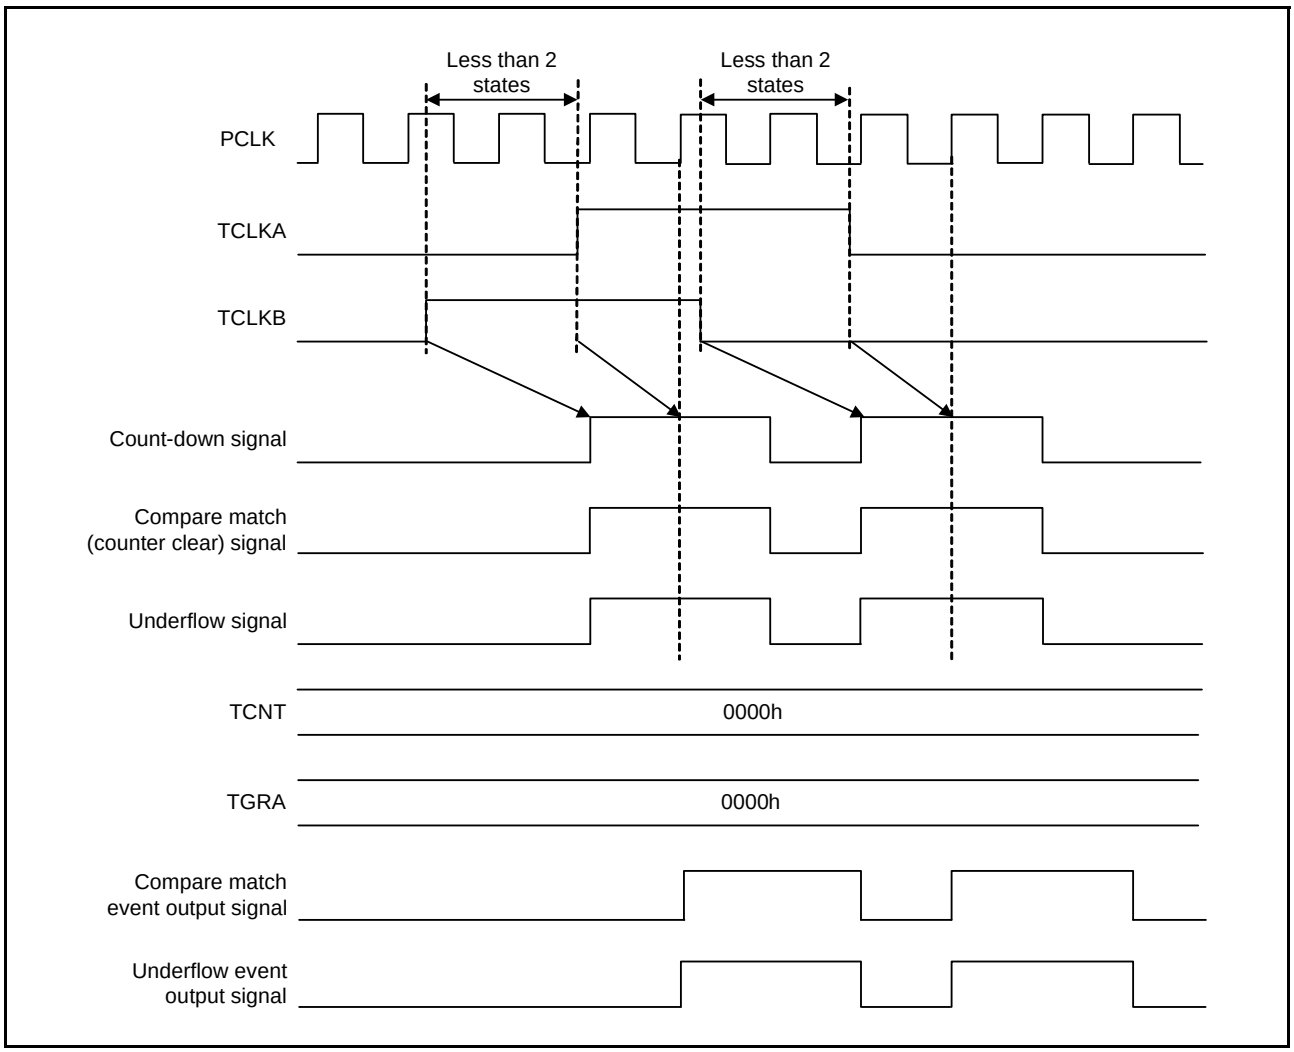

Figure 27.64 Continuous Output of the Underflow Event Output Signal

28. Programmable Pulse Generator (PPG)

The programmable pulse generator (PPG) generates pulse outputs by using the 16-bit timer pulse unit (TPU) and the multi-function timer pulse unit 3 (MTU3) as a time base.
This MCU has two PPG units, each of which controls up to 16 pulse output pins. The pulse outputs from the PPGs are divided into 4-bit groups that can operate all simultaneously and independently.

28.1 Overview

Table 28.1 lists the specifications of the PPG and Table 28.2 lists PPG functions.
Figure 28.1 and Figure 28.2 show block diagrams of the PPGs.

Table 28.1 Specifications of PPG

Item	Specifications
Number of output bits	Up to 32 bits*1
Pulse output	• Two units, each capable of output through four pin groups • Output trigger signals are selectable. • Non-overlapping operation is possible. • Inverted output is selectable.
Output data transfer	Can operate together with the DTC and DMAC (when TPU and MTU3 interrupts are in use)
Power consumption reducing function	Module-stop state can be set for each unit.

Note 1. When setting PPG output trigger in MTU3, make settings so that PCLKA run at the same frequency as PCLKB.

Table 28.2 List of PPG Functions

Item			PPG0	PPG1
PPG output trigger	MTU3 channels 0 to 3 (MTU0 to MTU3)*1	Compare match	○	○
		Input capture	○	○
	TPU (unit 0) channels 0 to 3 (TPU0 to TPU3)	Compare match	—	○
		Input capture	—	○
Non-overlapping operation			○	○
Output data transfer	DTC		○	○
	DMAC		○	○
Selecting inverted output			○	○

28.2 Register Descriptions

28.2.1 PPG Trigger Select Register (PTRSLR)

Address(es): 0008 81F0h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	PTRSL
Value after reset:	0	0	0	0	0	0	0	1

- PPG1.PTRSLR

Bit	Symbol	Bit Name	Description	R/W
b0	PTRSL	PPG Trigger Select	0: Selects the set of MTU0 to MTU3 of MTU3 as the trigger channels for PPG1. 1: Selects the set of TPU0 to TPU3 of TPU as the trigger channels for PPG1.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

PTRSL Bit (PPG Trigger Select)

This bit selects either MTU0 to MTU3 of MTU3 or TPU0 to TPU3 of TPU as a set of trigger channels for PPG1. When this bit is set to 0, MTU0 to MTU3 of MTU3 are selected as a set of trigger channels for PPG1. When it is set to 1, TPU0 to TPU3 of TPU are selected as a set of trigger channels for PPG1.

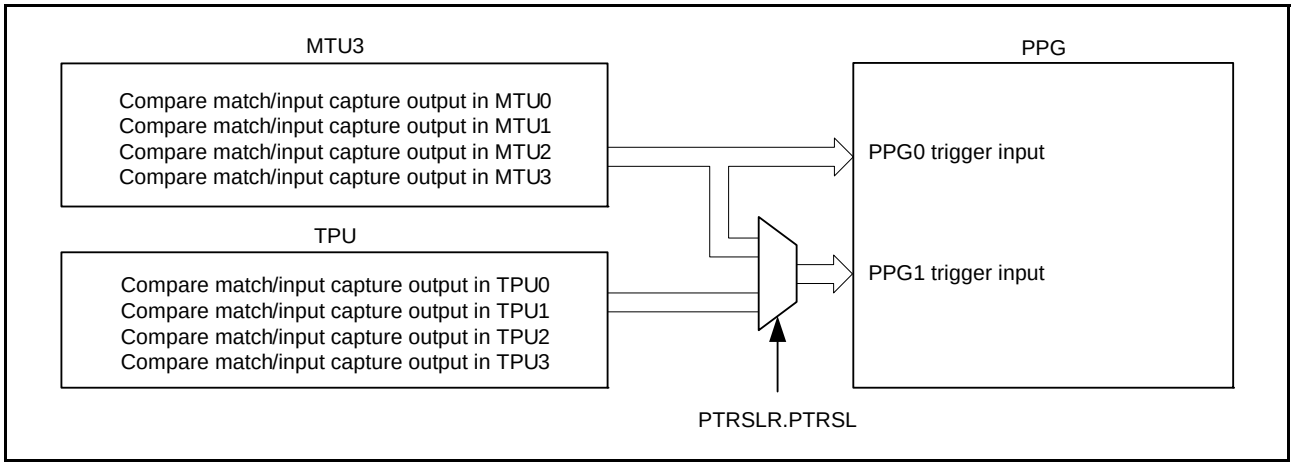

Figure 28.3 Block Diagram of PPG Trigger Selection

28.2.2 Next Data Enable Registers H (NDERH) Next Data Enable Registers L (NDERL)

Address(es): 0008 81E8h

	b7	b6	b5	b4	b3	b2	b1	b0
PPG0.NDERH	NDER 15	NDER 14	NDER 13	NDER 12	NDER 11	NDER 10	NDER9	NDER8
Value after reset:	0	0	0	0	0	0	0	0

b5	NDER 13	Next Data Transfer Enable		R/W
b6	NDER 14	Next Data Transfer Enable		R/W
b7	NDER 15	Next Data Transfer Enable		R/W

PPG0.NDERH selects the pins (PO15 to PO8) for outputs of pulse from the PPG on a bit-by-bit basis.

NDERi Bits (Next Data Transfer Enable) (i = 15 to 8)

When these bits are set to 1, the PPG0.PCR specified trigger transfers data from the corresponding bit in PPG0.NDRH to the bit in PPG0.PODRH. When these bits are set to 0, the data are not transferred from PPG0.NDRH to PPG0.PODRH.

- PPG0.NDERL

Bit	Symbol	Bit Name	Description	R/W
b0	NDER0	Next Data Transfer Enable	0: Data transfer is disabled. 1: Data transfer is enabled.	R/W
b1	NDER1	Next Data Transfer Enable		R/W
b2	NDER2	Next Data Transfer Enable		R/W
b3	NDER3	Next Data Transfer Enable		R/W

b5	NDER5	Next Data Transfer Enable		R/W
b6	NDER6	Next Data Transfer Enable		R/W
b7	NDER7	Next Data Transfer Enable		R/W

PPG0.NDERL selects the pins (PO7 to PO0) for outputs of pulse from the PPG on a bit-by-bit basis.

NDERi Bits (Next Data Transfer Enable) (i = 7 to 0)

When these bits are set to 1, the PPG0.PCR specified trigger transfers data from the corresponding bit in PPG0.NDRL to the bit in PPG0.PODRL. When these bits are set to 0, the data are not transferred from PPG0.NDRL to PPG0.PODRL.

Address(es): 0008 81F8h

b5	NDER 29	Next Data Transfer Enable		R/W
b6	NDER 30	Next Data Transfer Enable		R/W
b7	NDER 31	Next Data Transfer Enable		R/W

PPG1.NDERH selects the pins (PO31 to PO24) for outputs of pulse from the PPG on a bit-by-bit basis.

NDERi Bits (Next Data Transfer Enable) (i = 31 to 24)

When these bits are set to 1, the PPG1.PCR specified trigger transfers data from the corresponding bit in PPG1.NDRH to the bit in PPG1.PODRH. When these bits are set to 0, the data are not transferred from PPG1.NDRH to PPG1.PODRH.

- PPG1.NDERL

Bit	Symbol	Bit Name	Description	R/W
b0	NDER 16	Next Data Transfer Enable	0: Data transfer is disabled. 1: Data transfer is enabled.	R/W
b1	NDER 17	Next Data Transfer Enable		R/W
b2	NDER 18	Next Data Transfer Enable		R/W
b3	NDER 19	Next Data Transfer Enable		R/W
b4	NDER 20	Next Data Transfer Enable		R/W
b5	NDER 21	Next Data Transfer Enable		R/W
b6	NDER 22	Next Data Transfer Enable		R/W
b7	NDER 23	Next Data Transfer Enable		R/W

PPG1.NDERL selects the pins (PO23 to PO16) for outputs of pulse from the PPG on a bit-by-bit basis.

NDERi Bits (Next Data Transfer Enable) (i = 23 to 16)

When these bits are set to 1, the PPG1.PCR specified trigger transfers data from the corresponding bit in PPG1.NDRL to the bit in PPG1.PODRL. When these bits are set to 0, the data are not transferred from PPG1.NDRL to PPG1.PODRL.

28.2.3 Output Data Registers H (PODRH) Output Data Registers L (PODRL)

Address(es): 0008 81EAh

	b7	b6	b5	b4	b3	b2	b1	b0

b3	POD11	Output Data Register		R/W
b4	POD12	Output Data Register		R/W
b5	POD13	Output Data Register		R/W
b6	POD14	Output Data Register		R/W
b7	POD15	Output Data Register		R/W

PPG0.PODRH stores pulse output values. For bits corresponding to pins that have been set for pulse output by PPG0.NDERH, the output trigger transfers the values in PPG0.NDRH to this register.

PODi Bit (Output Data Register) (i = 15 to 8)

When an output trigger is generated during PPG operation, the values of bits for which data transfer is enabled in the PPG0.NDERH register are transferred from the PPG0.NDRH register to this register. Writing from the CPU is impossible while any of the NDERi (i = 15 to 8) bits in PPG0.NDERH is 1. The initial output level for the pulse signal can be set when the value in the PPG0.NDERH register is 00h.

- PPG0.PODRL

Bit	Symbol	Bit Name	Description	R/W
b0	POD0	Output Data Register	0: The low level is output on the POi pin. 1: The high level is output on the POi pin. (i = 7 to 0)	R/W
b1	POD1	Output Data Register		R/W
b2	POD2	Output Data Register		R/W
b3	POD3	Output Data Register		R/W
b4	POD4	Output Data Register		R/W
b5	POD5	Output Data Register		R/W
b6	POD6	Output Data Register		R/W
b7	POD7	Output Data Register		R/W

PPG0.PODRL stores pulse output values. For bits corresponding to pins that have been set for pulse output by PPG0.NDERL, the output trigger transfers the values in PPG0.NDRL to this register.

PODi Bit (Output Data Register) (i = 7 to 0)

When an output trigger is generated during PPG operation, the values of bits for which data transfer is enabled in the PPG0.NDERL register are transferred from the PPG0.NDRL register to this register. Writing from the CPU is impossible while any of the NDERi (i = 7 to 0) bits in PPG0.NDERL is 1. The initial output level for the pulse signal can be set when the value in the PPG0.NDERL register is 00h.

- PPG1.PODRH

Bit	Symbol	Bit Name	Description	R/W
b0	POD24	Output Data Register	0: The low level is output on the POi pin. 1: The high level is output on the POi pin. (i = 31 to 24)	R/W
b1	POD25	Output Data Register		R/W
b2	POD26	Output Data Register		R/W
b3	POD27	Output Data Register		R/W
b4	POD28	Output Data Register		R/W
b5	POD29	Output Data Register		R/W
b6	POD30	Output Data Register		R/W
b7	POD31	Output Data Register		R/W

PPG1.PODRH stores pulse output values. For bits corresponding to pins that have been set for pulse output by PPG1.NDERH, the output trigger transfers the values in PPG1.NDRH to this register.

PODi Bit (Output Data Register) (i = 31 to 24)

When an output trigger is generated during PPG operation, the values of bits for which data transfer is enabled in the PPG1.NDERH register are transferred from the PPG1.NDRH register to this register. Writing from the CPU is impossible while any of the NDERi (i = 31 to 24) bits in PPG1.NDERH is 1. The initial output level for the pulse signal can be set when the value in the PPG1.NDERH register is 00h.

- PPG1.PODRL

Bit	Symbol	Bit Name	Description	R/W
b0	POD16	Output Data Register	0: The low level is output on the POi pin. 1: The high level is output on the POi pin. (i = 23 to 16)	R/W
b1	POD17	Output Data Register		R/W
b2	POD18	Output Data Register		R/W
b3	POD19	Output Data Register		R/W
b4	POD20	Output Data Register		R/W
b5	POD21	Output Data Register		R/W
b6	POD22	Output Data Register		R/W
b7	POD23	Output Data Register		R/W

PPG1.PODRL stores pulse output values. For bits corresponding to pins that have been set for pulse output by PPG1.NDERL, the output trigger transfers the values in PPG1.NDRL to this register.

PODi Bit (Output Data Register) (i = 23 to 16)

When an output trigger is generated during PPG operation, the values of bits for which data transfer is enabled in the PPG1.NDERL register are transferred from the PPG1.NDRL register to this register. Writing from the CPU is impossible while any of the NDERi (i = 23 to 16) bits in PPG1.NDERL is 1. The initial output level for the pulse signal can be set when the value in the PPG1.NDERL register is 00h.

28.2.4 Next Data Registers H (NDRH) Next Data Registers L (NDRL)

b7	G3INV	Group 7 Output Polarity Change	0: Inverted output 1: Direct output	R/W

PPGn.PMR (n = 0, 1) selects the pulse output mode of the PPG on a group-by-group basis.
While inverted output is selected, a low-level pulse is output when the values in PPGn.PODRH and PPGn.PODRL are 1, and a high-level pulse is output when the values in PPGn.PODRH and PPGn.PODRL are 0.
In addition, when non-overlapping operation is selected, the PPG updates its output values on compare match A or B in an MTU3 or TPU channel that functions as an output trigger.
For details, see section 28.3.4, Non-Overlapping Pulse Output.

28.3 Operation

Figure 28.4 shows a schematic diagram of the PPG.
PPG pulse output is enabled when the corresponding bits in PPGn.NDERH and PPGn.NDERL (n = 0, 1) are set to 1 (data transfer is enabled).
An initial output value is determined by the initial settings in the corresponding PPGn.PODRH and PPGn.PODRL.
When the compare match event selected in PPGn.PCR occurs, the output values are updated by transfer of the values in the corresponding PPGn.NDRH and PPGn.NDRL to PPGn.PODRH and PPGn.PODRL, respectively.
Consecutive output of up to 16 bits of data is possible by writing new output data to PPGn.NDRH and PPGn.NDRL before the next compare match.

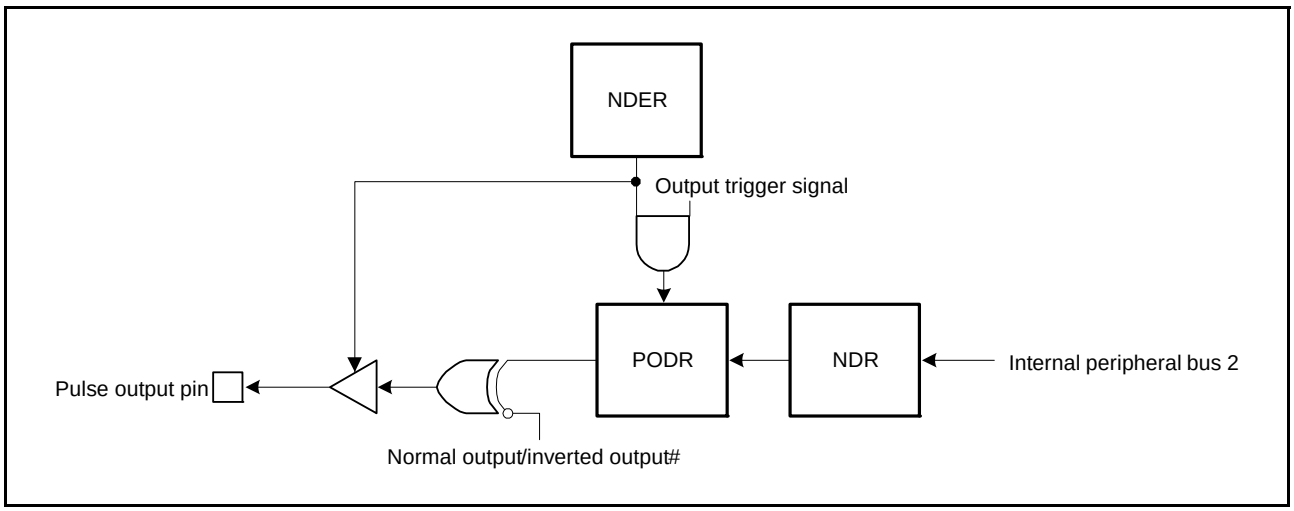

Figure 28.4 Schematic Diagram of PPG

28.3.1 Output Timing

When the selected compare match event occurs while pulse output is enabled, the values in PPGn.NDRH and PPGn.NDRL (n = 0, 1) are transferred to PPGn.PODRH and PPGn.PODRL, respectively, and then output on the corresponding pins.

Figure 28.5 shows the timing of the above operation. In this case, the timing when compare match A triggers normal output from groups 2 and 3 is shown.

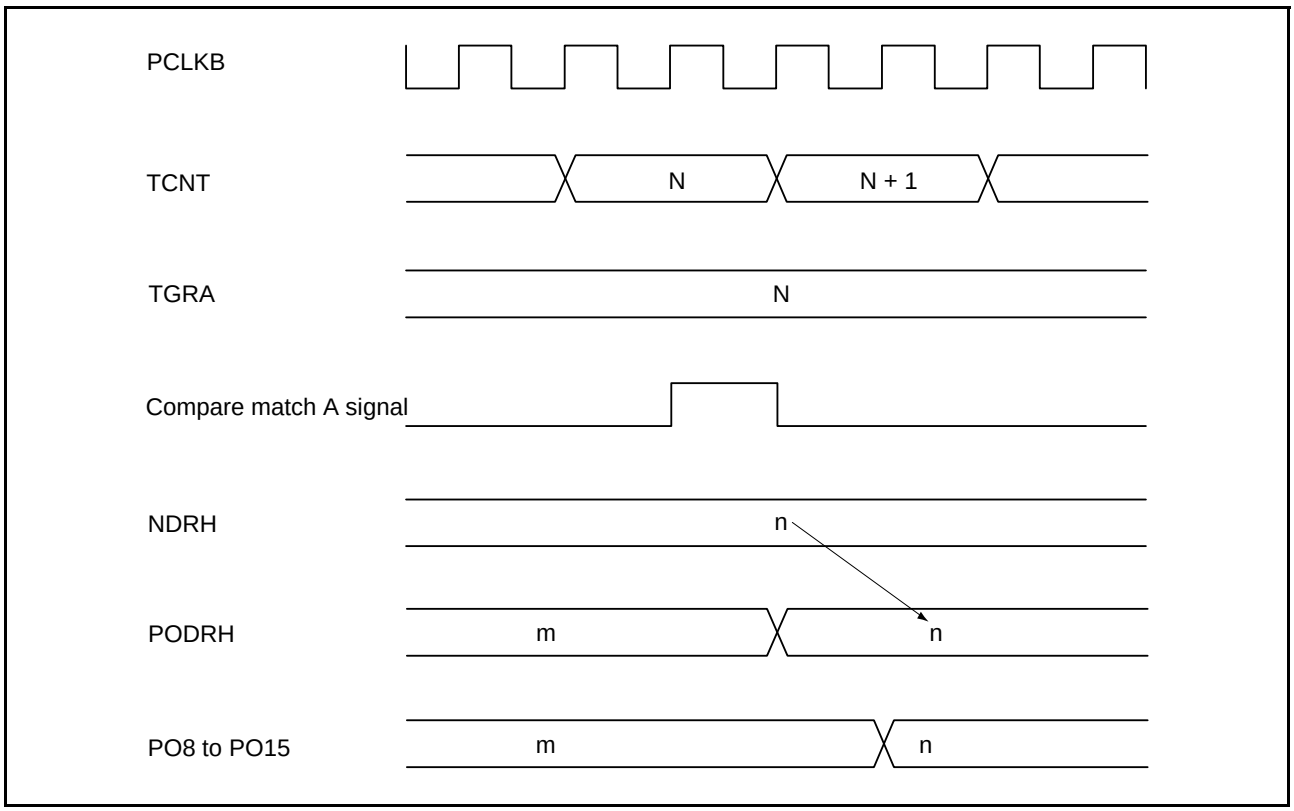

Figure 28.5 Timing of Transfer and Output of the Values in NDR (Example)

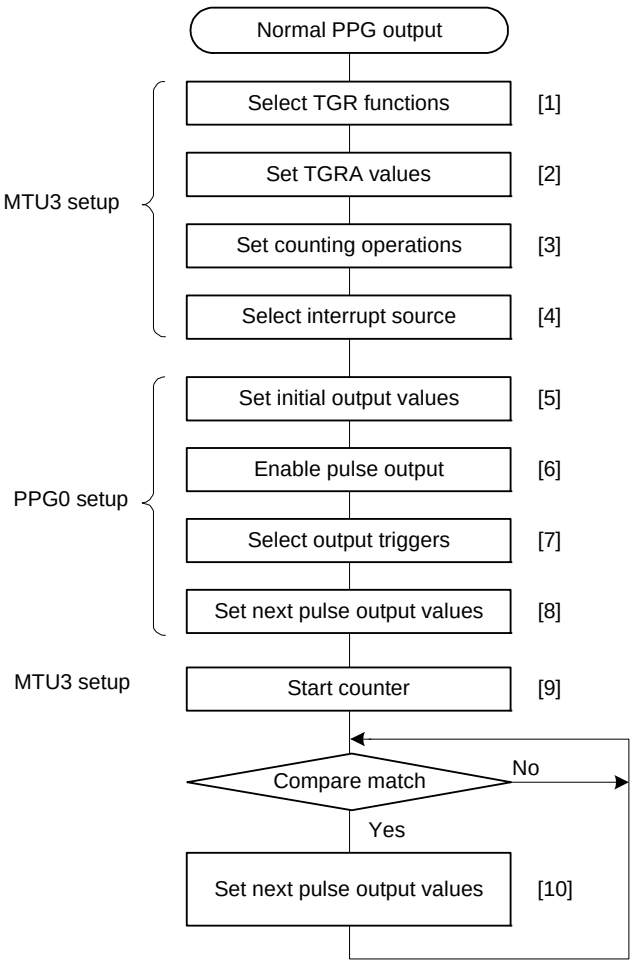
28.3.2 Sample Setup Procedure for Normal Pulse Output

Figure 28.6 and Figure 28.7 show sample procedures for setting normal pulse output.

(1) PPG0 Setting



[1] Use the TIOR register for MTU3 to set the TGRA register to an output compare register (toggle output).

[2] Set the PPG output trigger period.

[3] Select the counter clock source with the TCR.TPSC[2:0] bits. Select the counter clear source with the TCR.CCLR[2:0] bits.

[4] Enable the TGIA interrupt in TIER register. The DTC or DMAC can also be set up to transfer data to NDR.

[5] Set the initial output values in PODR register.

[6] Set the bits In NDER register for the pins to be used for pulse output to 1.

[7] Select the MTU3 compare match event to be used as the output trigger in PCR register.

[8] Set the next pulse output values in NDR register.

[9] Set the TSTR.CST bit to 1 to start the TCNT counter.

[10] At each TGIA interrupt, set the next output values in NDR register.

Figure 28.6 Sample Setup Procedure for Normal Pulse Output (PPG0 Setting)

(2) PPG1 Setting

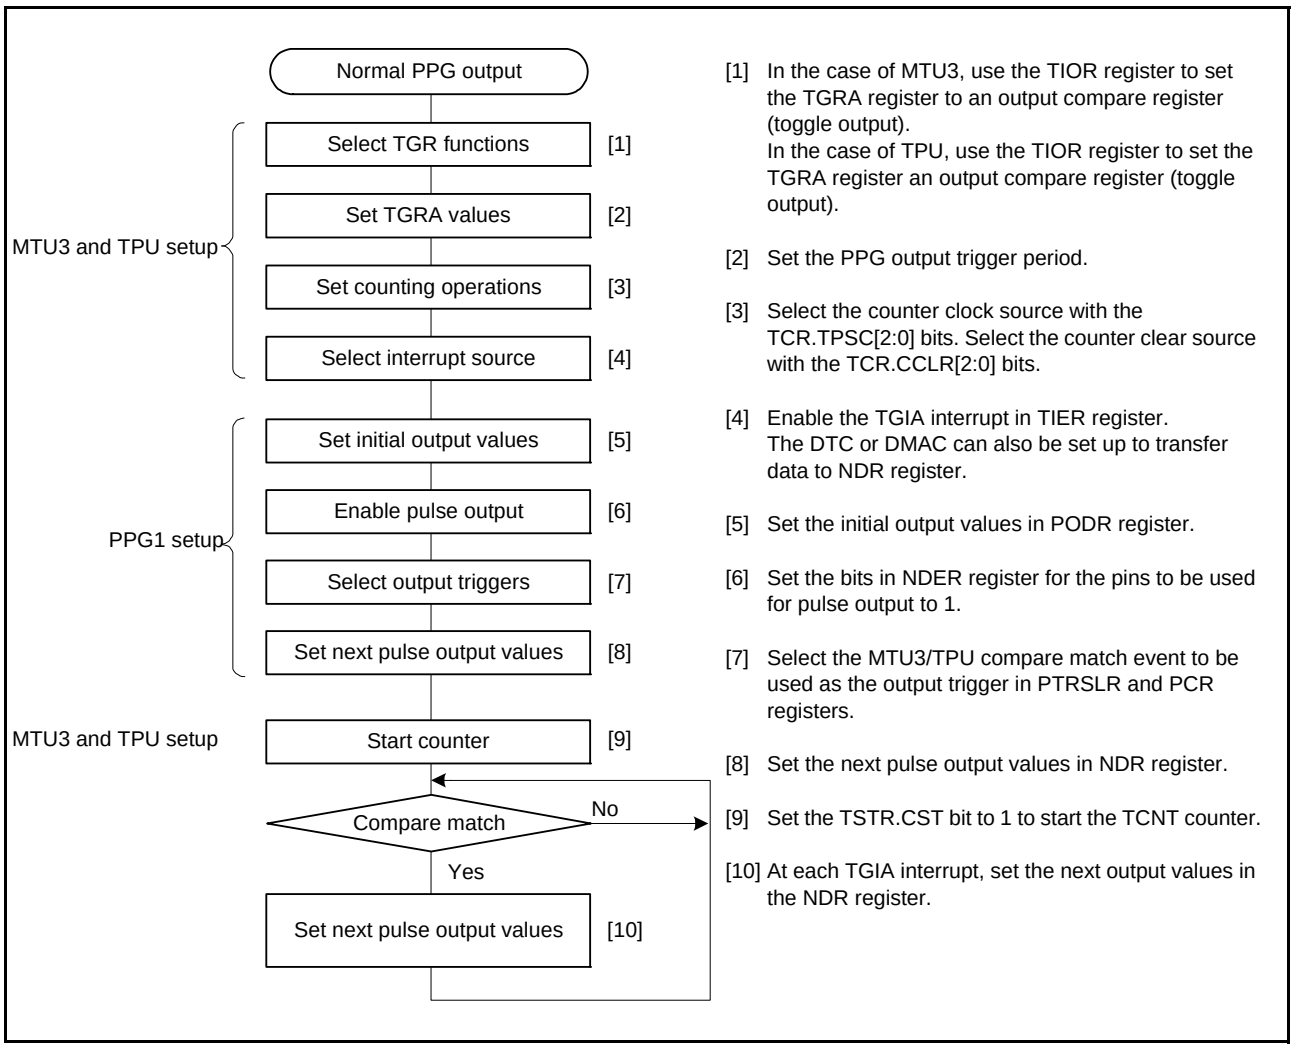


Figure 28.7 Sample Setup Procedure for Normal Pulse Output (PPG1 Setting)

28.3.3 Example of Normal Pulse Output (Example of Five-Phase Pulse Output)

Figure 28.8 shows an example in which pulse output from the PPG0 is used for cyclic five-phase pulse output.

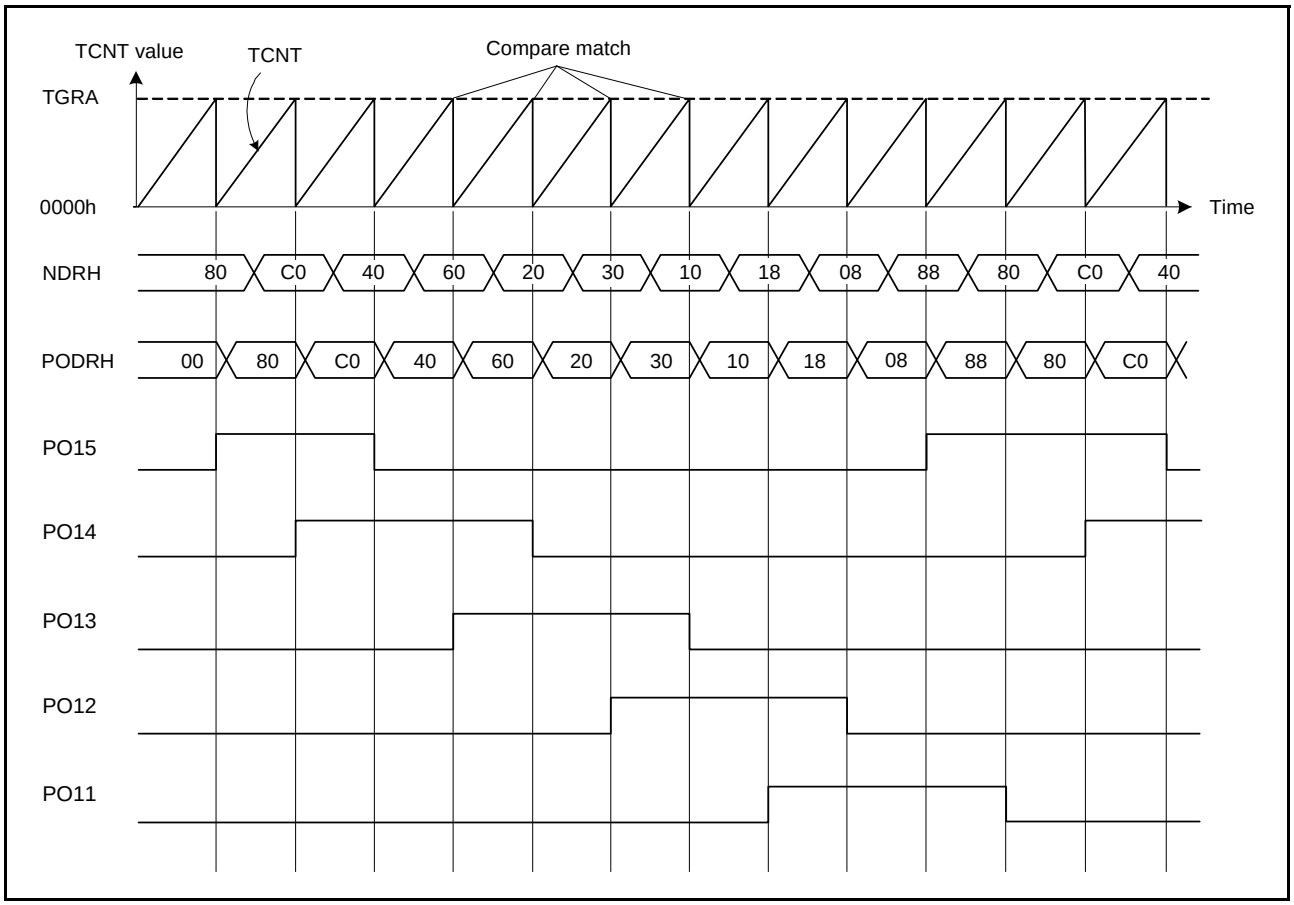

Figure 28.8 Example of Normal Pulse Output (Example of Five-Phase Pulse Output)

1. Set an output compare register of the MTUn.TGRA (n = 0 to 3) of MTU3 so that the corresponding compare match signal is the output trigger. Set a cycle in TGRA so that the counter will be cleared by compare match A. Set the MTUn.TIER.TGIEA bit to 1 to enable the compare match/input capture A (TGIAn) interrupt.
2. Write F8h to PPG0.NDERH, and set the G3CMS[1:0] and G2CMS[1:0] bits in PPG0.PCR to select the respective compare matches in the MTUn selected in the previous step to be the output triggers. Write output data 80h to PPG0.NDRH.
3. The timer counter in the MTU3 starts. When compare match A occurs, the values in PPG0.NDRH are transferred to PPG0.PODRH and output. The TGIAn interrupt handling routine writes the next output data C0h to PPG0.NDRH.
4. Five-phase pulse output (one or two phases active at a time) can be obtained subsequently by writing 40h, 60h, 20h, 30h, 10h, 18h, 08h, 88h... at successive TGIAn interrupts.
   If the DTC or DMAC is set for activation by the TGIAn interrupt, pulse output can be obtained without imposing a load on the CPU.

28.3.4 Non-Overlapping Pulse Output

During non-overlapping operation, data transfer from PPGn.NDRH and PPGn.NDRL (n = 0, 1) to PPGn.PODRH and PPGn.PODRL is performed as follows.

- On compare match A, the values in PPGn.NDRH and PPGn.NDRL are always transferred to PPGn.PODRH and PPGn.PODRL.
- On compare match B, data transfer proceeds for bits in PPGn.NDRH and PPGn.NDRL that have the value 0. It does not proceed for bits having the value 1.
  Figure 28.9 shows the non-overlapping pulse output operation.

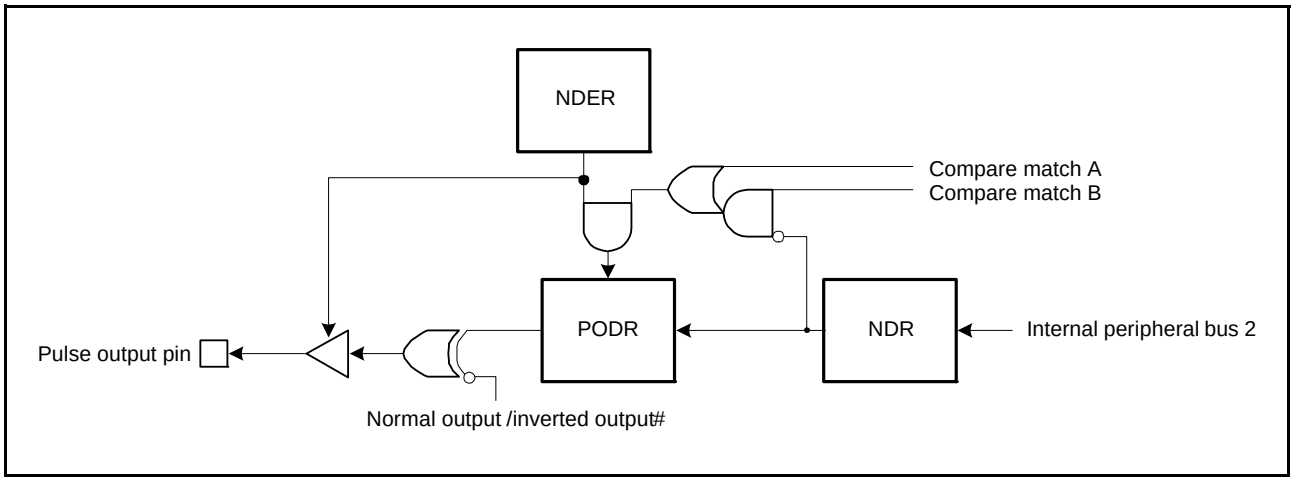

Figure 28.9 Non-Overlapping Pulse Output

Therefore, compare match B before compare match A allows 0-valued data to be transferred in advance of 1-valued data. Do not change the values in PPGn.NDRH and PPGn.NDRL during the interval from compare match B to compare match A (the non-overlap margin).
To transfer 0-valued data in advance of 1-valued data, write the next data to PPGn.NDRH and PPGn.NDRL from within the TGIA interrupt handling routine or by using a TGIA interrupt to activate transfer by the DTC or DMAC. In any case, the next data must be written before the next compare match B occurs.
Figure 28.10 shows the timing of the above procedure.

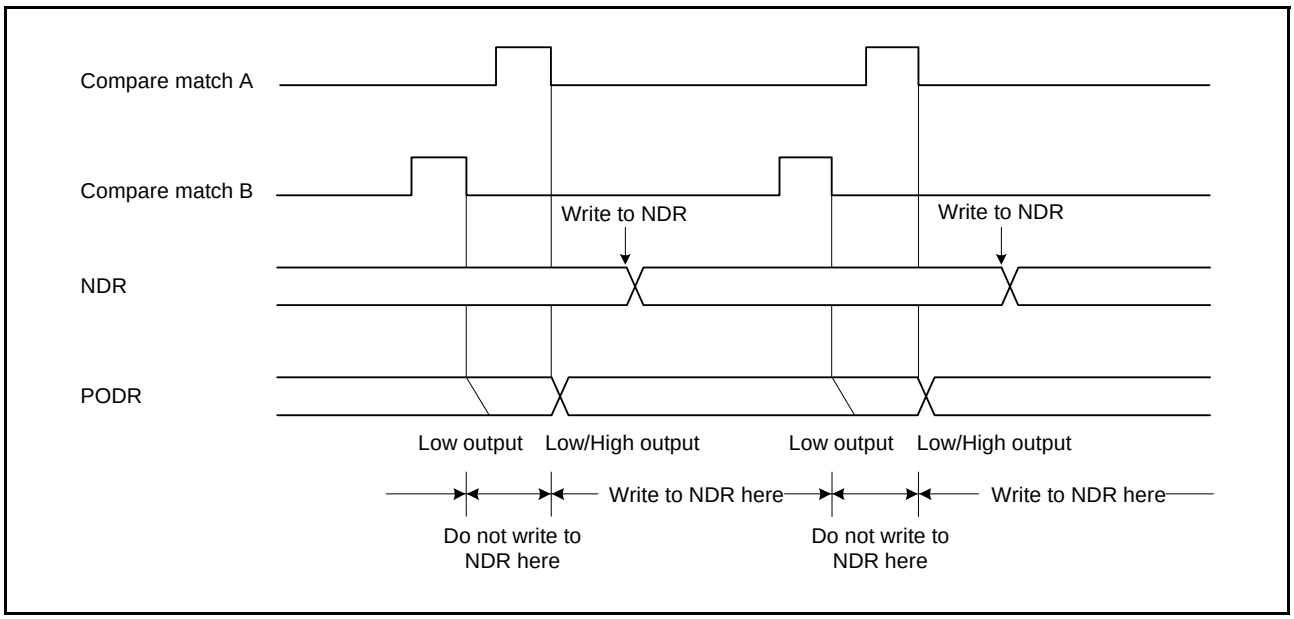

Figure 28.10 Non-Overlapping Operation and Write Timing to PPGn.NDRH and PPGn.NDRL

28.3.5 Sample Setup Procedure for Non-Overlapping Pulse Output

Figure 28.11 and Figure 28.12 show sample procedures for setting up non-overlapping pulse outputs.

(1) PPG0 Setting

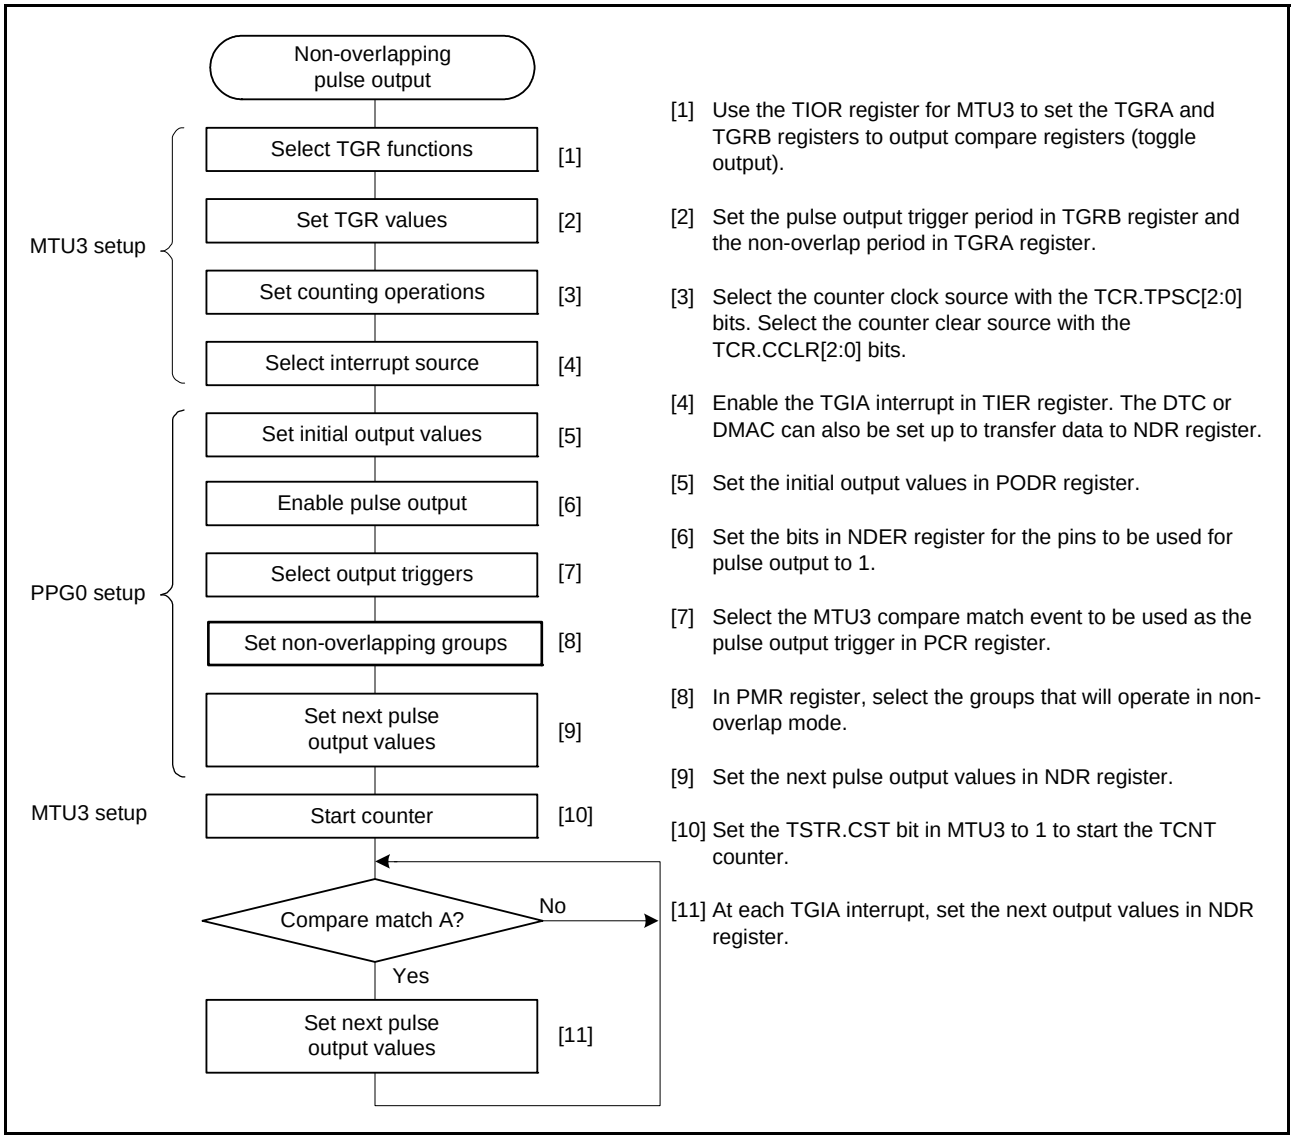

Figure 28.11 Sample Setup Procedure for Non-Overlapping Pulse Output (PPG0 Setting)

(2) PPG1 Setting

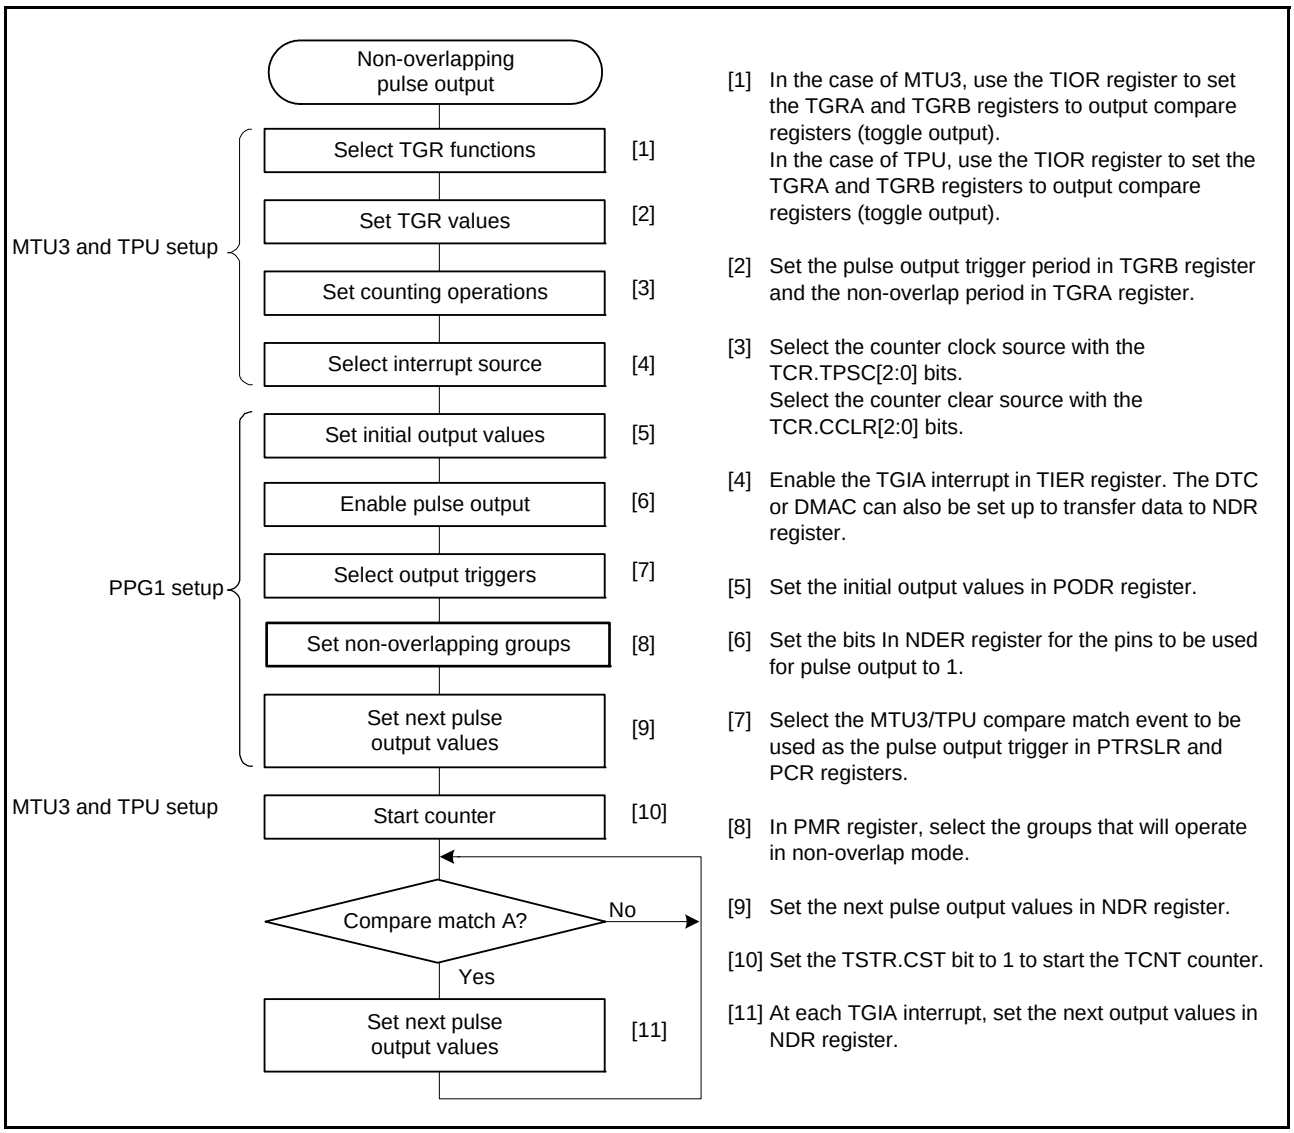

Figure 28.12 Sample Setup Procedure for Non-Overlapping Pulse Output (PPG1 Setting)

28.3.6 Example of Non-Overlapping Pulse Output (Example of Four-Phase Complementary Non-Overlapping Output)

Figure 28.13 shows an example in which pulse output from the PPG0 is used for four-phase complementary non-overlapping pulse output.

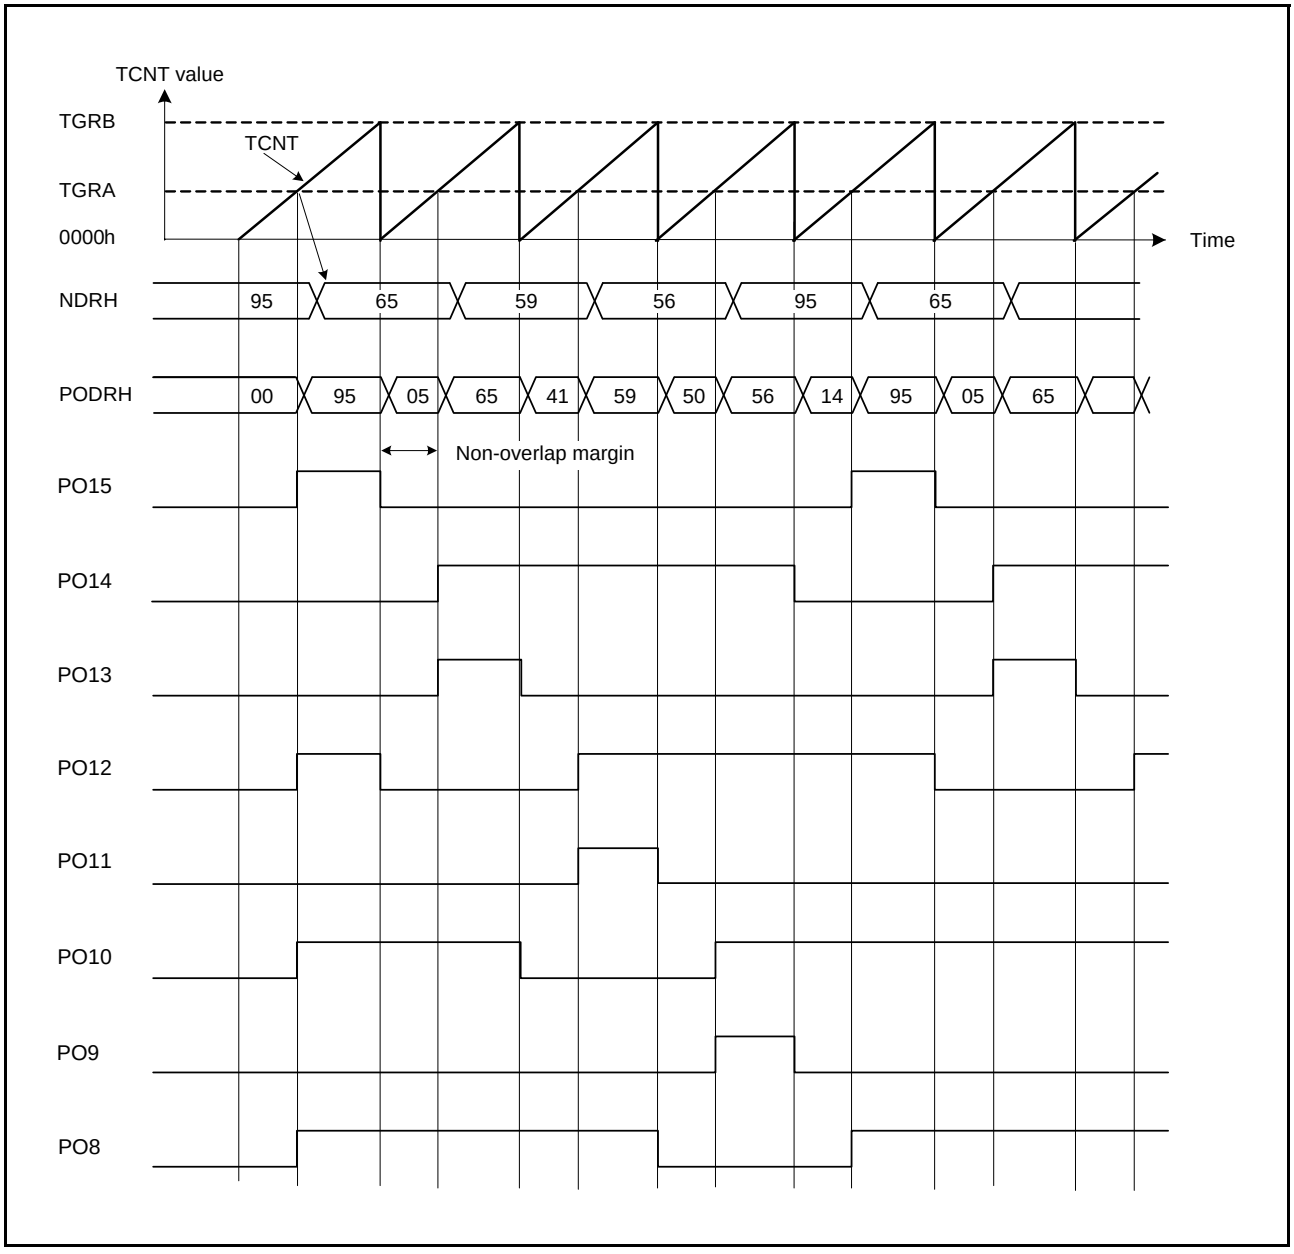

Figure 28.13 Example of Non-Overlapping Pulse Output (Four-Phase Complementary Non-Overlapping Output)

1. Set output compare registers of the MTUn.TGRA and MTUn.TGRB (n = 0 to 3) of MTU3 so that the corresponding compare match signals are the output triggers. Set the trigger period in TGRB and the non-overlap margin in TGRA, and set the counter to be cleared by compare match B. Set the MTUn.TIER.TGIEA bit to 1 to enable the compare match/input capture A (TGIAn) interrupt.
2. Write FFh in PPG0.NDERH, and set the G3CMS[1:0] and G2CMS[1:0] bits in PPG0.PCR to select the respective compare matches in the MTUn selected in the previous step to be the output triggers.
   Set the G3NOV and G2NOV bits in PPG0.PMR to 1 to select non-overlapping outputs. Write output data 95h in PPG0.NDRH.
3. The timer counter in the MTU3 starts. When a compare match with TGRB occurs, outputs change from high to low. When a compare match with TGRA occurs, outputs change from low to high (the change from low to high is delayed by the value set in TGRA).
   The TGIAn interrupt handling routine writes the next output data 65h in PPG0.NDRH.
4. Four-phase complementary non-overlapping pulse output can be obtained subsequently by writing 59h, 56h, 95h... at successive TGIAn interrupts.
   If the DTC or DMAC is set for activation by the TGIAn interrupt, pulse output can be obtained without imposing a load on the CPU.

28.3.7 Inverted Pulse Output

When the G3INV, G2INV, G1INV, and G0INV bits in PPG0.PMR are cleared to 0, the values that are the inverse of the respective values in PPG0.PODRH and PPG0.PODRL can be output.

Figure 28.14 shows the outputs when the G3INV and G2INV bits are cleared to 0 in addition to the settings in Figure 28.13.

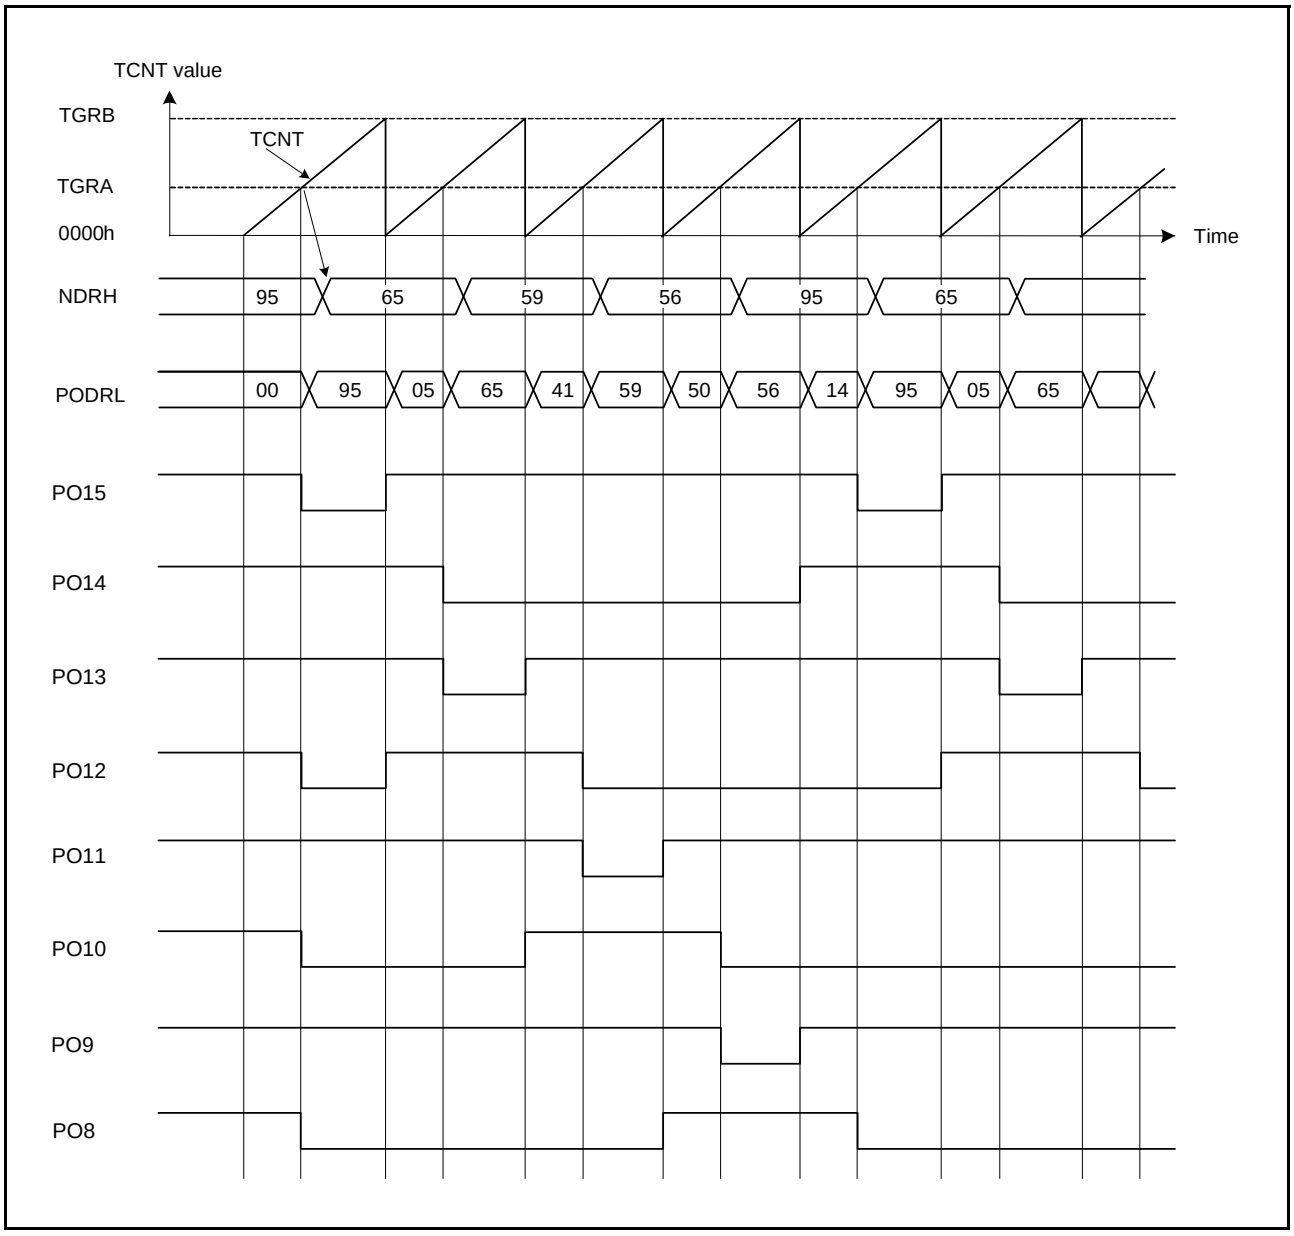

Figure 28.14 Inverted Pulse Output (Example)

28.3.8 Pulse Output Triggered by Input Capture

Pulse output from the PPG0 can be triggered by the MTU3 input capture as well as by compare match. When MTUn.TGRA (n = 0 to 3) functions as an input capture register in the MTU3 channel selected by PPG0.PCR, pulse output is triggered by the input capture signal.
Figure 28.15 shows the timing of pulse output triggered by input capture.

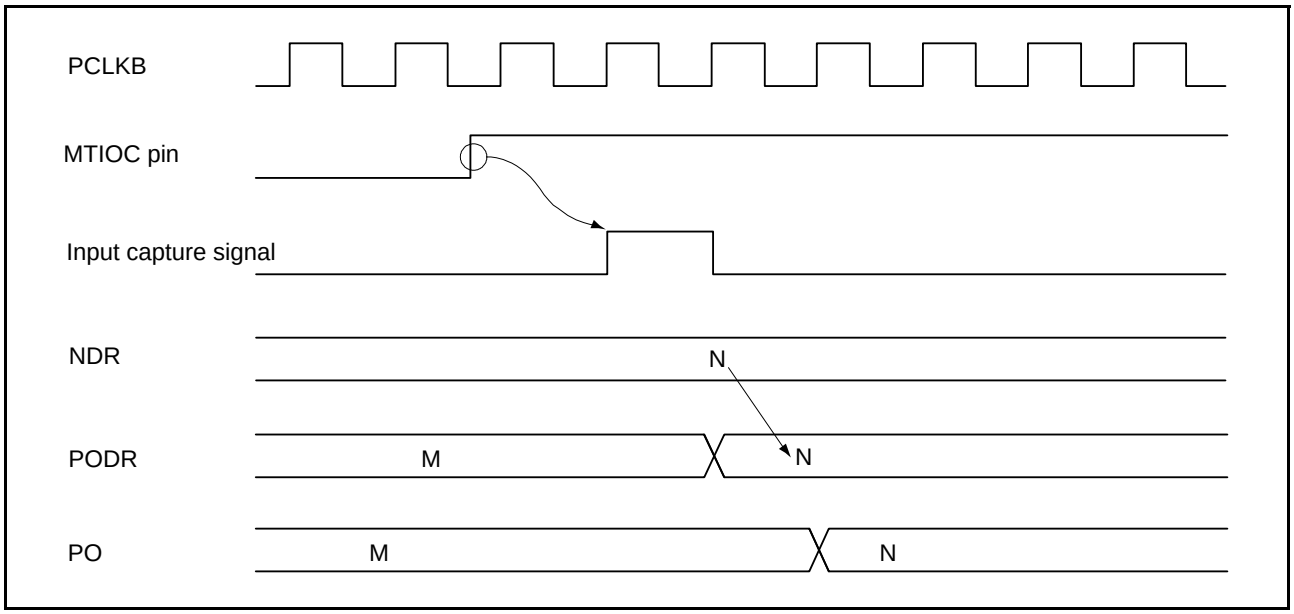

Figure 28.15 Timing of Pulse Output Triggered by Input Capture (Example)

28.4 Usage Note

28.4.1 Module-Stop Function Setting

Operation of the PPG can be disabled or enabled by the module stop control register. The initial setting is for operation of the PPG to be stopped. Register access is enabled by clearing module-stop state. For details, see section 11, Low Power Consumption.

29. 8-Bit Timer (TMR)

This MCU has two units (unit 0, unit 1) of an on-chip 8-bit timer (TMR) module that comprise two 8-bit counter channels, totaling four channels. The 8-bit timer module can be used to count external events and also be used as a multi-function timer in a variety of applications, such as generation of counter reset signal, interrupt requests, and pulse output with a desired duty cycle using a compare-match signal with two registers.
Unit 0 and unit 1 have the same functions, and can generate a baud rate clock for the SCI.
In this section, “PCLK” is used to refer to PCLKB.

29.1 Overview

Table 29.1 lists the specifications of the TMR. Table 29.2 lists the TMR functions.
Figure 29.1 shows a block diagram of the 8-bit timer module (unit 0), and Figure 29.2 shows that of the 8-bit timer module (unit 1).

Table 29.1 Specifications of TMR

Item	Description
Count clock	• Internal clock: PCLK/1, PCLK/2, PCLK/8, PCLK/32, PCLK/64, PCLK/1024, PCLK/8192 • External clock: external count clock
Number of channels	(8 bits × 2 channels) × 2 units
Compare match	• 8-bit mode (compare match A, compare match B) • 16-bit mode (compare match A, compare match B)
Counter clear	Selected by compare match A or B, or an external counter reset signal.
Timer output	Output pulses with a desired duty cycle or PWM output
Cascading of two channels	• 16-bit count mode 16-bit timer using TMR0 for the upper 8 bits and TMR1 for the lower 8 bits (TMR2 for the upper 8 bits and TMR3 for the lower 8 bits) • Compare match count mode TMR1 can be used to count TMR0 compare matches (TMR3 can be used to count TMR2 compare matches).
Interrupt sources	Compare match A, compare match B, and overflow
Event link function (Output)	Compare match A, compare match B, and overflow (TMR0 to TMR3)
Event link function (Input)	One of the following three operations proceeds in response to an event reception: (1) Counting start operation (TMR0 to TMR3) (2) Event counting operation (TMR0 to TMR3) (3) Counting restart operation (TMR0 to TMR3)
DTC activation	DTC can be activated by compare match A interrupts or compare match B interrupts.
A/D conversion start trigger of the A/D converter	Compare match A of TMR0 and TMR2
Capable of generating baud rate clock for SCI	Generates baud rate clock for SCI.*1
Low power consumption function	Each unit can be placed in a module stop state

Note 1. For details, see section 40, Serial Communications Interface (SCIg, SCIh).

Table 29.2 TMR Functions

Item		Unit 0			Unit 1

		TMRI2	Input	Inputs external counter reset
	TMR3	TMO3	Output	Outputs compare match
		TMCI3	Input	Inputs external count clock
		TMRI3	Input	Inputs external counter reset

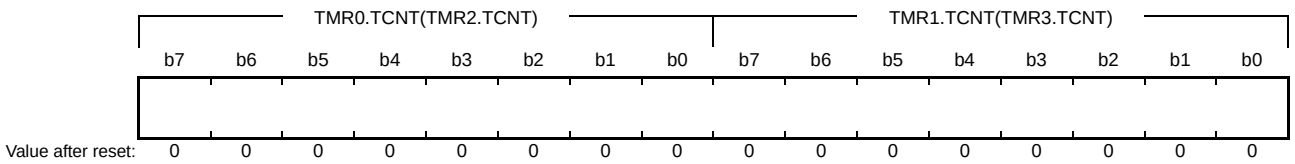
29.2 Register Descriptions

Table 29.4 Register Allocation for 16-Bit Access

Address	Upper 8 Bits	Lower 8 Bits
0008 8208h	TMR0.TCNT	TMR1.TCNT
0008 8204h	TMR0.TCORA	TMR1.TCORA
0008 8206h	TMR0.TCORB	TMR1.TCORB
0008 820Ah	TMR0.TCCR	TMR1.TCCR
0008 8218h	TMR2.TCNT	TMR3.TCNT
0008 8214h	TMR2.TCORA	TMR3.TCORA
0008 8216h	TMR2.TCORB	TMR3.TCORB
0008 821Ah	TMR2.TCCR	TMR3.TCCR

29.2.1 Timer Counter (TCNT)

Address(es): TMR0.TCNT 0008 8208h, TMR1.TCNT 0008 8209h, TMR2.TCNT 0008 8218h, TMR3.TCNT 0008 8219h



TCNT is an 8-bit readable/writable up-counter.
TMR0.TCNT and TMR1.TCNT (TMR2.TCNT and TMR3.TCNT) comprise a single 16-bit counter so they can be accessed together by a word transfer instruction.
The TCCR.CSS[1:0] and CKS[2:0] bits are used to select a count clock.
TCNT can be cleared by an external counter reset signal, compare match A, or compare match B. Which compare match to be used for clearing is selected by the TCR.CCLR[1:0] bits.
When TCNT overflows (its value changes from FFh to 00h), an overflow interrupt (low-level pulse) is output provided the interrupt request is enabled by the TCR.OVIE bit.
For details on the corresponding interrupt vector number, see section 15, Interrupt Controller (ICUA), and Table 29.6, TMR Interrupt Sources.

29.2.2 Time Constant Register A (TCORA)

Address(es): TMR0.TCORA 0008 8204h, TMR1.TCORA 0008 8205h, TMR2.TCORA 0008 8214h, TMR3.TCORA 0008 8215h

	TMR0.TCORA(TMR2.TCORA)								TMR1.TCORA(TMR3.TCORA)							
	b7	b6	b5	b4	b3	b2	b1	b0	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

TCORA is an 8-bit readable/writable register.
TMR0.TCORA and TMR1.TCORA (TMR2.TCORA and TMR3.TCORA) comprise a single 16-bit register so they can be accessed together by a word transfer instruction.
The value in TCORA is continually compared with the value in TCNT. When a match is detected, the corresponding compare match A is generated, and a compare match A interrupt (low-level pulse) is output provided the interrupt request is enabled by the TCR.CMIEA bit.
However, comparison is not performed during writing to TCORA. The timer output from the TMOn pin can be freely controlled by this compare match A and the settings of the TCSR.OSA[1:0] bits.

29.2.3 Time Constant Register B (TCORB)

Address(es): TMR0.TCORB 0008 8206h, TMR1.TCORB 0008 8207h, TMR2.TCORB 0008 8216h, TMR3.TCORB 0008 8217h

	TMR0.TCORB(TMR2.TCORB)								TMR1.TCORB(TMR3.TCORB)							
	b7	b6	b5	b4	b3	b2	b1	b0	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

TCORB is an 8-bit readable/writable register.
TMR0.TCORB and TMR1.TCORB (TMR2.TCORB and TMR3.TCORB) comprise a single 16-bit register so they can be accessed together by a word transfer instruction.
The value in TCORB is continually compared with the value in TCNT. When a match is detected, the corresponding compare match B is generated, and a compare match B interrupt (low-level pulse) is output provided the interrupt request is enabled by the TCR.CMIEB bit.
However, comparison is not performed during writing to TCORB. The timer output from the TMOn pin can be freely controlled by this compare match B and the settings of the TCSR.OSB[1:0] bits.

29.2.4 Timer Control Register (TCR)

Address(es): TMR0.TCR 0008 8200h, TMR1.TCR 0008 8201h, TMR2.TCR 0008 8210h, TMR3.TCR 0008 8211h

	b7	b6	b5	b4	b3	b2	b1	b0
	CMIEB	CMIEA	OVIE	CCLR[1:0]		—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4, b3	CCLR[1:0]	Counter Clear*1	b4 b3 0 0: Clearing is disabled 0 1: Cleared by compare match A 1 0: Cleared by compare match B 1 1: Cleared by the external counter reset signal (Select edge or level by the TMRIS bit in TCCR.)	R/W
b5	OVIE	Timer Overflow Interrupt Enable	0: Overflow interrupt requests (OVIn) are disabled 1: Overflow interrupt requests (OVIn) are enabled	R/W
b6	CMIEA	Compare Match Interrupt Enable A	0: Compare match A interrupt requests (CMIAn) are disabled 1: Compare match A interrupt requests (CMIAn) are enabled	R/W
b7	CMIEB	Compare Match Interrupt Enable B	0: Compare match B interrupt requests (CMIBn) are disabled 1: Compare match B interrupt requests (CMIBn) are enabled	R/W

Note 1. To use an external counter reset signal, set the corresponding pin function. For details, refer to section 22, I/O Ports and section 23, Multi-Function Pin Controller (MPC).

CCLR[1:0] Bits (Counter Clear)

Select the condition by which TCNT is cleared.

OVIE Bit (Timer Overflow Interrupt Enable)

Selects whether overflow interrupt requests (OVIn) issued by TCNT are enabled or disabled.

CMIEA Bit (Compare Match Interrupt Enable A)

Selects whether compare match A interrupt requests (CMIAn) that are issued when the value of TCORA corresponds to that of TCNT are enabled or disabled.

CMIEB Bit (Compare Match Interrupt Enable B)

Selects whether compare match B interrupt requests (CMIBn) that are issued when the value of TCORB corresponds to that of TCNT are enabled or disabled.

29.2.5 Timer Counter Control Register (TCCR)

Address(es): TMR0.TCCR 0008 820Ah, TMR1.TCCR 0008 820Bh, TMR2.TCCR 0008 821Ah, TMR3.TCCR 0008 821Bh

	b7	b6	b5	b4	b3	b2	b1	b0
	TMRIS	—	—	CSS[1:0]		CKS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CKS[2:0]	Clock Select*1	See Table 29.5.	R/W
b4, b3	CSS[1:0]	Clock Source Select	See Table 29.5.	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	TMRIS	Timer Reset Detection Condition Select	0: Cleared at rising edge of the external counter reset signal 1: Cleared when the external counter reset signal is high	R/W

Note 1. To use an external count clock, set the corresponding pin function. For details, refer to section 22, I/O Ports and section 23, Multi-Function Pin Controller (MPC).

CKS[2:0] Bits (Clock Select)
CSS[1:0] Bits (Clock Source Select)

The CKS[2:0] and CSS[1:0] bits select a clock. For details, see Table 29.5.

TMRIS Bit (Timer Reset Detection Condition Select)

This bit is enabled when the TCR.CCLR[1:0] bits are 11b (cleared by external counter reset signal) and selects the condition for detecting counter reset (level or edge).

Table 29.5 Clock Input to TCNT and Count Condition

Channel	TCCR Register CSS[1:0] b4	b3	CKS[2:0] b2	b1	b0	Description
TMR0 (TMR2)	0	0	—	0	0	Clock input prohibited
					1	Uses external count clock. Counts at rising edge*1.
				1	0	Uses external count clock. Counts at falling edge*1.
					1	Uses external count clock. Counts at both rising and falling edges*1.
	0	1	0	0	0	Uses internal clock. Counts at PCLK.
					1	Uses internal clock. Counts at PCLK/2.
				1	0	Uses internal clock. Counts at PCLK/8.
					1	Uses internal clock. Counts at PCLK/32.
			1	0	0	Uses internal clock. Counts at PCLK/64.
					1	Uses internal clock. Counts at PCLK/1024.
				1	0	Uses internal clock. Counts at PCLK/8192.
					1	Clock input prohibited
	1	0	—	—	—	Setting prohibited
	1	1	—	—	—	Counts at TMR1.TCNT (TMR3.TCNT) overflow signal*2.
TMR1 (TMR3)	0	0	—	0	0	Clock input prohibited
					1	Uses external count clock. Counts at rising edge*1.
				1	0	Uses external count clock. Counts at falling edge*1.
					1	Uses external count clock. Counts at both rising and falling edges*1.
	0	1	0	0	0	Uses internal clock. Counts at PCLK.
					1	Uses internal clock. Counts at PCLK/2.
				1	0	Uses internal clock. Counts at PCLK/8.
					1	Uses internal clock. Counts at PCLK/32.
			1	0	0	Uses internal clock. Counts at PCLK/64.
					1	Uses internal clock. Counts at PCLK/1024.
				1	0	Uses internal clock. Counts at PCLK/8192.
					1	Clock input prohibited
	1	0	—	—	—	Setting prohibited
	1	1	—	—	—	Counts at TMR0.TCNT (TMR2.TCNT) compare match A*2.

Note 1. To use an external count clock, set the corresponding pin function. For details, see section 22, I/O Ports and section 23, Multi-Function Pin Controller (MPC).

Note 2. If the clock input of TMR0 (TMR2) is the overflow signal of the TMR1.TCNT (TMR3.TCNT) counter and that of TMR1 (TMR3) is the compare match signal of the TMR0.TCNT (TMR2.TCNT) counter, no TCNT count clock is generated. Do not use this setting.

29.2.6 Timer Control/Status Register (TCSR)

- TMR0.TCSR, TMR2.TCSR

Address(es): TMR0.TCSR 0008 8202h, TMR2.TCSR 0008 8212h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	ADTE	OSB[1:0]		OSA[1:0]	
Value after reset:	x	x	x	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b1, b0	OSA[1:0]	Output Select A*1	b1 b0 0 0: No change 0 1: Low is output 1 0: High is output 1 1: Output is inverted (toggle output)	R/W
b3, b2	OSB[1:0]	Output Select B *1	b3 b2 0 0: No change 0 1: Low is output 1 0: High is output 1 1: Output is inverted (toggle output)	R/W
b4	ADTE	A/D Trigger Enable*2	0: A/D conversion start request in response to compare match A is disabled. 1: A/D conversion start request in response to compare match A is enabled.	R/W
b7 to b5	—	Reserved	These bits are read as an undefined value. The write value should be 1.	R/W

Note 1. When the OSA[1:0] and OSB[1:0] bits are all 0, the output enable signal corresponding to the TMOn pin is negated and a request for high-impedance output is issued to the I/O port. Timer output pin is low until the first compare match occurs after a reset when either of the OSA[1:0] or OSB[1:0] bits are 1.

Note 2. For the corresponding A/D channel, see section 57, 12-Bit A/D Converter (S12ADC).

OSA[1:0] Bits (Output Select A)

These bits select a method of TMOn pin output when compare match A of TCORA and TCNT occurs.

OSB[1:0] Bits (Output Select B)

These bits select a method of TMOn pin output when compare match B of TCORB and TCNT occurs.

- TMR1.TCSR, TMR3.TCSR

Address(es): TMR1.TCSR 0008 8203h, TMR3.TCSR 0008 8213h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	OSB[1:0]		OSA[1:0]	
Value after reset:	x	x	x	1	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b1, b0	OSA[1:0]	Output Select A*1	b1 b0 0 0: No change 0 1: Low is output 1 0: High is output 1 1: Output is inverted (toggle output)	R/W
b3, b2	OSB[1:0]	Output Select B *1	b3 b2 0 0: No change 0 1: Low is output 1 0: High is output 1 1: Output is inverted (toggle output)	R/W
b4	—	Reserved	This bit is read as 1. The write value should be 1.	R/W
b7 to b5	—	Reserved	These bits are read as an undefined value. The write value should be 1.	R/W

Note 1. When the OSA[1:0] and OSB[1:0] bits are all 0, the output enable signal corresponding to the TMOn pin is negated and a request for high-impedance output is issued to the I/O port. Timer output pin is low until the first compare match occurs after a reset when either of the OSA[1:0] or OSB[1:0] bits are 1.

OSA[1:0] Bits (Output Select A)

These bits select a method of TMOn pin output when compare match A of TCORA and TCNT occurs.

OSB[1:0] Bits (Output Select B)

These bits select a method of TMOn pin output when compare match B of TCORB and TCNT occurs.

29.2.7 Timer Counter Start Register (TCSTR)

Address(es): TMR0.TCSTR 0008 820Ch, TMR1.TCSTR 0008 820Dh, TMR2.TCSTR 0008 821Ch, TMR3.TCSTR 0008 821Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	TCS
Value after reset:	x	x	x	x	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	TCS	Timer Counter Status	0: Count stopped state in response to ELC. 1: Count start state in response to ELC.	R/W
b7 to b1	—	Reserved	These bits are read as an undefined value. The write value should be 0.	R/W

TCS Bit (Timer Counter Status)

The TCS bit is used to check the state of the timer count in response to ELC.

When this bit is read as 1, it shows the timer start state in response to ELC. When this bit is read as 0, it shows the timer stopped state in response to ELC.

This bit is cleared by writing 0. Do not write 1 to this bit.

The TCS bit is valid only when the count start operation is selected by the ELOPD register of the event controller (ELC). For details, see section 29.7, Link Operation by ELC, or section 21, Event Link Controller (ELC).

29.3 Operation

29.3.1 Pulse Output

Figure 29.3 shows an example of the 8-bit timer being used to generate a pulse output with a desired duty cycle.

1. Set the TCR.CCLR[1:0] bits to 01b (cleared by compare match A) so that TCNT is cleared at a compare match of TCORA.
2. Set the TCSR.OSA[1:0] bits to 10b (high output) and TCSR.OSB[1:0] bits to 01b (low output), causing the output to change to high at a compare match of TCORA and to low at a compare match of TCORB.

With these settings, the 8-bit timer provides pulses output at a cycle determined by TCORA with a pulse width determined by TCORB. No software intervention is required.
The timer output pin is low after the TCSR.OSA[1:0] or TCSR.OSB[1:0] bits are set until the first compare match occurs after a reset.

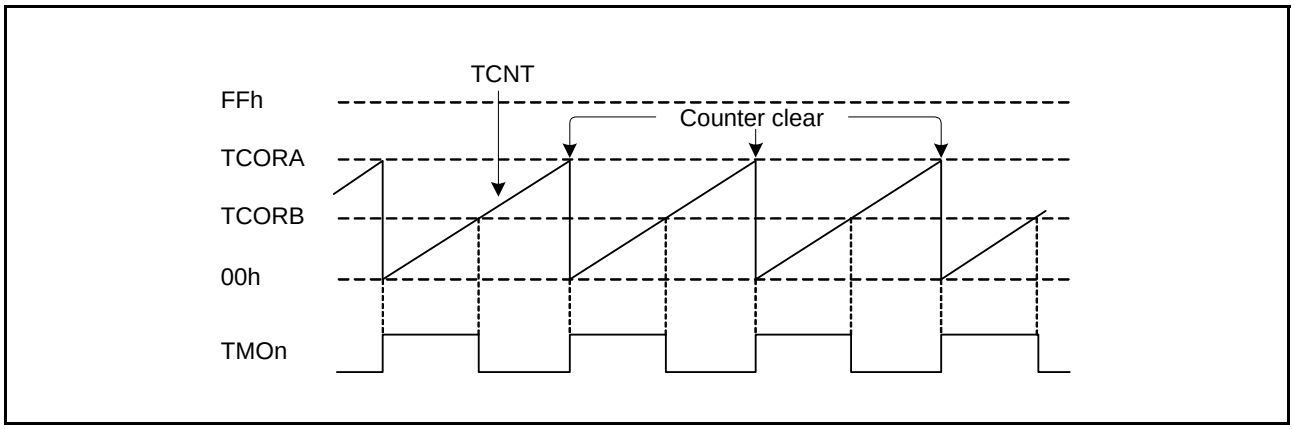


Figure 29.3 Example of Pulse Output (n = 0 to 3)

29.3.2 External Counter Reset Input

Figure 29.4 shows an example of the 8-bit timer being used to generate a pulse which is output after a desired delay time from a TMRIn input.

1. Set the TCR.CCLR[1:0] bits to 11b (cleared by external counter reset signal) and set the TMRIS bit in TCCR to 1 (cleared when the external counter reset signal is high) so that TCNT is cleared at the high level input of the TMRIn signal.
2. Set the TCSR.OSA[1:0] bits to 10b (high output) and the TCSR.OSB[1:0] bits to 01b (low output), causing the output to change to high at a compare match of TCORA and to low at a compare match of TCORB.

With these settings, the 8-bit timer provides pulses output at a desired delay time from a TMRIn input determined by TCORA and with a pulse width determined by TCORB and TCORA.

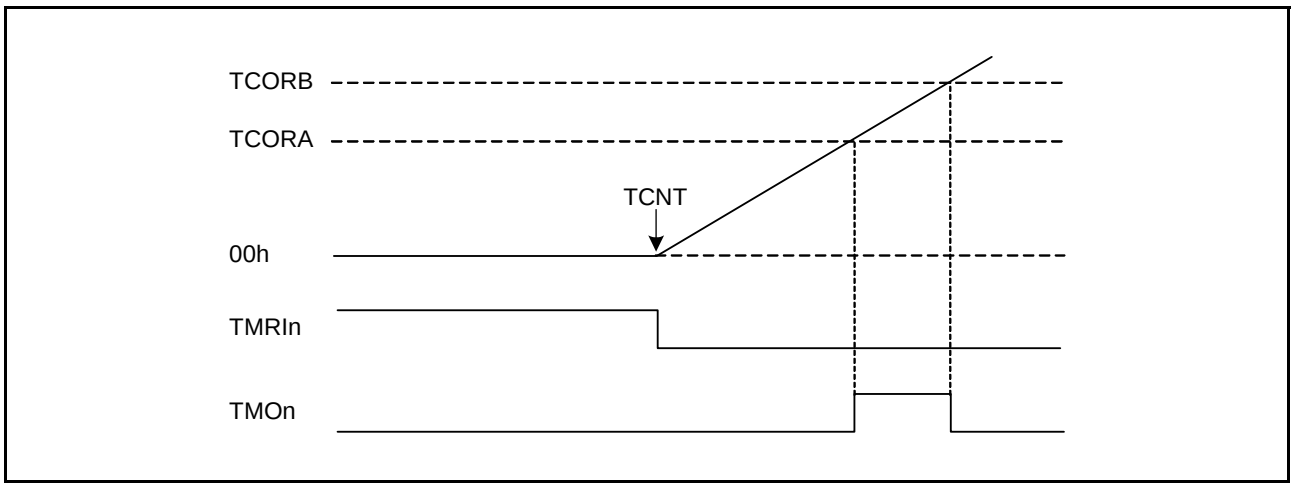

Figure 29.4 Example of External Counter Reset Signal Input (n = 0 to 3)

29.4 Operation Timing

29.4.1 TCNT Count Timing

Figure 29.5 shows the count timing of TCNT for internal clock. Figure 29.6 shows the count timing of TCNT for external clock.

Note that the external clock pulse width must be at least 1.5 PCLK cycles for increment at a single edge, and at least 2.5 PCLK cycles for increment at both edges. The counter will not increment correctly if the pulse width is less than these values.

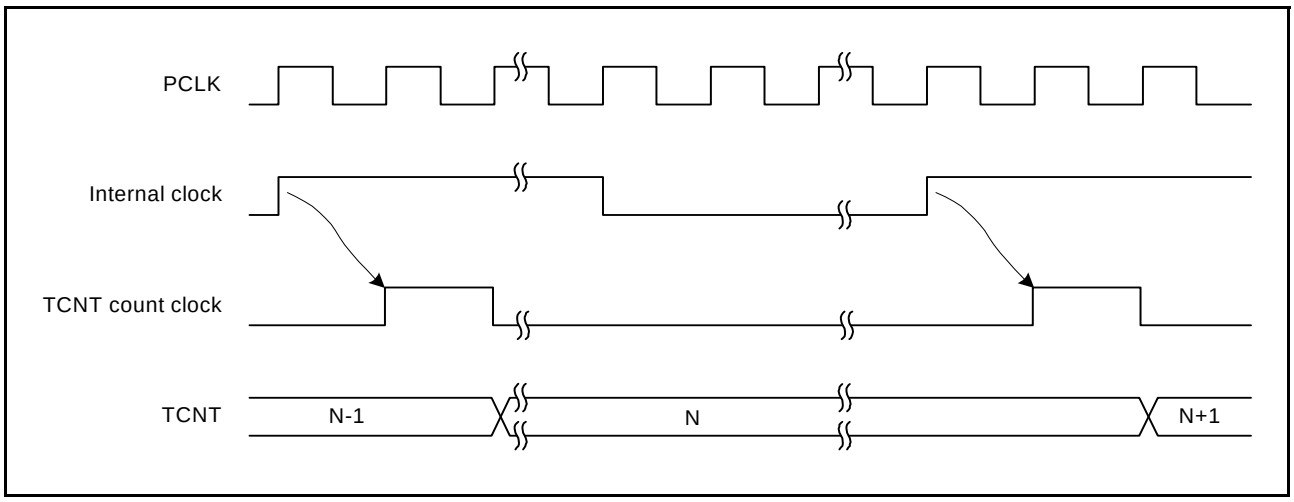

Figure 29.5 Count Timing for Internal Clock

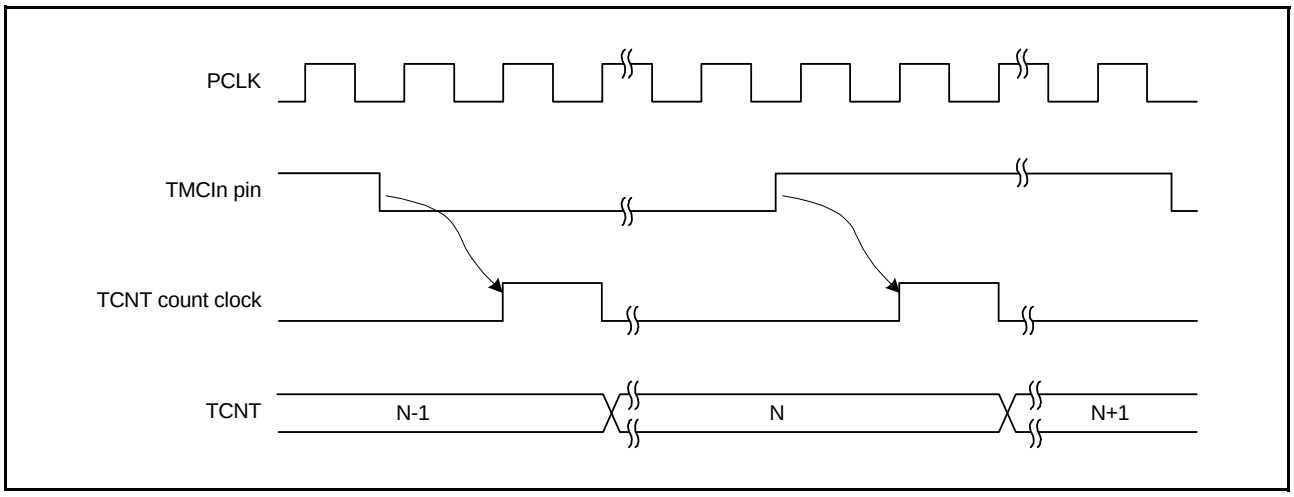

Figure 29.6 Count Timing for External Clock (at Both Edges)

29.4.2 Timing of Interrupt Signal Output on a Compare Match

A compare match refers to a match between the value of the TCORA or TCORB register and the TCNT, and a compare match interrupt signal is output at this time if the interrupt request is enabled. The compare match is generated in the last cycle in which the values match (at the time at which the value counted by TCNT to produce the match is updated). Accordingly, after a match between TCNT and the TCORA or TCORB register is detected, the compare match is not actually generated until the next cycle of the TCNT count clock. Figure 29.7 shows the timing of output of the interrupt signal.
For the corresponding interrupt vector number, see section 15, Interrupt Controller (ICUA) and Table 29.6.

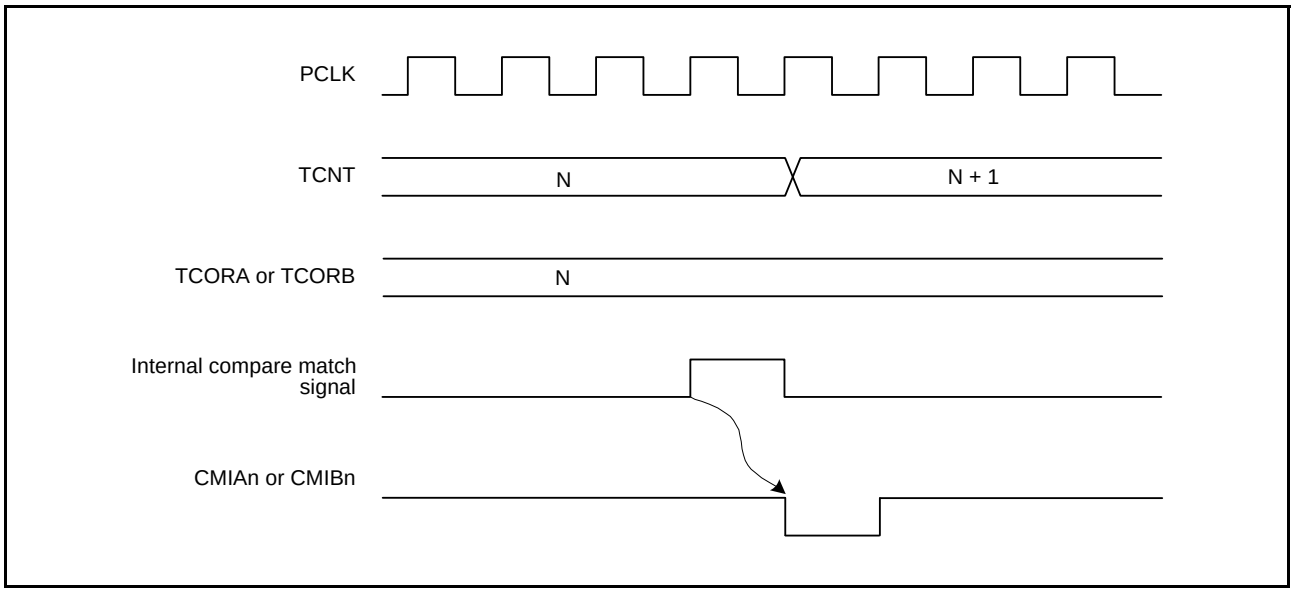

Figure 29.7 Timing of Interrupt Flag Setting to 1 at Compare Match (n = 0 to 3)

29.4.3 Timing of Timer Output Signal at Compare Match

When a compare match signal is generated, the output value specified by the TCSR.OSA[1:0] and OSB[1:0] bits is output on the timer output pin (TMOn).
Figure 29.8 shows the timing when the timer output is toggled by the compare match A signal.

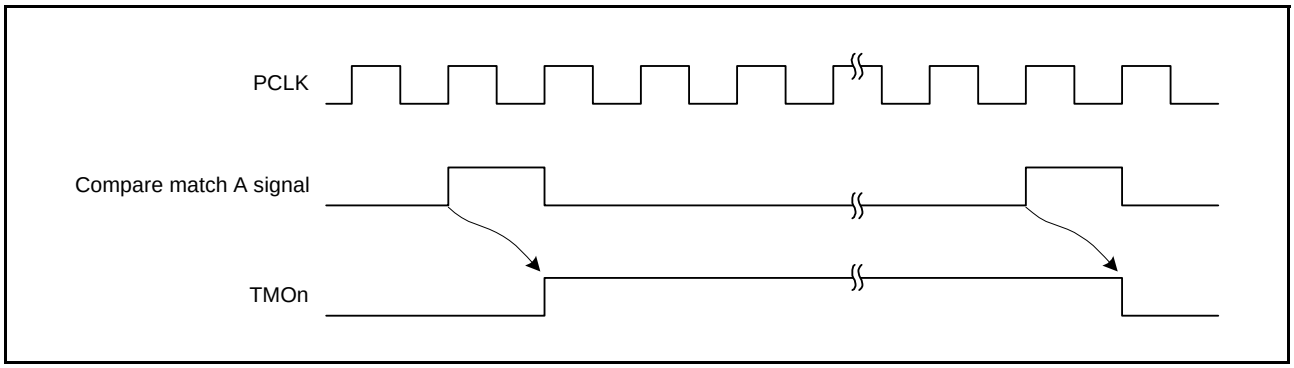

Figure 29.8 Timing of Timer Output Signal at Compare Match A Signal (n = 0 to 3)

29.4.4 Timing of Counter Clear by Compare Match

TCNT is cleared when compare match A or B occurs, depending on the settings of the TCR.CCLR[1:0] bits.
Figure 29.9 shows the timing of this operation.

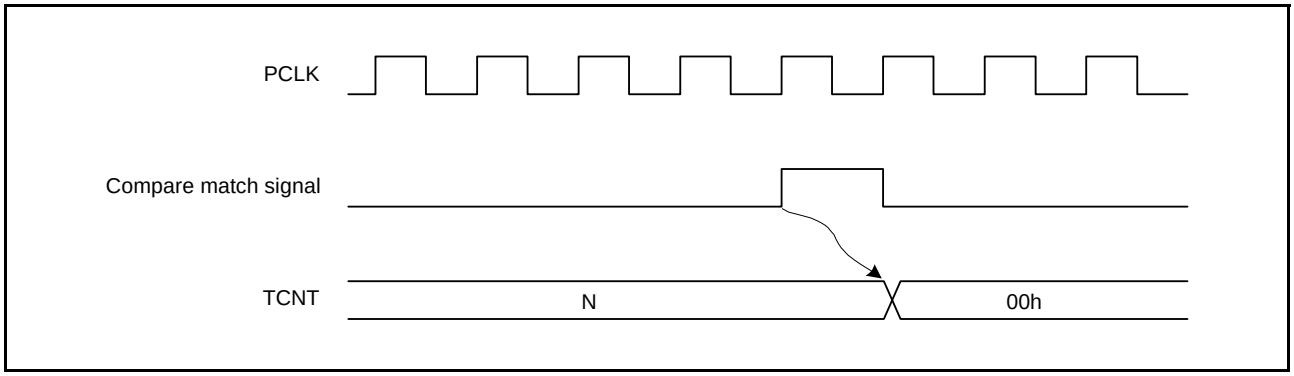

Figure 29.9 Timing of Counter Clear by Compare Match

29.4.5 Timing of the External Reset for TCNT

TCNT is cleared at the rising edge or high level of an external counter reset signal, depending on the settings of the TCR.CCLR[1:0] bits. At least 2 PCLK cycles are required from a reset input to clearing of TCNT.
Figure 29.10 and Figure 29.11 show the timing of this operation.

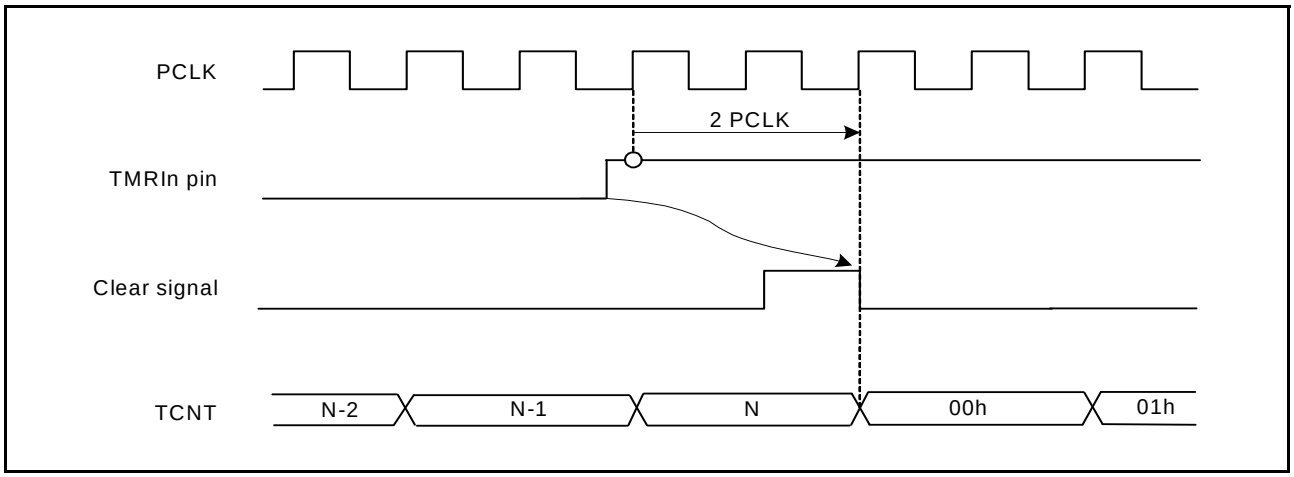

Figure 29.10 Clear Timing by External Counter Reset Signal (Rising Edge)

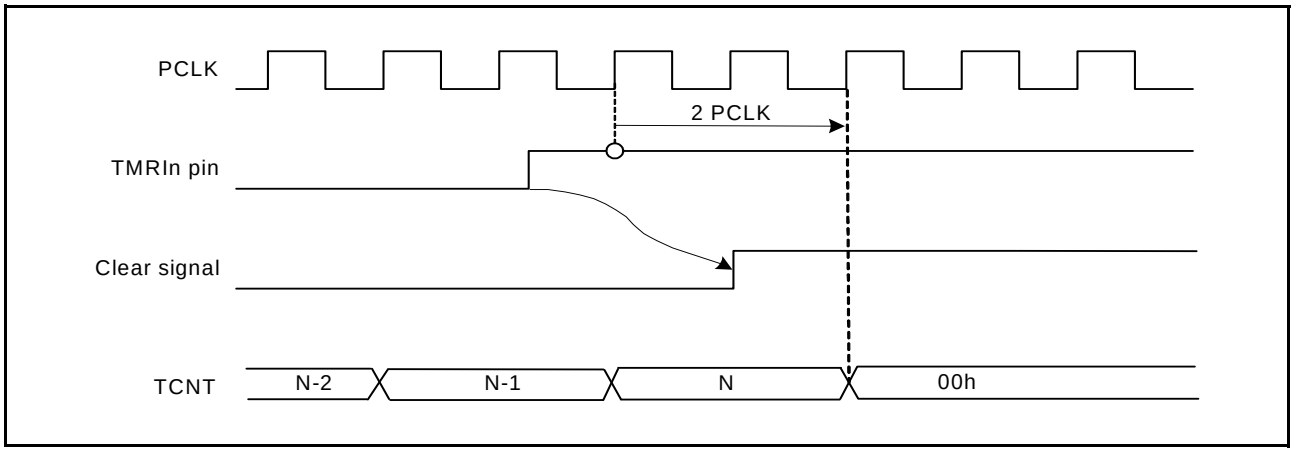

Figure 29.11 Clear Timing by External Counter Reset Signal (High Level)

29.4.6 Timing of Interrupt Signal Output on an Overflow

When TCNT overflows (changes from FFh to 00h), an overflow interrupt signal is output if this interrupt request is enabled.

Figure 29.12 shows the timing of output of the interrupt signal.

For the corresponding interrupt vector number, see section 15, Interrupt Controller (ICUA) and Table 29.6.

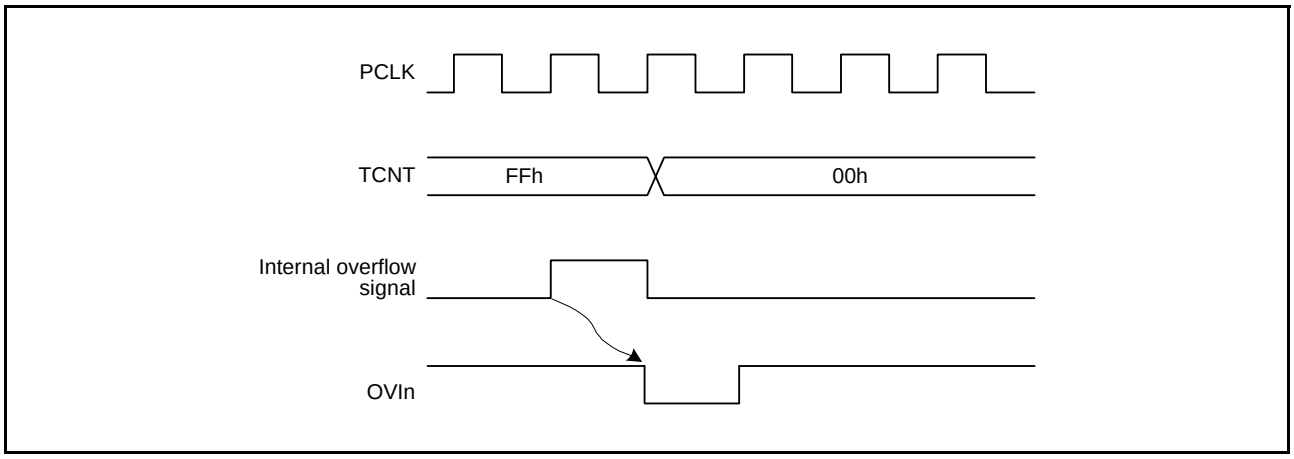

Figure 29.12 Timing of Overflow Interrupt Flag Setting to 1 (n = 0 to 3)

29.5 Operation with Cascaded Connection

If the CSS[1:0] bits in either TMR0.TCCR or TMR1.TCCR are set to 11b, the TMR of the two channels are cascaded. With this configuration, a single 16-bit timer could be used (16-bit counter mode) or compare matches of TMR0 could be counted by TMR1 (compare match count mode).

Supplementary information: This section describes unit 0. The operation of unit 1 with cascaded connection is the same as unit 0.

29.5.1 16-Bit Count Mode

When the TMR0.TCCR.CSS[1:0] bits are set to 11b, the timer functions as a single 16-bit timer with TMR0 occupying the upper 8 bits and TMR1 occupying the lower 8 bits.

(1) Counter Clear Specification

- The settings of the TMR0.TCR.CCLR[1:0] bits become effective for the 16-bit counter. If the TMR0.TCR.CCLR[1:0] bits have been set for counter clear at compare match, the 16-bit counter (TMR0.TCNT and TMR1.TCNT together) is cleared when a 16-bit compare match event occurs. The 16-bit counter (TMR0.TCNT and TMR1.TCNT together) is cleared even if counter clear by the TMRI0 pin has been set.
- The settings of the TMR1.TCR.CCLR[1:0] bits are ignored.

(2) Pin Output

- Control of output from the TMO0 pin by the TMR0.TCSR.OSA[1:0] and OSB[1:0] bits is in accordance with the 16-bit compare match conditions.
- Control of output from the TMO1 pin by the TMR1.TCSR.OSA[1:0] and OSB[1:0] bits is in accordance with the lower 8-bit compare match conditions.

29.5.2 Compare Match Count Mode

When the TMR1.TCCR.CSS[1:0] bits are set to 11b, TMR1.TCNT counts the number of occurrences of compare match A for TMR0. TMR0 and TMR1 are controlled independently. Conditions such as generation of interrupts, output from the TMOn (n = 0, 1) pin, and counter clear are in accordance with the settings for each channel.

29.6 Interrupt Sources

29.6.1 Interrupt Sources and DTC Activation

There are three interrupt sources for TMRn: CMIAn, CMIBn, and OVIn. Their interrupt sources and priorities are listed in Table 29.6.
It is also possible to activate the DTC by means of CMIAn and CMIBn interrupts.

Table 29.6 TMR Interrupt Sources

Name	Interrupt Sources	DTC Activation
CMIA0	TMR0.TCORA compare match	Possible
CMIB0	TMR0.TCORB compare match	Possible
OVI0	TMR0.TCNT overflow	Not possible
CMIA1	TMR1.TCORA compare match	Possible
CMIB1	TMR1.TCORB compare match	Possible
OVI1	TMR1.TCNT overflow	Not possible
CMIA2	TMR2.TCORA compare match	Possible
CMIB2	TMR2.TCORB compare match	Possible
OVI2	TMR2.TCNT overflow	Not possible
CMIA3	TMR3.TCORA compare match	Possible
CMIB3	TMR3.TCORB compare match	Possible
OVI3	TMR3.TCNT overflow	Not possible

29.6.2 Startup of the A/D Converter

The compare match A of TMR0 and TMR2 allows the A/D converter*1 to be started.
An A/D conversion start request is issued to the A/D converter in response to a generation of compare match A when the TMRn.TCSR.ADTE bit is 1 (i.e., when an A/D conversion request in response to compare match A is enabled). In this case, the conversion trigger for the 8-bit timer should be selected in the A/D converter to start A/D conversion.

Note 1. For the corresponding unit of the A/D converter, see section 57, 12-Bit A/D Converter (S12ADC).

Table 29.7 Startup of A/D Converter

Module Symbol	Unit	Target	A/D Startup Request	A/D Conversion Start Request
S12AD	0	Between TMR0.TCORA and TMR0.TCNT	Compare match	TMTRG0AN_0
S12AD1	1	Between TMR2.TCORA and TMR2.TCNT		TMTRG0AN_1

29.7 Link Operation by ELC

29.7.1 Event Signal Output to ELC

The TMR uses the event link controller (ELC) to perform link operation to the previously specified module using the interrupt request signal as the event signal. The TMR outputs compare match A, compare match B, and overflow signals as event signals. Channels that can be used in this way are TMR0 to TMR3.
The event signal can be output regardless of the setting of the corresponding interrupt request enable bits (TMRn.TCR.OVIE, TMRn.TCR.CMIEA, and TMRn.TCR.CMIEB (n = 0 to 3)). For details, see section 21, Event Link Controller (ELC).
The event output function can be used for the cascaded operation.

29.7.2 TMR Operation when Receiving an Event Signal from ELC

The TMR can perform either of the following operations upon the event previously specified by the ELSRn register of the ELC. However, the ELC does not support the cascaded operation.

(1) Count Start

When the TMR count start operation is selected by the ELOPD register of the ELC and the event specified by ELSRn occurs, the TCSTR.TCS bit is set to 1, starting the TMR count operation. After the TMR count start operation is selected by the ELOPD register of the ELC, use the TCCR.CKS[2:0] and CSS[1:0] bits to select the count source.
If the specified event occurs while the TCS bit is 1, the event is ignored.
Write 0 to the TCSTR.TCS bit to stop counting.
When the count start event is input in the count stopped state, the TMR starts counting again according to the CKS[2:0] and CSS[1:0] bits.
The TCS bit is valid only when the ELOPD.TMR0MD[1:0] and ELOPD.TMR2MD[1:0] bits of the ELC select the count start operation.

(2) Event Count

When the TMR event count operation is selected by the ELOPD register of the ELC and the event specified by ELSRn occurs, the events are counted as the count source regardless of the TCCR.CKS[2:0] and CSS[1:0] bit settings. Reading the counter value returns the number of events that have been actually input.

(3) Count Restart

When the TMR count restart operation is selected by the ELOPD register of the ELC and the event specified by ELSRn occurs, the TCNT counter value is modified to the initial value. If the CKS[2:0] and CSS[1:0] bit settings are not disabling the clock input, the count operation is continued.

29.7.3 Notes on Operating TMR According to an Event Signal from ELC

The following describes the notes on operating the TMR using the event link feature.

(1) Count Start

When the event specified by ELSRn occurs during the write cycle to the TCSTR.TCS bit, the cycle is not completed; setting 1 according to the event occurrence takes priority.

(2) Event Count

When the event specified by ELSRn occurs during the write cycle to the TCNT, the cycle is not completed; event count operation according to the event occurrence takes priority.

(3) Count Restart

When the event specified by ELSRn occurs during the write cycle to the TCNT, the cycle is not completed; count value initialization according to the event occurrence takes priority.

29.8 Usage Notes

29.8.1 Module Stop State Setting

Operation of the TMR can be disabled or enabled by using the module stop control registers. The initial setting is for halting of TMR operation. Register access becomes possible after release from the module stop state. For details, see section 11, Low Power Consumption.

29.8.2 Notes on Setting Cycle

If the compare match is selected for counter clear, TCNT is cleared at the last PCLK in the cycle in which the value of TCNT matches with that of TCORA or TCORB. TCNT updates the counter value at this last state. Therefore, the counter frequency is obtained by the following formula (f: Counter frequency, PCLK: Operating frequency, N: TCORA and TCORB register setting value).

$$f = PCLK / (N + 1)$$

29.8.3 Conflict between TCNT Write and Counter Clear

If a counter clear signal is generated concurrently with CPU write to TCNT, the clear takes priority and the write is not performed as shown in Figure 29.13.

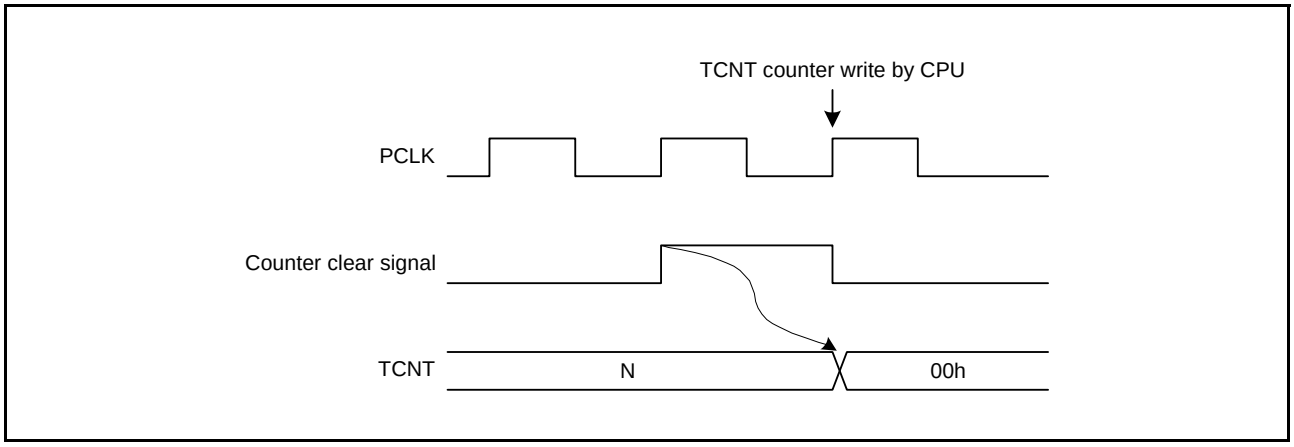

Figure 29.13 Conflict between TCNT Write and Counter Clear

29.8.4 Conflict between TCNT Write and Increment

Even if a counting-up signal is generated concurrently with CPU write to TCNT, the counting-up is not performed and the write takes priority as shown in Figure 29.14.

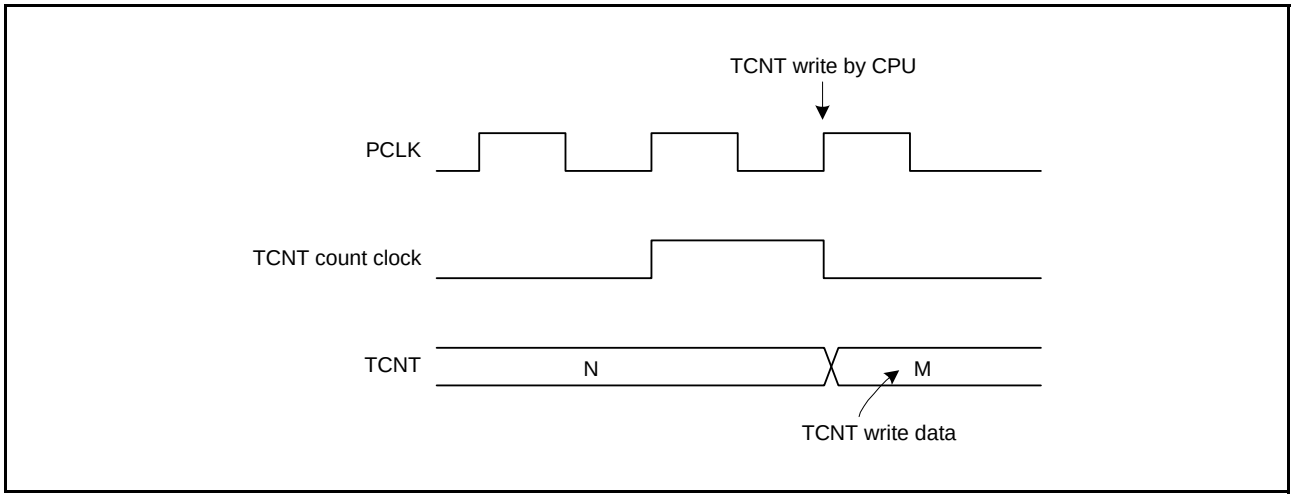

Figure 29.14 Conflict between TCNT Write and Increment

29.8.5 Conflict between TCORA or TCORB Write and Compare Match

Even if a compare match signal is generated simultaneously with CPU write to TCORA or TCORB as shown in Figure 29.15, the write takes priority and the compare match signal does not reach High level.

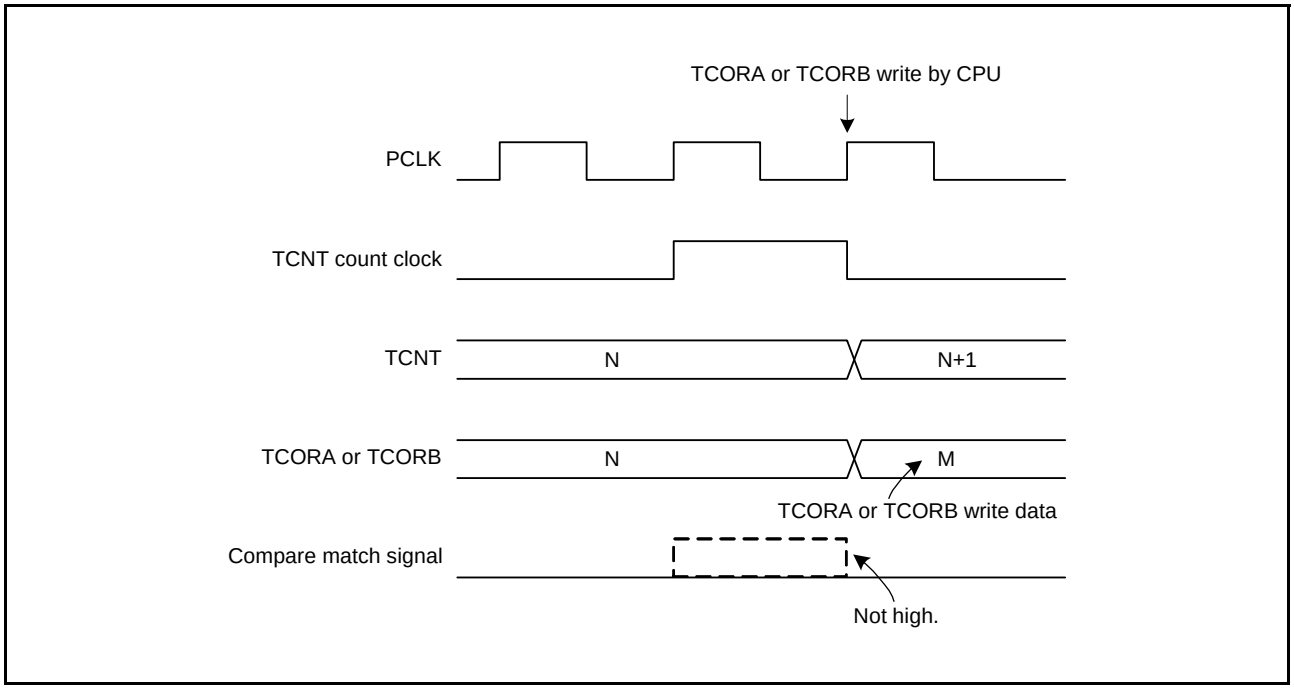

Figure 29.15 Conflict between TCORA or TCORB Write and Compare Match

29.8.6 Conflict between Compare Matches A and B

If compare match events A and B occur at the same time, the 8-bit timer operates in accordance with the priorities for the output methods high for compare match A and compare match B, as listed in Table 29.8.

Table 29.8 Timer Output Priorities

Output Setting	Priority
Toggle output	High
High output	↑
Low output	
No change	Low

29.8.7 Switching of Internal Clocks and TCNT Operation

TCNT may be incremented erroneously depending on when the internal clock is switched. Table 29.9 lists the relationship between the timing at which the internal clock is switched (by writing to the TCCR.CKS[2:0] bits) and the operation of TCNT.

When TCNT count clock is generated from an internal clock, the rising edge of the internal clock pulse are always monitored. If the signal levels of the clocks before and after switching change from low to high as shown in No. 2 in Table 29.9, the change is considered as an edge. Therefore, a TCNT count clock is generated and TCNT is incremented. The erroneous increment of TCNT can also happen when switching between internal and internal clocks.

Table 29.9 Switching of Internal Clocks and TCNT Operation (1/2)

No.	Timing to Change the TCCR.CKS[2:0] Bits	TCNT Counter Operation
1	Switching from low to low*1	2	Switching from low to high*2	
Table 29.9 Switching of Internal Clocks and TCNT Operation (2/2)

No.	Timing to Change the TCCR.CKS[2:0] Bits	TCNT Counter Operation
3	Switching from high to low*4	4	Switching from high to high	
Note 1. Includes switching from low to stop, and from stop to low.
Note 2. Includes switching from stop to high.
Note 3. Generated because the change of the signal levels is considered as an edge; TCNT counter is incremented.
Note 4. Includes switching from high to stop.

29.8.8 Clock Source Setting with Cascaded Connection

If 16-bit counter mode and compare match count mode are specified at the same time, count clocks for TMR0.TCNT and TMR1.TCNT (TMR2.TCNT and TMR3.TCNT) are not generated, and the counter stops. Do not specify 16-bit counter mode and compare match count mode simultaneously.

29.8.9 Continuous Output of Compare Match Interrupt Signal

When TCORA or TCORB is set to 00h, PCLK/1 is set as the internal clock, and compare match is set as the counter clear source, the TCNT counter remains 00h and is not updated, and a compare match interrupt signal is output continuously to form a flat signal level.
At this time, the interrupt controller cannot detect the second and subsequent interrupts.
Figure 29.16 shows operation timing when the compare match interrupt signal is continuously output.

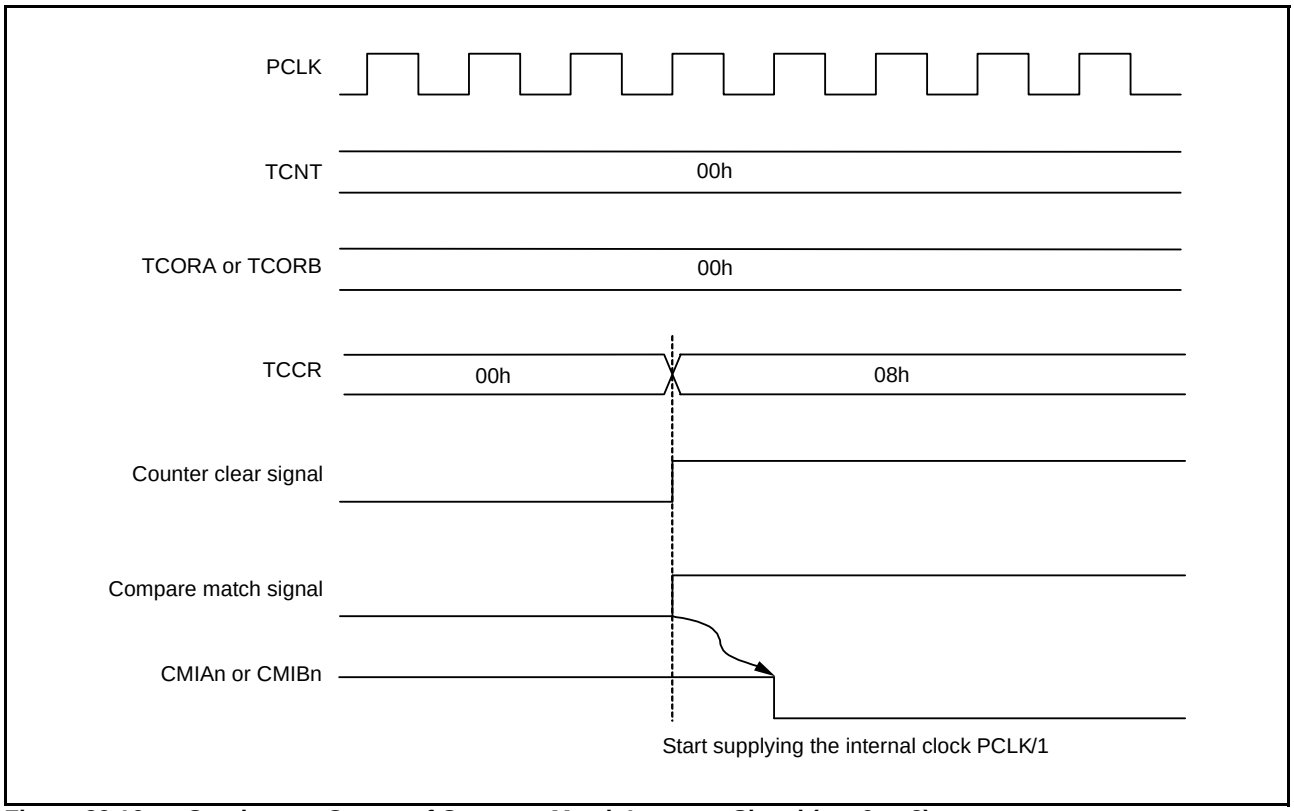

Figure 29.16 Continuous Output of Compare Match Interrupt Signal (n = 0 to 3)

30. Compare Match Timer (CMT)

This MCU has two on-chip compare match timer (CMT) units (unit 0 and unit 1), each consisting of a two-channel 16-bit timer (i.e., a total of four channels). The CMT has a 16-bit counter, and can generate interrupts at set intervals.
In this section, “PCLK” is used to refer to PCLKB.

30.1 Overview

Table 30.1 lists the specifications for the CMT.
Figure 30.1 shows a block diagram of the CMT (unit 0). A two-channel CMT constitutes a unit. Unit 0 and unit 1 are the same in terms of specifications. Compare match timer start register 0 (CMSTR0) and compare match interrupts (CMI0 and CMI1) of unit 0 correspond to compare match timer start register 1 (CMSTR1) and compare match interrupts (CMI2 and CMI3) of unit 1.

Table 30.1 CMT Specifications

Item	Description
Count clocks	• Four frequency dividing clocks One clock from PCLK/8, PCLK/32, PCLK/128, and PCLK/512 can be selected for each channel.
Interrupt	A compare match interrupt can be requested for each channel.
Event link function (output)	An event signal is output upon a CMT1 compare match.
Event link function (input)	Linking to the specified module is possible. CMT1 count start, event counter, or count restart operation is possible.
Low power consumption function	Each unit can be placed in a module stop state.

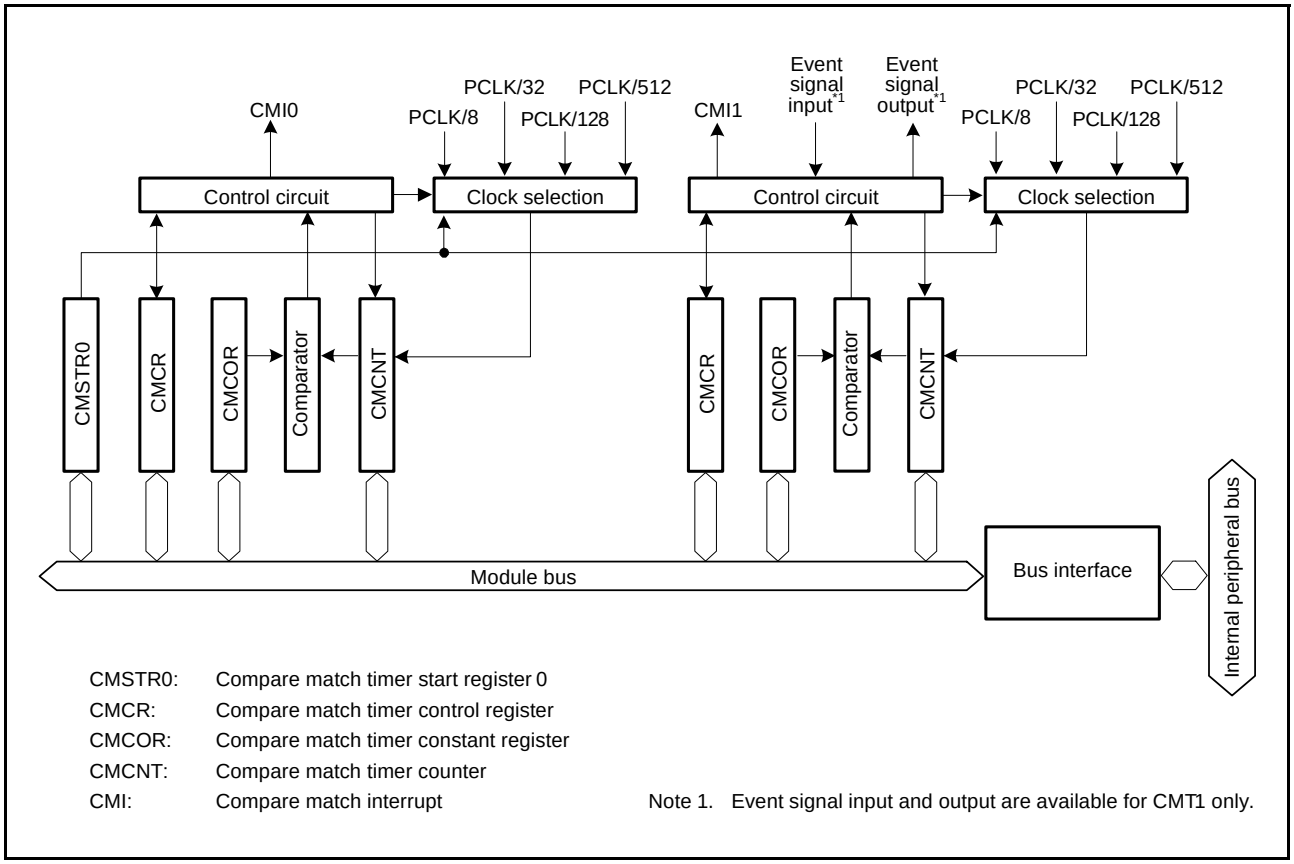

Figure 30.1 CMT (Unit 0) Block Diagram

30.2 Register Descriptions

30.2.1 Compare Match Timer Start Register 0 (CMSTR0)

Address(es): 0008 8000h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STR1	STR0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STR0	Count Start 0	0: CMT0.CMCNT count is stopped. 1: CMT0.CMCNT count is started.	R/W
b1	STR1	Count Start 1	0: CMT1.CMCNT count is stopped. 1: CMT1.CMCNT count is started.	R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

30.2.2 Compare Match Timer Start Register 1 (CMSTR1)

Address(es): 0008 8010h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STR3	STR2
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STR2	Count Start 2	0: CMT2.CMCNT count is stopped. 1: CMT2.CMCNT count is started.	R/W
b1	STR3	Count Start 3	0: CMT3.CMCNT count is stopped. 1: CMT3.CMCNT count is started.	R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

30.2.3 Compare Match Timer Control Register (CMCR)

Address(es): CMT0.CMCR 0008 8002h, CMT1.CMCR 0008 8008h, CMT2.CMCR 0008 8012h, CMT3.CMCR 0008 8018h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	CMIE	—	—	—	—	CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	x	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKS[1:0]	Clock Select	b1 b0 0 0: PCLK/8 0 1: PCLK/32 1 0: PCLK/128 1 1: PCLK/512	R/W
b5 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	CMIE	Compare Match Interrupt Enable	0: Compare match interrupt (CMIn) disabled 1: Compare match interrupt (CMIn) enabled	R/W
b7	—	Reserved	This bit is read as undefined. The write value should be 1.	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

CKS[1:0] Bits (Clock Select)

These bits select the count source from four frequency dividing clocks obtained by dividing the peripheral module clock (PCLK).

When the CMSTRm.STRn (m = 0, 1; n = 0 to 3) bit is set to 1, the CMCNT counter starts counting up on the clock selected with the CKS[1:0] bits.

CMIE Bit (Compare Match Interrupt Enable)

The CMIE bit enables or disables compare match interrupt (CMIn) (n = 0 to 3) generation when the CMCNT counter and the CMCOR register values match.

30.2.4 Compare Match Counter (CMCNT)

Address(es): CMT0.CMCNT 0008 8004h, CMT1.CMCNT 0008 800Ah, CMT2.CMCNT 0008 8014h, CMT3.CMCNT 0008 801Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CMCNT counter is a readable/writable up-counter.
When an frequency dividing clock is selected by the CMCR.CKS[1:0] bits and the CMSTRm.STRn (m = 0, 1; n = 0 to 3) bit is set to 1, the CMCNT counter starts counting up using the selected clock.
When the value in the CMCNT counter and the value in the CMCOR register match, the CMCNT counter is set to 0000h. At the same time, a compare match interrupt (CMIn) (n = 0 to 3) is generated.

30.2.5 Compare Match Constant Register (CMCOR)

Address(es): CMT0.CMCOR 0008 8006h, CMT1.CMCOR 0008 800Ch, CMT2.CMCOR 0008 8016h, CMT3.CMCOR 0008 801Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The CMCOR register is a readable/writable register to set a value for compare match with the CMCNT counter.

30.3 Operation

30.3.1 Periodic Count Operation

When an frequency dividing clock is selected by the CMCR.CKS[1:0] bits and the CMSTRm.STRn (m = 0, 1; n = 0 to 3) bit is set to 1, the CMCNT counter starts counting up using the selected clock.
When the value in the counter and the value in the register match, a compare match interrupt (CMIn) (n = 0 to 3) is generated. The CMCNT counter then starts counting up again from 0000h. Figure 30.2 shows the operation of the CMCNT counter.

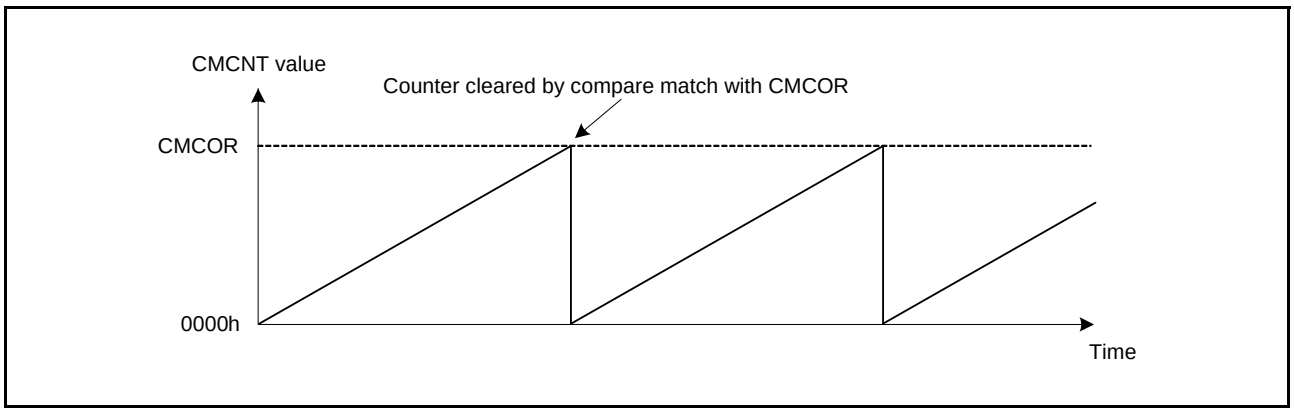

Figure 30.2 CMCNT Counter Operation

30.3.2 CMCNT Count Timing

As the count clock to be input to the CMCNT counter, one of four frequency dividing clocks (PCLK/8, PCLK/32, PCLK/128, and PCLK/512) obtained by dividing the peripheral module clock (PCLK) can be selected with the CMCR.CKS[1:0] bits. Figure 30.3 shows the timing of the CMCNT counter.

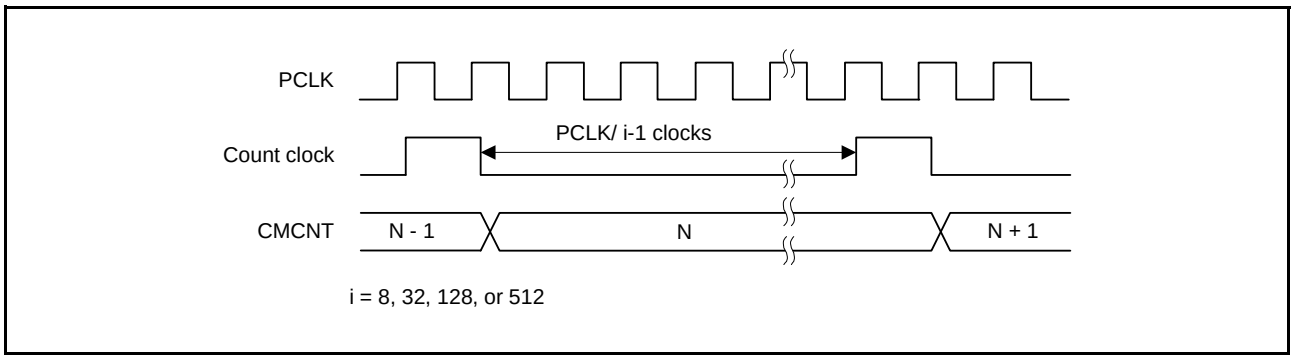

Figure 30.3 CMCNT Count Timing

30.4 Interrupts

30.4.1 Interrupt Sources

The CMT has channels and each of them to which a different vector address is allocated has a compare match interrupt (CMIn) (n = 0 to 3). When a compare match interrupt occurs, the corresponding interrupt request is output.
When the interrupt request is used to generate a CPU interrupt, the priority of channels can be changed by the interrupt controller settings. For details, see section 15, Interrupt Controller (ICUA).

Table 30.2 CMT Interrupt Sources

Name	Interrupt Sources	DTC Activation	DMAC Activation
CMI0	Compare match in CMT0	Possible	Possible
CMI1	Compare match in CMT1	Possible	Possible
CMI2	Compare match in CMT2	Possible	Possible
CMI3	Compare match in CMT3	Possible	Possible

30.4.2 Timing of Compare Match Interrupt Generation

When the CMCNT counter and the CMCOR register match, a compare match interrupt (CMIn) (n = 0 to 3) is generated. A compare match signal is generated at the last state in which the values match (the timing when the CMCNT counter updates the matched count value). That is, after a match between the CMCOR register and the CMCNT counter, the compare match signal is not generated until the next the CMCNT counter input clock.
Figure 30.4 shows the timing of a compare match interrupt.

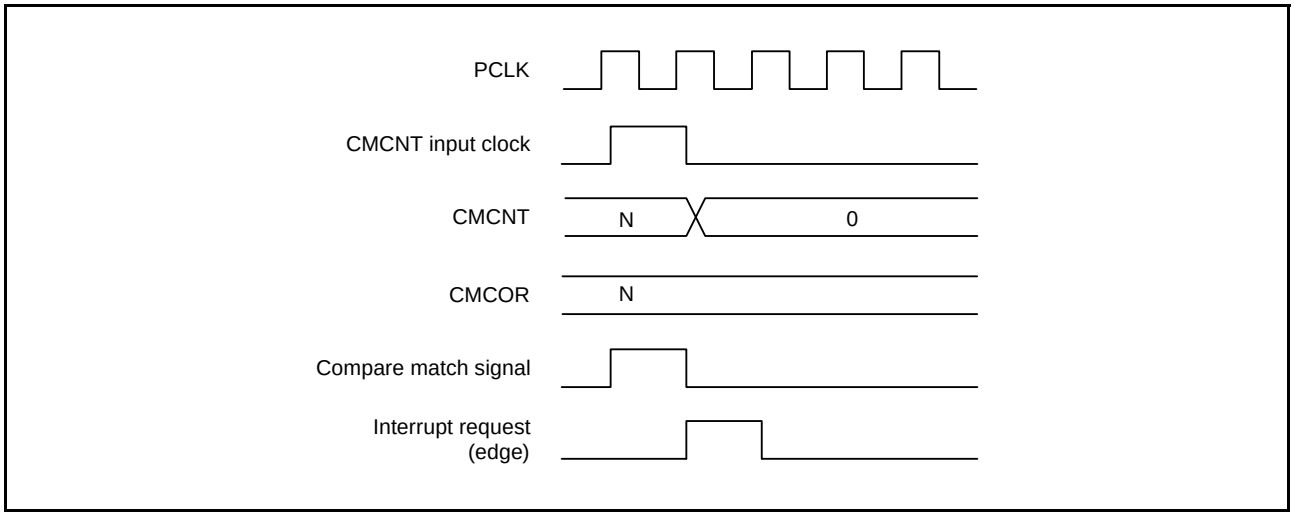

Figure 30.4 Timing of a Compare Match Interrupt

30.5 Link Operations by ELC

30.5.1 Event Signal Output to ELC

The CMT uses the event link controller (ELC) to perform link operation to a preset module using the interrupt request signal as the event signal. The CMT outputs the event signal upon a CMT1 compare match.
The event signal can be output regardless of the setting of the corresponding interrupt request enable bit (CMTn.CMCR.CMIE).

30.5.2 CMT Operation When Receiving an Event Signal from ELC

The CMT can perform either of the following operations upon the event preset by the ELSR7 register of the ELC.

(1) Count Start

When the CMT count start operation is selected by the ELOPC register of the ELC and the event specified by ELSR7 occurs, the CMSTR0.STR1 bit is set to 1, starting the CMT count operation.
However, if the specified event occurs while the CMSTR0.STR1 bit is 1, the event is ignored.

(2) Event Count

When the CMT event count operation is selected by the ELOPC register of the ELC and the event specified by ELSR7 occurs with the CMSTR0.STR1 bit being 1, the events are counted as the count source regardless of the CMT1.CMCR.CKS[1:0] bit setting. Reading the counter value returns the number of events that have been actually input.

(3) Count Restart

When the CMT count restart operation is selected by the ELOPC register of the ELC and the event specified by ELSR7 occurs, the CMT1.CMCNT counter value is modified to the initial value. If the CMSTR0.STR1 bit is 1 here, the count operation can be continued.

30.5.3 Notes on Operating CMT According to an Event Signal from ELC

The following describes the notes on operating the CMT using the event link feature.

(1) Count Start

When the event specified by ELSR7 occurs during the write cycle to the CMSTR0.STR1 bit, the cycle is not completed; setting 1 according to the event occurrence takes priority.

(2) Event Count

When the event specified by ELSR7 occurs during the write cycle to the CMT1.CMCNT, the cycle is not completed; event count operation according to the event occurrence takes priority.

(3) Count Restart

When the event specified by ELSR7 occurs during the write cycle to the CMT1.CMCNT, the cycle is not completed; count value initialization according to the event occurrence takes priority.

30.6 Usage Notes

30.6.1 Setting the Module Stop Function

The CMT can be enabled or disabled using the module stop control register. After a reset, the CMT is in the module stop state. The registers can be accessed by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

30.6.2 Conflict between CMCNT Counter Writing and Compare Match

When the compare match signal is generated while writing to the CMCNT counter, clearing the CMCNT counter has priority over writing to it. In this case, the CMCNT counter is not written to. Figure 30.5 shows the timing to clear the CMCNT counter.

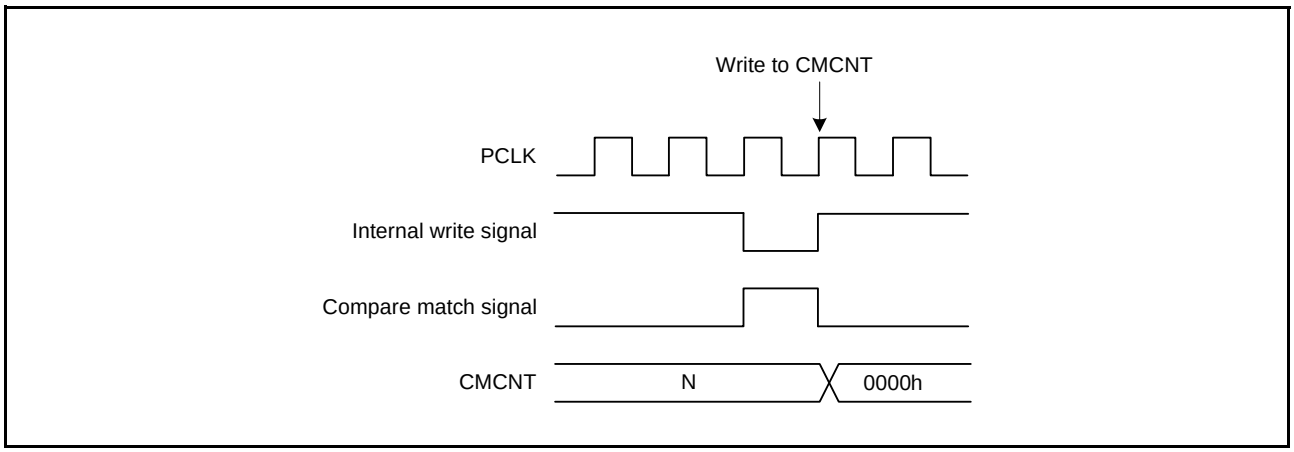

Figure 30.5 Conflict between CMCNT Counter Writing and Compare Match

30.6.3 Conflict between CMCNT Counter Writing and Incrementing

If writing to the counter and the incrementing conflict, the writing has priority over the incrementing. Figure 30.6 shows the timing to write the CMCNT counter.

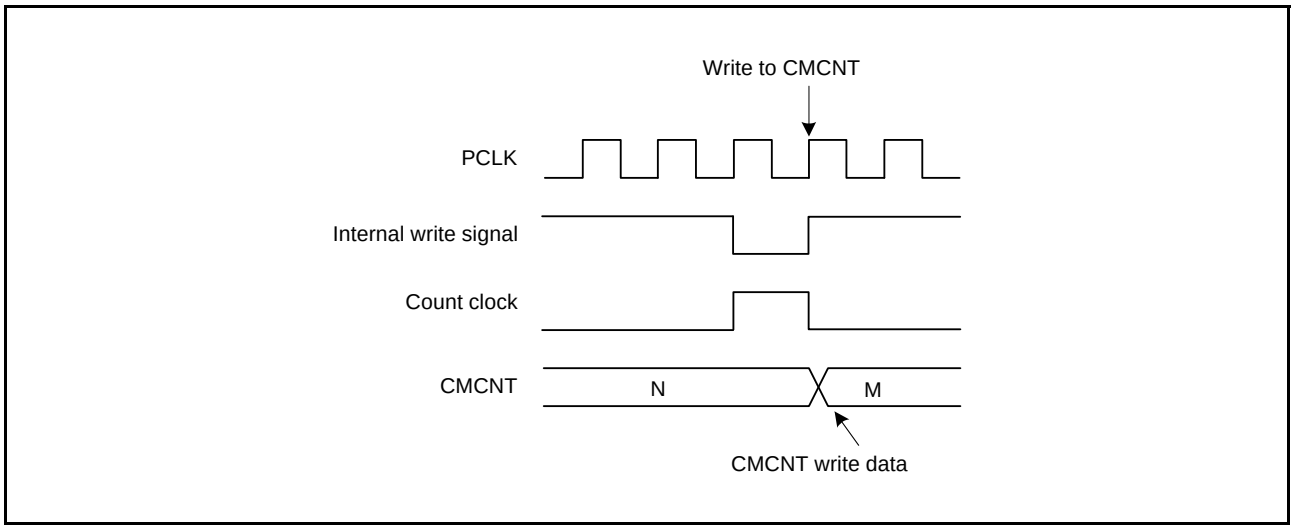

Figure 30.6 Conflict between CMCNT Counter Writing and Incrementing

31. Compare Match Timer W (CMTW)

This MCU includes two units (unit 0 and unit 1) with one channel of 32-bit compare match timer W (CMTW).
CMTW has a 32-bit counter and can generate interrupts each time a set period elapses.
In this section, “PCLK” is used to refer to PCLKB.

31.1 Overview

Table 31.1 shows the specifications of the CMTW.
Figure 31.1 shows a block diagram of the CMTW0 and Figure 31.2 shows a block diagram of the CMTW1.

Table 31.1 CMTW Specifications

Item	Function
Number of channels	Two channels (unit 0, unit 1)
Timer counter	16-bit/32-bit selectable up-counter The counter returns to 0000 0000h after a compare match.
Prescaler	Four dividing clocks are output. Selectable from any of PCLK/8, PCLK/32, PCLK/128, and PCLK/512
Input capture	Up to two input capture input signals available.
Output compare	Up to two output compare output signals available.
Compare match	One compare match available (no output compare output pin used).
Interrupts	Compare match interrupt Input capture 0 and 1 interrupts Output compare 0 and 1 interrupts
Event link function (output) (Unit 0)	Compare match
Event link function (input) (Unit 0)	One of the following operations is enabled after an event is accepted: • Count start operation • Event count operation • Count restart operation
Low power consumption function	Each unit can be placed in a module stop state.

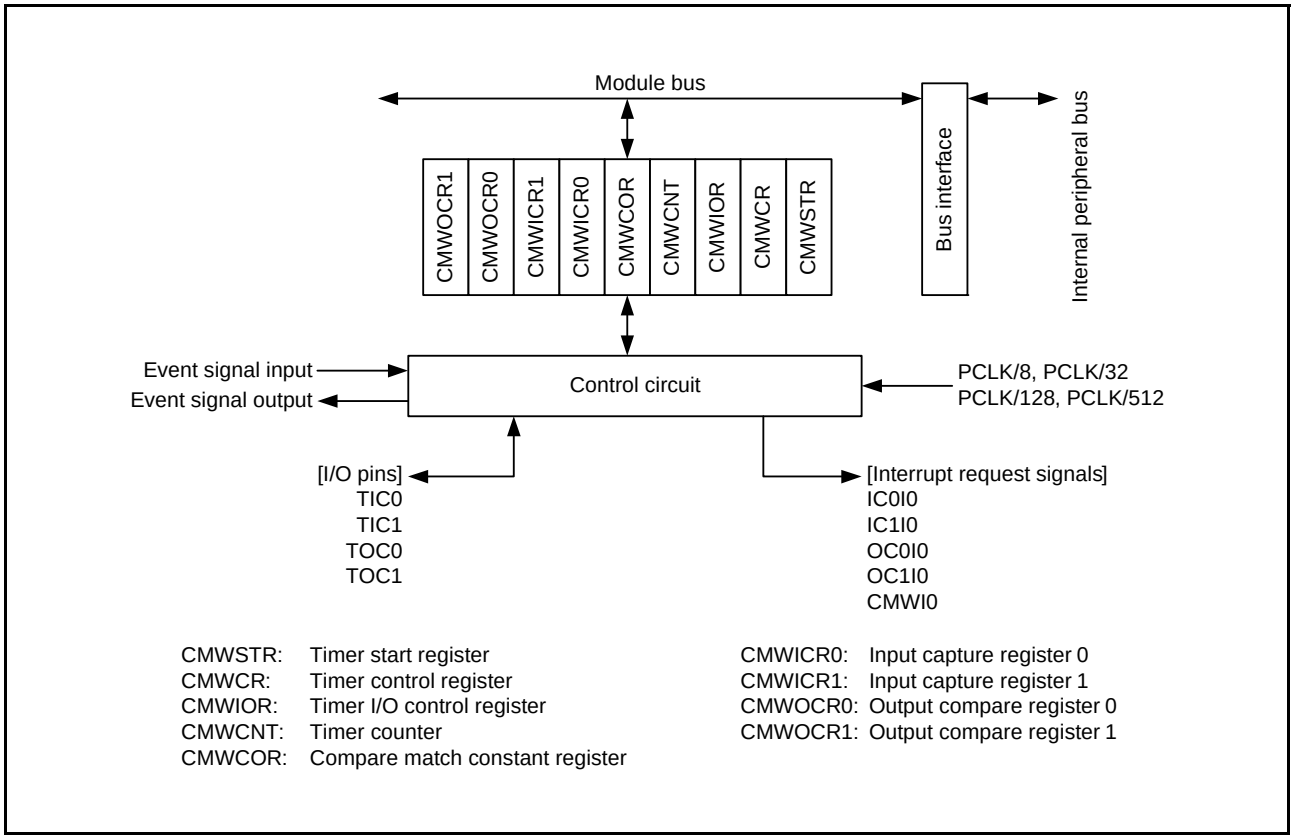

Figure 31.1 CMTW0 Block Diagram

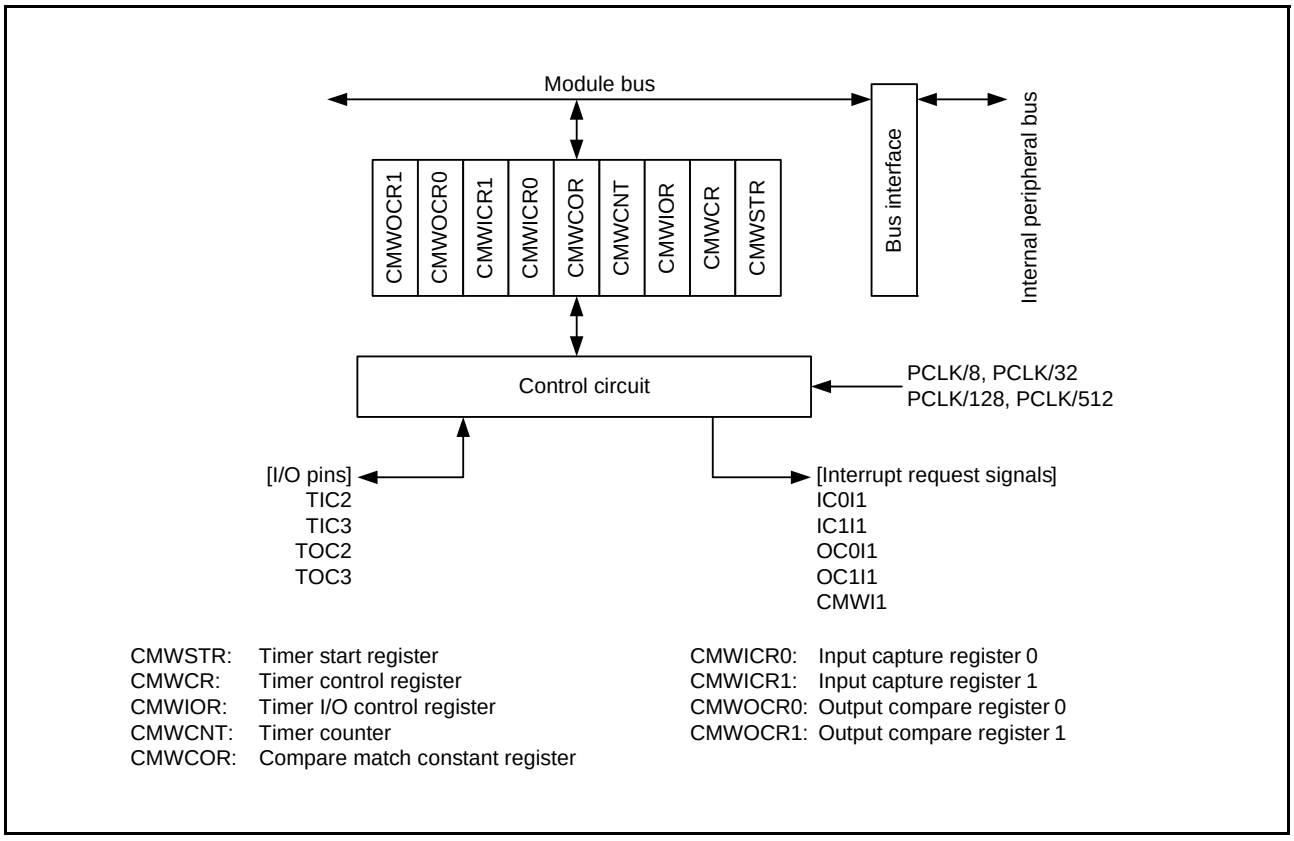

Figure 31.2 CMTW1 Block Diagram

Table 31.2 shows the CMTW pin configuration.

Table 31.2 CMTW Pin Configuration

Unit	Pin Name	I/O	Description
CMTW0	TIC0	Input	Input capture input for the CMTW0.CMWICR0 register
	TIC1	Input	Input capture input for the CMTW0.CMWICR1 register
	TOC0	Output	Output compare output for the CMTW0.CMWOCR0 register
	TOC1	Output	Output compare output for the CMTW0.CMWOCR1 register
CMTW1	TIC2	Input	Input capture input for the CMTW1.CMWICR0 register
	TIC3	Input	Input capture input for the CMTW1.CMWICR1 register
	TOC2	Output	Output compare output for the CMTW1.CMWOCR0 register
	TOC3	Output	Output compare output for the CMTW1.CMWOCR1 register

31.2 Register Descriptions

31.2.1 Timer Start Register (CMWSTR)

Address(es): CMTW0.CMWSTR 0009 4200h, CMTW1.CMWSTR 0009 4280h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STR	Counter Start	0: CMWCNT counter count is stopped. (The value immediately before count operation stops is retained and the count operation is stopped.) 1: CMWCNT counter count is started.	R/W
b15 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

STR Bit (Counter Start)

Specifies whether the timer counter operates or is stopped. The relevant prescaler operates or is stopped according to the settings of the STR bit.

31.2.2 Timer Control Register (CMWCR)

Address(es): CMTW0.CMWCR 0009 4204h, CMTW1.CMWCR 0009 4284h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CCLR[2:0]			—	—	—	CMS	—	OC1IE	OC0IE	IC1IE	IC0IE	CMWIE	—	CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKS[1:0]	Clock Select	b1 b0 0 0: PCLK/8 0 1: PCLK/32 1 0: PCLK/128 1 1: PCLK/512	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	CMWIE	Compare Match Interrupt Request Enable	0: Interrupt request (CMWI) disabled 1: Interrupt request (CMWI) enabled	R/W
b4	IC0IE	Input Capture 0 Interrupt Request Enable	0: Interrupt request (IC0I) disabled 1: Interrupt request (IC0I) enabled	R/W
b5	IC1IE	Input Capture 1 Interrupt Request Enable	0: Interrupt request (IC1I) disabled 1: Interrupt request (IC1I) enabled	R/W
b6	OC0IE	Output Compare 0 Interrupt Request Enable	0: Interrupt request (OC0I) disabled 1: Interrupt request (OC0I) enabled	R/W
b7	OC1IE	Output Compare 1 Interrupt Request Enable	0: Interrupt request (OC1I) disabled 1: Interrupt request (OC1I) enabled	R/W
b8	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b9	CMS	Timer Counter Size	0: 32 bits 1: 16 bits	R/W
b12 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b13	CCLR[2:0]	Counter Clear	b15 b14 b13 0 0 0: CMWCNT counter cleared by CMWCOR register compare match 0 0 1: Clearing of CMWCNT counter disabled 0 1 0: Clearing of CMWCNT counter disabled 0 1 1: Clearing of CMWCNT counter disabled 1 0 0: CMWCNT counter cleared by CMWICR0 register input capture 1 0 1: CMWCNT counter cleared by CMWICR1 register input capture 1 1 0: CMWCNT counter cleared by CMWOCR0 register compare match 1 1 1: CMWCNT counter cleared by CMWOCR1 register compare match	R/W

The CMWCR register should be set while the timer counter (CMWCNT) operation is stopped.

CKS[1:0] Bits (Clock Select)

Select the clock to be input to the CMWCNT counter among four internal clocks obtained by dividing the peripheral module clock (PCLK). When the CMWSTR.STR bit is set to 1, the CMWCNT counter starts counting based on the clock selected with the CMWCR.CKS[1:0] bits.

CMWIE Bit (Compare Match Interrupt Request Enable)

Enables or disables compare match interrupt request (CMWI) generation when the CMWCNT counter and the CMWCOR register values match.

IC0IE Bit (Input Capture 0 Interrupt Request Enable)

Enables or disables input capture 0 interrupt request (IC0I) generation when input capture is generated in the CMWICR0 register.

IC1IE Bit (Input Capture 1 Interrupt Request Enable)

Enables or disables input capture 1 interrupt request (IC1I) generation when input capture is generated in the CMWICR1 register.

OC0IE Bit (Output Compare 0 Interrupt Request Enable)

Enables or disables output compare 0 interrupt request (OC0I) generation when the CMWCNT counter and the CMWOCR0 register values match.

OC1IE Bit (Output Compare 1 Interrupt Request Enable)

Enables or disables output compare 1 interrupt request (OC1I) generation when the CMWCNT counter and CMWOCR1 register values match.

CMS Bit (Timer Counter Size)

Selects either 16 or 32 bits as the size of the timer counter (CMWCNT). The size selected with the CMS bit is valid in the CMWCOR, CMWICR0, CMWICR1, CMWOCR0, and CMWOCR1 registers.

CCLR[2:0] Bits (Counter Clear)

Select the CMWCNT counter clearing source.

31.2.3 Timer I/O Control Register (CMWIOR)

Address(es): CMTW0.CMWIOR 0009 4208h, CMTW1.CMWIOR 0009 4288h

Note 1. After reset, low is output until the CMWIOR register is set.

31.2.4 Timer Counter (CMWCNT)

Address(es): CMTW0.CMWCNT 0009 4210h, CMTW1.CMWCNT 0009 4290h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CMWCNT counter is a readable/writable up-counter.
Before starting count operation, the timer control register (CMWCR) should be set. When the 16-bit counter size is selected with the CMS bit in the timer control register (CMWCR), bits 15 to 0 in this register are valid. When writing to the CMWCNT counter, write data in 32-bit units with the upper bits set to 0000h. The CMWCNT counter can only be accessed in longword units.
When the CMWSTR.STR bit is set to 1, the CMWCNT counter starts counting. When the CMWSTR.STR bit is set to 0, the CMWCNT counter retains the value immediately before a stop of counting and stops counting.

31.2.5 Compare Match Constant Register (CMWCOR)

Address(es): CMTW0.CMWCOR 0009 4214h, CMTW1.CMWCOR 0009 4294h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The CMWCOR register is a readable/writable register that specifies the time up to a compare match between the timer counter (CMWCNT) value and CMWCOR value. When the 16-bit counter size is selected with the CMS bit in the timer control register (CMWCR), bits 15 to 0 in this register are valid. When writing to the CMWCOR register, write data in 32-bit units with the upper bits set to 0000h. The CMWCOR register can only be accessed in longword units. To detect an overflow, set the CMWCOR register value to FFFF FFFFh (32-bit count operation) or 0000 FFFFh (16-bit count operation). When the CMWCNT counter is set to 0, a compare match interrupt request (CMWI) can be used as an overflow detection signal.

31.2.6 Input Capture Registers 0 and 1 (CMWICR0 and CMWICR1)

Address(es): CMTW0.CMWICR0 0009 4218h, CMTW0.CMWICR1 0009 421Ch, CMTW1.CMWICR0 0009 4298h, CMTW1.CMWICR1 0009 429Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CMWICR register is a read-only register in which the CMWCNT value is stored when an input capture is generated. When the 16-bit counter size is selected with the CMS bit in the timer control register (CMWCR), bits 15 to 0 in these registers are valid. Writing to these registers is invalid. The CMWICR register can only be accessed in longword units.

31.2.7 Output Compare Registers 0 and 1 (CMWOCR0 and CMWOCR1)

Address(es): CMTW0.CMWOCR0 0009 4220h, CMTW0.CMWOCR1 0009 4224h, CMTW1.CMWOCR0 0009 42A0h, CMTW1.CMWOCR1 0009 42A4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The CMWOCR register is a readable/writable register that set the value to be compared when an output compare is generated.
When the 16-bit counter size is selected with the CMS bit in the timer control register (CMWCR), bits 15 to 0 of these registers become valid. When writing to these registers, write data in 32-bit units with the upper bits set to 0000h.
The CMWOCR register can only be accessed in longword units. The initial value of CMWOCR0 and CMWOCR1 registers is FFFF FFFFh.

31.3 Operation

When the CMWCR register is set and then the STR bit in CMWSTR is set to 1, the CMTW starts count operation. Setting the CMWSTR.STR bit to 0 enables the CMWCNT counter to retain the value immediately before a stop of counting and stop counting. Setting the CMWIOR register enables using the compare match function, input capture input function, and output compare output function.

31.3.1 Period Count Operation

When the counter clock is selected by using the CMWCR.CKS[1:0] bits and the CMWSTR.STR bit is set to 1, the CMWCNT counter starts counting cycles of the selected clock. When clearing of the counter is selected by the CMWCR.CCLR[2:0] bits and the counter clearing source is generated, the CMWCNT counter is cleared to 0000 0000h and continues counting. When clearing of the counter is not selected, an overflow is generated when FFFF FFFFh changes to 0000 0000h during 32-bit count operation and 0000 FFFFh changes to 0000 0000h during 16-bit count operation, and the CMWCNT counter continues counting.

31.3.2 Compare Match Function

When the values of the CMWCNT counter and CMWCOR register match, the CMWCNT counter is cleared to 0000 0000h. At this time, a compare match interrupt request (CMWI) is generated. The CMWCNT counter restarts counting from 0000 0000h.
To enable overflow detection, the CMWCOR register value should be set to FFFF FFFFh (when the counter size is 32 bits) or 0000 FFFFh (when the counter size is 16 bits). When the values of the CMWCNT counter and CMWCOR register match, the CMWCNT counter is cleared to 0000 0000h. In this case, the compare match interrupt request (CMWI) is generated. The CMWCNT counter then restarts counting from 0000 0000h.
Figure 31.3 shows an example of procedure for setting compare match operation.

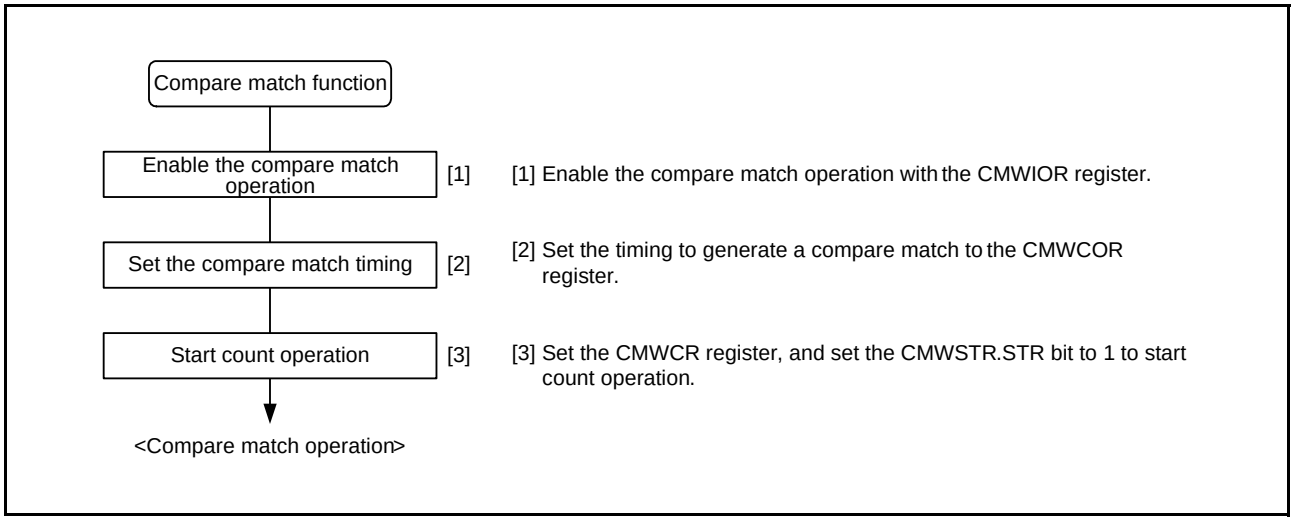

Figure 31.3 Procedure for Setting Compare Match Operation

Figure 31.4 shows an example when compare match with CMWCOR is set as a counter clearing source.

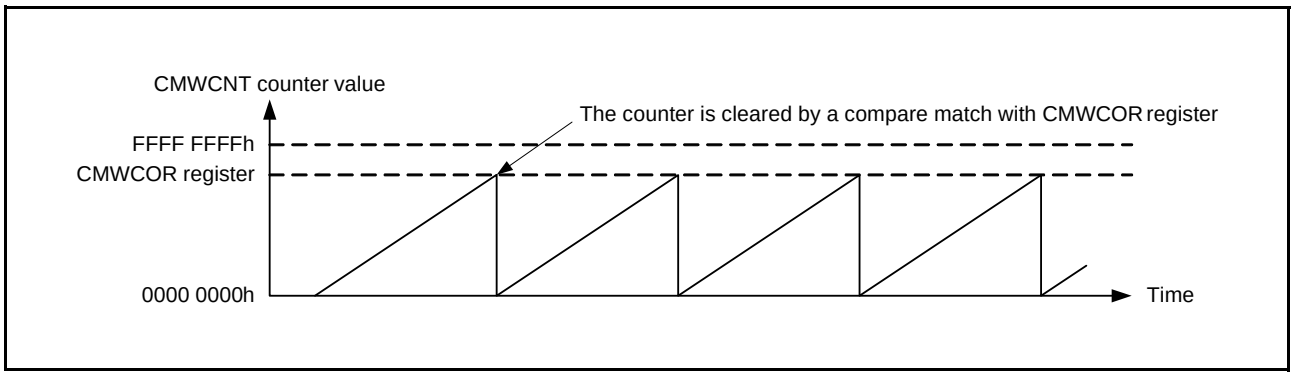

Figure 31.4 Example of Compare Match Operation

Figure 31.5 shows an example when CMWCOR is set to FFFF FFFFh and an overflow is detected.

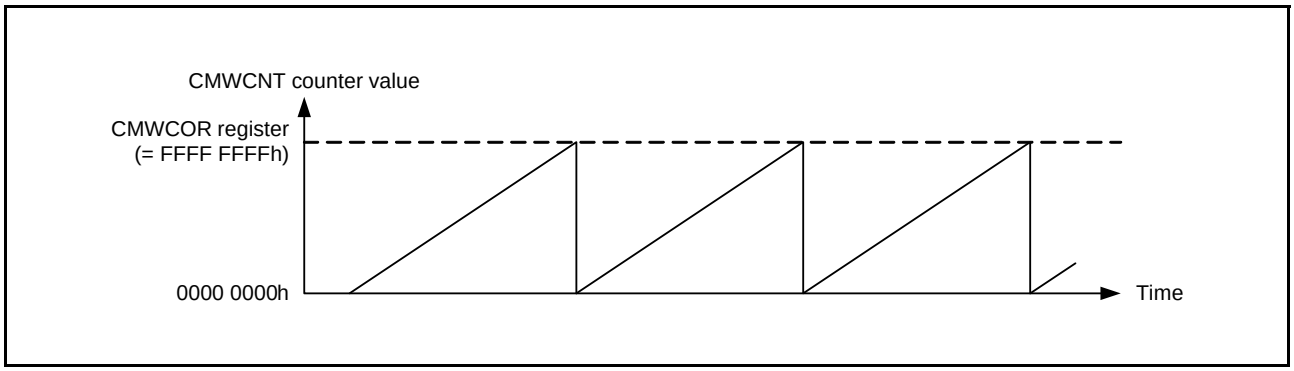

Figure 31.5 Example of Compare Match Operation (Overflow Detected)

31.3.3 Output Compare Function

The output compare function can be used for toggle waveform output. When the CMWCNT counter value matches either of the values of the CMWOCR0 or CMWOCR1 register, the output compare interrupt request (OC0I or OC1I) is generated. Figure 31.6 shows an example of procedure for setting output compare operation.

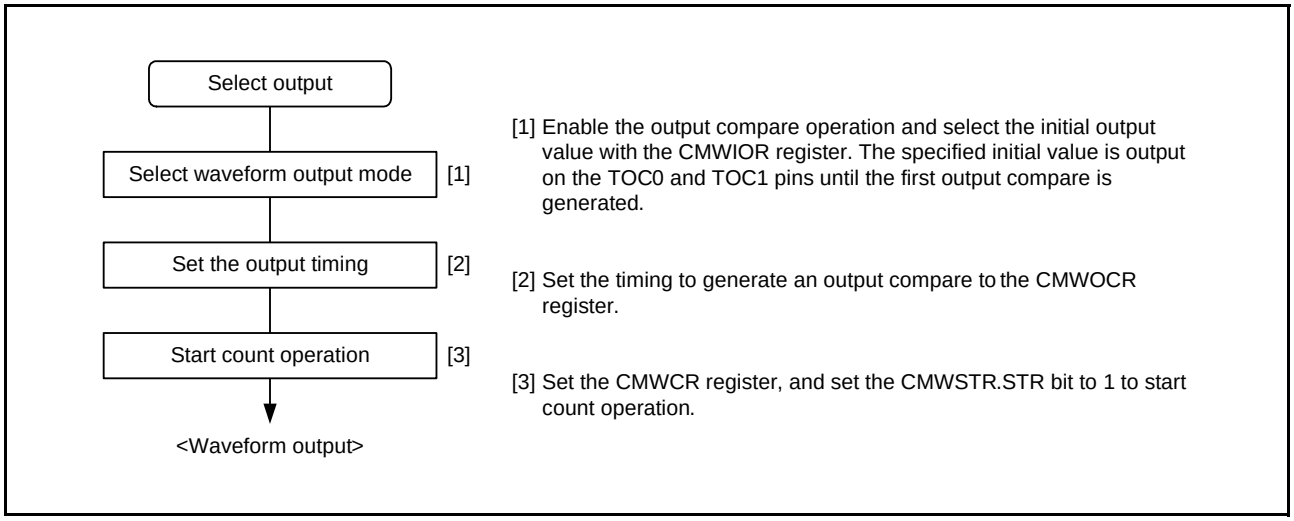

Figure 31.6 Procedure for Setting Output Compare Operation

Figure 31.7 shows an example of toggle waveform output from the TOC0 and TOC1 pins when the counter is set to be cleared by compare match with the CMWOCR1 register.

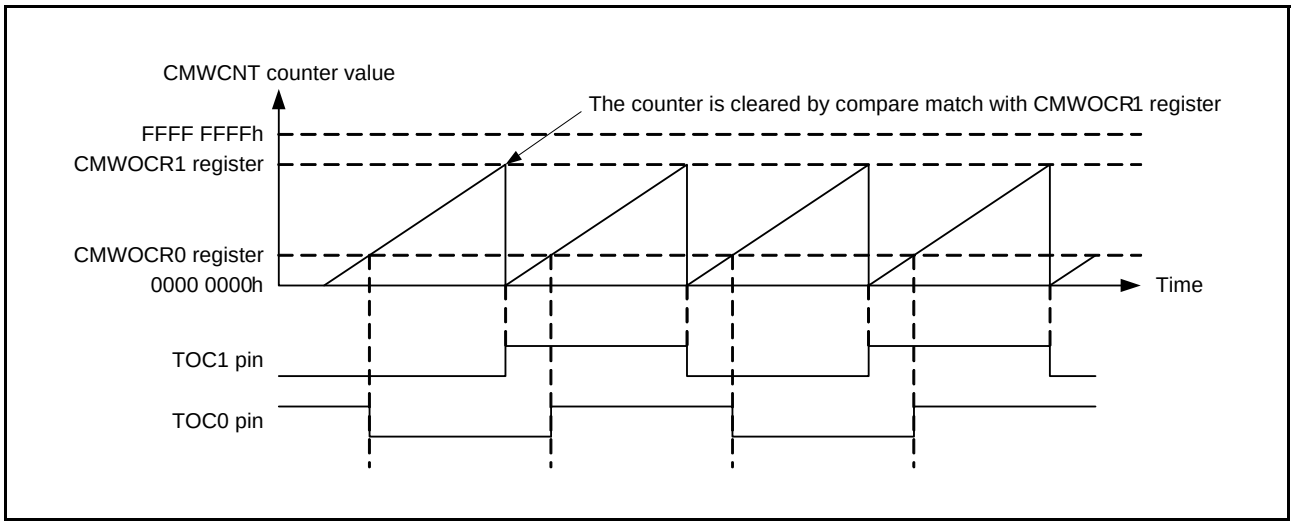

Figure 31.7 Example of Output Compare Operation (Unit 0)

31.3.4 Input Capture Function

Through detecting the edge on the TIC0 and TIC1 pin input, the CMWCNT counter value can be transferred to the CMWICR0 and CMWICR1 registers, respectively. The edges to be detected can be selected from among the rising edge alone, falling edge alone, and both the rising and falling edges. When the CMWCNT counter value is transferred to the CMWICR0 or CMWICR1 register using the input capture operation, an input capture interrupt request (IC0I or IC1I) is generated. Figure 31.8 shows an example of procedure for setting input capture operation.

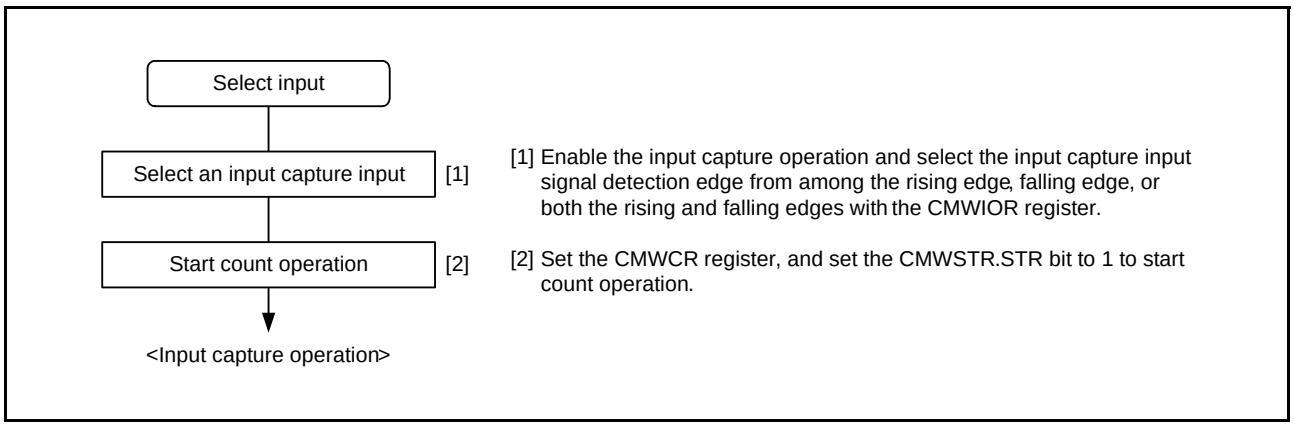

Figure 31.8 Procedure for Setting Input Capture Operation

Figure 31.9 shows an example in which both edges are selected for the TIC0 pin input capture detection edge and the falling edge for the TIC1 pin, and the CMWCNT counter is cleared by a CMWICR1 register input capture.

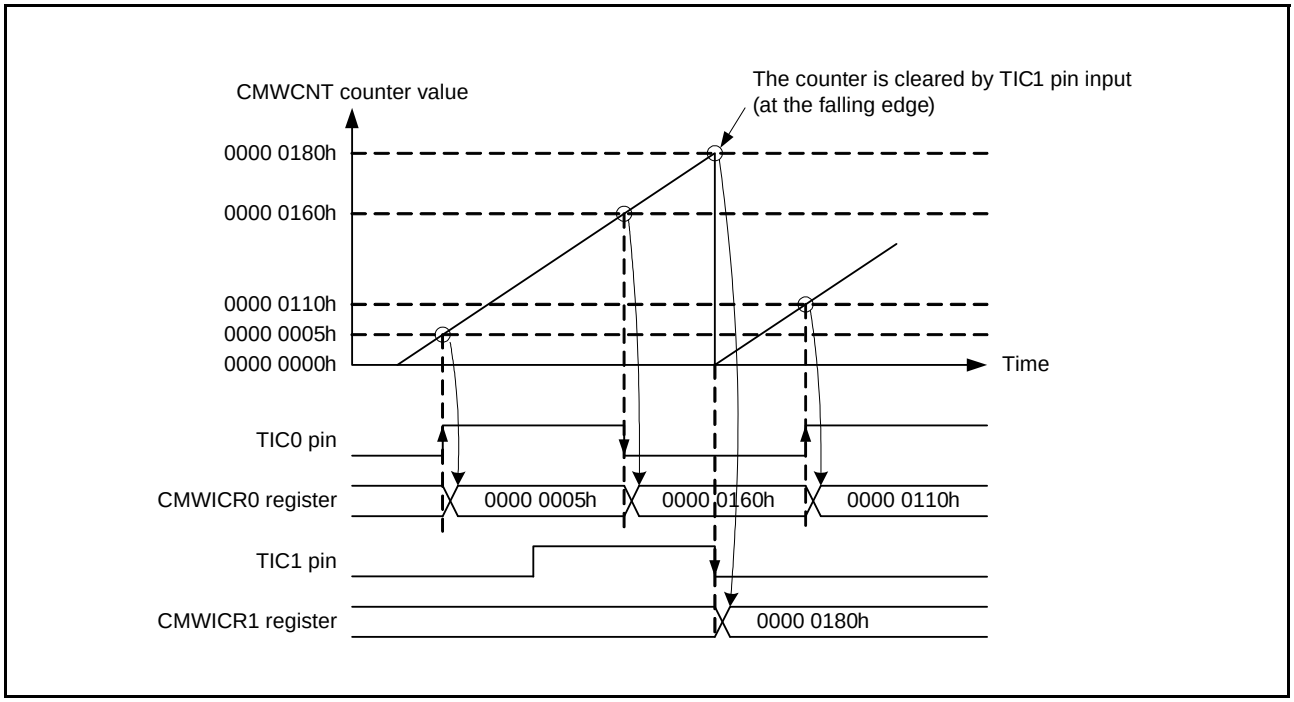

Figure 31.9 Example of Input Capture Operation (Unit 0)

31.3.5 Counter Size

With the CMTW, either 16 or 32 bits can be selected as the counter size by using the CMWCR.CMS bit.
When the counter is used as a 16-bit counter, set the value of the CMWCOR register in 32-bit units with the upper 16 bits set to 0000h. 0000 FFFFh should be set to detect an overflow. Similarly, set the values of the CMWOCR0 and CMWOCR1 registers in 32-bit units with the upper 16 bits set to 0000h. Read the CMWOCR0 and CMWOCR1 registers in 32-bit units. The upper 16 bits can be read as 0000h.

31.3.6 Count Timing of CMWCNT Counter

By setting the CMWCR.CKS[1:0] bits, one of four clocks (PCLK/8, PCLK/32, PCLK/128, and PCLK/512) obtained by dividing the peripheral module clock (PCLK) can be selected as the counter clock to be input to the CMWCNT counter. Figure 31.10 shows the timing.

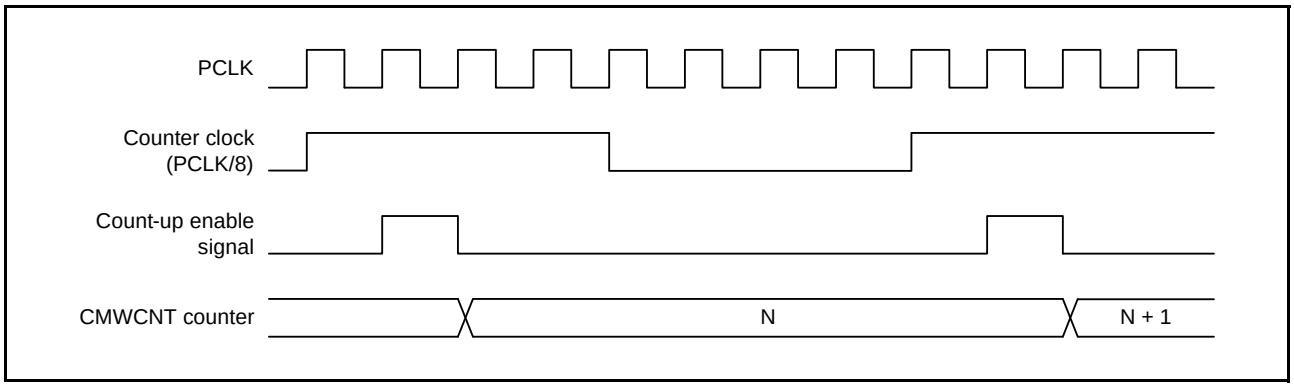

Figure 31.10 Count Timing (PCLK/8)

31.3.7 Output Compare Output Timing

A compare match signal is generated in the last state in which the CMWOCR register and CMWCNT counter values match (the CMWCNT counter value is updated immediately after the state). The compare match signal is generated if the CMWCNT count-up enable signal is input after a match between the CMWOCR register and CMWCNT counter values. When a compare match signal is generated, output of the output compare pin (TOC pin) is toggled.
Figure 31.11 shows output compare output timing.

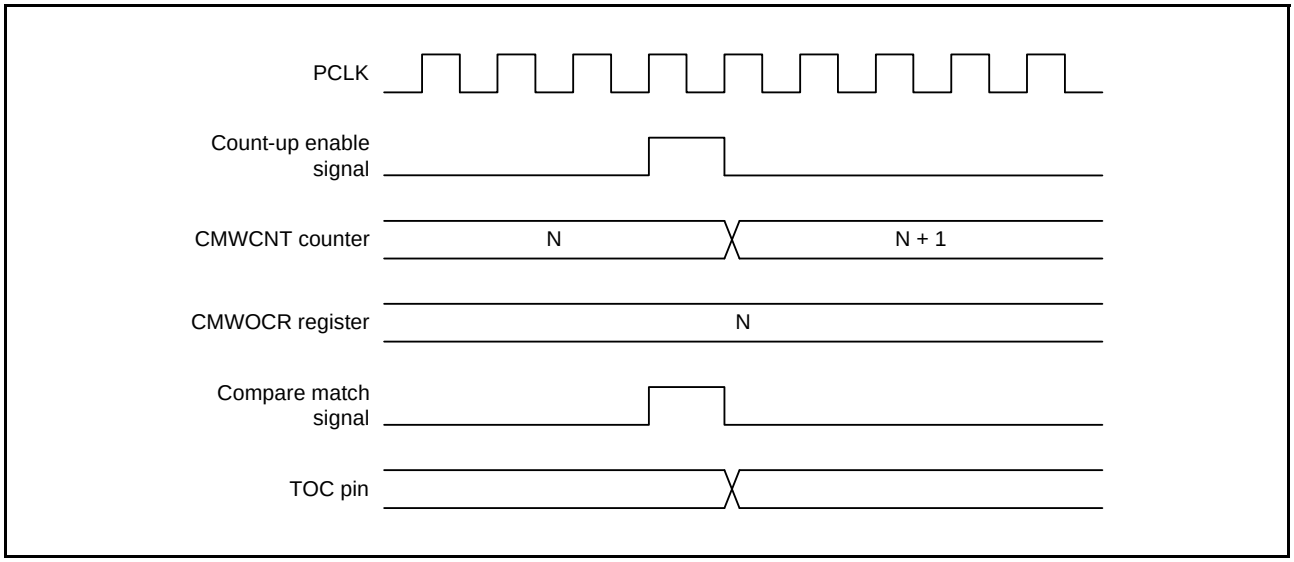

Figure 31.11 Output Compare Output Timing

31.3.8 Input Capture Timing

Figure 31.12 shows the timing of input capture operation at both edges.
When the edge of the TIC0 and TIC1 pins is detected, the CMWCNT counter value is transferred to the CMWICR0 and CMWICR1 registers, respectively.

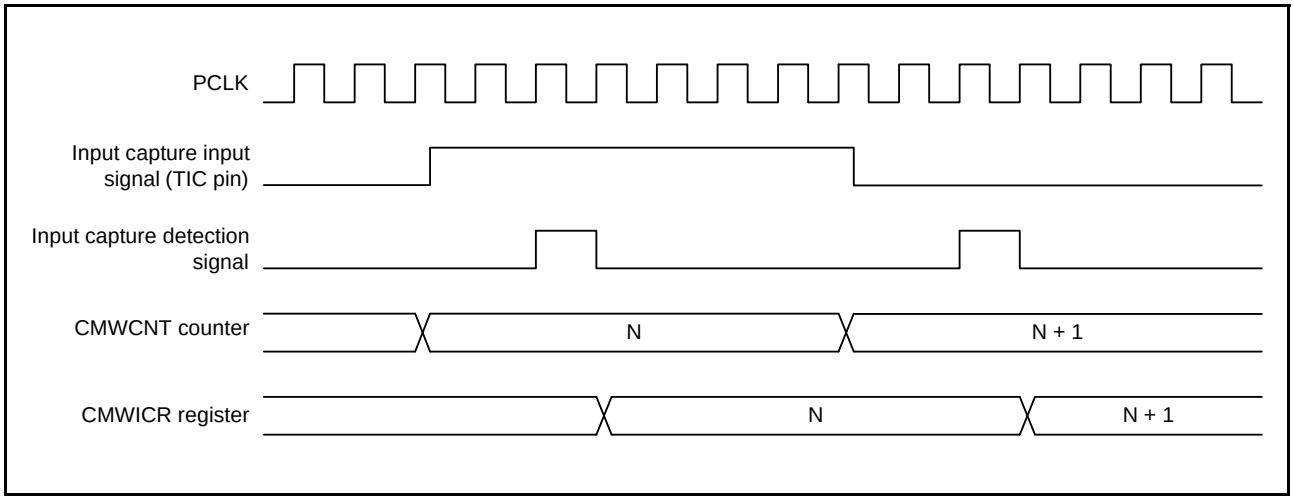

Figure 31.12 Input Capture Timing (Unit 0, Both-Edge Detection)

31.4 Interrupts

31.4.1 CMTW Interrupt Sources and DTC/DMAC Transfer Requests

The CMTW has five interrupt sources: two input capture interrupt requests (IC0I and IC1I), two output compare interrupt requests (OC0I and OC1I), and a compare match interrupt request (CMWI).

Table 31.3 shows the interrupt sources. The interrupt sources can be enabled or disabled using the IC0IE, IC1IE, OC0IE, OC1IE, and CMWIE bits in CMWCR and are separately generated to the interrupt controller.

Each interrupt request can activate the direct memory access controller (DMAC) or data transfer controller (DTC). When the DMAC is used for data transfer, an interrupt request is not generated to the CPU. For generating an interrupt request to the CPU during data transfer using the DTC, refer to section 20, Data Transfer Controller (DTCa).

Table 31.3 CMTW Interrupt Sources

Unit	Name	Interrupt Request	Interrupt Request Enable Bit	DMAC/DTC Activation
CMTW0	CMWI0	Compare match of CMTW0.CMWCOR register	CMTW0.CMWCR.CMWIE	Possible
	IC0I0	Input capture of CMTW0.CMWICR0 register	CMTW0.CMWCR.IC0IE	Possible
	IC1I0	Input capture of CMTW0.CMWICR1 register	CMTW0.CMWCR.IC1IE	Possible
	OC0I0	Output compare of CMTW0.CMWOCR0 register	CMTW0.CMWCR.OC0IE	Possible
	OC1I0	Output compare of CMTW0.CMWOCR1 register	CMTW0.CMWCR.OC1IE	Possible
CMTW1	CMWI1	Compare match of CMTW1.CMWCOR register	CMTW1.CMWCR.CMWIE	Possible
	IC0I1	Input capture of CMTW1.CMWICR0 register	CMTW1.CMWCR.IC0IE	Possible
	IC1I1	Input capture of CMTW1.CMWICR1 register	CMTW1.CMWCR.IC1IE	Possible
	OC0I1	Output compare of CMTW1.CMWOCR0 register	CMTW1.CMWCR.OC0IE	Possible
	OC1I1	Output compare of CMTW1.CMWOCR1 register	CMTW1.CMWCR.OC1IE	Possible

31.4.2 Timing of Compare Match Interrupt Generation

When the values of the CMWCNT counter and CMWCOR register match, a compare match interrupt request (CMWI) is generated. The compare match signal is generated at the end of the cycle where the values matched (i.e. when the CMWCNT counter is updated from the matching counter value).The compare match signal, therefore, is not generated until a count-up enable signal is generated after the values of the CMWCNT counter and CMWCOR register have matched. Figure 31.13 shows the timing of compare match interrupt generation.

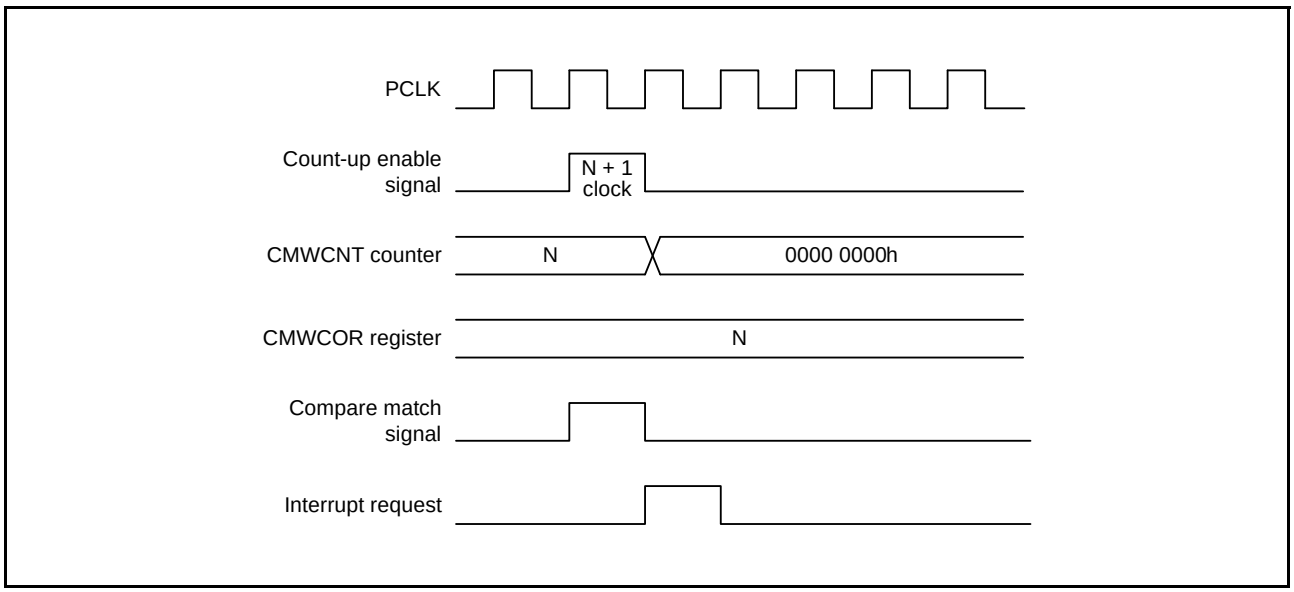

Figure 31.13 Timing of Compare Match Interrupt Generation

(a) Timing of Output Compare Interrupt Generation

Figure 31.14 shows the timing of output compare interrupt generation.

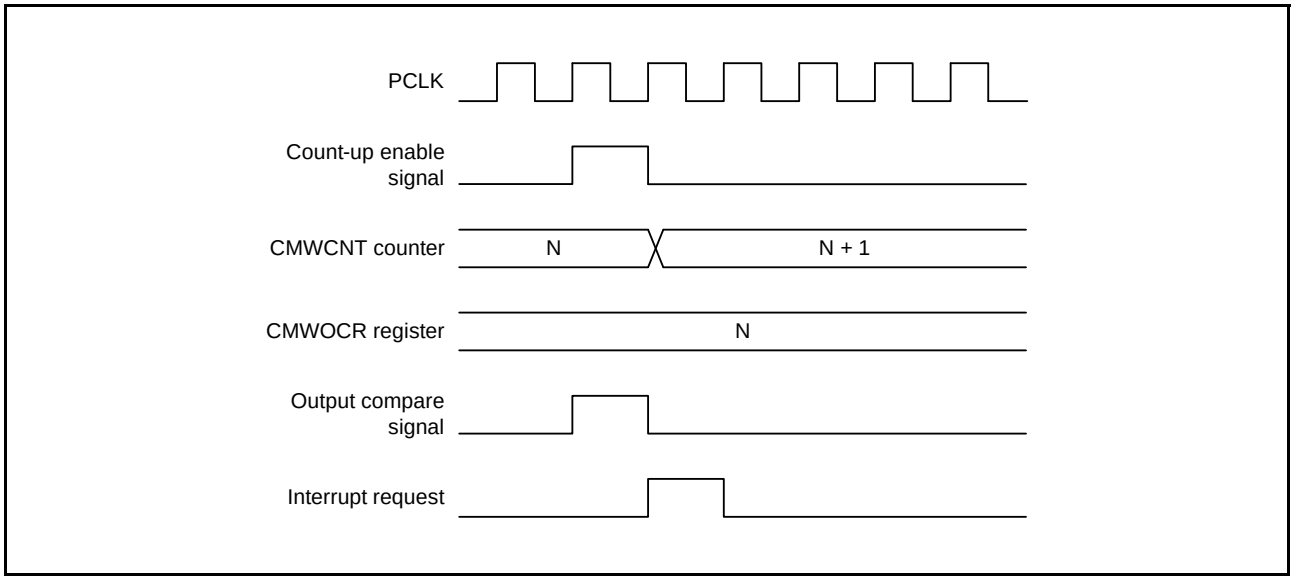

Figure 31.14 Timing of Output Compare Interrupt Generation

(b) Timing of Input Capture Interrupt Generation

Figure 31.15 shows the timing of input capture interrupt generation.

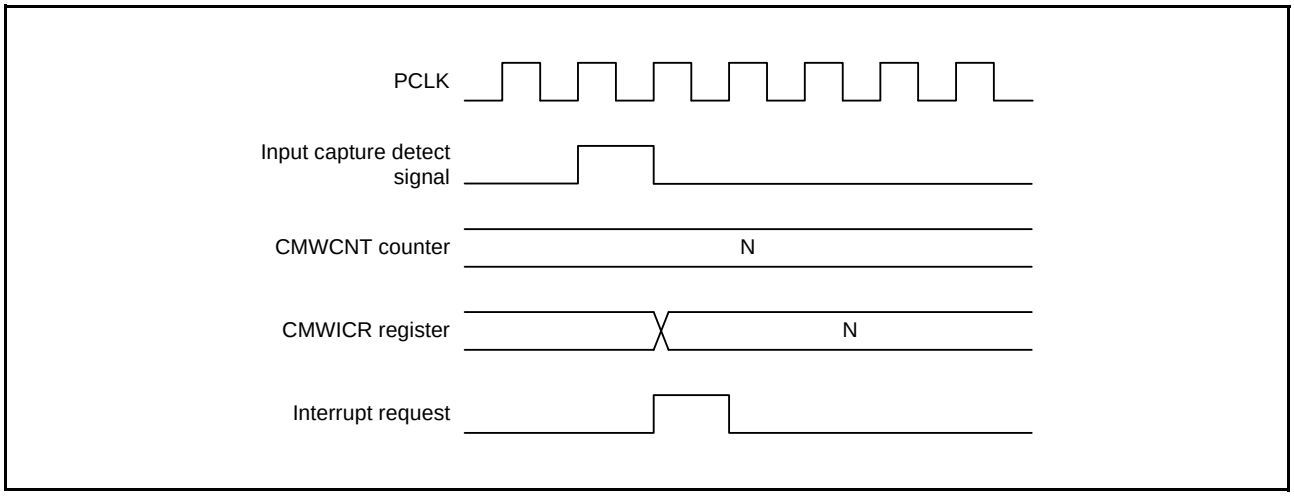

Figure 31.15 Timing of Input Capture Interrupt Generation

31.5 Link Operations by ELC

31.5.1 Event Signal Output to ELC

The CMTW uses the event link controller (ELC) to perform link operation to a preset module using the interrupt request signal as the event signal.
The CMTW outputs the event signal upon a compare match. The corresponding channel is channel 0. The event signal can be output regardless of the corresponding interrupt request enable bit (CMWCR.CMWIE).
For details, refer to section 21, Event Link Controller (ELC).

(1) Compare Match Event

In response to a compare match, the CMTW simultaneously issues an interrupt request and a compare match event signal to the ELC. The event signal is issued regardless of the settings of the corresponding interrupt request enable bit (CMWCR.CMWIE bit).

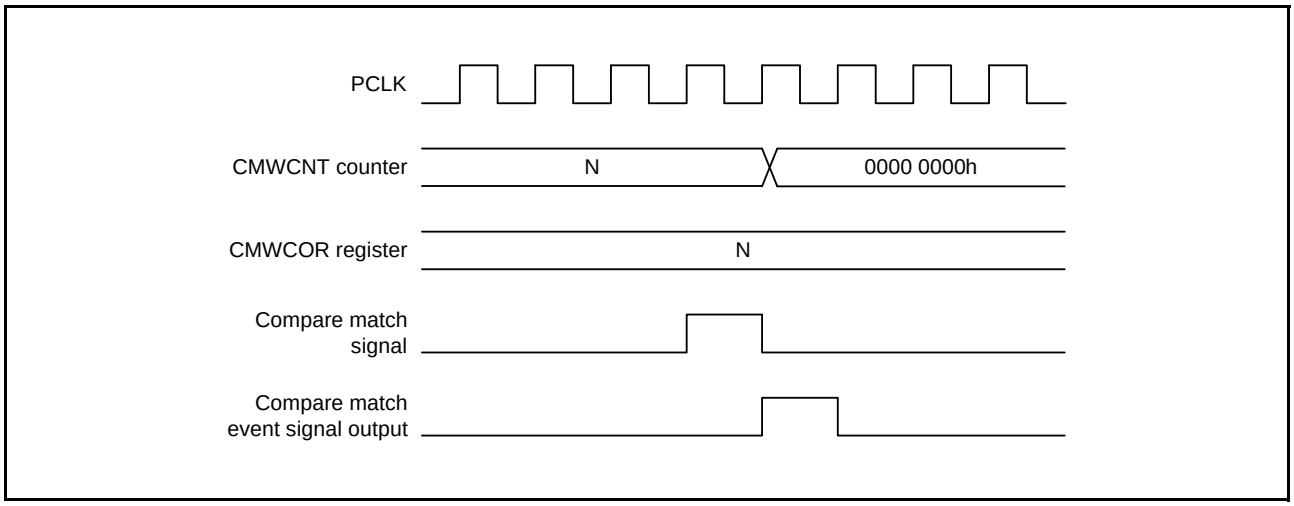

Figure 31.16 Timing of Issuing a Compare Match Event Signal

31.5.2 CMTW Operation When Receiving an Event Signal from ELC

The CMTW can perform any of the following operations according to the event preset by the ELSRn register of the ELC.

(1) Count Start

The CMTW count start operation is selected by the ELOPH register of the ELC. If the event specified by the ELSRn register occurs, the CMWSTR.STR bit is set to 1, starting the CMTW count operation.
However, if the specified event occurs while the CMWSTR.STR bit is 1, the event is ignored.

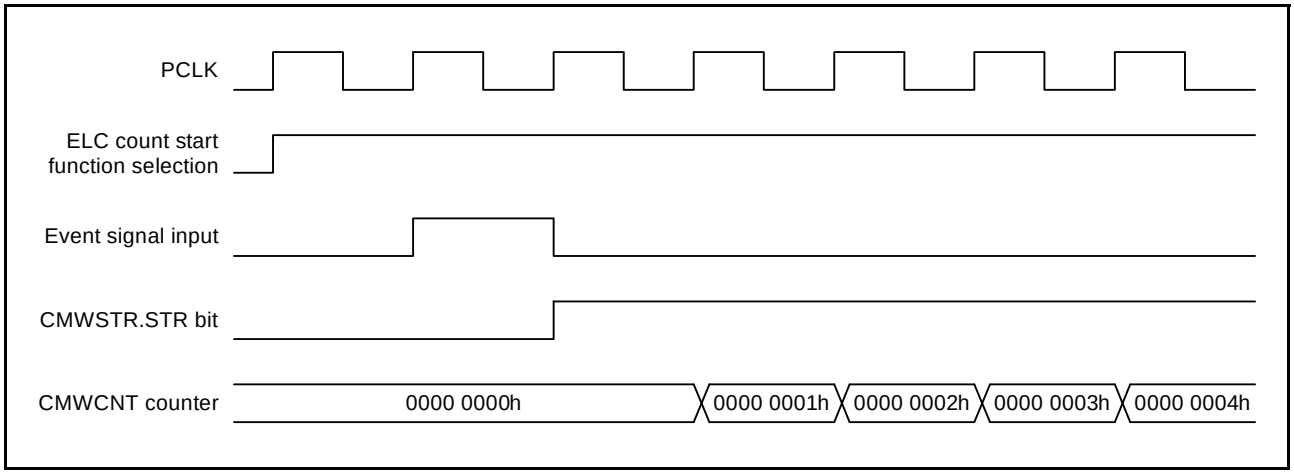

Figure 31.17 Count Start Operation on Acceptance of the Event Signal

(2) Event Count

The CMTW event count operation is selected by the ELOPH register of the ELC. If the event specified by the ELSRn register occurs when the CMWCR.STR bit is 1, the event is counted as the count source regardless of the CMWCR.CKS[1:0] bit setting.
Reading the counter value returns the number of events that have been actually input.

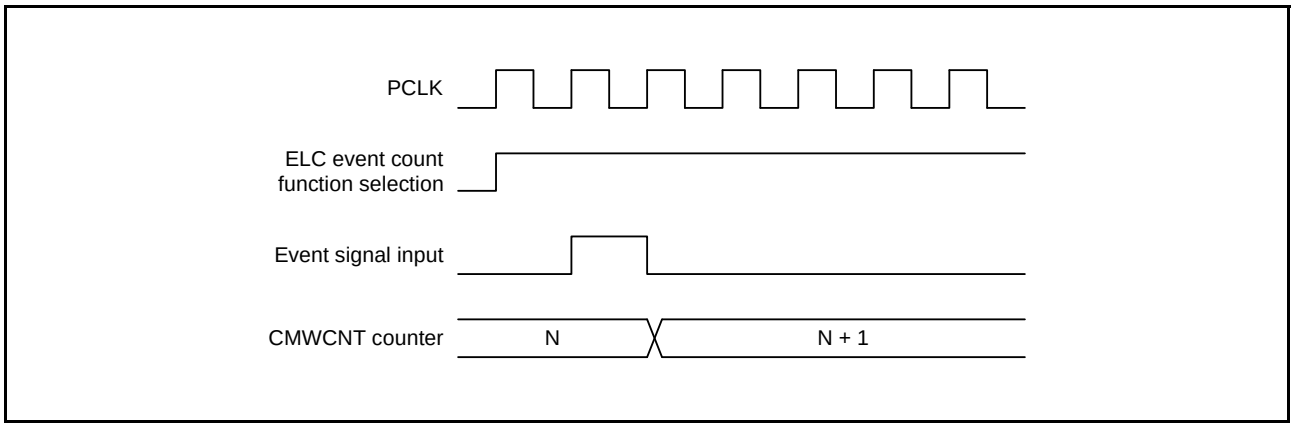

Figure 31.18 Event Count Operation on Acceptance of the Event Signal

(3) Count Restart

The CMTW count restart operation is selected by the ELOPH register of the ELC. If the event specified by the ELSRn register occurs, the CMWCNT counter value is set to 0. If the CMWSTR.STR bit is 1, the count operation can be continued.

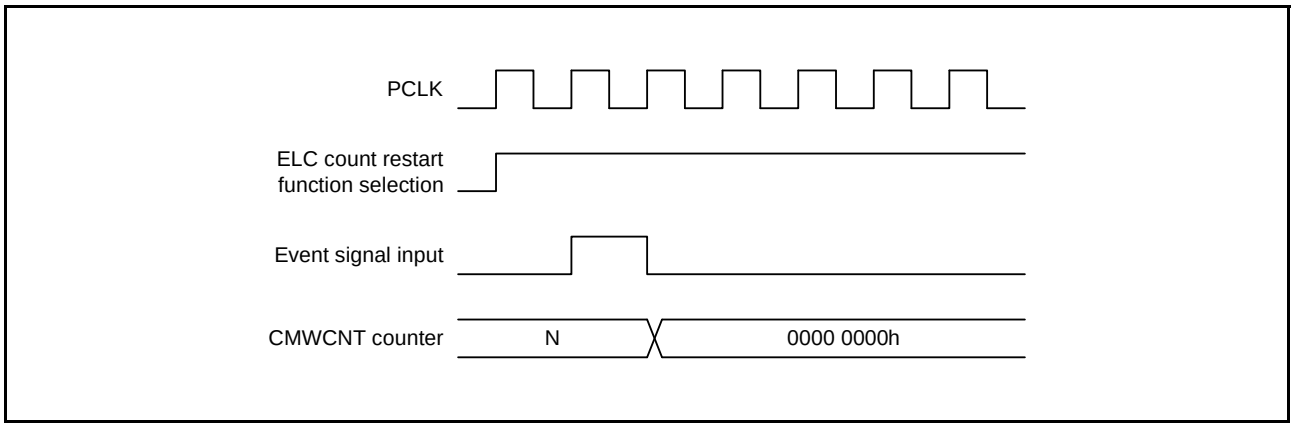

Figure 31.19 Count Restart Operation on Acceptance of the Event Signal

31.5.3 Conflict between Event Link Operation and Register Access

The followings are the notes on using CMTW for event link operations.
Table 31.4 lists count operations when event link operation and register access conflict.

Table 31.4 Count Operations When Event Link Operation and Register Access Conflict

Event Link Operation	Register Access	CMWCNT Counter Status	Operation to be Performed
Count start	Writing to the CMWSTR.STR bit	Stopped state	Count start
		Compare match	Count start
		Counting up	Count start
Event count	Writing to CMWCNT counter	—	Event count
	Writing to CMWCOR register	Compare match	Compare match
Count restart	Writing to CMWCNT counter	Other than compare match	Count restart
	Writing to CMWCNT counter	Compare match	Compare match
	(No access to registers)	Compare match	Compare match
(No events)	Writing to CMWCNT counter	Compare match	Output of compare match interrupt request Writing to CMWCNT counter
		Counting up	Writing to CMWCNT counter
	Writing to CMWCOR register	Compare match	Compare match
	Writing to CMWOCR register	Compare match	Compare match
	Reading from CMWCNT counter	Counting up	Counting up and reading of the previous value

(1) Count Start

When writing to the STR bit in the CMWSTR register and acceptance of the event signal are in contention, writing to the STR bit does not proceed since setting of the STR bit to 1 in response to the event takes priority.

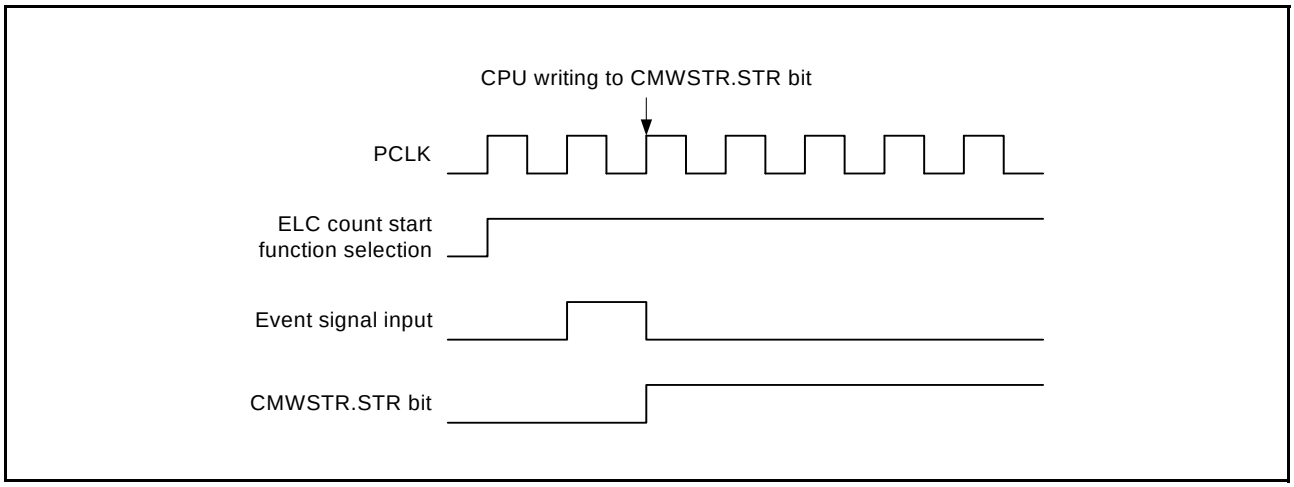

Figure 31.20 Conflict between Event Acceptance and Register Access in Count Start Operation

(2) Event Count

When writing to the CMWCNT counter and acceptance of the event signal are in contention, writing to the CMWCNT counter does not proceed since the count operation in response to the event takes priority.

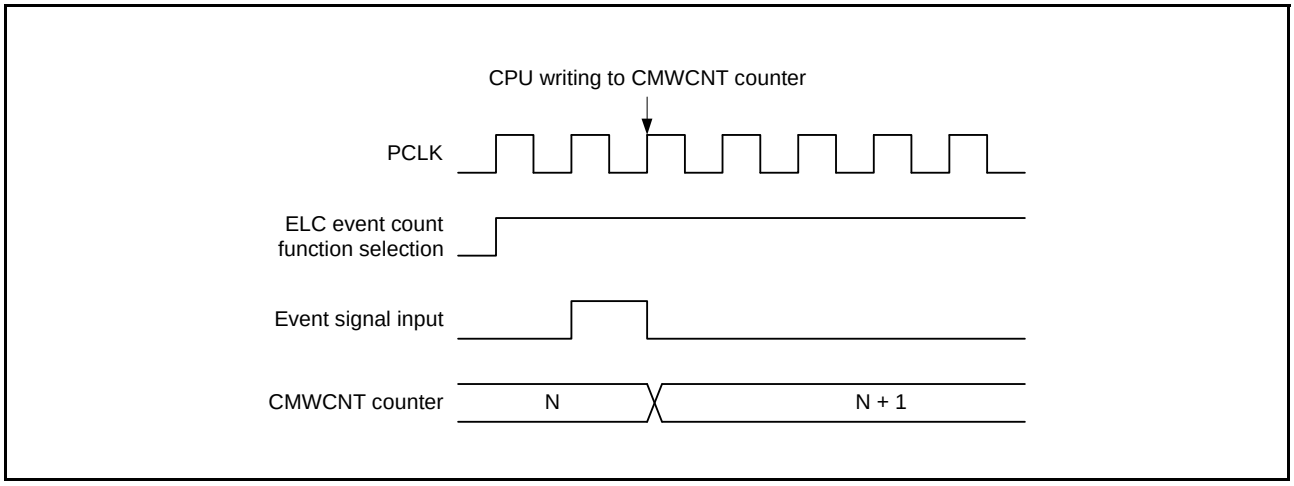

Figure 31.21 Conflict between Event Acceptance and Register Access in Event Counting Operation

(3) Count Restart

When writing to the CMWCNT counter and acceptance of the event signal are in contention, writing to the CMWCNT counter does not proceed since the counter value initialization in response to the event occurrence takes priority.

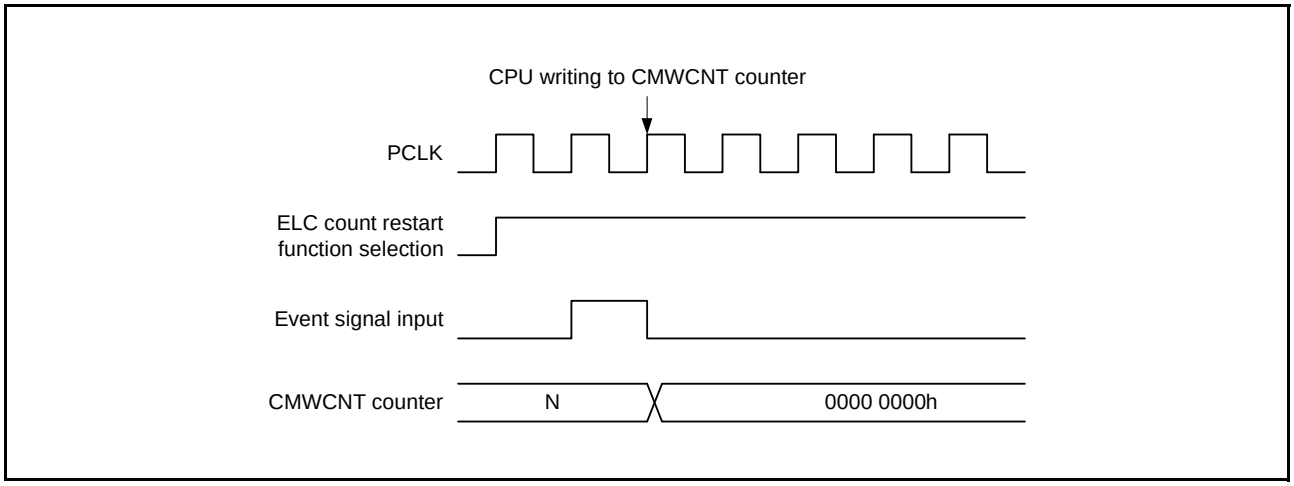

Figure 31.22 Conflict between Event Acceptance and Register Access in Count Restart Operation

31.6 Usage Notes

31.6.1 Setting the Module Stop Function

The CMTW operation can be enabled and disabled using the MSTPCRA register. With the initial value, the CMTW is stopped. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

31.6.2 Conflict between CMWCNT Counter Writing and Compare Match

If the compare match signal is generated during writing to the CMWCNT counter, the compare match request is output but the counter is not cleared since writing to the counter takes priority.
Figure 31.23 shows the timing of conflict between CMWCNT counter writing and compare match.

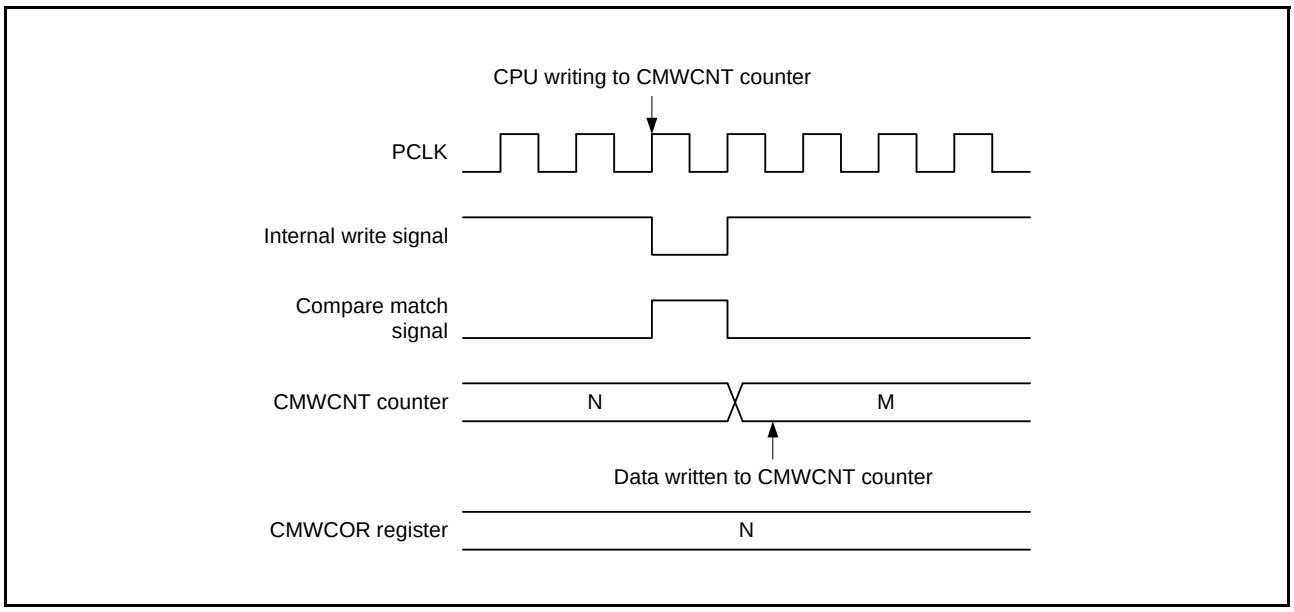

Figure 31.23 Conflict between CMWCNT Counter Writing and Compare Match

31.6.3 Conflict between CMWCNT Counter Writing and Incrementing or Clearing

In case of conflict between incrementation or clearing of the CMWCNT counter and writing to the CMWCNT counter, the counter is not actually incremented or cleared since writing to the CMWCNT counter takes priority.
Figure 31.24 shows the timing in the case of contention between writing to the CMWCNT counter and incrementation or clearing.

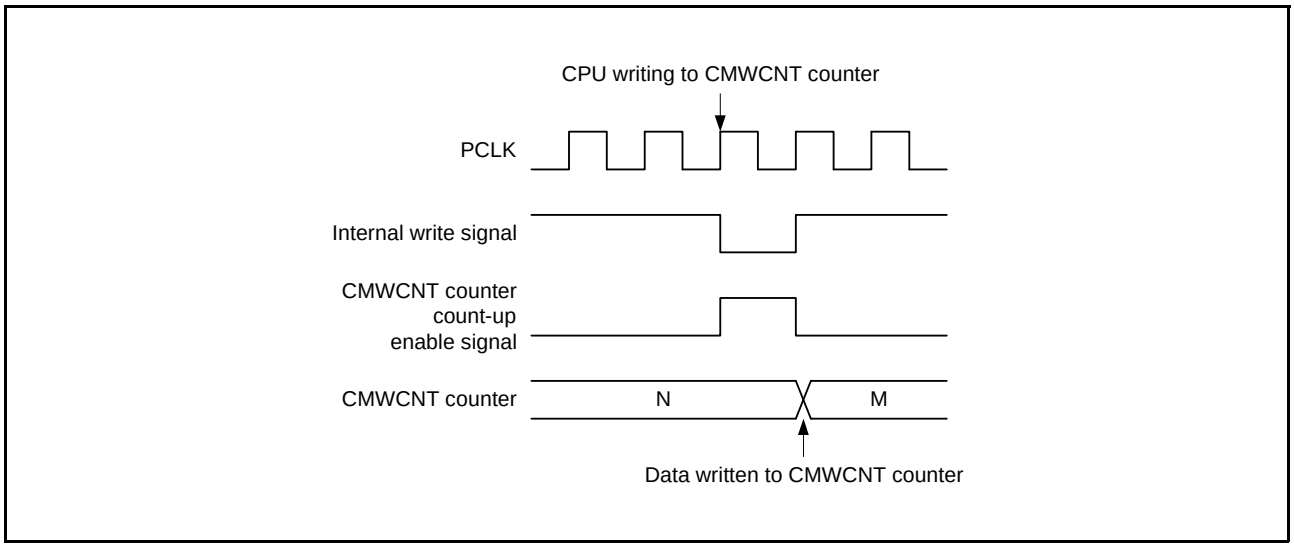

Figure 31.24 Conflict between CMWCNT Counter Writing and Incrementing

31.6.4 Conflict between CMWCOR Register Writing and Compare Match

If the compare match is generated during the CMWCOR register write cycle, the writing to the CMWCOR register takes priority and also the compare match signal is output.
Figure 31.25 shows the timing of conflict between CMWCOR register writing and compare match.

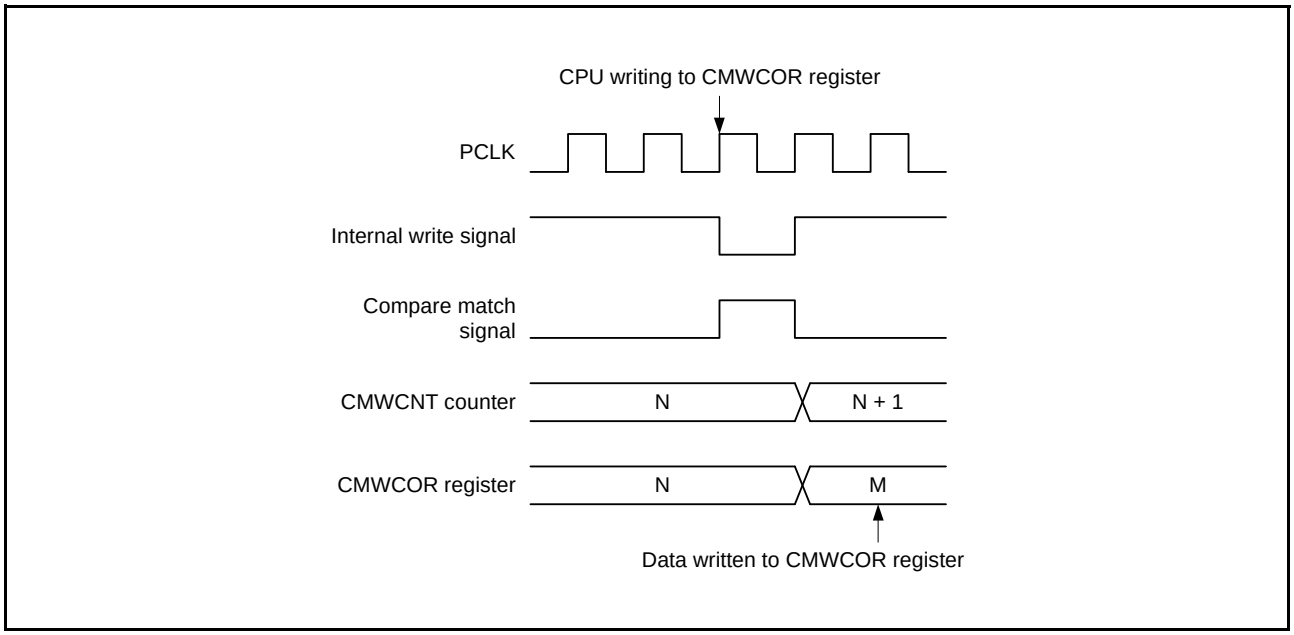

Figure 31.25 Conflict between CMWCOR Register Writing and Compare Match

31.6.5 Conflict between CMWOCR Register Writing and Compare Match

If the compare match is generated during the CMWOCR register write cycle, the writing to the CMWOCR register takes priority and also the compare match signal is output.
Figure 31.26 shows the timing of conflict between CMWOCR register writing and compare match.

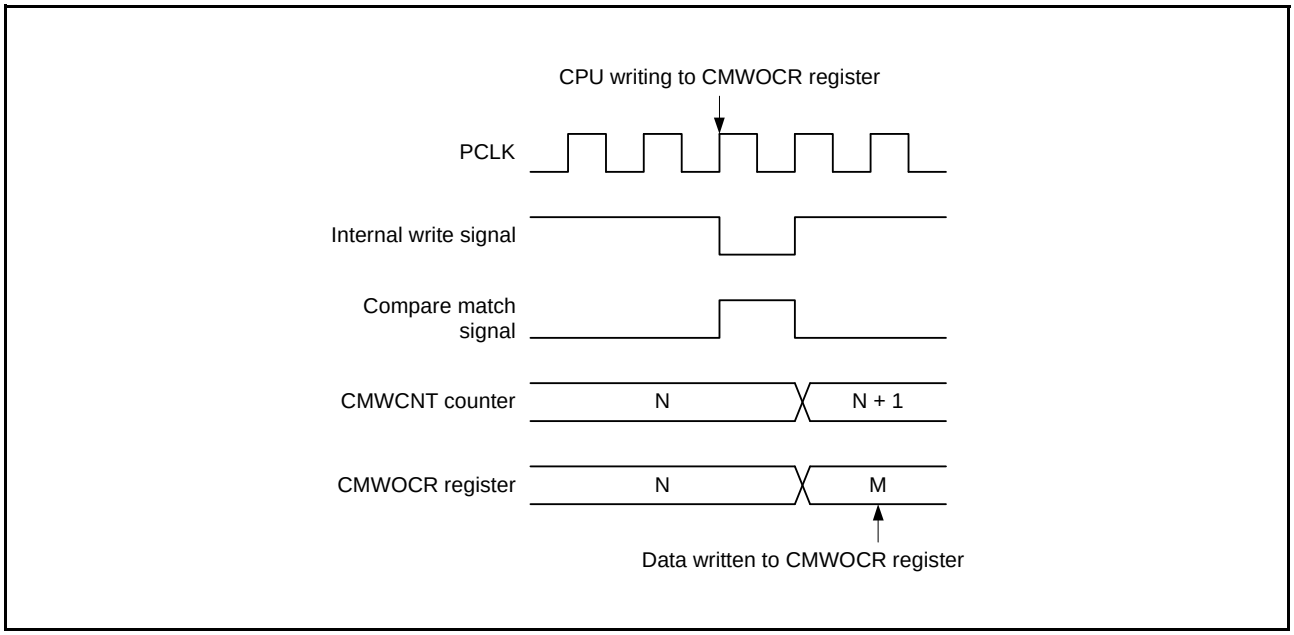

Figure 31.26 Conflict between CMWOCR Register Writing and Compare Match

31.6.6 Conflict between CMWCNT Counter Reading and Incrementing or Clearing

If the CMWCNT counter incrementing or clearing process occurs at the same time that the data of the CMWCNT counter is read, the value having been in the CMWCNT counter before incremented or cleared is read.
Figure 31.27 shows the timing of conflict between CMWCNT counter reading and incrementing.

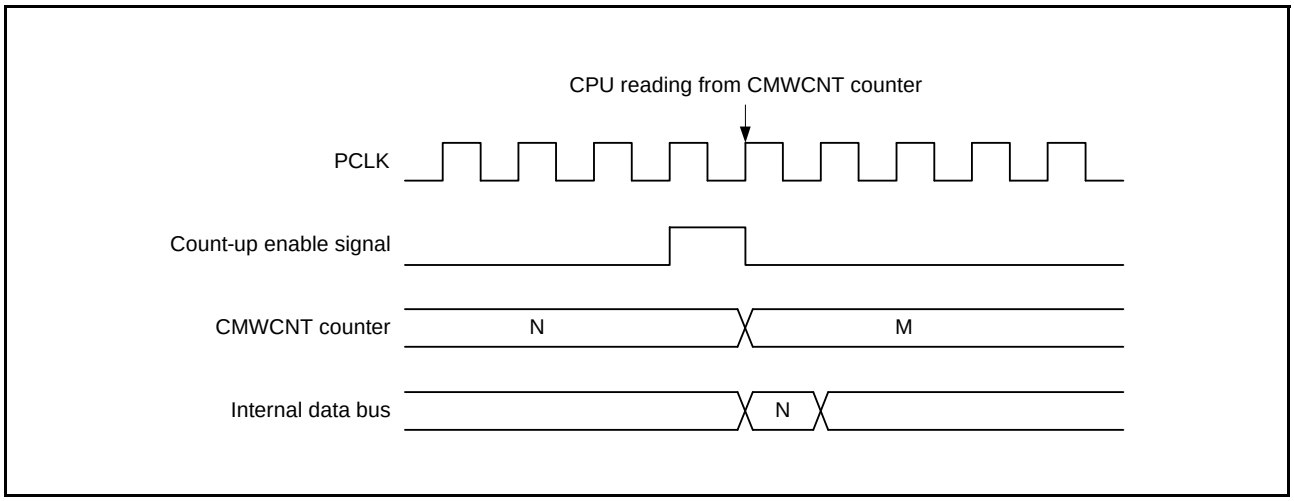

Figure 31.27 Conflict between CMWCNT Counter Reading and Incrementing

31.6.7 Conflict between CMWICR Register Reading and Input Capture

If the input capture detection signal is generated at the same time that the data of the CMWICR register is read, the value having been in the CMWICR register before updated by input capture transfer is read.
Figure 31.28 shows the timing of conflict between CMWICR register reading and input capture.

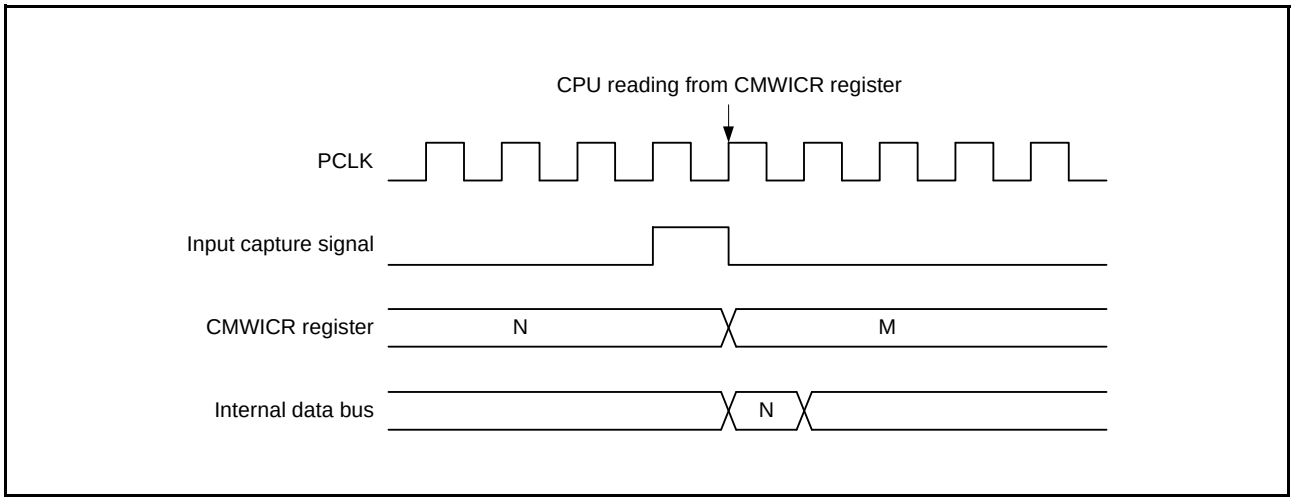

Figure 31.28 Conflict between CMWICR Register Reading and Input Capture

32. Realtime Clock (RTCd)

In this section, “PCLK” is used to refer to PCLKB.

32.1 Overview

The RTC has two types of counting modes: calendar count mode and binary count mode. They are used by switching the register settings.
For calendar count mode, the RTC has a 100 year calendar from 2000 to 2099 and automatically adjusts dates for leap years.
For binary count mode, the RTC does not count in terms of years, months, dates, day-of-week, hours, or minutes; it counts seconds, and retains the information as a serial value. This mode can be used for calendars other than the Gregorian calendar.
The count source of the time counters is selectable as the sub-clock or main clock.
The RTC uses the 128-Hz clock which is acquired by the count source divided by the prescaler as the reference clock.
Year, month, date, day-of-week, a.m./p.m. (in 12-hour mode), hour, minute, second, or 32-bit binary is counted in 1/128 second units.

Table 32.1 lists the specifications of the RTC, Figure 32.1 shows a block diagram of the RTC, and Table 32.2 shows the pin configuration of the RTC.

Table 32.1 RTC Specifications

Item	Description
Count mode	Calendar count mode/binary count mode
Count source*1	Sub-clock (XCIN) or main clock (EXTAL)
Clock and calendar functions	• Calendar count mode Year, month, date, day-of-week, hour, minute, second are counted, BCD display 12 hours/24 hours mode switching function 30 seconds adjustment function (a number less than 30 is rounded down to 00 seconds, and 30 seconds or more are rounded up to one minute) Automatic adjustment function for leap years • Binary count mode Count seconds in 32 bits, binary display • Common to both modes Start/stop function The sub-second digit is displayed in binary units (1 Hz, 2 Hz, 4 Hz, 8 Hz, 16 Hz, 32 Hz, or 64 Hz). Clock error correction function Clock (1 Hz/64 Hz) output
Interrupts	• Alarm interrupt (ALM) As an alarm interrupt condition, selectable which of the below is compared with: - Calendar count mode: Year, month, date, day-of-week, hour, minute, or second can be selected - Binary count mode: Each bit of the 32-bit binary counter • Periodic interrupt (PRD) 2 seconds, 1 second, 1/2 second, 1/4 second, 1/8 second, 1/16 second, 1/32 second, 1/64 second, or 1/256 second can be selected as an interrupt period. • Carry interrupt (CUP) An interrupt is generated at either of the following timings: - When a carry from the 64-Hz counter to the second counter is generated. - When the 64-Hz counter is changed and the R64CNT register is read at the same time. • Recovery from software standby mode or deep software standby mode can be performed by an alarm interrupt or periodic interrupt
Time capture function	• Times can be captured when the edge of the time capture event input pin is detected. For every event input, month, date, hour, minute, and second are captured or 32-bit binary counter value is captured.
Event link function	Periodic event output

Note 1. Satisfy the frequency of the peripheral module clock (PCLKB) ≥ the frequency of the count source.

RADJ: Time error adjustment register

RSECAR/BCNT0AR: Second alarm register/Binary counter 0 alarm register
RMINAR/BCNT1AR: Minute alarm register/Binary counter 1 alarm register
RHRAR/BCNT2AR: Hour alarm register/Binary counter 2 alarm register
RWKAR/BCNT3AR: Day-of-week alarm register/Binary counter 3 alarm register
RDAYAR/BCNT0AER: Date alarm register/Binary counter 0 alarm enable register
RMONAR/BCNT1AER: Month alarm register/Binary counter 1 alarm enable register
RYRAR/BCNT2AER: Year alarm register/Binary counter 2 alarm enable register
RYRAREN/BCNT3AER: Year alarm enable register/Binary counter 3 alarm enable register
RTCCRn: Time capture control register n
RSECCPn/BCNT0CPn: Second capture register n/BCNT0 capture register n
RMINCPn/BCNT1CPn: Minute capture register n/BCNT1 capture register n
RHRCPn/BCNT2CPn: Hour capture register n/BCNT2 capture register n
RDAYCPn/BCNT3CPn: Date capture register n/BCNT3 capture register n
RMONCPn: Month capture register n

Figure 32.1 Block Diagram of RTC

Table 32.2 Pin Configuration of RTC

Pin Name	I/O	Function
XTAL	Output	These pins are used to connect a crystal. The EXTAL pin can also be used to input an external clock. For details, refer to section 9.3.2, External Clock Input.
EXTAL	Input	
XCIN	Input	Connect a 32.768-kHz crystal to these pins.
XCOUT	Output	
RTCOUT	Output	This pin is used to output a 1-Hz/64-Hz waveform, but not in deep software standby mode.
RTCIC0	Input	Time capture event input pins
RTCIC1	Input	
RTCIC2	Input	

32.2 Register Descriptions

When writing to or reading from RTC registers, do so in accordance with section 32.6.5, Notes When Writing to and Reading from Registers.

If the value in an RTC register after a reset is given as x (undefined bits) in the list, it is not initialized by a reset. When RTC enters the reset state or a low power consumption state during counting operations (i.e. while the RCR2.START bit is 1), the year, month, day of the week, date, hours, minutes, seconds, and 64-Hz counters continue to operate. However, when the count source is the main clock, the main clock is not stopped by a reset other than a deep software standby reset. For details, refer to Table 6.2, Targets to be Initialized by Each Reset Source. Note that a reset generated during writing to or updating of a register might destroy the register value. In addition, do not allow the chip to enter software standby mode or deep software standby mode immediately after setting any of these registers. For details, refer to section 32.6.4, Transitions to Low Power Consumption Modes after Setting Registers.

32.2.1 64-Hz Counter (R64CNT)

Address(es): RTC.R64CNT 0008 C400h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	F1HZ	F2HZ	F4HZ	F8HZ	F16HZ	F32HZ	F64HZ
Value after reset:	0	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	F64HZ	64 Hz	Indicate the state between 1 Hz and 64 Hz of the sub-second digit.	R
b1	F32HZ	32 Hz		R
b2	F16HZ	16 Hz		R
b3	F8HZ	8 Hz		R
b4	F4HZ	4 Hz		R
b5	F2HZ	2 Hz		R
b6	F1HZ	1 Hz		R
b7	—	Reserved	This bit is read as 0. Writing to this bit has no effect.	R

The R64CNT counter is used in both calendar count mode and in binary count mode.

The 64-Hz counter (R64CNT) generates a period of one second by counting the 128-Hz reference clock.

The state in the sub-second range can be confirmed by reading this counter.

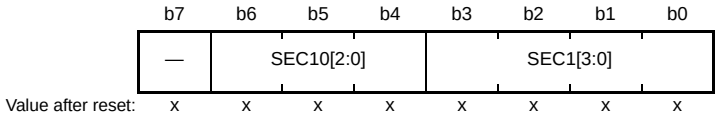
This counter is set to 00h by an RTC software reset or executing 30-second adjustment.

To read this counter, follow the procedure in section 32.3.5, Reading 64-Hz Counter and Time.

32.2.2 Second Counter (RSECCNT)/Binary Counter 0 (BCNT0)

(1) In calendar count mode:

Address(es): RTC.RSECCNT 0008 C402h



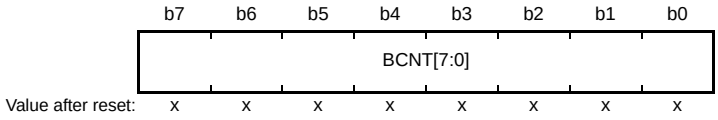
x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	SEC1[3:0]	1-Second Count	Counts from 0 to 9 every second. When a carry is generated, 1 is added to the tens place.	R/W
b6 to b4	SEC10[2:0]	10-Second Count	Counts from 0 to 5 for 60-second counting.	R/W
b7	—	Reserved	Set this bit to 0. It is read as the set value.	R/W

The RSECCNT counter is used for setting and counting the BCD-coded second value. It counts carries generated once per second in the 64-Hz counter.
The setting range is decimal 00 to 59. The RTC will not operate normally if any other value is set. Before writing to this register, be sure to stop the count operation through the setting of the START bit in RCR2.
After writing to the RSECCNT register, confirm that its value has actually changed before proceeding with further processing. Refer to section 32.6.5, Notes When Writing to and Reading from Registers for notes on accessing registers.

(2) In binary count mode:

Address(es): RTC.BCNT0 0008 C402h



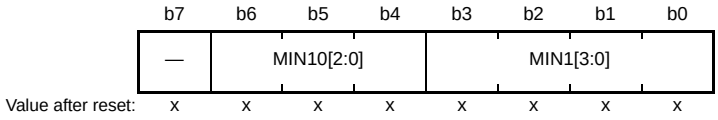
x: Undefined

The BCNT0 counter is a readable/writable 32-bit binary counter b7 to b0.
The 32-bit binary counter performs count operation by a carry generating for each second of the 64-Hz counter.
Before writing to this register, be sure to stop the count operation through the setting of the START bit in RCR2.
To read this counter, follow the procedure in section 32.3.5, Reading 64-Hz Counter and Time.

32.2.3 Minute Counter (RMINCNT)/Binary Counter 1 (BCNT1)

(1) In calendar count mode:

Address(es): RTC.RMINCNT 0008 C404h



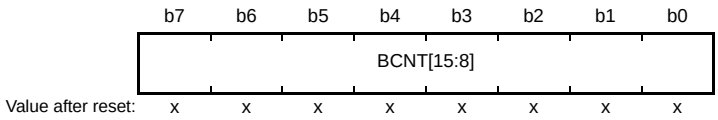
x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	MIN1[3:0]	1-Minute Count	Counts from 0 to 9 every minute. When a carry is generated, 1 is added to the tens place.	R/W
b6 to b4	MIN10[2:0]	10-Minute Count	Counts from 0 to 5 for 60-minute counting.	R/W
b7	—	Reserved	Set this bit to 0. It is read as the set value.	R/W

The RMINCNT counter is used for setting and counting the BCD-coded minute value. It counts carries generated once per minute in the second counter.
A value from 00 through 59 (in BCD) can be specified; if a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, be sure to stop the count operation through the setting of the START bit in RCR2.
After writing to the RMINCNT counter, confirm that its value has actually changed before proceeding with further processing. Refer to section 32.6.5, Notes When Writing to and Reading from Registers for notes on accessing registers.

(2) In binary count mode:

Address(es): RTC.BCNT1 0008 C404h



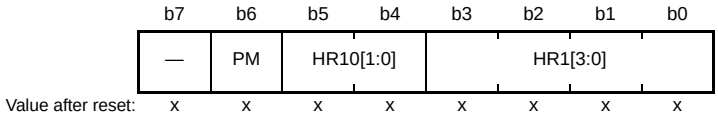
x: Undefined

The BCNT1 counter is a readable/writable 32-bit binary counter b15 to b8.
The 32-bit binary counter performs count operation by a carry generating for each second of the 64-Hz counter.
Before writing to this register, be sure to stop the count operation through the setting of the START bit in RCR2.
To read this counter, follow the procedure in section 32.3.5, Reading 64-Hz Counter and Time.

32.2.4 Hour Counter (RHRCNT)/Binary Counter 2 (BCNT2)

(1) In calendar count mode:

Address(es): RTC.RHRCNT 0008 C406h



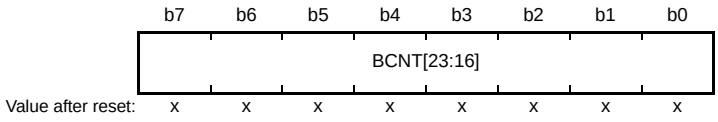
x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	HR1[3:0]	1-Hour Count	Counts from 0 to 9 once per hour. When a carry is generated, 1 is added to the tens place.	R/W
b5, b4	HR10[1:0]	10-Hour Count	Counts from 0 to 2 once per carry from the ones place.	R/W
b6	PM	PM	Time Counter Setting for a.m./p.m. 0: a.m. 1: p.m.	R/W
b7	—	Reserved	Set this bit to 0. It is read as the set value.	R/W

The RHRCNT counter is used for setting and counting the BCD-coded hour value. It counts carries generated once per hour in the minute counter.
The specifiable time differs according to the setting in the hours mode bit (RCR2.HR24).
When the RCR2.HR24 bit is 0: From 00 to 11 (in BCD)
When the RCR2.HR24 bit is 1: From 00 to 23 (in BCD)
If a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, be sure to stop the count operation through the setting of the START bit in RCR2.
The PM bit is only enabled when the RCR2.HR24 bit is 0. Otherwise, the setting in the PM bit has no effect.
After writing to the RHRCNT counter, confirm that its value has actually changed before proceeding with further processing. Refer to section 32.6.5, Notes When Writing to and Reading from Registers for notes on accessing registers.

(2) In binary count mode:

Address(es): RTC.BCNT2 0008 C406h



x: Undefined

The BCNT2 counter is a readable/writable 32-bit binary counter b23 to b16.
The 32-bit binary counter performs count operation by a carry generating for each second of the 64-Hz counter.
Before writing to this register, be sure to stop the count operation through the setting of the START bit in RCR2.
To read this counter, follow the procedure in section 32.3.5, Reading 64-Hz Counter and Time.

32.2.5 Day-of-Week Counter (RWKCNT)/Binary Counter 3 (BCNT3)

(1) In calendar count mode:

Address(es): RTC.RWKCNT 0008 C408h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	DAYW[2:0]		
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	DAYW[2:0]	Day-of-Week Counting	b2 b0 0 0 0: Sunday 0 0 1: Monday 0 1 0: Tuesday 0 1 1: Wednesday 1 0 0: Thursday 1 0 1: Friday 1 1 0: Saturday 1 1 1: Setting Prohibited	R/W
b7 to b3	—	Reserved	Set these bits to 0. They are read as the set value.	R/W

The RWKCNT counter is used for setting and counting in the coded day-of-week value. It counts carries generated once per day in the hour counter.
A value from 0 through 6 can be specified; if a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, be sure to stop the count operation through the setting of the START bit in RCR2.
Refer to section 32.6.5, Notes When Writing to and Reading from Registers for notes on accessing registers.

(2) In binary count mode:

Address(es): RTC.BCNT3 0008 C408h

	b7	b6	b5	b4	b3	b2	b1	b0
	BCNT[31:24]							
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

The BCNT3 counter is a readable/writable 32-bit binary counter b31 to b24.
The 32-bit binary counter performs count operation by a carry generating for each second of the 64-Hz counter.
Before writing to this register, be sure to stop the count operation through the setting of the START bit in RCR2.
To read this counter, follow the procedure in section 32.3.5, Reading 64-Hz Counter and Time.

32.2.6 Date Counter (RDAYCNT)

Address(es): RTC.RDAYCNT 0008 C40Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	DATE10[1:0]		DATE1[3:0]			
Value after reset:	0	0	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	DATE1[3:0]	1-Day Count	Counts from 0 to 9 once per day. When a carry is generated, 1 is added to the tens place.	R/W
b5, b4	DATE10[1:0]	10-Day Count	Counts from 0 to 3 once per carry from the ones place.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The RDAYCNT counter is used in calendar count mode.
The RDAYCNT counter is used for setting and counting the BCD-coded date value. It counts carries generated once per day in the hour counter. The count operation depends on the month and whether the year is a leap year.
Leap years are determined according to whether the year counter (RYRCNT) value is divisible by 400, 100, and 4.
A value from 01 through 31 (in BCD) can be specified; if a value outside of this range is specified, the RTC does not operate correctly. (When specifying a value, note that the range of specifiable days depends on the month and whether the year is a leap year.) Before writing to this register, be sure to stop the count operation through the setting of the START bit in RCR2.
After writing to the RHRCNT counter, confirm that its value has actually changed before proceeding with further processing. Refer to section 32.6.5, Notes When Writing to and Reading from Registers for notes on accessing registers.

32.2.7 Month Counter (RMONCNT)

Address(es): RTC.RMONCNT 0008 C40Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	MON10	MON1[3:0]			
Value after reset:	0	0	0	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	MON1[3:0]	1-Month Count	Counts from 0 to 9 once per month. When a carry is generated, 1 is added to the tens place.	R/W
b4	MON10	10-Month Count	Counts from 0 to 1 once per carry from the ones place.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The RMONCNT counter is used in calendar count mode.
The RMONCNT counter is used for setting and counting the BCD-coded month value. It counts carries generated once per month in the date counter.
A value from 01 through 12 (in BCD) can be specified; if a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, be sure to stop the count operation through the setting of the START bit in RCR2.
After writing to the RMONCNT counter, confirm that its value has actually changed before proceeding with further processing. Refer to section 32.6.5, Notes When Writing to and Reading from Registers for notes on accessing registers.

32.2.8 Year Counter (RYRCNT)

Address(es): RTC.RYRCNT 0008 C40Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	YR10[3:0]				YR1[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	YR1[3:0]	1-Year Count	Counts from 0 to 9 once per year. When a carry is generated, 1 is added to the tens place.	R/W
b7 to b4	YR10[3:0]	10-Year Count	Counts from 0 to 9 once per carry from ones place. When a carry is generated in the tens place, 1 is added to the hundreds place.	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The RYRCNT counter is used in calendar count mode.

The RYRCNT counter is used for setting and counting the BCD-coded year value. It counts carries generated once per year in the month counter.

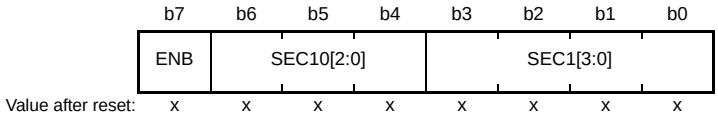
A value from 00 through 99 (in BCD) can be specified; if a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, be sure to stop the count operation through the setting of the START bit in RCR2.

After writing to the RYRCNT counter, confirm that its value has actually changed before proceeding with further processing. Refer to section 32.6.5, Notes When Writing to and Reading from Registers for notes on accessing registers.

32.2.9 Second Alarm Register (RSECAR)/Binary Counter 0 Alarm Register (BCNT0AR)

(1) In calendar count mode:

Address(es): RTC.RSECAR 0008 C410h



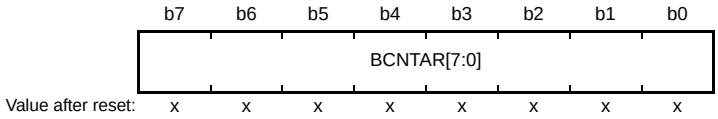
x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	SEC1[3:0]	1 Second	Value for the ones place of seconds	R/W
b6 to b4	SEC10[2:0]	10 Seconds	Value for the tens place of seconds	R/W
b7	ENB	ENB	0: The register value is not compared with the RSECCNT counter value. 1: The register value is compared with the RSECCNT counter value.	R/W

The RSECAR register is an alarm register corresponding to the BCD-coded second counter RSECCNT. When the ENB bit is set to 1, the RSECAR value is compared with the RSECCNT value. From among the alarm registers (RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, and RYRAREN), only those selected with the ENB bits set to 1 are compared with the corresponding counters. When the respective values all match, the IR flag corresponding to the ALM interrupt is set to 1.
RSECAR values from 00 through 59 (in BCD) can be specified; if a value outside of this range is specified, the RTC does not operate correctly.
After writing to the RSECAR register, confirm that its value has actually changed before proceeding with further processing. Refer to section 32.6.5, Notes When Writing to and Reading from Registers for notes on accessing registers.
This register is set to 00h by an RTC software reset.

(2) In binary count mode:

Address(es): RTC.BCNT0AR 0008 C410h



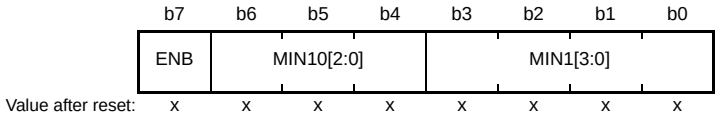
x: Undefined

The BCNT0AR counter is a readable/writable alarm register corresponding to 32-bit binary counter b7 to b0.
This register is set to 00h by an RTC software reset.

32.2.10 Minute Alarm Register (RMINAR)/Binary Counter 1 Alarm Register (BCNT1AR)

(1) In calendar count mode:

Address(es): RTC.RMINAR 0008 C412h



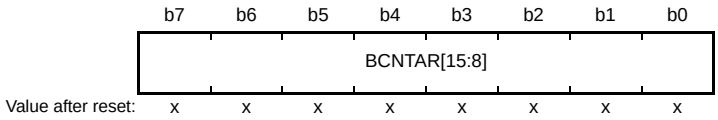
x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	MIN1[3:0]	1 Minute	Value for the ones place of minutes	R/W
b6 to b4	MIN10[2:0]	10 Minutes	Value for the tens place of minutes	R/W
b7	ENB	ENB	0: The register value is not compared with the RMINCNT counter value. 1: The register value is compared with the RMINCNT counter value.	R/W

The RMINAR register is an alarm register corresponding to the BCD-coded minute counter RMINCNT. When the ENB bit is set to 1, the RMINAR value is compared with the RMINCNT value. From among the alarm registers (RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, and RYRAREN), only those selected with the ENB bits set to 1 are compared with the corresponding counters. When the respective values all match, the IR flag corresponding to the ALM interrupt is set to 1.
RMINAR values from 00 through 59 (in BCD) can be specified; if a value outside of this range is specified, the RTC does not operate correctly.
After writing to the RMINAR register, confirm that its value has actually changed before proceeding with further processing. Refer to section 32.6.5, Notes When Writing to and Reading from Registers for notes on accessing registers.
This register is set to 00h by an RTC software reset.

(2) In binary count mode:

Address(es): RTC.BCNT1AR 0008 C412h



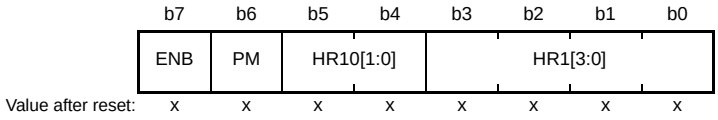
x: Undefined

The BCNT1AR counter is a readable/writable alarm register corresponding to 32-bit binary counter b15 to b8.
This register is set to 00h by an RTC software reset.

32.2.11 Hour Alarm Register (RHRAR)/Binary Counter 2 Alarm Register (BCNT2AR)

(1) In calendar count mode:

Address(es): RTC.RHRAR 0008 C414h



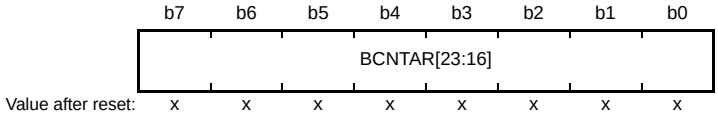
x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	HR1[3:0]	1 Hour	Value for the ones place of hours	R/W
b5, b4	HR10[1:0]	10 Hours	Value for the tens place of hours	R/W
b6	PM	PM	Time Alarm Setting for a.m./p.m. 0: a.m. 1: p.m.	R/W
b7	ENB	ENB	0: The register value is not compared with the RHRCNT counter value. 1: The register value is compared with the RHRCNT counter value.	R/W

The RHRAR register is an alarm register corresponding to the BCD-coded hour counter RHRCNT. When the ENB bit is set to 1, the RHRAR value is compared with the RHRCNT value. From among the alarm registers (RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, and RYRAREN), only those selected with the ENB bits set to 1 are compared with the corresponding counters. When the respective values all match, the IR flag corresponding to the ALM interrupt is set to 1.
The specifiable time differs according to the setting in the hours mode bit (RCR2.HR24).
When the RCR2.HR24 bit is 0: From 00 to 11 (in BCD)
When the RCR2.HR24 bit is 1: From 00 to 23 (in BCD)
If a value outside of this range is specified, the RTC does not operate correctly.
When the RCR2.HR24 bit is 0, be sure to set the PM bit.
When the RCR2.HR24 bit is 1, the setting in the PM bit has no effect.
After writing to the RHRAR register, confirm that its value has actually changed before proceeding with further processing. Refer to section 32.6.5, Notes When Writing to and Reading from Registers for notes on accessing registers.
This register is set to 00h by an RTC software reset.

(2) In binary count mode:

Address(es): RTC.BCNT2AR 0008 C414h



x: Undefined

The BCNT2AR counter is a readable/writable alarm register corresponding to 32-bit binary counter b23 to b16.
This register is set to 00h by an RTC software reset.

32.2.12 Day-of-Week Alarm Register (RWKAR)/Binary Counter 3 Alarm Register (BCNT3AR)

(1) In calendar count mode:

Address(es): RTC.RWKAR 0008 C416h

	b7	b6	b5	b4	b3	b2	b1	b0
	ENB	—	—	—	—	DAYW[2:0]		
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	DAYW[2:0]	Day-of-Week Setting	b2 b0 0 0 0: Sunday 0 0 1: Monday 0 1 0: Tuesday 0 1 1: Wednesday 1 0 0: Thursday 1 0 1: Friday 1 1 0: Saturday 1 1 1: Setting Prohibited	R/W
b6 to b3	—	Reserved	Set these bits to 0. They are read as the set value.	R/W
b7	ENB	ENB	0: The register value is not compared with the RWKCNT counter value. 1: The register value is compared with the RWKCNT counter value.	R/W

The RWKAR register is an alarm register corresponding to the coded day-of-week counter RWKCNT. When the ENB bit is set to 1, the RWKAR value is compared with the RWKCNT value. From among the alarm registers (RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, and RYRAREN), only those selected with the ENB bits set to 1 are compared with the corresponding counters. When the respective values all match, the IR flag corresponding to the ALM interrupt is set to 1.

RWKAR values from 0 through 6 (in BCD) can be specified; if a value outside of this range is specified, the RTC does not operate correctly.

After writing to the RWKAR register, confirm that its value has actually changed before proceeding with further processing. Refer to section 32.6.5, Notes When Writing to and Reading from Registers for notes on accessing registers.

This register is set to 00h by an RTC software reset.

(2) In binary count mode:

Address(es): RTC.BCNT3AR 0008 C416h

	b7	b6	b5	b4	b3	b2	b1	b0
	BCNTAR[31:24]							
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

The BCNT3AR counter is a readable/writable alarm register corresponding to 32-bit binary counter b31 to b24.

This register is set to 00h by an RTC software reset.

32.2.13 Date Alarm Register (RDAYAR)/Binary Counter 0 Alarm Enable Register (BCNT0AER)

(1) In calendar count mode:

Address(es): RTC.RDAYAR 0008 C418h

	b7	b6	b5	b4	b3	b2	b1	b0
	ENB	—	DATE10[1:0]		DATE1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	DATE1[3:0]	1 Day	Value for the ones place of days	R/W
b5, b4	DATE10[1:0]	10 Days	Value for the tens place of days	R/W
b6	—	Reserved	Set this bit to 0. It is read as the set value.	R/W
b7	ENB	ENB	0: The register value is not compared with the RDAYCNT counter value. 1: The register value is compared with the RDAYCNT counter value.	R/W

The RDAYAR register is an alarm register corresponding to the BCD-coded date counter RDAYCNT. When the ENB bit is set to 1, the RDAYAR value is compared with the RDAYCNT value. From among the alarm registers (RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, and RYRAREN), only those selected with the ENB bits set to 1 are compared with the corresponding counters. When the respective values all match, the IR flag corresponding to the ALM interrupt is set to 1.
RDAYAR values from 01 through 31 (in BCD) can be specified; if a value outside of this range is specified, the RTC does not operate correctly.
After writing to the RDAYAR register, confirm that its value has actually changed before proceeding with further processing. Refer to section 32.6.5, Notes When Writing to and Reading from Registers for notes on accessing registers.
This register is set to 00h by an RTC software reset.

(2) In binary count mode:

Address(es): RTC.BCNT0AER 0008 C418h

	b7	b6	b5	b4	b3	b2	b1	b0
	ENB[7:0]							
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

The BCNT0AER register is a readable/writable register for setting the alarm enable corresponding to 32-bit binary counter b7 to b0. Among the ENB[31:0] bits, the binary counter (BCNT[31:0]) corresponding to the bits which are set to 1 and the binary alarm register (BCNTAR[31:0]) are compared, and when all match, the IR flag corresponding to the ALM interrupt becomes 1.
This register is set to 00h by an RTC software reset.

32.2.14 Month Alarm Register (RMONAR)/Binary Counter 1 Alarm Enable Register (BCNT1AER)

(1) In calendar count mode:

Address(es): RTC.RMONAR 0008 C41Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	ENB	—	—	MON10	MON1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	MON1[3:0]	1 Month	Value for the ones place of months	R/W
b4	MON10	10 Months	Value for the tens place of months	R/W
b6, b5	—	Reserved	Set these bits to 0. They are read as the set value.	R/W
b7	ENB	ENB	0: The register value is not compared with the RMONCNT counter value. 1: The register value is compared with the RMONCNT counter value.	R/W

The RMONAR register is an alarm register corresponding to the BCD-coded month counter RMONCNT. When the ENB bit is set to 1, the RMONAR value is compared with the RMONCNT value. From among the alarm registers (RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, and RYRAREN), only those selected with the ENB bits set to 1 are compared with the corresponding counters. When the respective values all match, the IR flag corresponding to the ALM interrupt is set to 1.
RMONAR values from 01 through 12 (in BCD) can be specified; if a value outside of this range is specified, the RTC does not operate correctly.
After writing to the RMONAR register, confirm that its value has actually changed before proceeding with further processing. Refer to section 32.6.5, Notes When Writing to and Reading from Registers for notes on accessing registers.
This register is set to 00h by an RTC software reset.

(2) In binary count mode:

Address(es): RTC.BCNT1AER 0008 C41Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	ENB[15:8]							
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

The BCNT1AER register is a readable/writable register for setting the alarm enable corresponding to 32-bit binary counter b15 to b8. Among the ENB[31:0] bits, the binary counter (BCNT[31:0]) corresponding to the bits which are set to 1 and the binary alarm register (BCNTAR[31:0]) are compared, and when all match, the IR flag corresponding to the ALM interrupt becomes 1.
This register is set to 00h by an RTC software reset.

32.2.15 Year Alarm Register (RYRAR)/Binary Counter 2 Alarm Enable Register (BCNT2AER)

(1) In calendar count mode:

Address(es): RTC.RYRAR 0008 C41Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	YR10[3:0]				YR1[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	YR1[3:0]	1 Year	Value for the ones place of years	R/W
b7 to b4	YR10[3:0]	10 Years	Value for the tens place of years	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The RYRAR register is an alarm register corresponding to the BCD-coded year counter RYRCNT.
RYRAR values from 00 through 99 (in BCD) can be specified; if a value outside of this range is specified, the RTC does not operate correctly.
After writing to the RYRAR register, confirm that its value has actually changed before proceeding with further processing. Refer to section 32.6.5, Notes When Writing to and Reading from Registers for notes on accessing registers.
This register is set to 0000h by an RTC software reset.

(2) In binary count mode:

Address(es): RTC.BCNT2AER 0008 C41Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	ENB[23:16]							
Value after reset:	0	0	0	0	0	0	0	0	x	x	x	x	x	x	x	x

x: Undefined

The BCNT2AER register is a readable/writable register for setting the alarm enable corresponding to 32-bit binary counter b23 to b16. Among the ENB[31:0] bits, the binary counter (BCNT[31:0]) corresponding to the bits which are set to 1 and the binary alarm register (BCNTAR[31:0]) are compared, and when all match, the IR flag corresponding to the ALM interrupt becomes 1.
This register is set to 0000h by an RTC software reset.

32.2.16 Year Alarm Enable Register (RYRAREN)/Binary Counter 3 Alarm Enable Register (BCNT3AER)

(1) In calendar count mode:

Address(es): RTC.RYRAREN 0008 C41Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	ENB	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	Set these bits to 0. They are read as the set value.	R/W
b7	ENB	ENB	0: The register value is not compared with the RYRCNT counter value. 1: The register value is compared with the RYRCNT counter value.	R/W

When the ENB bit in the RYRAREN register is set to 1, the RYRAR value is compared with the RYRCNT value. From among the alarm registers (RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, and RYRAREN), only those selected with the ENB bits set to 1 are compared with the corresponding counters. When the respective values all match, the IR flag corresponding to the ALM interrupt is set to 1.
This register is set to 00h by an RTC software reset.

(2) In binary count mode:

Address(es): RTC.BCNT3AER 0008 C41Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	ENB[31:24]							
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

The BCNT3AER register is a readable/writable register for setting the alarm enable corresponding to 32-bit binary counter b31 to b24. Among the ENB[31:0] bits, the binary counter (BCNT[31:0]) corresponding to the bits which are set to 1 and the binary alarm register (BCNTAR[31:0]) are compared, and when all match, the IR flag corresponding to the ALM interrupt becomes 1.
This register is set to 00h by an RTC software reset.

32.2.17 RTC Control Register 1 (RCR1)

Address(es): RTC.RCR1 0008 C422h

	b7	b6	b5	b4	b3	b2	b1	b0
	PES[3:0]				RTCOS	PIE	CIE	AIE
Value after reset:	x	x	x	x	0	x	0	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	AIE	Alarm Interrupt Enable	0: An alarm interrupt request is disabled. 1: An alarm interrupt request is enabled.	R/W
b1	CIE	Carry Interrupt Enable	0: A carry interrupt request is disabled. 1: A carry interrupt request is enabled.	R/W
b2	PIE	Periodic Interrupt Enable	0: A periodic interrupt request is disabled. 1: A periodic interrupt request is enabled.	R/W
b3	RTCOS	RTCOUT Output Select	0: RTCOUT outputs 1 Hz. 1: RTCOUT outputs 64 Hz.	R/W
b7 to b4	PES[3:0]	Periodic Interrupt Select	b7 b4 0 1 1 0: A periodic interrupt is generated every 1/256 second.*1 0 1 1 1: A periodic interrupt is generated every 1/128 second. 1 0 0 0: A periodic interrupt is generated every 1/64 second. 1 0 0 1: A periodic interrupt is generated every 1/32 second. 1 0 1 0: A periodic interrupt is generated every 1/16 second. 1 0 1 1: A periodic interrupt is generated every 1/8 second. 1 1 0 0: A periodic interrupt is generated every 1/4 second. 1 1 0 1: A periodic interrupt is generated every 1/2 second. 1 1 1 0: A periodic interrupt is generated every 1 second. 1 1 1 1: A periodic interrupt is generated every 2 seconds. Other than above: No periodic interrupts are generated.	R/W

Note 1. When the main clock is selected (RCR4.RCKSEL = 1) while PES[3:0] = 0110b, a periodic interrupt is generated every 1/128 second.

The RCR1 register is used in both calendar count mode and in binary count mode.
Bits AIE, PIE, and PES[3:0] are updated synchronously with the count source. When the RCR1 register is modified, check that all the bits have been updated before proceeding to the next processing.

AIE Bit (Alarm Interrupt Enable)

This bit enables or disables alarm interrupt requests.
If the times indicated by the counters and alarm settings match in deep software standby mode, the MCU returns from the mode regardless of the value of the AIE bit.

CIE Bit (Carry Interrupt Enable)

This bit enables and disables interrupt requests when a carry to the RSECCNT/BCNT0 register occurs, or when a carry to the 64-Hz counter (R64CNT) occurs while reading the 64-Hz counter.

PIE Bit (Periodic Interrupt Enable)

This bit enables or disabled a periodic interrupt.
If the periods indicated by the counters and PES[3:0] settings match in deep software standby mode, the MCU returns from the mode regardless of the value of the PIE bit.

RTCOS Bit (RTCOUT Output Select)

This bit selects the RTCOUT output period. The RTCOS bit must be rewritten while count operation is stopped (the RCR2.START bit is 0) and RTCOUT output is disabled (the RCR2.RTCOE bit is 0). When the RTCOUT is output to an external pin, the RCR2.RTCOE bit must be enabled. For details on controlling I/O ports, refer to section 23.4.1, Procedure for Specifying Input/Output Pin Function.

PES[3:0] Bits (Periodic Interrupt Select)

These bits specify the period for the periodic interrupt. A periodic interrupt is generated with the period specified by these bits.

32.2.18 RTC Control Register 2 (RCR2)

Address(es): RTC.RCR2 0008 C424h

	b7	b6	b5	b4	b3	b2	b1	b0
	CNTMD	HR24	AADJP	AADJE	RTCOE	ADJ30	RESET	START
Value after reset:	x	x	x	x	0	0	0	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	START	Start	0: Prescaler and counter are stopped. 1: Prescaler and counter operate normally.	R/W
b1	RESET	RTC Software Reset	• In writing 0: Writing is invalid. 1: The prescaler and the target registers for RTC software reset*1 are initialized • In reading 0: In normal time operation, or an RTC software reset has completed. 1: During an RTC software reset	R/W
b2	ADJ30	30-Second Adjustment*2	• In writing 0: Writing is invalid. 1: 30-second adjustment is executed. • In reading 0: In normal time operation, or 30-second adjustment has completed. 1: During 30-second adjustment	R/W
b3	RTCOE	RTCOUT Output Enable	0: RTCOUT output disabled. 1: RTCOUT output enabled.	R/W
b4	AADJE	Automatic Adjustment Enable *3, *4	0: Automatic adjustment is disabled. 1: Automatic adjustment is enabled.	R/W
b5	AADJP	Automatic Adjustment Period Select*3, *4	0: The RADJ.ADJ[5:0] setting value is adjusted from the count value of the prescaler every minute (every 32 seconds in binary counter mode). 1: The RADJ.ADJ[5:0] setting value is adjusted from the count value of the prescaler every 10 seconds (every 8 seconds in binary counter mode).	R/W
b6	HR24	Hours Mode*2, *4	0: The RTC operates in 12-hour mode. 1: The RTC operates in 24-hour mode.	R/W
b7	CNTMD	Count Mode Select	0: The calendar count mode. 1: The binary count mode.	R/W

Note 1. R64CNT, RSECAR/BCNT0AR, RMINAR/BCNT1AR, RHRAR/BCNT2AR, RWKAR/BCNT3AR, RDAYAR/BCNT0AER, RMONAR/BCNT1AER, RYRAR/BCNT2AER, RYRAREN/BCNT3AER, RADJ, RTCCRy, RSECCPy/BCNT0CPy, RMINCPy/BCNT1CPy, RHRCPy/BCNT2CPy, RDAYCPy/BCNT3CPy, RMONCPy, RCR2.ADJ30, RCR2.AADJE, RCR2.AADJP
Note 2. This bit is reserved in binary counter mode. The write value should be 0.
Note 3. When the main clock is selected, the setting of this bit is disabled.
Note 4. After writing to this bit, confirm that its value has actually changed before proceeding with further processing. Refer to section 32.6.5, Notes When Writing to and Reading from Registers for notes on accessing registers.

The RCR2 register is related to hours mode, automatic adjustment function, enabling the RTCOUT output, 30-second adjustment, RTC software reset, and controlling count operation.

START Bit (Start)

This bit stops or restarts the prescaler or counter (clock) operation.

The START bit is updated in synchronization with the count source. When the START bit is modified, check that the bit is updated before proceeding to the next processing.

RESET Bit (RTC Software Reset)

This bit initializes the prescaler and registers to be reset by RTC software reset.
When 1 is written to the RESET bit, the initialization starts in synchronization with the count source. When the initialization is completed, the RESET bit is automatically set to 0.
When 1 is written to the RESET bit, check that the bit is set to 0, and then make next settings.

ADJ30 Bit (30-Second Adjustment)

This bit is for 30-second adjustment.
When 1 is written to the ADJ30 bit, the RSECCNT value of 30 seconds or less is rounded down to 00 second and the value of 30 seconds or more is rounded up to 1 minute.
The 30-second adjustment is performed in synchronization with the count source. When 1 is written to this bit, the ADJ30 bit is automatically set to 0 after the 30-second adjustment is completed. In case when 1 is written to the ADJ30 bit, check that the bit is set to 0, and then make next settings.
When the 30-second adjustment is performed, the prescaler and R64CNT are also reset.
The ADJ30 bit is set to 0 by an RTC software reset.
This bit is reserved in binary counter mode. The write value should be 0.

RTCOE Bit (RTCOUT Output Enable)

This bit enables output of a 1-Hz/64-Hz clock signal from the RTCOUT pin.
Use the START bit to stop counting by the counters before changing the value of the RTCOE bit. Do not stop counting (write 0 to the START bit) and change the value of the RTCOE bit at the same time.
When RTCOUT signal is to be output from an external pin, set the RTCOE bit to 1 and set up the port control for the pin.

AADJE Bit (Automatic Adjustment Enable)

This bit controls (enables or disables) automatic adjustment.
Set the plus–minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJE bit.
The AADJE bit is set to 0 by an RTC software reset.

AADJP Bit (Automatic Adjustment Period Select)

This bit selects the automatic-adjustment period.
Set the plus–minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJP bit.
The AADJP bit is set to 0 by an RTC software reset.

HR24 Bit (Hours Mode)

This bit specifies whether the RTC will operate in 12- or 24-hour mode.
Use the START bit to stop counting by the counters before changing the value of the HR24 bit. Do not stop counting (write 0 to the START bit) and change the value of the HR24 bit at the same time.
This bit is reserved in binary counter mode. The write value should be 0.

CNTMD Bit (Count Mode Select)

This bit specifies whether the RTC count mode is operated in calendar count mode or in binary count mode.
When setting the count mode, execute an RTC software reset and start again from the initial settings.
This bit is updated synchronously with the count source, and its value is fixed before the RTC software reset is completed.
For details on initial settings, refer to section 32.3.1, Outline of Initial Settings of Registers after Power On.

32.2.19 RTC Control Register 3 (RCR3)

Address(es): RTC.RCR3 0008 C426h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	RTCDV[2:0]			RTCEN
Value after reset:	0	0	0	0	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	RTCEN	Sub-Clock Oscillator Control	0: Sub-clock oscillator is stopped. 1: Sub-clock oscillator is operating.	R/W
b3 to b1	RTCDV[2:0]	Sub-Clock Oscillator Drive Capacity Control	b3 b1 0 0 0: Setting prohibited 0 0 1: Drive capacity for low CL 0 1 0: Setting prohibited 0 1 1: Setting prohibited 1 0 0: Setting prohibited 1 0 1: Setting prohibited 1 1 0: Drive capacity for standard CL 1 1 1: Setting prohibited	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The RCR3 register is used for controlling the sub-clock oscillator in the clock generation circuit. For details on controlling the sub-clock oscillator, refer to section 9, Clock Generation Circuit.
This register is a function common to calendar count mode and binary count mode.
When this register is modified, check that all the bits have been updated before proceeding to the next processing.

RTCEN Bit (Sub-Clock Oscillator Control)

The RTCEN bit and a clock generation circuit register (the SOSCCR.SOSTP bit) control whether to operate or stop the sub-clock oscillator. If one of the bits is set so as to enable the operation, the sub-clock oscillator runs.
When using the sub-clock as the count source to the RTC, set the sub-clock oscillator using the RTCEN bit.
When the main clock is selected (RCR4.RCKSEL bit = 1), making the sub-clock oscillator run or stop is controlled only by the SOSCCR.SOSTP bit regardless of the value set in the RTCEN bit.

RTCDV[2:0] Bits (Sub-Clock Oscillator Drive Capacity Control)

These bits control the drive capacity of the sub-clock oscillator.
It must be noted that the oscillation accuracy of the sub-clock oscillator is affected if the RTCDV[2:0] bits are set to 001b (drive capacity for low CL) when an on-chip debugging emulator is attached. The oscillation accuracy is not affected when the RCR3.RTCDV[2:0] bits are set to 110b (drive capacity for standard CL).
Before modifying the RTCDV[2:0] bits, be sure to stop the sub-clock oscillator. When the main clock is selected (RCR4.RCKSEL bit = 1), making the sub-clock oscillator run or stop is controlled only by the SOSCCR.SOSTP bit regardless of the value set in the RTCEN bit.

32.2.19.1 Notes on using a low CL crystal unit

When the RCR3.RTCDV[2:0] bits are 001b (drive capacity for low CL), the oscillator is susceptible to noise. Especially when the signal level of any pin near the XCIN or XCOUT pin is changed, the oscillation accuracy of the sub-clock oscillator may be affected. The accuracy is affected differently depending on the board traces and how the signal level of any pin near the XCIN or XCOUT pin is changed. When designing a board using a low CL crystal unit, refer to the application note “Design Guide for Low CL Sub-clock Circuits” (R01AN1187EJ) to reduce the influence from noise. The following are examples that may significantly affect oscillation accuracy:

(1) When connecting an on-chip debugging emulator to the FINED pin

Since the FINED pin (FINE interface pin) is near the XCIN and XCOUT pins, the oscillation accuracy of the sub-clock oscillator is affected when using the FINED pin in debugging. When using the FINED pin in debugging, keep using the low CL crystal unit and set the RCR3.RTCDV[2:0] bits to 110b (drive capacity for standard CL). However, this measure may affect the reliability of the crystal unit. Therefore, use this measure only when using an on-chip debugging emulator. Set the RCR3.RTCDV[2:0] bits to 001b (drive capacity for low CL) in mass production programs. The oscillation accuracy is not affected when connecting an on-chip debugging emulator to a JTAG pin (TCK, TRST, TMS, TDI, or TDO pin).

(2) When supplying an external clock to the main clock oscillator

When inputting an external clock to the EXTAL pin, the oscillation accuracy of the sub-clock oscillator may be affected. When inputting an inverted external clock to the XTAL pin, the oscillation accuracy will be affected more significantly.

32.2.20 RTC Control Register 4 (RCR4)

Address(es): RTC.RCR4 0008 C428h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	RCKSEL
Value after reset:	0	0	0	0	0	0	0	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	RCKSEL	Count Source Select	0: Sub-clock oscillator is selected. 1: Main clock oscillator is selected.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The RCR4 register is used for selecting the count source. This function is used in both calendar count mode and binary count mode.
When the RCKSEL bit is set to 0, the time is counted with the sub-clock. When the bit is set to 1, the time is counted with the main clock.

RCKSEL Bit (Count Source Select)

This bit selects the count source from the sub-clock and the main clock.
The count source should be selected only once before the initial settings of the RTC registers at power on.

32.2.21 Frequency Register H/L (RFRH/RFRL)

Address(es): RTC.RFRH 0008 C42Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

	RFC[15:0]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

- RFRH register

Bit	Symbol	Bit Name	Description	R/W
b0	RFC[16]	Frequency Divide Ratio Setting	Set the divide ratio of the main clock to generate the reference clock of 128 Hz. If the setting value in the RFC[16:0] bits is n, the prescaler divides the main clock by n + 1.	R/W
b15 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

- RFRL register

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	RFC[15:0]	Frequency Divide Ratio Setting	Set the divide ratio of the main clock to generate the reference clock of 128 Hz. If the setting value in the RFC[16:0] bits is n, the prescaler divides the main clock by n + 1.	R/W

RFRH/RFRL is a register for controlling the prescaler when the main clock is selected.
The RTC time counter operates on a 128-Hz clock signal as the reference clock. Therefore, when the main clock is selected, the main clock is divided by the prescaler to generate a 128-Hz clock signal. Set the frequency divide ratio in the RFC[16:0] bits to generate a 128-Hz clock from the main clock frequency. As for the calculation method, refer to the formula below.

A value from 0 0007h through 1 FFFFh can be specified in the RFC[16:0] bits; if a value outside of this range is specified, the RTC does not operate correctly. Rewrite this register while the RCR2.START bit is 0 (counter is stopped). In addition, the range of the main clock frequency that can be used to generate a 128-Hz clock is 1.024 kHz to 16.778 MHz.
The frequency of the peripheral module clock and the main clock should be in the relationship that the peripheral module clock ≥ the main clock.

- Calculation method of frequency comparison value

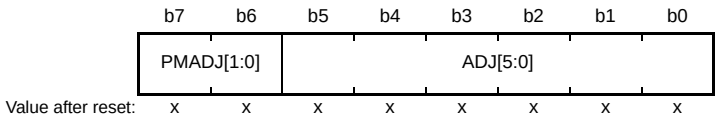
RFC[16:0] = (Main clock frequency) ÷ 128 – 1

Table 32.3 RFRH/L Register Settings by the Main Clock Frequency

Main Clock Frequency	RFRH/L Register Setting Value
4 MHz	0000 7A11h
8 MHz	0000 F423h
10 MHz	0001 312Ch
12 MHz	0001 6E35h
16 MHz	0001 E847h

32.2.22 Time Error Adjustment Register (RADJ)

Address(es): RTC.RADJ 0008 C42Eh



x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	ADJ[5:0]	Adjustment Value	These bits specify the adjustment value from the prescaler.	R/W
b7, b6	PMADJ[1:0]	Plus–Minus	b7 b6 0 0: Adjustment is not performed. 0 1: Adjustment is performed by the addition to the prescaler. 1 0: Adjustment is performed by the subtraction from the prescaler. 1 1: Setting prohibited	R/W

Adjustment is performed by the addition to or subtraction from the prescaler.
In case when the automatic adjustment enable (RCR2.AADJE) bit is 0, adjustment is performed when writing to the RADJ.
In case when the RCR2.AADJE bit is 1, adjustment is performed in the interval specified by the automatic adjustment period select (RCR2.AADJP) bit.
The current adjustment by software (disabling automatic adjustment) may be invalid if the following adjustment value is specified within 320 cycles of the count source after the register setting. To perform adjustment consecutively, wait for 320 cycles or more of the count source after the register setting and then specify the next adjustment value.
RADJ is updated in synchronization with the count source. When RADJ is modified, check that all the bits have been updated before continuing with further processing.
This register is set to 00h by an RTC software reset.
The setting of this register is enabled only when the sub-clock is selected.
When the main clock is selected, adjustment is not performed.

ADJ[5:0] Bits (Adjustment Value)

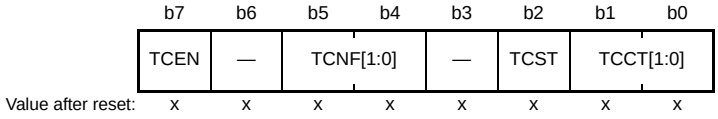
These bits specify the adjustment value (the number of sub-clock cycles) from the prescaler.

PMADJ[1:0] Bits (Plus–Minus)

These bits select whether the clock is set ahead or back depending on the error-adjustment value set in the ADJ[5:0] bits.

32.2.23 Time Capture Control Register y (RTCCRy) (y = 0 to 2)

Address(es): RTC.RTCCR0 0008 C440h, RTC.RTCCR1 0008 C442h, RTC.RTCCR2 0008 C444h



x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b1, b0	TCCT[1:0]	Time Capture Control	b1 b0 0 0: No event is detected. 0 1: Rising edge is detected. 1 0: Falling edge is detected. 1 1: Both edges are detected.	R/W
b2	TCST	Time Capture Status	0: No event is detected. 1: An event is detected.*1	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5, b4	TCNF[1:0]	Time Capture Noise Filter Control	b5 b4 0 0: The noise filter is off. 0 1: Setting prohibited 1 0: The noise filter is on (count source). 1 1: The noise filter is on (count source by divided by 32).	R/W
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	TCEN	Time Capture Event Input Pin Enable	0: The RTCICn pin is disabled as the time capture event input. 1: The RTCICn pin is enabled as the time capture event input. (n = 0 to 2)	R/W

Note 1. Indicates that an event has been detected. Writing 1 to this bit has no effect. Writing 0 sets this bit to 0.

The RTCCRy register is used both in calendar count mode and in binary count mode.
RTCCR0, RTCCR1, and RTCCR2 control the RTCIC0, RTCIC1, and RTCIC2 pins, respectively.
RTCCRy is updated in synchronization with the count source. When RTCCRy is modified, check that all the bits except for the TCST bit have been updated before continuing with further processing.
This register is set to 00h by an RTC software reset.

TCCT[1:0] Bits (Time Capture Control)

These bits control the edge detection of the time capture event input pins (RTCIC0, RTCIC1, and RTCIC2). The detection edge is selectable. The TCCT[1:0] bits should be set while the TCEN bit is 1.

TCST Bit (Time Capture Status)

This bit indicates that an event of the time capture event input pins (RTCIC0, RTCIC1, and RTCIC2) has been detected. When the TCST bit is 0, no event is detected.
When the TCST bit is 1, this bit indicates that an event of the corresponding pin has been detected and the capture register is valid. When multiple events have been detected, the capture time for the first event is retained.
If an event is detected while the count operation is stopped (the RCR2.START bit is 0), the captured value is not guaranteed. In this case, set the TCST bit to 0 for deleting the captured value.
Writing 0 sets the TCST bit to 0. In addition, writing any other value except 0 has no effect.
Set the TCST bit while the TCCT[1:0] bits are 00b (no event is detected).
The TCST bit is set to 0 in synchronization with the count source. When the TCST bit is set to 0, check that the bit has been updated before continuing with further processing.

TCNF[1:0] Bits (Time Capture Noise Filter Control)

These bits control the noise filter of the time capture event input pins (RTCIC0, RTCIC1, and RTCIC2).
When the noise filter is on, the count source divided by 1 or divided by 32 is selectable. In this case, when the input level on the time capture event input pin matches three consecutive times at the set sampling period, the input level is determined.
Set the TCNF[1:0] bits while the TCCT[1:0] bits are 00b (no event is detected). When the noise filter is used, set the TCNF[1:0] bits, wait for three cycles of the specified sampling period, and then set the TCCT[1:0] bits. Set the TCNF[1:0] bits when the TCEN bit is 1.

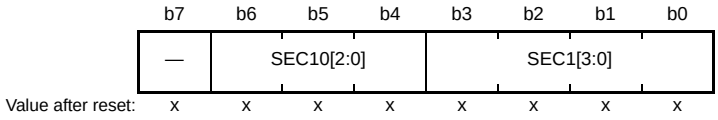
TCEN Bit (Time Capture Event Input Pin Enable)

This bit enables or disables the time capture event input pins (RTCIC0, RTCIC1, and RTCIC2).
When the sub-clock is selected (RCR4.RCKSEL bit = 0) and the sub-clock oscillator is stopped (RCR3.RTCEN bit = 0), the time capture event input pins (RTCIC0, RTCIC1, and RTCIC2) are disabled regardless of the value of the TCEN bit.
When the functions of the time capture event input pins (RTCIC0, RTCIC1, and RTCIC2) are multiplexed, set the port control and enable this bit. In this case, the port control should be set first. If the TCEN bit is set to 0, set also the TCCT[1:0] bits to 00b.

32.2.24 Second Capture Register y (RSECCPy) (y = 0 to 2)/BCNT0 Capture Register y (BCNT0CPy) (y = 0 to 2)

(1) In calendar count mode:

Address(es): RTC.RSECCP0 0008 C452h, RTC.RSECCP1 0008 C462h, RTC.RSECCP2 0008 C472h



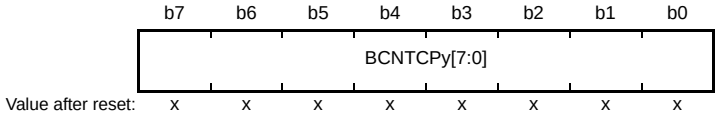
x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	SEC1[3:0]	1-Second Capture	Capture value for the ones place of seconds	R
b6 to b4	SEC10[2:0]	10-Second Capture	Capture value for the tens place of seconds	R
b7	—	Reserved	This bit is read as 0 after an RTC software reset.	R

RSECCPy is a read-only register that captures the RSECCNT value when a time capture event is detected.
The event detection times detected by the RTCIC0, RTCIC1, and RTCIC2 pins are stored in the RSECCP0, RSECCP1, and RSECCP2 registers, respectively.
This register is set to 00h by an RTC software reset.
Before reading from this register, be sure to stop the time capture event detection through the setting of the RTCCRy.TCCT[1:0] bits.

(2) In binary count mode:

Address(es): RTC.BCNT0CP0 0008 C452h, RTC.BCNT0CP1 0008 C462h, RTC.BCNT0CP2 0008 C472h



x: Undefined

BCNT0CPy is a read-only register that captures the BCNT0 value when a time capture event is detected.
The event detection times detected by the RTCIC0, RTCIC1, and RTCIC2 pins are stored in the BCNT0CP0, BCNT0CP1, and BCNT0CP2 registers, respectively.
This register is set to 00h by an RTC software reset.
Before reading from this register, be sure to stop the time capture event detection through the setting of the RTCCRy.TCCT[1:0] bits.

32.2.25 Minute Capture Register y (RMINCPy) (y = 0 to 2)/BCNT1 Capture Register y (BCNT1CPy) (y = 0 to 2)

(1) In calendar count mode:

Address(es): RTC.RMINCP0 0008 C454h, RTC.RMINCP1 0008 C464h, RTC.RMINCP2 0008 C474h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	MIN10[2:0]			MIN1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	MIN1[3:0]	1-Minute Capture	Capture value for the ones place of minutes	R
b6 to b4	MIN10[2:0]	10-Minute Capture	Capture value for the tens place of minutes	R
b7	—	Reserved	This bit is read as 0 after an RTC software reset.	R

RMINCPy is a read-only register that captures the RMINCNT value when a time capture event is detected.
The event detection times detected by the RTCIC0, RTCIC1, and RTCIC2 pins are stored in the RMINCP0, RMINCP1, and RMINCP2 registers, respectively.
This register is set to 00h by an RTC software reset.
Before reading from this register, be sure to stop the time capture event detection through the setting of the RTCCRy.TCCT[1:0] bits.

(2) In binary count mode:

Address(es): RTC.BCNT1CP0 0008 C454h, RTC.BCNT1CP1 0008 C464h, RTC.BCNT1CP2 0008 C474h

	b7	b6	b5	b4	b3	b2	b1	b0
	BCNTCPy[15:8]							
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

BCNT1CPy is a read-only register that captures the BCNT1 value when a time capture event is detected.
The event detection times detected by the RTCIC0, RTCIC1, and RTCIC2 pins are stored in the BCNT1CP0, BCNT1CP1, and BCNT1CP2 registers, respectively.
This register is set to 00h by an RTC software reset.
Before reading from this register, be sure to stop the time capture event detection through the setting of the RTCCRy.TCCT[1:0] bits.

32.2.26 Hour Capture Register y (RHRCPy) (y = 0 to 2)/BCNT2 Capture Register y (BCNT2CPy) (y = 0 to 2)

(1) In calendar count mode:

Address(es): RTC.RHRCP0 0008 C456h, RTC.RHRCP1 0008 C466h, RTC.RHRCP2 0008 C476h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	PM	HR10[1:0]		HR1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	HR1[3:0]	1-Hour Capture	Capture value for the ones place of hours	R
b5, b4	HR10[1:0]	10-Hour Capture	Capture value for the tens place of hours	R
b6	PM	PM	0: a.m. 1: p.m.	R
b7	—	Reserved	This bit is read as 0 after an RTC software reset.	R

RHRCPy is a read-only register that captures the RHRCNT value when a time capture event is detected.
The event detection times detected by the RTCIC0, RTCIC1, and RTCIC2 pins are stored in the RHRCP0, RHRCP1, and RHRCP2 registers, respectively.
The PM bit is only enabled when the RCR2.HR24 bit is 0 (in 12-hour mode).
This register is set to 00h by an RTC software reset.
Before reading from this register, be sure to stop the time capture event detection through the setting of the RTCCRy.TCCT[1:0] bits.

(2) In binary count mode:

Address(es): RTC.BCNT2CP0 0008 C456h, RTC.BCNT2CP1 0008 C466h, RTC.BCNT2CP2 0008 C476h

	b7	b6	b5	b4	b3	b2	b1	b0
	BCNTCPy[23:16]							
Value after reset:	x	x	x	x	x	x	x	x

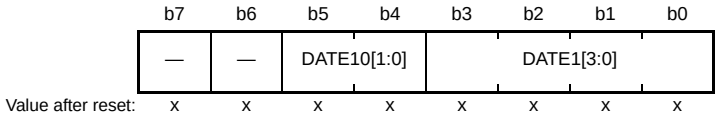
x: Undefined

BCNT2CPy is a read-only register that captures the BCNT2 value when a time capture event is detected.
The event detection times detected by the RTCIC0, RTCIC1, and RTCIC2 pins are stored in the BCNT2CP0, BCNT2CP1, and BCNT2CP2 registers, respectively.
This register is set to 00h by an RTC software reset.
Before reading from this register, be sure to stop the time capture event detection through the setting of the RTCCRy.TCCT[1:0] bits.

32.2.27 Date Capture Register y (RDAYCPy) (y = 0 to 2)/BCNT3 Capture Register y (BCNT3CPy) (y = 0 to 2)

(1) In calendar count mode:

Address(es): RTC.RDAYCP0 0008 C45Ah, RTC.RDAYCP1 0008 C46Ah, RTC.RDAYCP2 0008 C47Ah



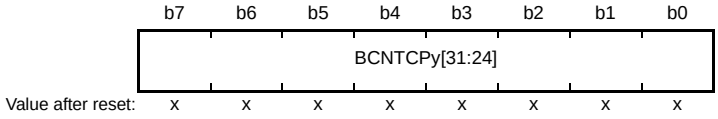
x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	HR1[3:0]	1-Day Capture	Capture value for the ones place of days	R
b5, b4	HR10[1:0]	10-Day Capture	Capture value for the tens place of days	R
b7, b6	—	Reserved	These bits are read as 0 after an RTC software reset.	R

RDAYCPy is a read-only register that captures the RDAYCNT value when a time capture event is detected.
The event detection times detected by the RTCIC0, RTCIC1, and RTCIC2 pins are stored in the RDAYCP0, RDAYCP1, and RDAYCP2 registers, respectively.
This register is set to 00h by an RTC software reset.
Before reading from this register, be sure to stop the time capture event detection through the setting of the RTCCRy.TCCT[1:0] bits.

(2) In binary count mode:

Address(es): RTC.BCNT3CP0 0008 C45Ah, RTC.BCNT3CP1 0008 C46Ah, RTC.BCNT3CP2 0008 C47Ah



x: Undefined

BCNT3CPy is a read-only register that captures the BCNT3 value when a time capture event is detected.
The event detection times detected by the RTCIC0, RTCIC1, and RTCIC2 pins are stored in the BCNT3CP0, BCNT3CP1, and BCNT3CP2 registers, respectively.
This register is set to 00h by an RTC software reset.
Before reading from this register, be sure to stop the time capture event detection through the setting of the RTCCRy.TCCT[1:0] bits.

32.2.28 Month Capture Register y (RMONCPy) (y = 0 to 2)

Address(es): RTC.RMONCP0 0008 C45Ch, RTC.RMONCP1 0008 C46Ch, RTC.RMONCP2 0008 C47Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	MON10	MON1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	HR1[3:0]	1-Month Capture	Capture value for the ones place of months	R
b4	HR10[1:0]	10-Month Capture	Capture value for the tens place of months	R
b7 to b5	—	Reserved	These bits are read as 0	R

RMONCPy is a read-only register that captures the RMONCNT value when a time capture event is detected. The event detection times detected by the RTCIC0, RTCIC1, and RTCIC2 pins are stored in the RMONCP0, RMONCP1, and RMONCP2 registers, respectively.

This register is set to 00h by an RTC software reset.

Before reading from this register, be sure to stop the time capture event detection through the setting of the RTCCRy.TCCT[1:0] bits.

32.3 Operation

32.3.1 Outline of Initial Settings of Registers after Power On

After the power is turned on, the initial settings for the clock setting, count mode setting, time error adjustment, time setting, alarm, interrupt, and time capture control register should be performed.

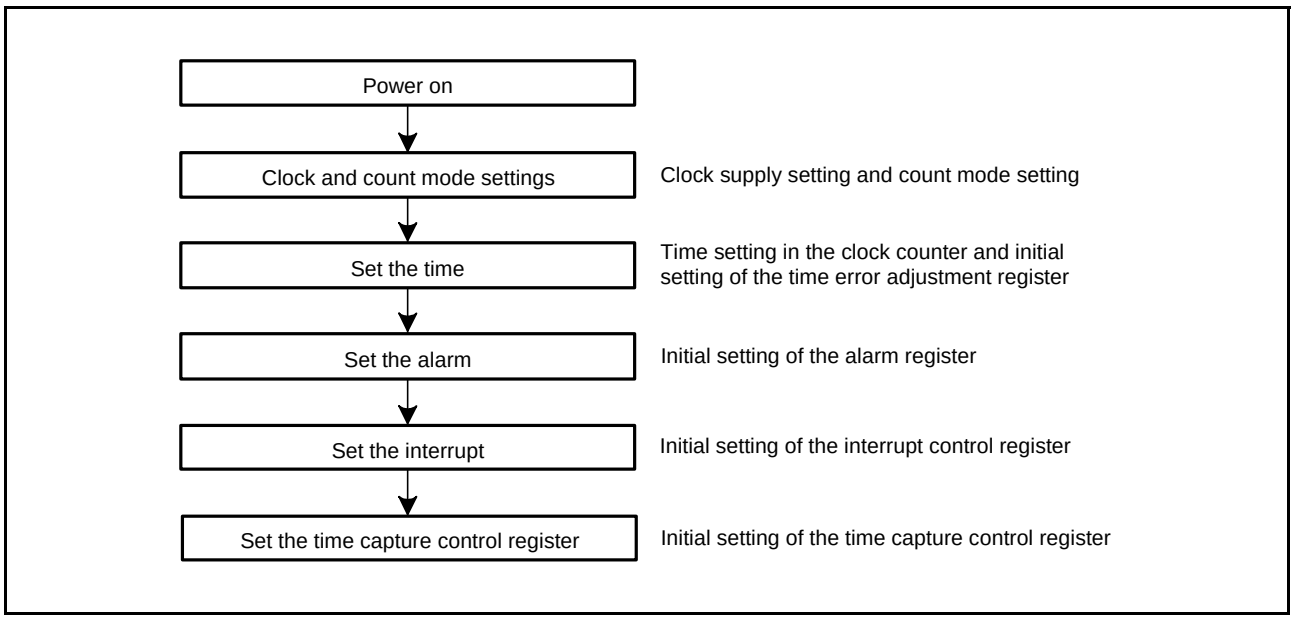


Figure 32.2 Outline of Initial Settings after Power On

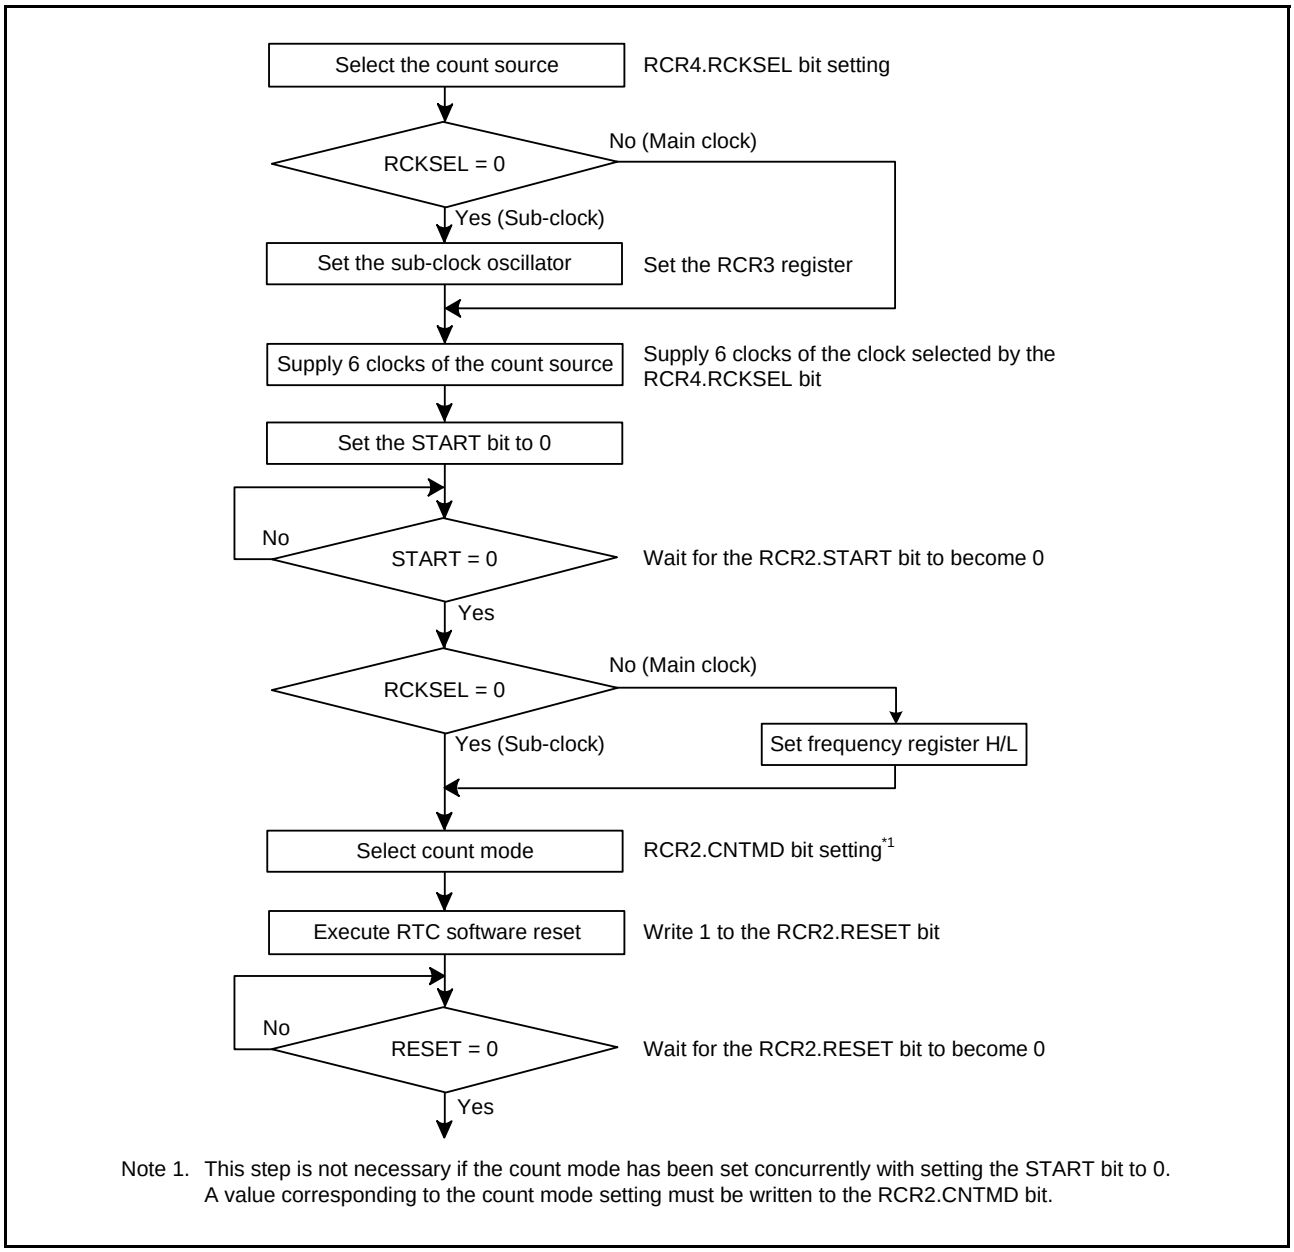
32.3.2 Clock and Count Mode Setting Procedure

Figure 32.3 shows how to set the clock and the count mode.

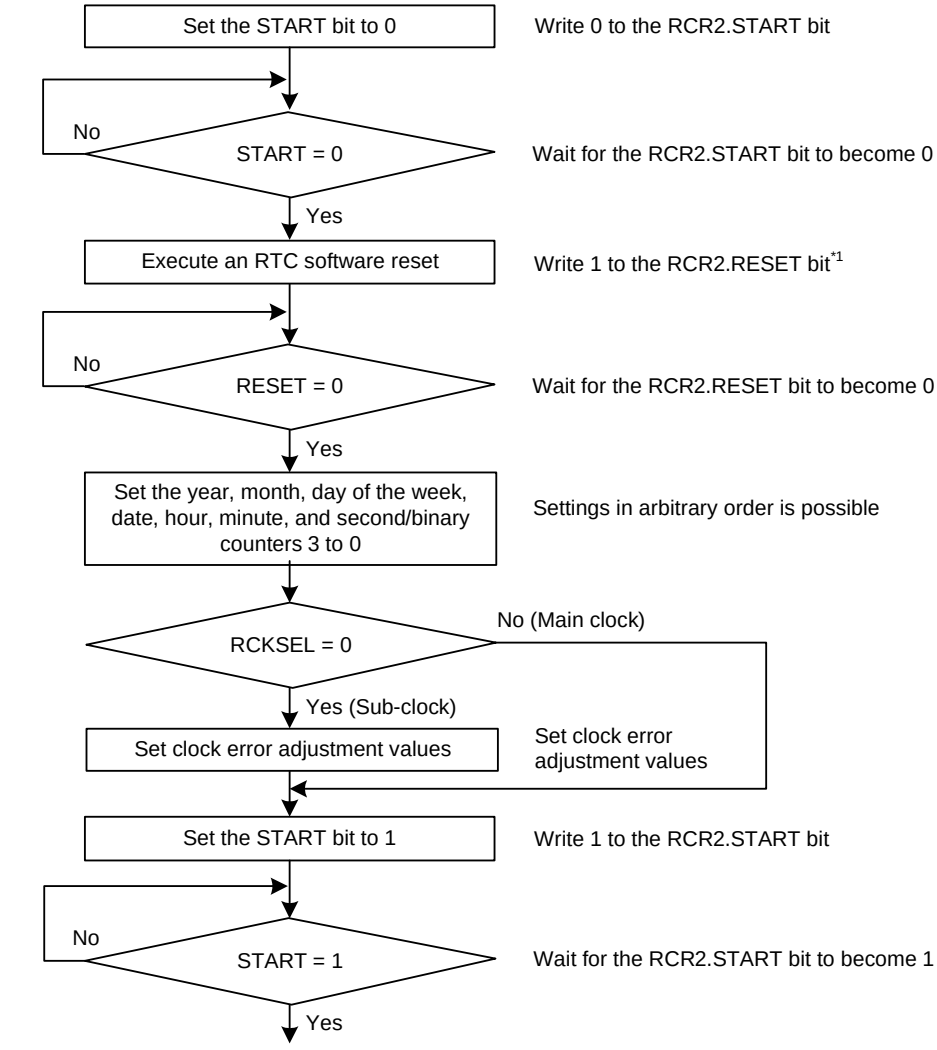


Note 1. This step is not necessary if the count mode has been set concurrently with setting the START bit to 0. A value corresponding to the count mode setting must be written to the RCR2.CNTMD bit.

Figure 32.3 Clock and Count Mode Setting Procedure

32.3.3 Setting the Time

Figure 32.4 shows how to set the time.



Note 1. This step is not necessary for the time-setting procedure because an RTC software reset is executed in the clock setting procedure of the initial settings for the power supply.

Figure 32.4 Setting the Time

32.3.4 30-Second Adjustment

Figure 32.5 shows how to execute 30-second adjustment.

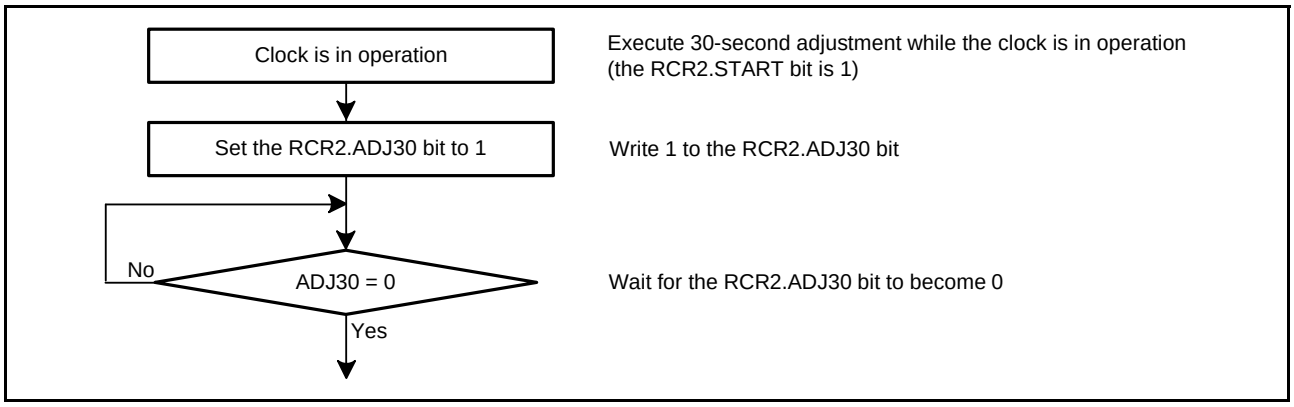


Figure 32.5 30-Second Adjustment

32.3.5 Reading 64-Hz Counter and Time

Figure 32.6 shows how to read the 64-Hz counter and time.

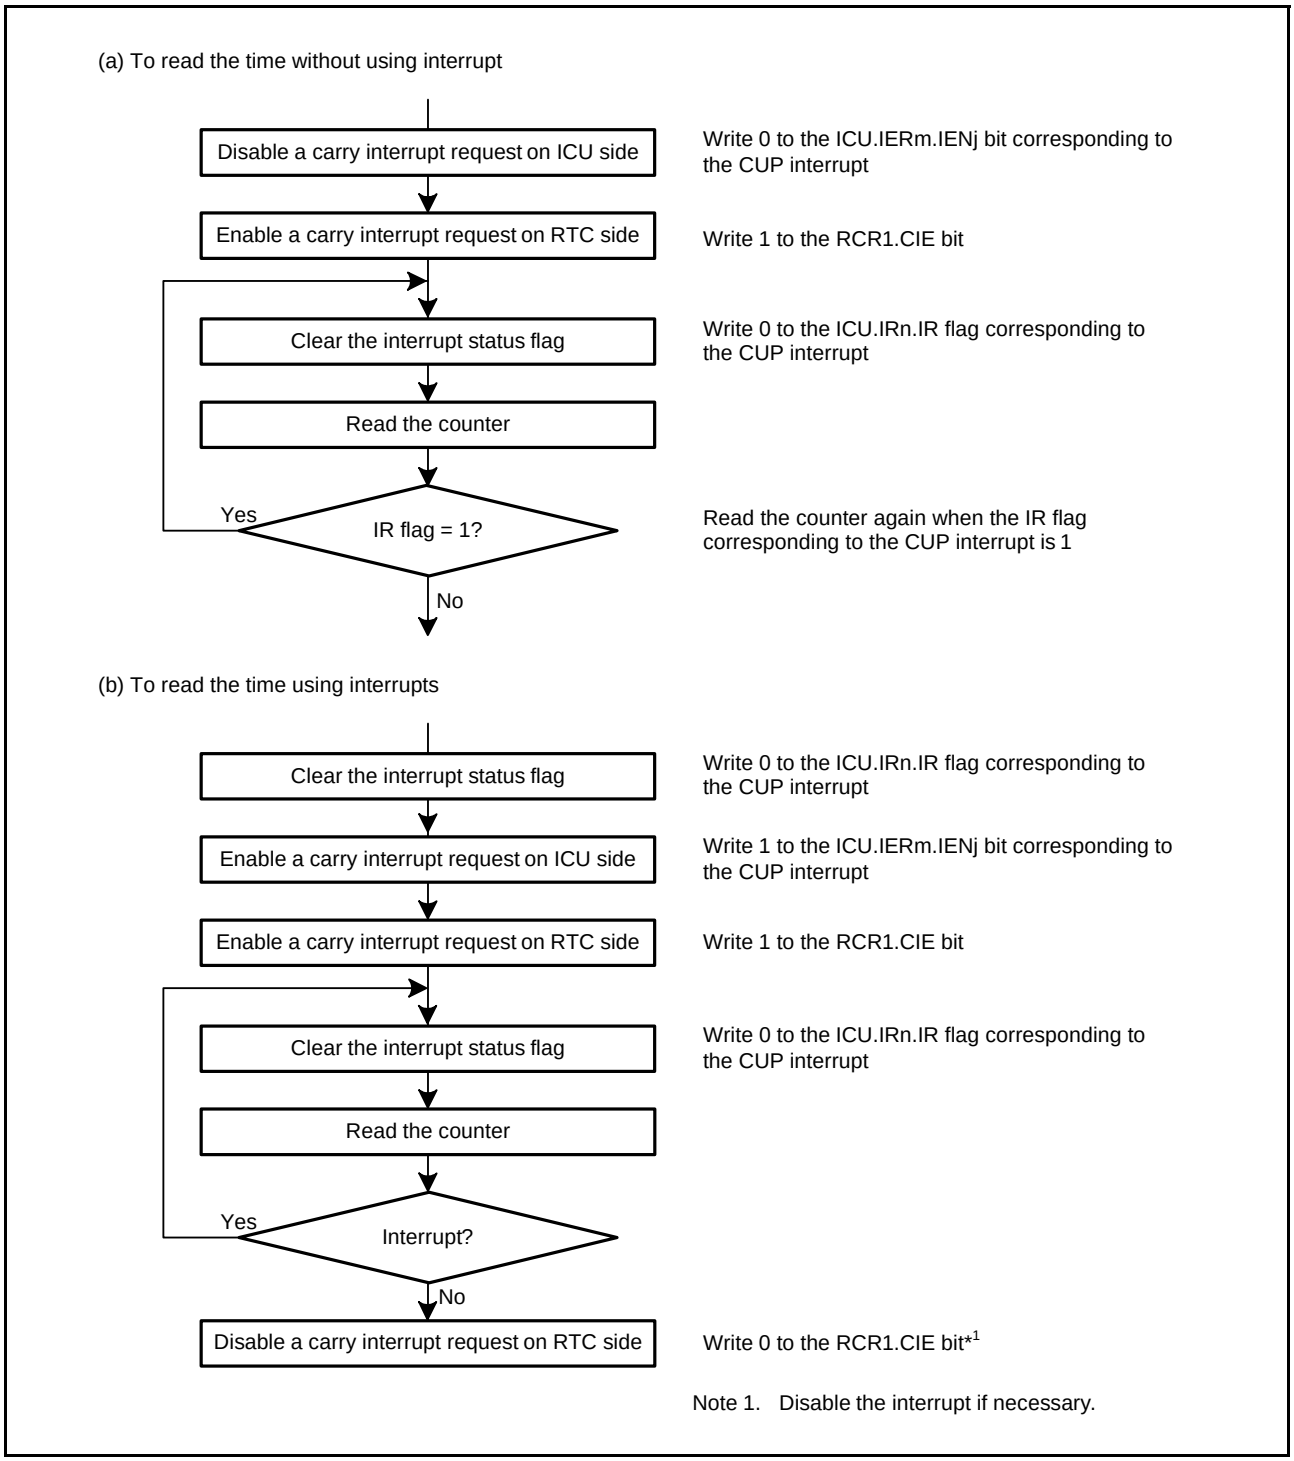

Figure 32.6 Reading Time

If a carry occurs while the 64-Hz counter and time are being read, the correct time will not be obtained, so they must be read again. The procedure for reading the time without using interrupts is shown in (a) in Figure 32.6, and the procedure using carry interrupts in (b). To keep the program simple, method (a) should be used in most cases.

32.3.6 Alarm Function

Figure 32.7 shows how to use the alarm function.

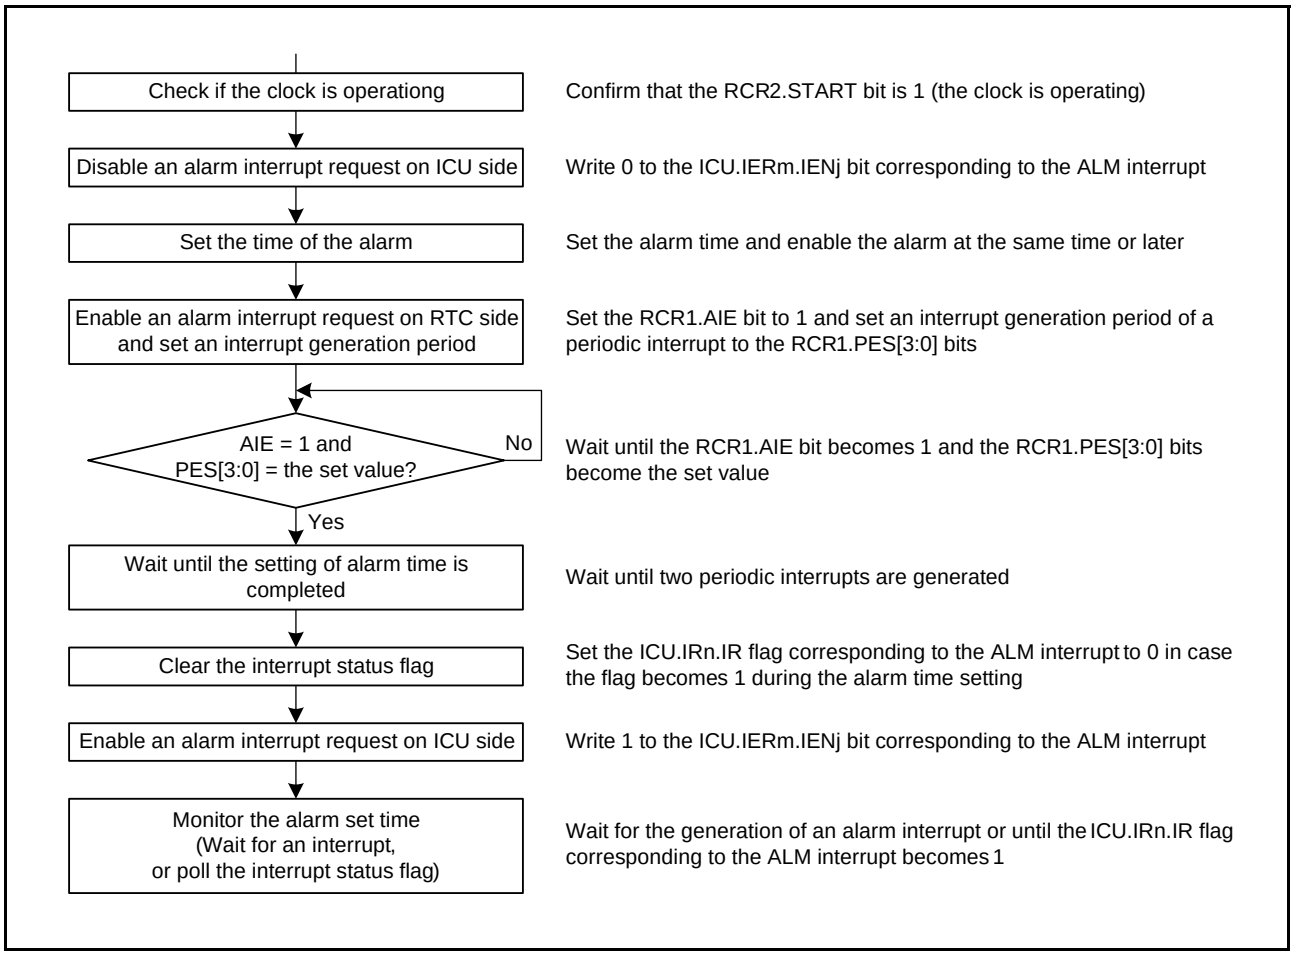

Figure 32.7 Using Alarm Function

In calendar count mode, an alarm can be generated by any one of year, month, date, day-of-week, hour, minute or second, or any combination of those. Write 1 to the ENB bit in the alarm registers involved in the alarm setting, and set the alarm time in the lower bits. Write 0 to the ENB bit in registers not involved in the alarm setting.

In binary count mode, an alarm can be generated in any bit combination of 32 bits. Write 1 to the ENB bit of the alarm enable register corresponding to the target bit of the alarm, and set the alarm time to the alarm register. For bits that are not target of the alarm, write 0 to the ENB bit of the alarm enable register.

When the counter and the alarm time match, the IR flag corresponding to the ALM interrupt is set to 1. Alarm detection can be confirmed by reading this bit, but an interrupt should be used in most cases. If 1 has been set in the interrupt request enable bit corresponding to the ALM interrupt, an alarm interrupt is generated in the event of alarm, enabling the alarm to be detected.

Writing 0 sets the IR flag corresponding to the ALM interrupt to 0.

When the counter and the alarm time match in a low power consumption state, the MCU returns from the low power consumption state. In deep software standby mode, the MCU returns from the deep software standby mode even when the alarm interrupt request is disabled.

32.3.7 Procedure for Disabling Alarm Interrupt

Figure 32.8 shows the procedure for disabling the enabled alarm interrupt request.

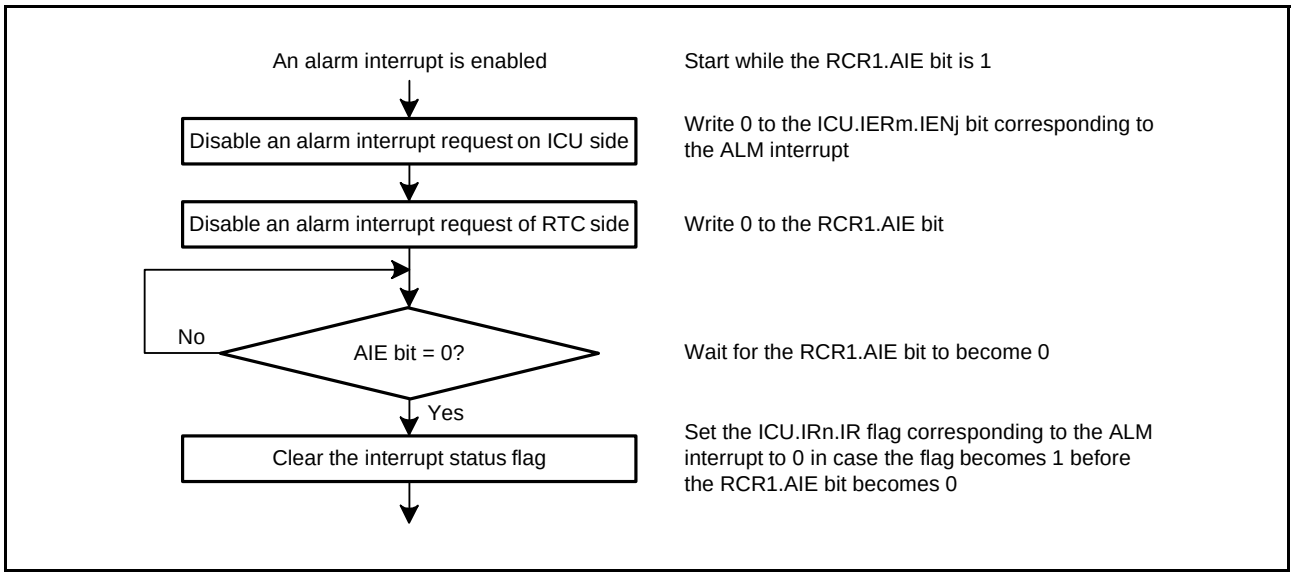

Figure 32.8 Procedure for Disabling Alarm Interrupt Request

32.3.8 Time Error Adjustment Function

The time error adjustment function is used to correct errors (running fast or slow) in the time due to the precision of oscillation by the sub-clock. Since 32,768 cycles of the sub-clock constitute 1 second of operation when the sub-clock is selected, the clock runs fast if the sub-clock frequency is high and slow if the sub-clock frequency is low. This function can be used to correct errors due to the clock running fast or slow.
Two types of time error adjustment functions are provided: automatic adjustment and adjustment by software.
Use the RCR2.AADJE bit to select automatic adjustment or adjustment by software.

32.3.8.1 Automatic Adjustment

Enable automatic adjustment by setting the RCR2.AADJE bit to 1.
Automatic adjustment is the addition or subtraction of the value counted by the prescaler to or from the value in the RADJ register every time the adjustment period selected by the RCR2.AADJE bit elapses.
Examples are shown below.

[Example 1] Sub-clock running at 32.769 kHz
Adjustment procedure:
When the sub-clock is running at 32.769 kHz, 1 second elapses every 32,769 clock cycles. The RTC is meant to run at 32,768 clock cycles, so the clock runs fast by one clock cycle every second. The time on the clock is fast by 60 clock cycles per minute, so adjustment can take the form of setting the clock back by 60 cycles every minute.

Register settings: (when RCR2.CNTMD = 0)

- RCR2.AADJP = 0 (adjustment every minute)
- RADJ.PMADJ[1:0] = 10b (adjustment is performed by the subtraction from the prescaler.)
- RADJ.ADJ[5:0] = 60 (3Ch)

[Example 2] Sub-clock running at 32.766 kHz
Adjustment procedure:
When the sub-clock is running at 32.766 kHz, 1 second elapses every 32,766 clock cycles. The RTC is meant to run at 32,768 clock cycles, so the clock runs slow by two clock cycles every second. The time on the clock is slow by 20 clock cycles every 10 seconds, so adjustment can take the form of setting the clock forward by 20 cycles every 10 seconds.

Register settings: (when RCR2.CNTMD = 0)

- RCR2.AADJP = 1 (adjustment every 10 seconds)
- RADJ.PMADJ[1:0] = 01b (adjustment is performed by the addition to the prescaler.)
- RADJ.ADJ[5:0] = 20 (14h)

[Example 3] Sub-clock running at 32.764 kHz
Adjustment procedure:
At 32.764 kHz, 1 second elapses on 32,764 clock cycles. Since the RTC operates for 32,768 clock cycles as 1 second, the clock is delayed for four clock cycles per second. In 8 seconds, the delay is 32 clock cycles, so correction can be made by proceeding the clock for 32 clock cycles every 8 seconds.

Register settings when the RCR2.CNTMD bit is 1

- RCR2.AADJP = 1 (adjustment every 8 seconds)
- RADJ.PMADJ[1:0] = 01b (adjustment is performed by the addition to the prescaler.)
- RADJ.ADJ[5:0] = 32 (20h)

32.3.8.2 Adjustment by Software

Enable adjustment by software by setting the RCR2.AADJE bit to 0.
Adjustment by software is the addition or subtraction of the value counted by the prescaler to or from the value in the RADJ register at the time of execution of an instruction for writing to the RADJ register.
An example is shown below.

[Example 1] Sub-clock running at 32.769 kHz
Adjustment procedure:
When the sub-clock is running at 32.769 kHz, 1 second elapses every 32,769 clock cycles. The RTC is meant to run at 32,768 clock cycles, so the clock runs fast by one clock cycle every second. The time on the clock is fast by one clock cycle per second, so adjustment can take the form of setting the clock back by one cycle every second.

Register settings:

- RADJ.PMADJ[1:0] = 10b (adjustment is performed by the subtraction from the prescaler.)
- RADJ.ADJ[5:0] = 1 (01h)
  This is written to the RADJ register once per 1-second interrupt.

32.3.8.3 Procedure for Changing the Mode of Adjustment

When changing the mode of adjustment, change the value of the AADJE bit in RCR2 after setting the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).

Changing from adjustment by software to automatic adjustment:

(1) Set the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).
(2) Set the RCR2.AADJE bit to 1 (automatic adjustment is enabled).
(3) Use the RCR2.AADJP bit to select the period of adjustment.
(4) In RADJ, set the PMADJ[1:0] bits for addition or subtraction and the ADJ[5:0] bits to the value for use in time error adjustment.

Changing from adjustment by software to automatic adjustment:

(1) Set the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).
(2) Set the RCR2.AADJE bit to 0 (adjustment by software is enabled).
(3) Proceed with adjustment by setting the RADJ.PMADJ[1:0] bits for addition or subtraction and the RADJ.ADJ[5:0] bits to the value for use in time error adjustment at the desired time. After that, the time is adjusted every time a value is written to the RADJ register.

32.3.8.4 Procedure for Stopping Adjustment

Stop adjustment by setting the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).

32.3.8.5 Capturing the Time

The RTC is capable of storing the month, date, hour, minute and second/binary counters 3 to 0 by detecting an edge of a signal on a time capture event input pin.

A noise filter can also be used on a time capture event input pin. If the noise filter is enabled, the TCST bit is set to 1 when the input level on the pin matches three times.

The noise filter can be switched on or off for each of the time capture event input pins. Operation when the noise filter is off is shown in Figure 32.9 and operation when the noise filter is on is shown in Figure 32.10.

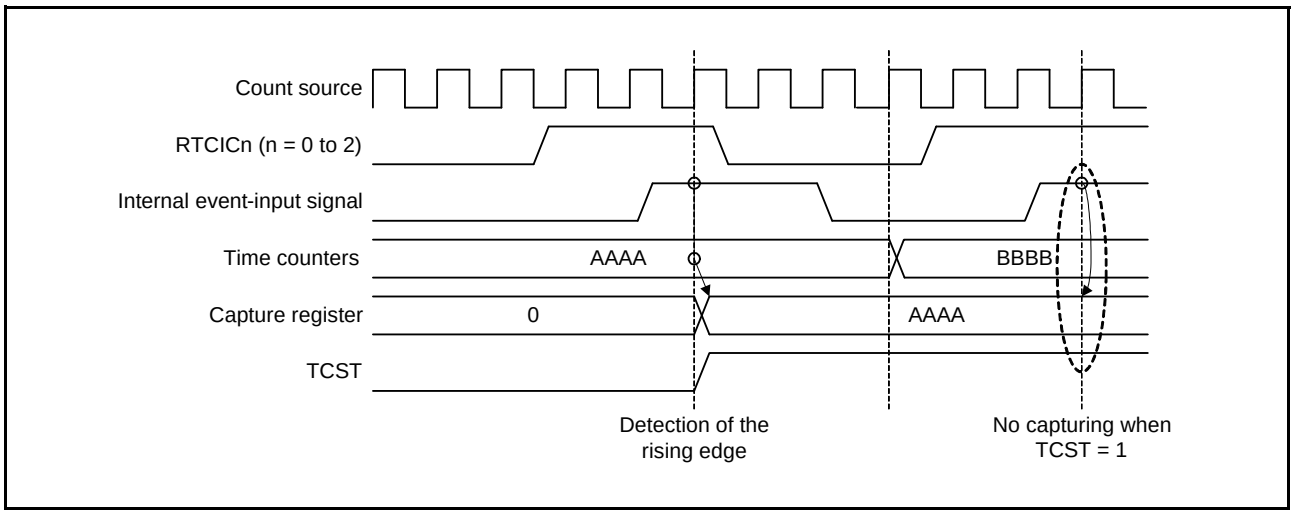

Figure 32.9 Timing of a Time Capture Operation (with the Filter Off)

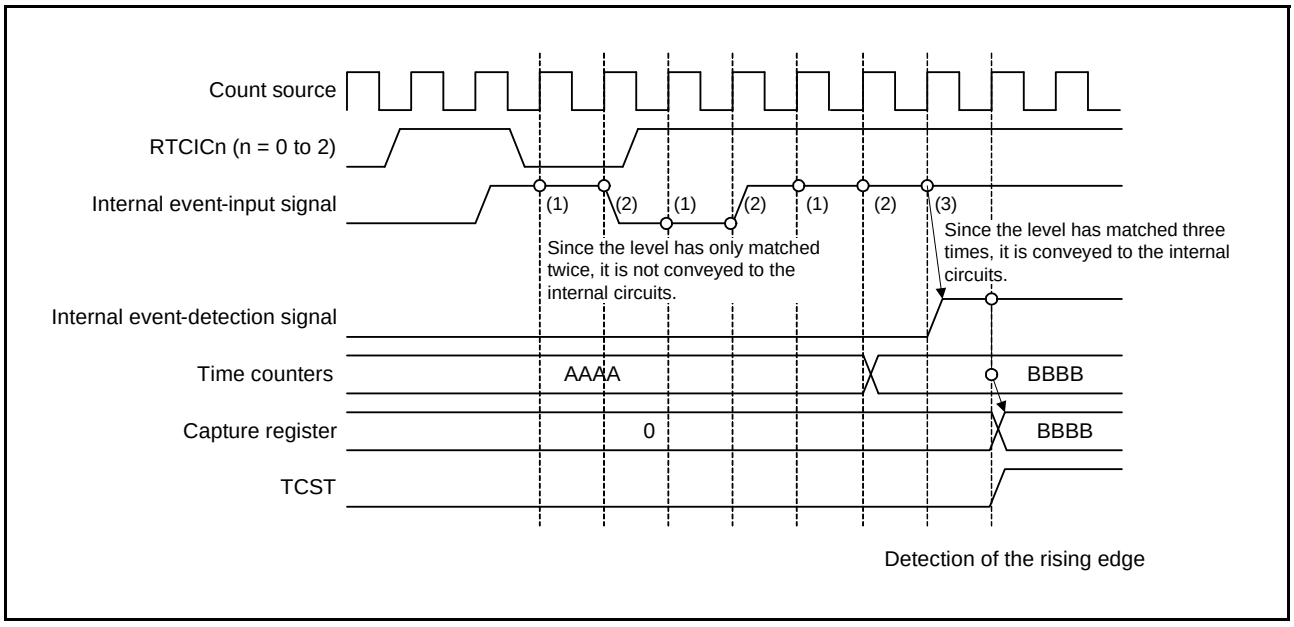

Figure 32.10 Timing of a Time Capture Operation (with the Filter On)

32.4 Interrupt Sources

There are three interrupt sources in the realtime clock. Table 32.4 lists interrupt sources for the RTC.

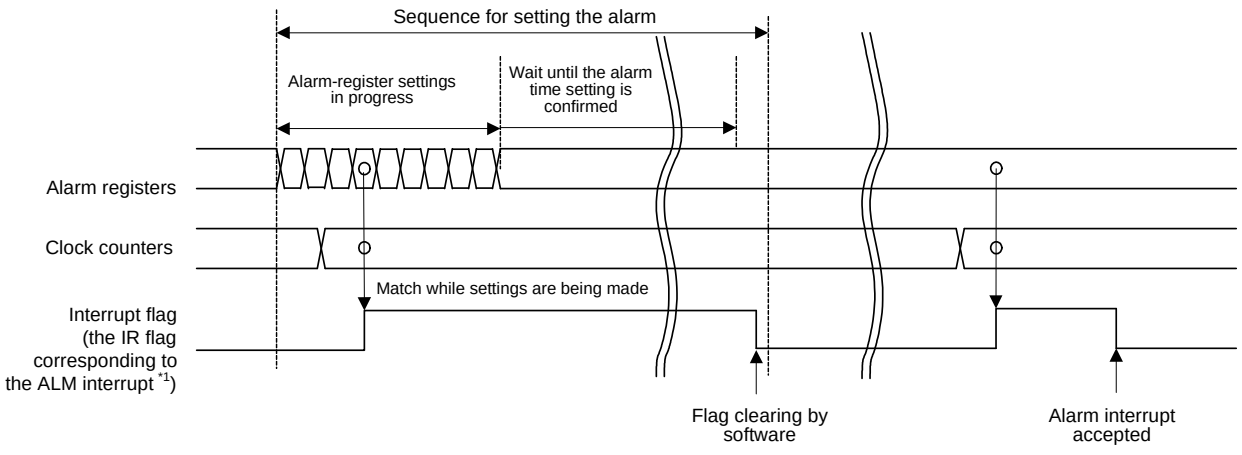
Table 32.4 RTC Interrupt Sources

Name	Interrupt Sources
ALM	Alarm interrupt
PRD	Periodic interrupt
CUP	Carry interrupt

(1) Alarm interrupt (ALM)

This interrupt is generated according to the result of comparison between the alarm registers and realtime clock counters (for details, refer to section 32.3.6, Alarm Function).

Since there is a possibility that the interrupt flag may be set to 1 when the settings of the alarm registers match the clock counters, wait for the alarm time settings to be confirmed and set the IR flag corresponding to the ALM interrupt to 0 again after modifying values of the alarm registers. Once the interrupt flag for the alarm interrupt has been set to 1 and the state has returned to non-matching of the alarm registers and clock counters, the flag will not be set again until there is a further match or the values of the alarm registers are modified again.



Note 1. Refer to the Interrupt Controller section for details on the corresponding interrupt vector number .

Figure 32.11 Timing Chart for the Alarm Interrupt (ALM)

(2) Periodic interrupt (PRD)

This interrupt is generated at intervals of 2 seconds, 1 second, 1/2 second, 1/4 second, 1/8 second, 1/16 second, 1/32 second, 1/64 second, 1/128 second, or 1/256 second. The interrupt interval can be selected through the RCR1.PES[3:0] bits.

(3) Carry interrupt (CUP)

This interrupt is generated when a carry to the second counter/binary counter 0 occurred or a carry to the R64CNT counter occurred during read access to the 64-Hz counter.

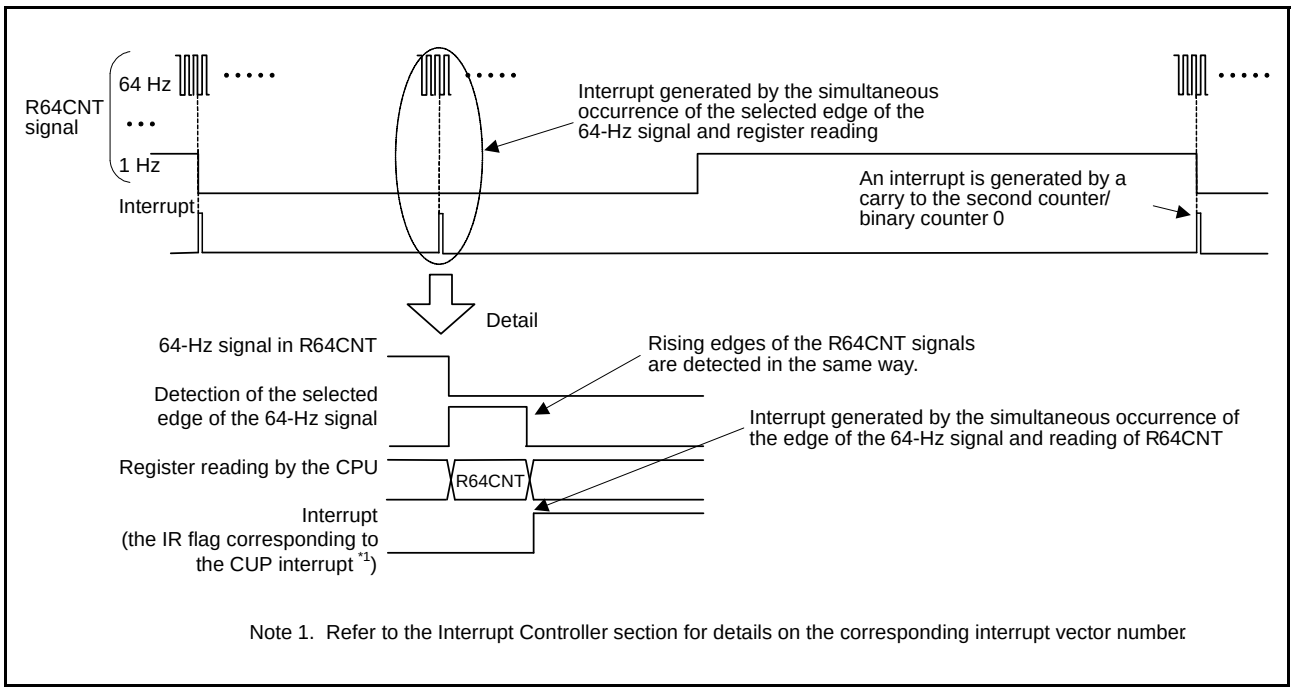


Figure 32.12 Carry Interrupt (CUP) Timing Chart

32.5 Event Link Output

The RTC outputs the following event signals for the event link controller (ELC), and these can be used to initiate operations by other modules selected in advance.

(1) Periodic event output

The periodic event signal is output at the interval selected from among 1/256, 1/128, 1/64, 1/32, 1/16, 1/8, 1/4, 1/2, 1, and 2 seconds by the setting of the RCR1.PES[3:0] bits.

The event generation period immediately after the event generation is selected is not guaranteed.

Note: If event linking from the RTC is to be used, only make the ELC settings after making the RTC settings (initialization, time settings, etc.). Making the RTC settings after the ELC settings can lead to the output of unexpected event signals.

32.5.1 Interrupt Handling and Event Linking

The RTC has a bit to enable or disable periodic interrupts. An interrupt request signal is output for the CPU when an interrupt source is generated while the corresponding enable bit is enabled.

In contrast, an event link output signal is sent to other modules as an event signal via the ELC when an interrupt source is generated, regardless of the setting of the corresponding interrupt enable bit.

Note: Although alarm and periodic interrupts can still be output during software standby or deep software standby, the periodic event signals for the ELC are not output.

32.6 Usage Notes

32.6.1 Register Writing during Counting

The following registers should not be written to during counting (while the RCR2.START bit = 1).

RSECCNT/BCNT0, RMINCNT/BCNT1, RHRCNT/BCNT2, RDAYCNT, RWKCNT/BCNT3, RMONCNT, RYRCNT, RCR1.RTCOS, RCR2.RTCOE, RCR2.HR24, RFRH, RFRL

The counter must be stopped before writing to any of the above registers.

32.6.2 Use of Periodic Interrupts

The procedure for using periodic interrupts is shown in Figure 32.13.
The generation and period of the periodic interrupt can be changed by the setting of the RCR1.PES[3:0] bits. However, since the prescaler, R64CNT, and RSECCNT/BCNT0 are used to generate interrupts, the interrupt period is not guaranteed immediately after setting of the RCR1.PES[3:0] bits.
Furthermore, stopping/restarting or resetting counter operation, reset by RTC software, and the 30-second adjustment by changing the RCR2 value affects the interrupt period. When the time error adjustment function is used, the interrupt generation period after adjustment is added or subtracted according to the adjustment value.

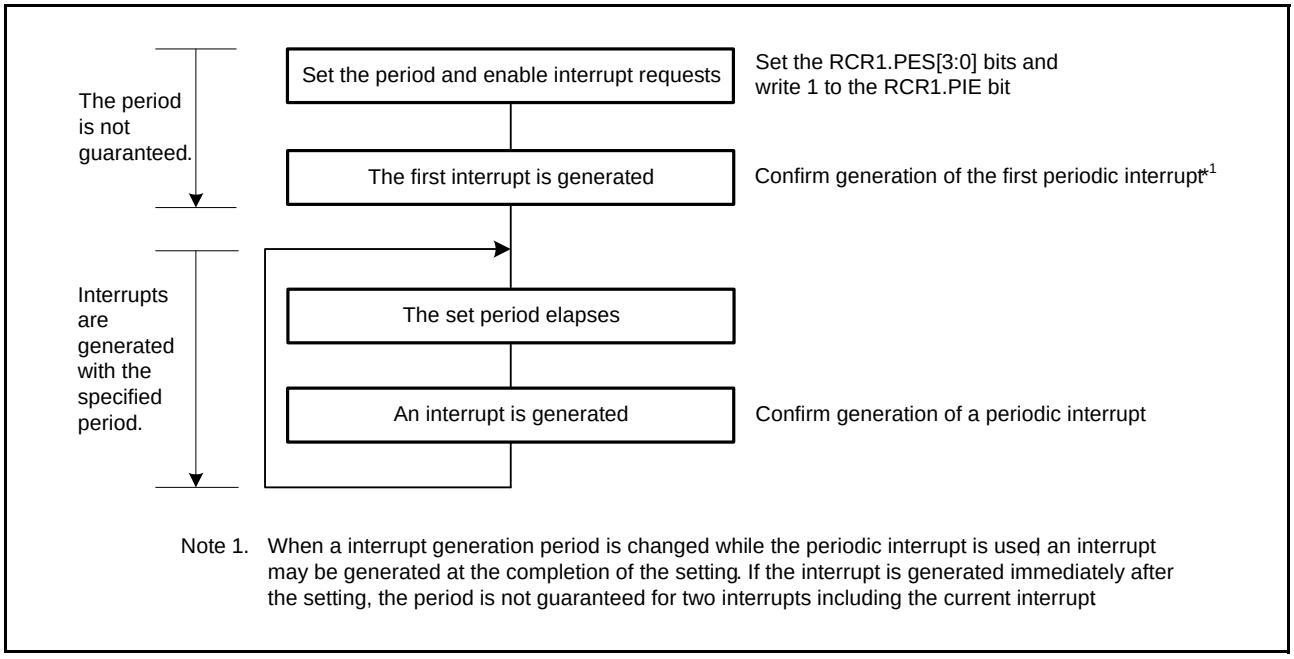

Figure 32.13 Using Periodic Interrupt Function

32.6.3 RTCOUT (1-Hz/64-Hz) Clock Output

Stopping/restarting or resetting counter operation, reset by RTC software, and the 30-second adjustment by changing the RCR2 value affects the period of RTCOUT (1-Hz/64-Hz) output. When the time error adjustment function is used, the period of RTCOUT (1-Hz/64-Hz) output after adjustment is added or subtracted according to the adjustment value.

32.6.4 Transitions to Low Power Consumption Modes after Setting Registers

A transition to a low power consumption state (software standby mode, deep software standby mode, or battery backup) during writing to or updating of an RTC register might destroy the register's value. After setting a register, confirm that the setting is in place before initiating a transition to a low power consumption state.

32.6.5 Notes When Writing to and Reading from Registers

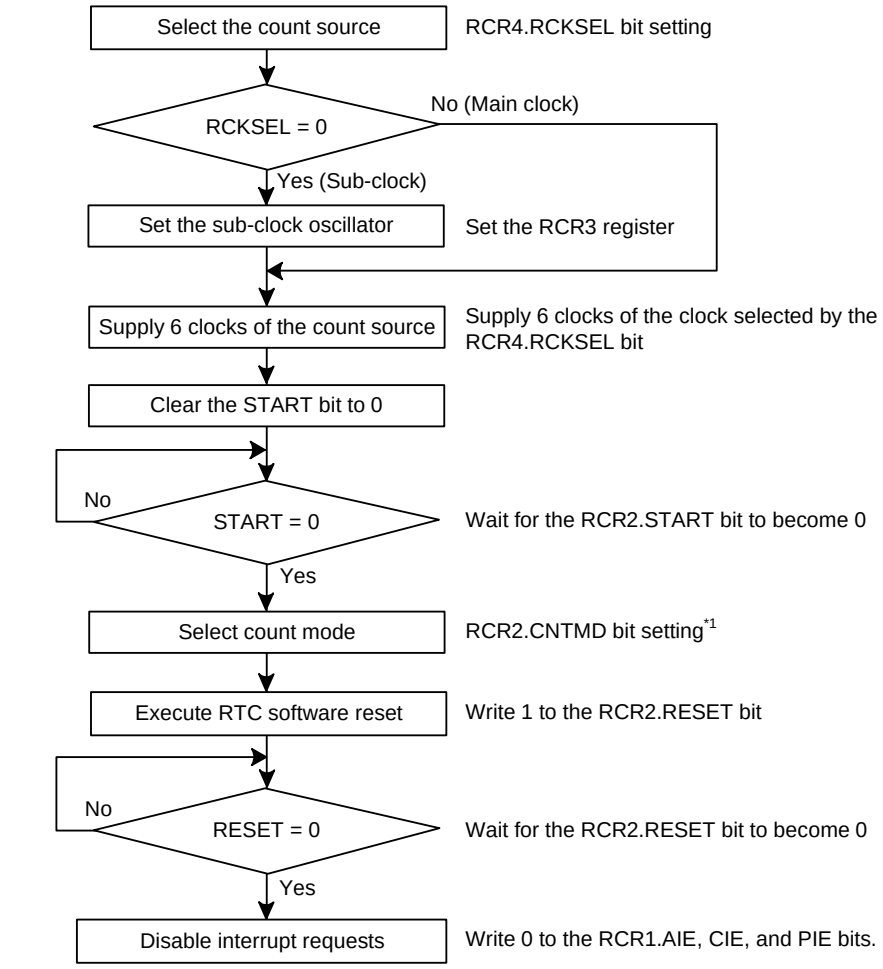
- When reading a counter register such as the second counter after having written to the counter register, follow the procedure in section 32.3.5, Reading 64-Hz Counter and Time.
- The value written to the count registers, alarm registers, year alarm enable register, bits RCR2.AADJE, AADJP, and HR24, RCR3, RCR4, RFRH, or RFRL register is reflected when four read operations are performed after writing.
- The values written to the RCR1.CIE, RTCOS, and RCR2.RTCOE bits can be read immediately after writing.
- To read the value from the timer counter after return from a reset, deep software standby mode, software standby mode, or the battery backup state, wait for1/128 second while the clock is operating (RCR2.START bit = 1).
- After a reset is generated, write to the RTC register when six cycles of the count source have elapsed.

32.6.6 Changing the Count Mode

When changing the count mode (calendar/binary), set the RCR2.START bit to 0, stop counting operation, then start again from the initial setting. For details on initial setting, refer to section 32.3.1, Outline of Initial Settings of Registers after Power On.

32.6.7 Initialization Procedure When the Realtime Clock is Not to be Used

Registers in the RTC are not initialized by a reset. Accordingly, depending on the initial state, the generation of an unintentional interrupt request or operation of the counter may lead to increased power consumption.
For products that do not require a realtime clock, initialize the registers by following the initialization procedure shown in Figure 32.14.
Alternatively, when the sub-clock is not used as the system clock or realtime clock, the counter can be stopped by writing 0 (sub-clock oscillator is selected) to the RCR4.RCKSEL bit and stopping the sub-clock.
When making the setting to stop the sub-clock, write 0 to the RCR3.RTCEN bit and write 1 to the SOSCCR.SOSTP bit.
For details on the setting of the SOSCCR.SOSTP bit, refer to section 9, Clock Generation Circuit.



Note 1. This step is not necessary if the count mode has been set concurrently with setting the START bit to 0.

Figure 32.14 Initialization Procedure

33. Watchdog Timer (WDTA)

The watchdog timer (WDT) is a 14-bit down-counter. It can be used to reset this MCU when the counter underflows because its value cannot be refreshed due to the system being out of control.
In addition, a non-maskable interrupt can be generated by an underflow.
The refresh-permitted period can be set to refresh the counter and used as the condition to detect when the system runs out of control.
In this section, “PCLK” is used to refer to PCLKB.

33.1 Overview

Table 33.1 lists the specifications of the WDT and Figure 33.1 shows a block diagram of the WDT.

Table 33.1 WDT Specifications

Item	Specifications
Count source	Peripheral module clock (PCLK)
Clock division ratio	Divide by 4, 64, 128, 512, 2048, or 8192
Counter operation	Counting down using a 14-bit down-counter
Conditions for starting the counter	• Auto-start mode: Counting automatically starts after a reset or after an underflow or refresh error occurs • Register start mode: Counting is started by refresh operation (writing to the WDTRR register)
Conditions for stopping the counter	• Reset (the down-counter and other registers return to their initial values) • A counter underflows or a refresh error is generated
Window function	Window start and end positions can be specified (refresh-permitted and refresh-prohibited periods)
Watchdog timer Reset sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error)
Non-maskable interrupt/interrupt sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error)
Reading the counter value	The down-counter value can be read by the WDTSR register.

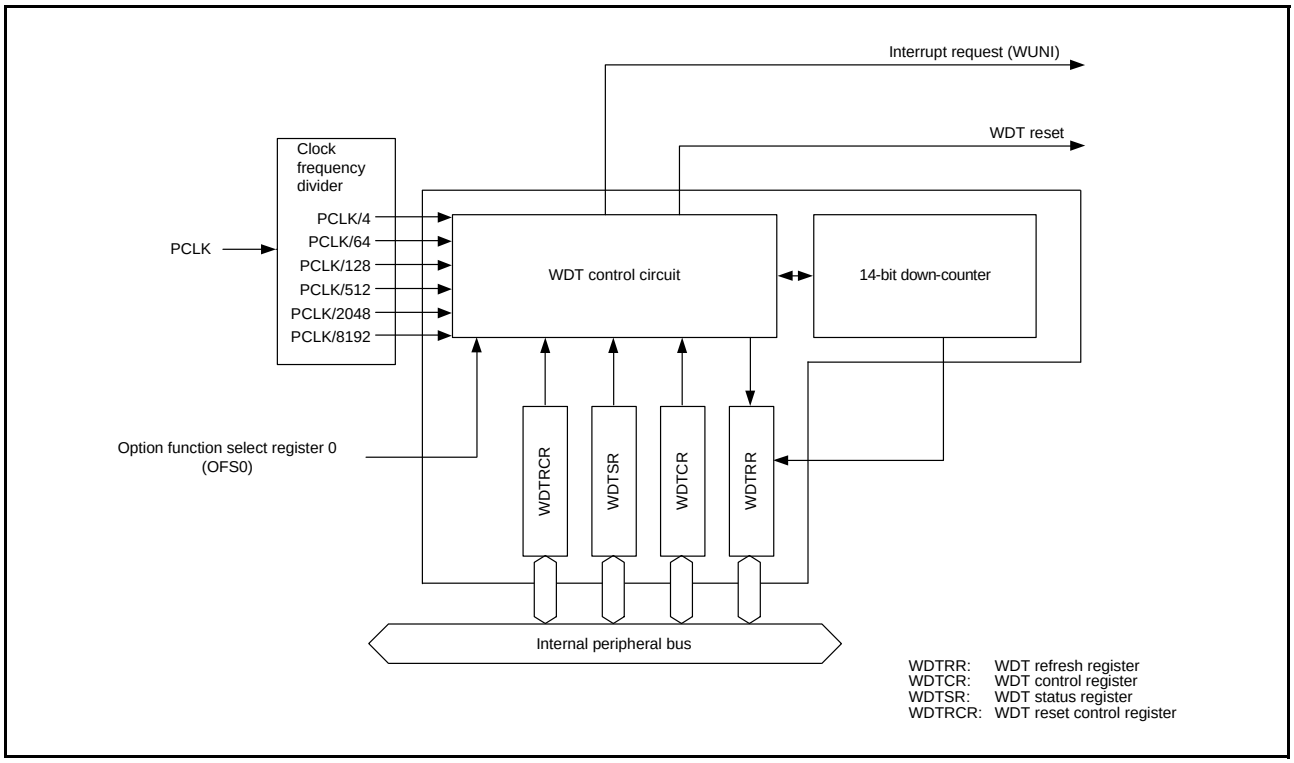


Figure 33.1 WDT Block Diagram

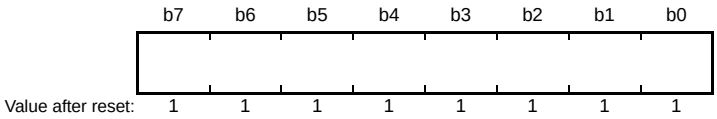
33.2 Register Descriptions

33.2.1 WDT Refresh Register (WDTRR)

Address(es): 0008 8020h



Bit	Description	R/W
b7 to b0	The down-counter is refreshed by writing 00h and then writing FFh to this register	R/W

WDTRR refreshes the down-counter of the WDT.
The down-counter of the WDT is refreshed by writing 00h and then writing FFh to WDTRR (refresh operation) within the refresh-permitted period.
After the down-counter has been refreshed, it starts counting down from the value selected by setting the WDT timeout period select bits (OFS0.WDTTOPS[1:0]) in option function select register 0 in auto-start mode. In register start mode, counting down starts from the value selected by setting the timeout period selection bits (WDTCR.TOPS[1:0]) in the WDT control register.
When 00h is written, the read value is 00h, when a value other than 00h is written, the read value is FFh.
For details of the refresh operation, refer to section 33.3.3, Refresh Operation.

33.2.2 WDT Control Register (WDTCR)

Address(es): 0008 8022h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b11, b10	—	Reserved	These bits are read as 0 and cannot be modified.	R
b13, b12	RPSS[1:0]	Window Start Position Selection	b13 b12 0 0: 25% 0 1: 50% 1 0: 75% 1 1: 100% (window start position is not specified)	R/W
b15, b14	—	Reserved	These bits are read as 0 and cannot be modified.	R

There are some restrictions on writing to the WDTCR register. For details, refer to section 33.3.2, Control over Writing to the WDTCR and WDTRCR Registers.
In auto-start mode, the settings in the WDTCR register are disabled, and the settings in option function select register 0 (OFS0) are enabled. The bit setting made to the WDTCR register can also be made in OFS0 register. For details, refer to section 33.3.7, Correspondence between Option Function Select Register 0 (OFS0) and WDT Registers.

TOPS[1:0] Bits (Timeout Period Selection)

These bits select the timeout period (period until the down-counter underflows) from among 1024, 4096, 8192, and 16384 cycles, taking the divided clock specified by the CKS[3:0] bits as one cycle.
After the down-counter is refreshed, the combination of the CKS[3:0] and TOPS[1:0] bits determines the time (number of PCLK cycles) until the counter underflows.
Relations between the CKS[3:0] and TOPS[1:0] bit settings, the timeout period, and the number of PCLK cycles are listed in Table 33.2.

Table 33.2 Timeout Period Settings

CKS[3:0] Bits				TOPS[1:0] Bits		Clock Division Ratio	Timeout Period (Number of Cycles)	Cycles of PCLK Clock
b7	b6	b5	b4	b1	b0			
0	0	0	1	0	0	Divide-by-4	1024	4096

				0	1		4096	524288
				1	0		8192	1048576
				1	1		16384	2097152
0	1	1	0	0	0	Divide-by-512	1024	524288
				0	1		4096	2097152
				1	0		8192	4194304
				1	1		16384	8388608
0	1	1	1	0	0	Divide-by-2048	1024	2097152
				0	1		4096	8388608
				1	0		8192	16777216
				1	1		16384	33554432
1	0	0	0	0	0	Divide-by-8192	1024	8388608
				0	1		4096	33554432
				1	0		8192	67108864
				1	1		16384	134217728

CKS[3:0] Bits (Clock Division Ratio Selection)

These bits specify the division ration of the clock used for the down-counter. The division ration can be selected from among the peripheral module clock (PCLK) divided by 4, 64, 128, 512, 2048, and 8192. Combined with the TOPS[1:0] bit setting, a count period between 4,096 and 134,217,728 cycles of the PCLK clock can be selected for the WDT.

RPES[1:0] Bits (Window End Position Selection)

These bits specify the window end position that indicates the refresh-permitted period. 75%, 50%, 25%, or 0% of the timeout period can be selected for the window end position. The selected window end position should be a value smaller than the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is enabled.

RPSS[1:0] Bits (Window Start Position Selection)

These bits specify the window start position that indicates the refresh-permitted period. 25%, 50%, 75%, or 100% of the timeout period can be selected for the window end position. The window start position should be set to a value greater the window end position. If the window start position is set to a value smaller than or equal to the window end position, the window end position is set to 0%.

Table 33.3 lists the counter values for the window start and end positions and Figure 33.2 shows the refresh-permitted period set by the RPSS[1:0], RPES[1:0], and TOPS[1:0] bits.

Table 33.3 Relationship between Timeout Period and Window Start and End Counter Values

TOPS[1:0] Bits		Timeout Period		Window Start and End Counter Value			
		Cycles	Counter Value	100%	75%	50%	25%
0	0	1024	03FFh	03FFh	02FFh	01FFh	00FFh
0	1	4096	0FFFh	0FFFh	0BFFh	07FFh	03FFh
1	0	8192	1FFFh	1FFFh	17FFh	0FFFh	07FFh
1	1	16384	3FFFh	3FFFh	2FFFh	1FFFh	0FFFh

RPSS[1:0] Bits		RPES[1:0] Bits		Window	
b13	b12	b9	b8	Start (%)	End (%)
1	1	1	1	100	0
		1	0		25
		0	1		50
		0	0		75
1	0	1	1	75	0
		1	0		25
		0	1		50
		0	0		75
0	1	1	1	50	0
		1	0		25
		0	1		50
		0	0		75
0	0	1	1	25	0
		1	0		25
		0	1		50
		0	0		75

Note: If window end setting ≥ window start setting, the window end setting is set to 0%.

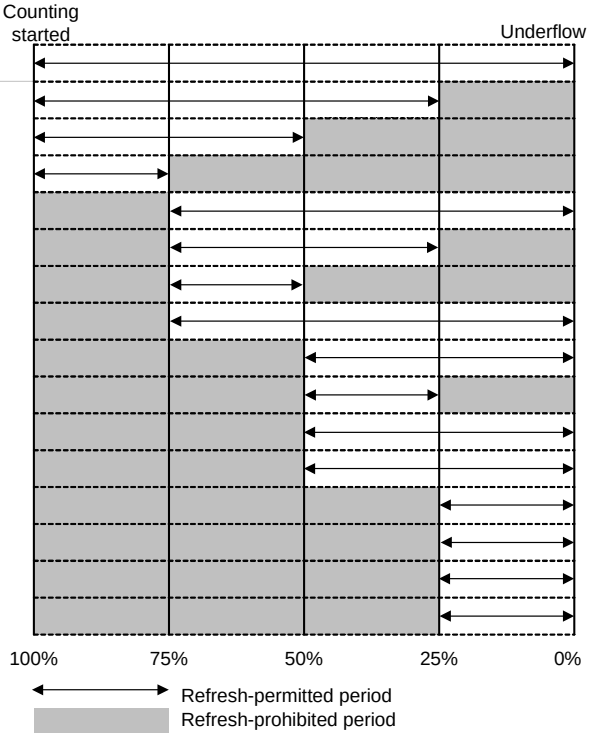

Figure 33.2 RPSS[1:0] and RPES[1:0] Bit Settings and the Refresh-Permitted Period

33.2.3 WDT Status Register (WDTSR)

Address(es): 0008 8024h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	REFEF	UNDFF	CNTVAL[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b13 to b0	CNTVAL[13:0]	Down-Counter Value	Value counted by the down-counter	R
b14	UNDFF	Underflow Flag	0: No underflow occurred 1: Underflow occurred	R(/W) *1
b15	REFEF	Refresh Error Flag	0: No refresh error occurred 1: Refresh error occurred	R(/W) *1

Note 1. Only 0 can be written to clear the flag.

CNTVAL[13:0] Bits (Down-Counter Value)

Read these bits to confirm the value of the down-counter, but note that the read value may differ from the actual count by a value of one count.

UNDFF Flag (Underflow Flag)

Read this flag to confirm whether or not an underflow has occurred in the down-counter.
The value 1 indicates that the down-counter has underflowed. The value 0 indicates that the down-counter has not underflowed.
Write 0 to the UNDFF flag to set the value to 0. Writing 1 has no effect.

REFEF Flag (Refresh Error Flag)

Read this flag to confirm whether or not a refresh error (performing a refresh operation during a refresh-prohibited period) has occurred.
The value 1 indicates that a refresh error has occurred. The value 0 indicates that no refresh error has occurred.
Write 0 to the REFEF flag to set the value to 0. Writing 1 has no effect.

33.2.4 WDT Reset Control Register (WDTRCR)

Address(es): 0008 8026h

	b7	b6	b5	b4	b3	b2	b1	b0
	RSTIRQS	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0 and cannot be modified.	R
b7	RSTIRQS	Reset Interrupt Request Selection	0: Non-maskable interrupt request or interrupt request output is enabled 1: Reset output is enabled	R/W

There are some restrictions on writing to the WDTRCR register. For details, refer to section 33.3.2, Control over Writing to the WDTCR and WDTRCR Registers.

In auto-start mode, the WDTRCR register settings are disabled, and the settings in option function select register 0 (OFS0) are enabled. The bit setting made to the WDTCR register can also be made in the OFS0 register. For details, refer to section 33.3.7, Correspondence between Option Function Select Register 0 (OFS0) and WDT Registers.

33.2.5 Option Function Select Register 0 (OFS0)

For details on the OFS0 register, refer to section 33.3.7, Correspondence between Option Function Select Register 0 (OFS0) and WDT Registers.

33.3 Operation

33.3.1 Count Operation in Each Start Mode

The WDT has two start modes: auto-start mode, in which counting automatically starts after release from the reset state, and register start mode, in which counting is started by refreshing (writing to the register).
In auto-start mode, counting automatically starts after release from the reset state in accordance with the settings in option function select register 0 (OFS0) in the ROM.
In register start mode, counting is started by refreshing (writing to the register) after the respective registers are set after release from the reset state.
Select auto-start mode or register start mode by setting the WDT start mode select bit (OFS0.WDTSTRT) in the OFS0 register.
When the auto-start mode is selected, the settings in the WDT control register (WDTCR) and WDT reset control register (WDTRCR) are disabled, and the settings in the OFS0 register are enabled.
On the other hand, when the register start mode is selected, the setting of the OFS0 register is disabled, and the settings of the WDT control register (WDTCR) and WDT reset control register (WDTRCR) are enabled.

33.3.1.1 Register Start Mode

When the WDT start mode select bit (OFS0.WDTSTRT) is 1, register start mode is selected, and the WDT control register (WDTCR) and WDT reset control register (WDTRCR) are enabled.
After the reset state is released, set the clock division ratio, window start and end positions, and timeout period in the WDTCR register, and the reset output or interrupt request output in the WDTRCR register. Then, refresh the down-counter to start counting down from the value set by the timeout period selection bits (WDTCR.TOPS[1:0]).
Thereafter, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is re-set each time the counter is refreshed and counting down continues. The WDT does not output the reset signal as long as this continues. However, if the down-counter underflows because the down-counter cannot be refreshed due to a program runaway, or if a refresh error occurs because the counter was refreshed outside the refresh-permitted period, the WDT outputs a reset signal or a non-maskable interrupt request/interrupt request (WUNI). Reset output or interrupt request output can be selected by setting the WDT reset interrupt request selection bit (WDTRCR.RSTIRQS).

Figure 33.3 shows an example of operation under the following conditions.

- Register start mode (OFS0.WDTSTRT = 1)
- Reset output is enabled (WDTRCR.RSTIRQS = 1)
- The window start position is 75% (WDTCR.RPSS[1:0] = 10b)
- The window end position is 25% (WDTCR.RPES[1:0] = 10b)

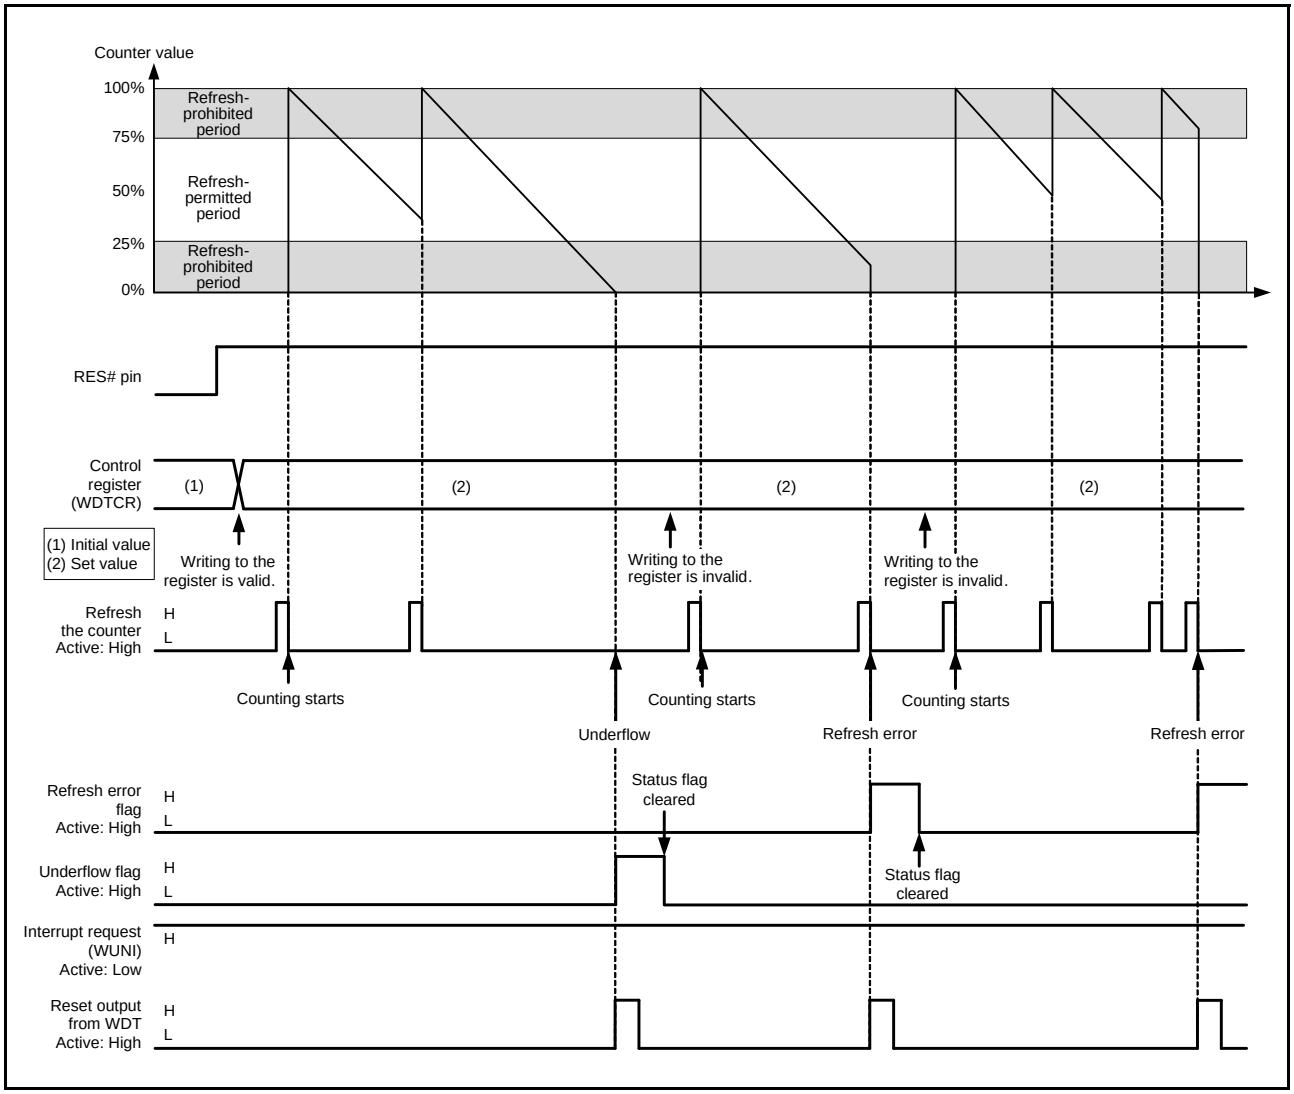

Figure 33.3 Operation Example in Register Start Mode

33.3.1.2 Auto-Start Mode

When the WDT start mode select bit (OFS0.WDTSTRT) in option function select register 0 (OFS0) is 0, auto-start mode is selected, the WDT control register (WDTCR) and WDT reset control register (WDTRCR) are disabled, and the settings in the OFS0 register are enabled.
Within the reset state, the setting values (clock division ratio, window start and end positions, timeout period, and reset output or interrupt request) of option function select register 0 (OFS0) are set in the WDT registers.
When the reset state is released, the down-counter automatically starts counting down from the value set by the WDT timeout period select bits (OFS0.WDTTOPS[1:0]).
After that, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is re-set each time the counter is refreshed and counting down continues. The WDT does not output the reset signal as long as this continues.
However, if the down-counter underflows because refreshing of the down-counter is not possible due to the program having entered crashed execution or if a refresh error occurs due to refreshing outside the refresh-permitted period, the WDT outputs the reset signal or non-maskable interrupt request/interrupt request (WUNI).
After the reset signal or non-maskable interrupt request/interrupt request is output of for one cycle of counting, the value of the timeout period is set in the down-counter counting is restarted.
Reset output or interrupt request output can be selected by setting the WDT reset interrupt request select bit (OFS0.WDTRSTIRQS).

Figure 33.4 shows an example of operation (non-maskable interrupt) under the following conditions.

- Auto start mode (OFS0.WDTSTRT = 0)
- Non-maskable interrupt request output is enabled (OFS0.WDTRSTIRQS = 0)
- The window start position is 75% (WDTCR.RPSS[1:0] = 10b)
- The window end position is 25% (WDTCR.RPES[1:0] = 10b)

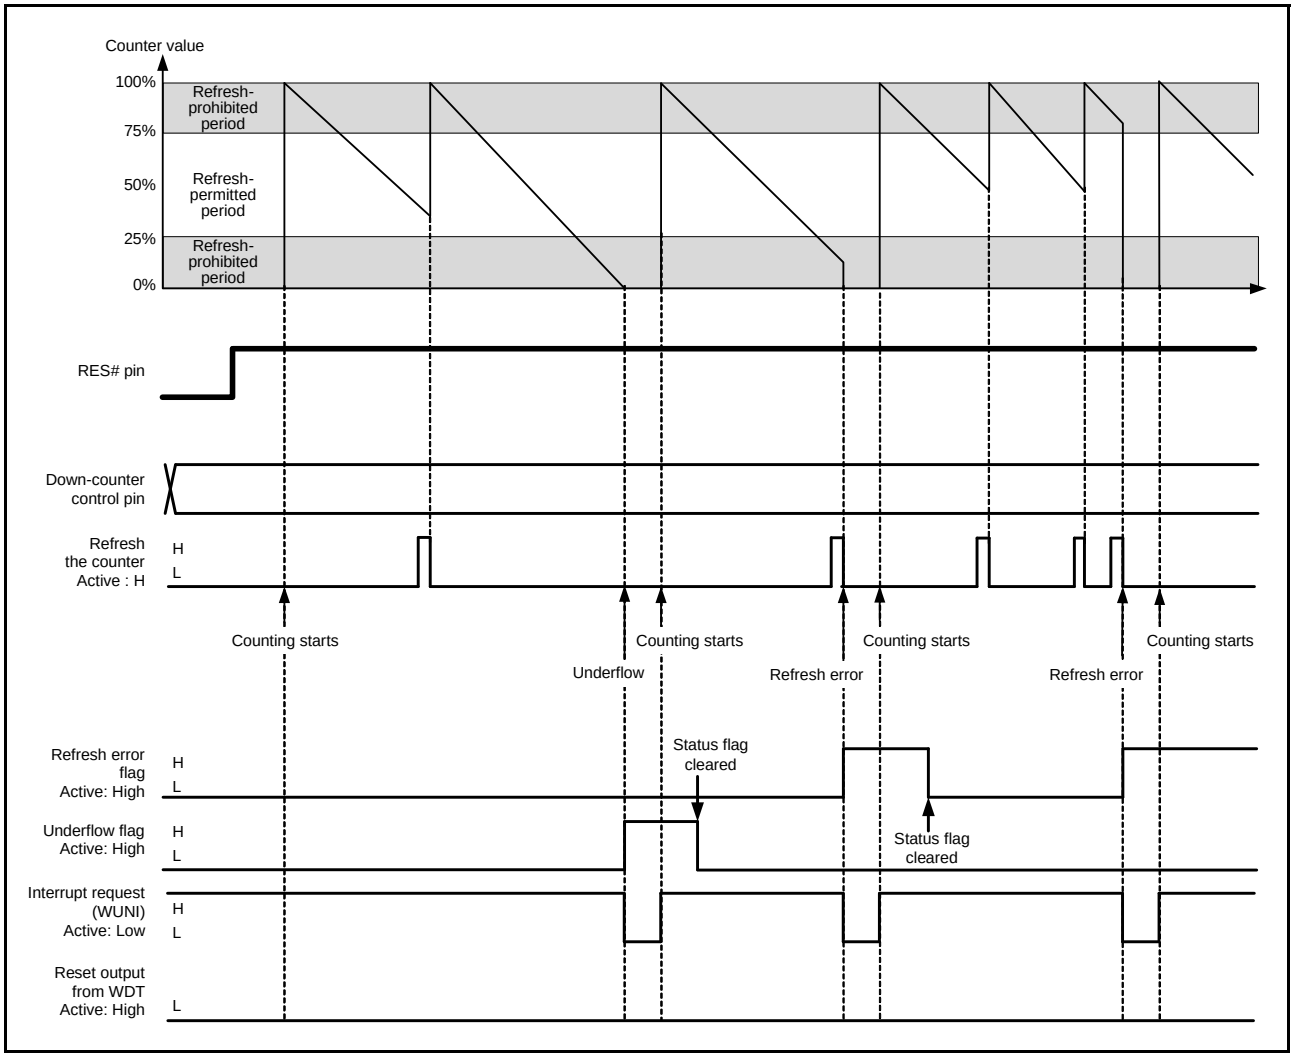

Figure 33.4 Operation Example in Auto-Start Mode

33.3.2 Control over Writing to the WDTCR and WDTRCR Registers

Writing to the WDT control register (WDTCR) or WDT reset control register (WDTRCR) is only possible once between the release from the reset state and the first refresh operation.
After a refresh operation (counting starts) or by writing to WDTCR or WDTRCR, the protection signal in the WDT becomes 1 to protect WDTCR and WDTRCR against subsequent attempts at writing.
This protection is released by the reset source of the WDT. With other reset sources, the protection is not released.
Figure 33.5 shows control waveforms produced in response to writing to the WDTCR.

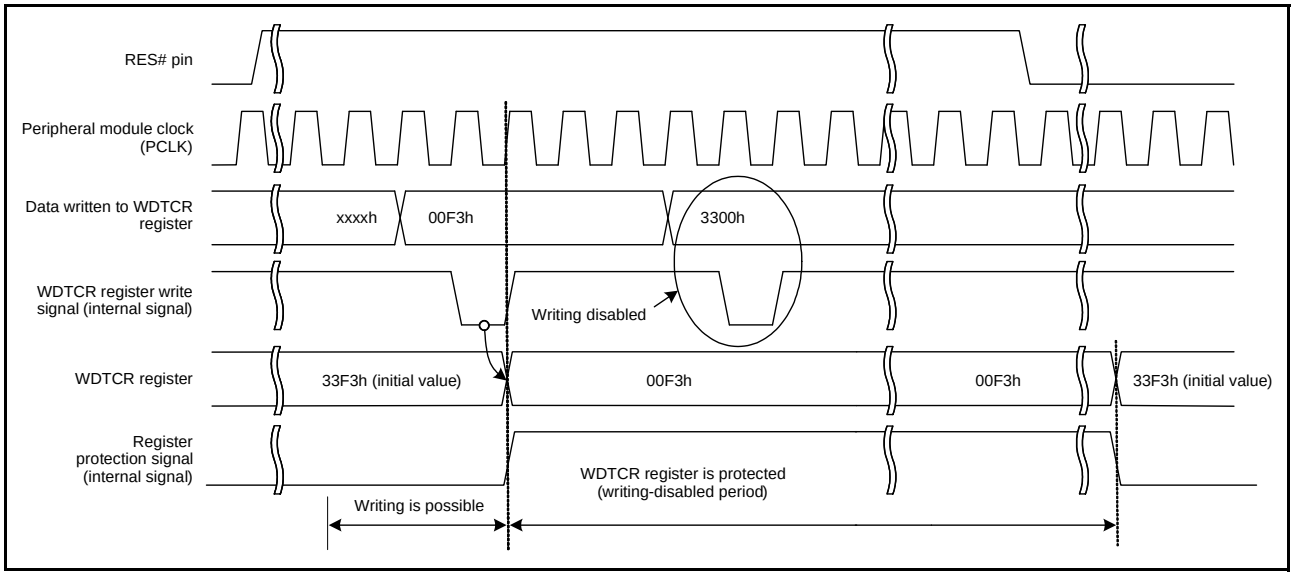

Figure 33.5 Control Waveforms Produced in Response to Writing to the WDTCR Register

33.3.3 Refresh Operation

The down-counter is refreshed by writing the values 00h and then FFh to the WDT refresh register (WDTRR). If a value other than FFh is written after 00h, the down-counter is not refreshed. After such invalid writing, correct refreshing is performed by again writing to 00h and then FFh to the WDTRR register.
Even if a register other than WDTRR is accessed or WDTRR is read between writing 00h and writing FFh to WDTRR, correct refreshing will be done.
Writing to refresh the counter must be performed within the refresh-permitted period. Whether writing is done within the refresh-permitted period is determined when writing FFh. For this reason, correct refreshing will be done even if 00h is written outside the refresh-permitted period.

[Sample sequences of writing that are valid for refreshing the counter]

- 00h → FFh
- 00h (n–1-th time) → 00h (nth time) → FFh
- 00h → access to another register or read from WDTRR → FFh

[Sample sequences of writing that are not valid for refreshing the counter]

- 23h (a value other than 00h) → FFh
- 00h → 54h (a value other than FFh)
- 00h→ AAh (00h and a value other than FFh) → FFh

After FFh is written to the WDT refresh register (WDTRR), refreshing the down-counter requires up to four cycles of the signal for counting. Therefore, writing FFh to the WDTRR should be completed four-count cycles before the down-counter underflows.

Figure 33.6 shows the WDT refresh-operation waveforms when the clock division ratio = PCLK/64.

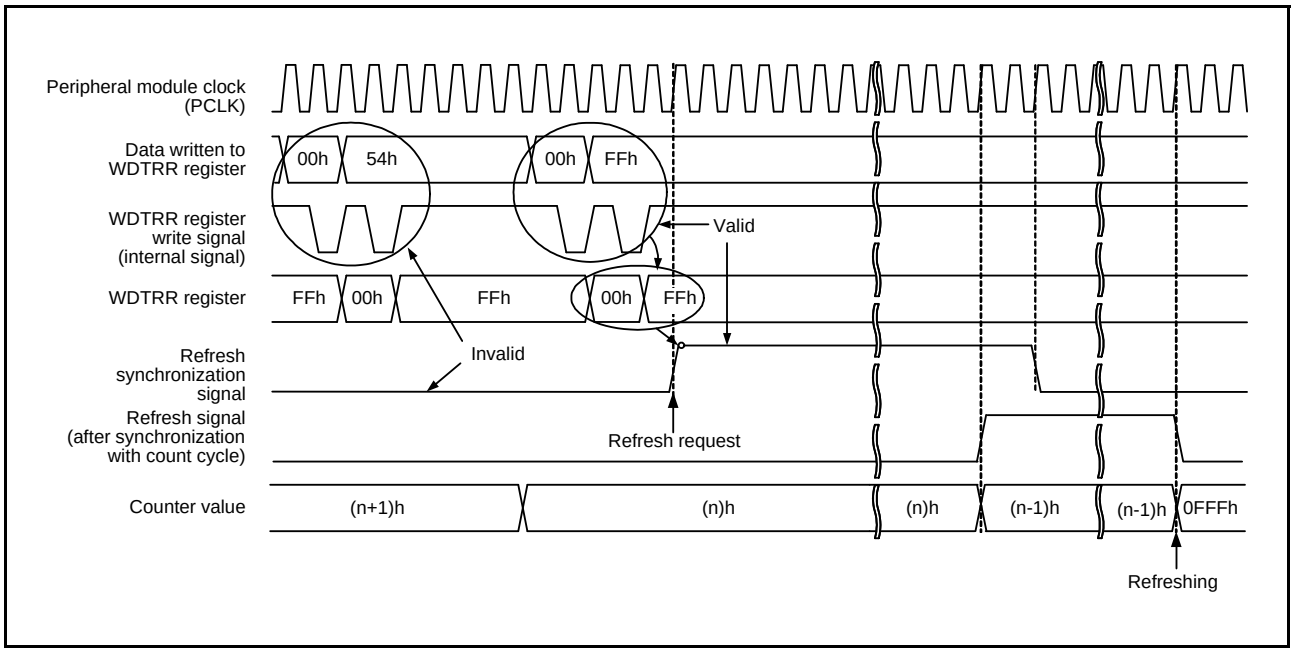

Figure 33.6 WDT Refresh Operation Waveforms (WDTCR.CKS[3:0] = 0100b, WDTCR.TOPS[1:0] = 01b)

33.3.4 Reset Output

When the reset interrupt selection bit (WDTRCR.RSTIRQS) is set to 1 in register start mode or when the WDT reset interrupt request select bit (OFS0.WDTRSTIRQS) in option function select register 0 (OFS0) is set to 1 in auto-start mode, a reset signal is output for one-count cycle when an underflow in the down-counter or a refresh error occurs.
In register start mode, the down-counter is initialized (all bits set to 0) and stopped in that state after output of the reset signal. After the reset state is released and the program is restarted, the counter is set up again and counting down is started by refreshing.
In auto-start mode, counting down automatically starts after the reset state is released.

33.3.5 Interrupt Source

When the reset interrupt selection bit (WDTRCR.RSTIRQS) is set to 0 in register start mode or when the WDT reset interrupt request select bit (OFS0.WDTRSTIRQS) in option function select register 0 (OFS0) is set to 0 in auto-start mode, an interrupt (WUNI) signal is generated when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt and an interrupt. For details, refer to section 15, Interrupt Controller (ICUA).

Table 33.4 WDT Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
WUNI	Down-counter underflow Refresh error	Not possible	Not possible

33.3.6 Reading the Down-Counter Value

The WDT stores the counter value in the down-counter value (WDTSR.CNTVAL[13:0]) bits of the WDT status register. Thus, the counter value can be checked through the WDTSR.CNTVAL[13:0] bits.

Figure 33.7 shows the processing for reading the WDT down-counter value when the clock division ratio = PCLK/64.

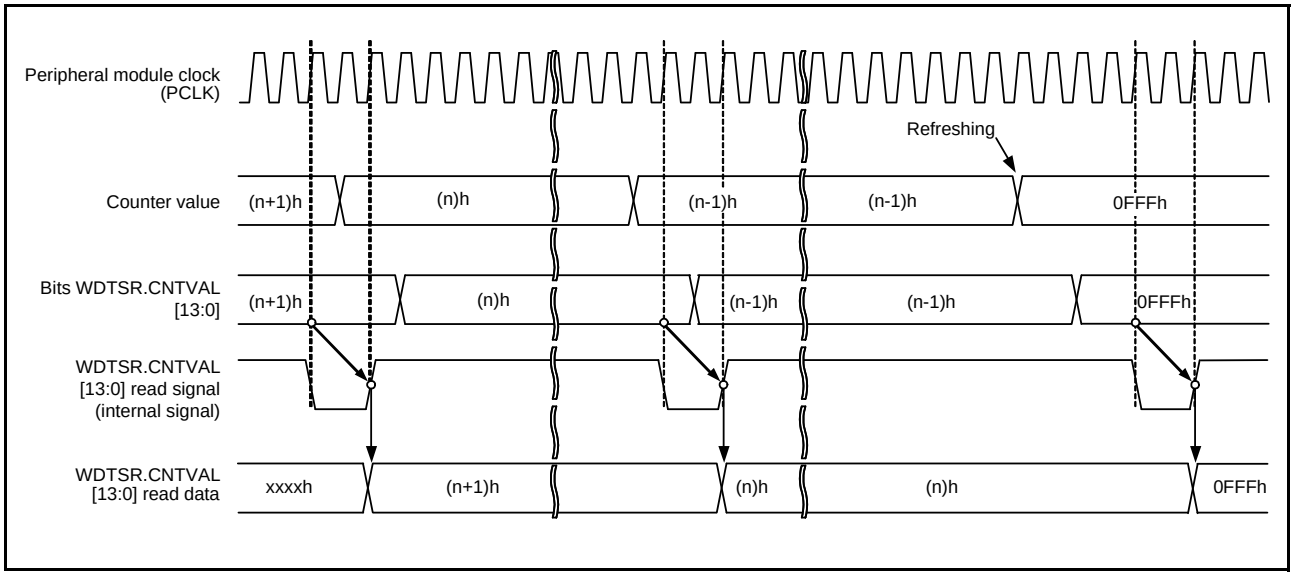

Figure 33.7 Processing for Reading WDT Down-Counter Value (WDTCR.CKS[3:0] = 0100b, WDTCR.TOPS[1:0] = 01b)

33.3.7 Correspondence between Option Function Select Register 0 (OFS0) and WDT Registers

Table 33.5 lists the correspondence between option function select register 0 (OFS0) used in auto-start mode and the registers used in register start mode.

Do not change the OFS0 register setting during WDT operation.

For details on option function select register 0 (OFS0), refer to section 7.2.3, Option Function Select Register 0 (OFS0).

Table 33.5 Correspondence between Option Function Select Register 0 (OFS0) and WDT Registers

Target of Control	Function	OFS0 Register (Enabled in Auto-Start Mode) OFS0.WDTSTRT = 0	WDT Registers (Enabled in Register Start Mode) OFS0.WDTSTRT = 1
Down-counter	Timeout period selection	OFS0.WDTTOPS[1:0]	WDTCR.TOPS[1:0]
	Clock division ratio selection	OFS0.WDTCKS[3:0]	WDTCR.CKS[3:0]
	Window start position selection	OFS0.WDTRPSS[1:0]	WDTCR.RPSS[1:0]

Reset output or interrupt request output	Reset output or interrupt request output selection	OFS0.WDTRSTIRQS	WDTRCR.RSTIRQS

34. Independent Watchdog Timer (IWDTa)

In this section, “PCLK” is used to refer to PCLKB.

34.1 Overview

The independent watchdog timer (IWDT) can be used to detect programs being out of control.
The user can detect when a program runs out of control if an underflow occurs, by creating a program that refreshes the IWDT counter before it underflows.
The functions of the IWDT are different from those of the WDT in the following respects.

- The divided IWDT-dedicated low-speed clock (IWDTCLK) is used as the count source (not affected by the PCLK).
- When making a transition to sleep mode, software standby mode, deep software standby mode, or all-module clock stop mode, the IWDTCSTPR.SLCSTP bit or the OFS0.IWDTSLCSTP bit can be used to select whether to stop the counter or not.

Table 34.1 lists the specifications of the IWDT and Figure 34.1 shows a block diagram of the IWDT.

Table 34.1 IWDT Specifications

Item	Description
Count source*1	IWDT-dedicated clock (IWDTCLK)
Clock divide ratio	Divide by 1, 16, 32, 64, 128, or 256
Counter operation	Counting down using a 14-bit down-counter
Conditions for starting the counter	• Counting automatically starts after a reset (auto-start mode) • Counting is started (register start mode) by refreshing the counter (writing 00h and then FFh to the IWDTRR register).
Conditions for stopping the counter	• Reset (the down-counter and other registers return to their initial values) • A counter underflows or a refresh error occurs Counting restarts (In auto-start mode, counting automatically restarts after a reset or after a non-maskable interrupt request/interrupt request is output. In register start mode, counting restarts after refreshing.)
Window function	Window start and end positions can be specified (refresh-permitted and refresh-prohibited periods)
Reset output sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error)
Non-maskable interrupt/ interrupt sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error)
Reading the counter value	The down-counter value can be read by the IWDTSR register.
Event link function (output)	• Down-counter underflow event output • Refresh error event output
Output signal (internal signal)	• Reset output • Interrupt request output • Sleep mode count stop control output
Auto-start mode (controlled by option function select register 0 (OFS0))	• Selecting the clock frequency divide ratio after a reset (OFS0.IWDTCKS[3:0] bits) • Selecting the timeout period of the independent watchdog timer (OFS0.IWDTTOPS[1:0] bits) • Selecting the window start position in the independent watchdog timer (OFS0.IWDTRPSS[1:0] bits) • Selecting the window end position in the independent watchdog timer (OFS0.IWDTRPES[1:0] bits) • Selecting the reset output or interrupt request output (OFS0.IWDTRSTIRQS bit) • Selecting the down-count stop function at transition to sleep mode, software standby mode, deep software standby mode, or all-module clock stop mode (OFS0.IWDTSLCSTP bit)
Register start mode (controlled by the IWDT registers)	• Selecting the clock frequency divide ratio after refreshing (IWDTCR.CKS[3:0] bits) • Selecting the timeout period of the independent watchdog timer (IWDTCR.TOPS[1:0] bits) • Selecting the window start position in the independent watchdog timer (IWDTCR.RPSS[1:0] bits) • Selecting the window end position in the independent watchdog timer (IWDTCR.RPES[1:0] bits) • Selecting the reset output or interrupt request output (IWDTRCR.RSTIRQS bit) • Selecting the down-count stop function at transition to sleep mode, software standby mode, deep software standby mode, or all-module clock stop mode (IWDTCSTPR.SLCSTP bit)

Note 1. Satisfy the frequency of the peripheral module clock (PCLK) ≥ 4 × (the frequency of the count source after divide).

To use the IWDT, the IWDT-dedicated clock (IWDTCLK) should be supplied so that the IWDT operates even if the peripheral module clock (PCLK) stops. The bus interface and registers operate with PCLK, and the 14-bit counter and control circuits operate with IWDTCLK.
Figure 34.1 is a block diagram of the IWDT.

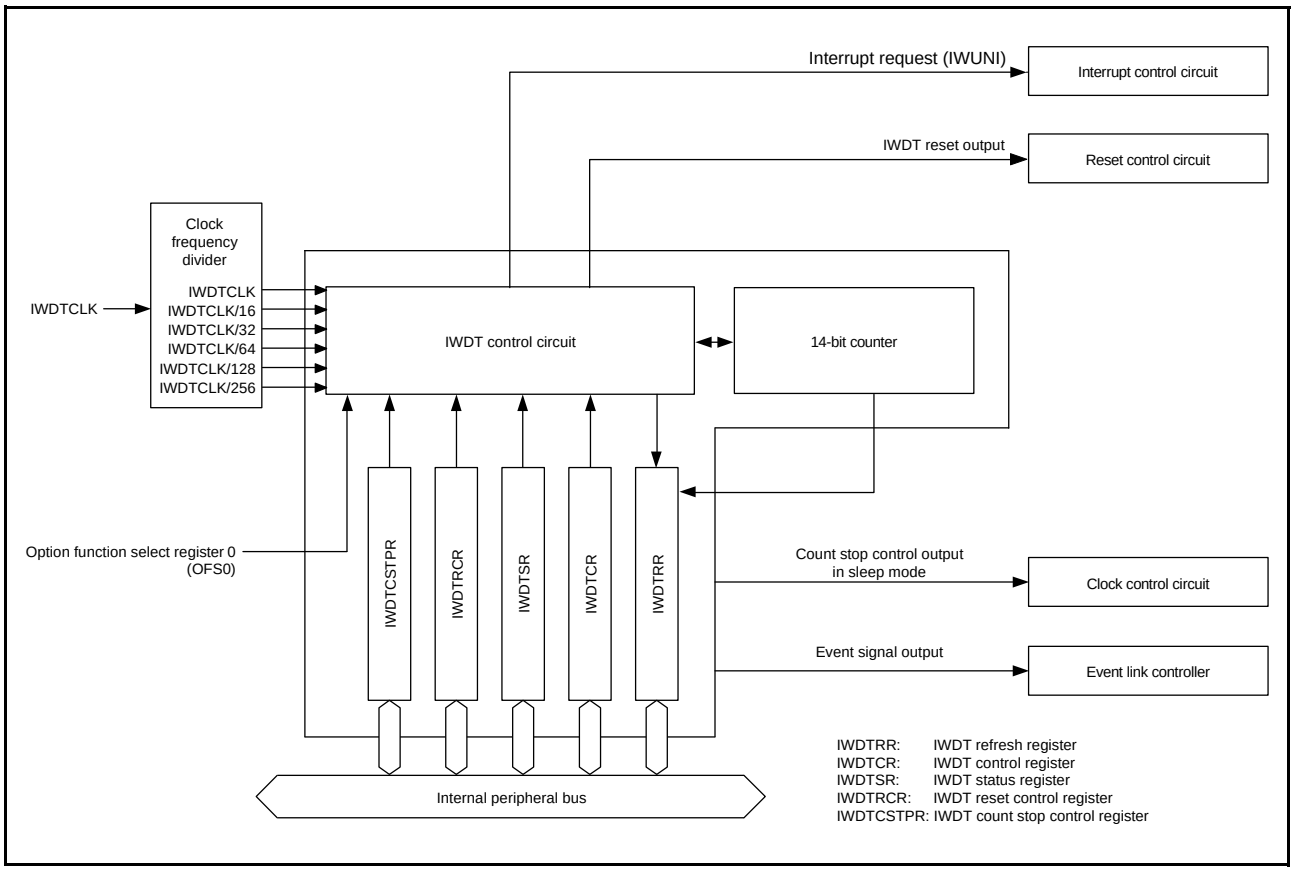

Figure 34.1 IWDT Block Diagram

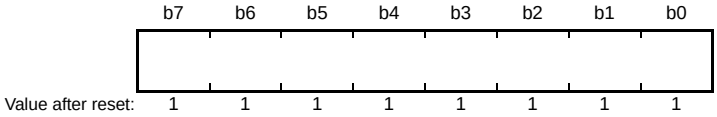
34.2 Register Descriptions

34.2.1 IWDT Refresh Register (IWDTRR)

Address(es): IWDT.IWDTRR 0008 8030h



Bit	Description	R/W
b7 to b0	The counter is refreshed by writing 00h and then writing FFh to this register.	R/W

The IWDTRR register refreshes the counter of the IWDT.
The counter of the IWDT is refreshed by writing 00h and then writing FFh to the IWDTRR register (refresh operation) within the refresh-permitted period.
After the counter has been refreshed, it starts counting down from the value selected by the IWDT timeout period select bits (OFS0.IWDTTOPS[1:0]) in option function select register 0 (OFS0) in auto-start mode. In register start mode, counting down starts from the value selected by setting the timeout period select bits (TOPS[1:0]) in the IWDT control register (IWDTCR) in the first refresh operation after release from the reset state.
When 00h is written, the read value is 00h. When a value other than 00h is written, the read value is FFh.
For details of the refresh operation, refer to section 34.3.3, Refresh Operation.

34.2.2 IWDT Control Register (IWDTCR)

Address(es): IWDT.IWDTCR 0008 8032h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	RPSS[1:0]		—	—	RPES[1:0]		CKS[3:0]				—	—	TOPS[1:0]

b15, b14	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R

There are some restrictions on writing to the IWDTCR register. For details, refer to section 34.3.2, Control over Writing to the IWDTCR, IWDTRCR, and IWDTCSTPR Registers.

In auto-start mode, the settings in the IWDTCR register are disabled, and the settings in option function select register 0 (OFS0) are enabled. The bit setting made to the IWDTCR register can also be made in option function select register 0 (OFS0). For details, refer to section 34.3.8, Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers.

TOPS[1:0] Bits (Timeout Period Select)

These bits select the timeout period (period until the counter underflows) from among 1024, 4096, 8196, or 16384 cycles, taking the divided clock specified by the CKS[3:0] bits as one cycle.
After the counter is refreshed, the combination of the CKS[3:0] and TOPS[1:0] bits determines the time (number of IWDTCLK cycles) until the counter underflows.
Relations between the CKS[3:0] and TOPS[1:0] bit setting, the timeout period, and the number of IWDTCLK cycles are listed in Table 34.2.

Table 34.2 Settings and Timeout Periods

CKS[3:0] Bits				TOPS[1:0] Bits				
b7	b6	b5	b4	b1	b0	Clock Divide Ratio	Timeout Period (Number of Cycles)	Cycles of IWDTCLK
0	0	0	0	0	0	No division	1024	1024
				0	1		4096	4096
				1	0		8192	8192
				1	1		16384	16384
0	0	1	0	0	0	Divide-by-16	1024	16384
				0	1		4096	65536
				1	0		8192	131072
				1	1		16384	262144
0	0	1	1	0	0	Divide-by-32	1024	32768
				0	1		4096	131072
				1	0		8192	262144
				1	1		16384	524288
0	1	0	0	0	0	Divide-by-64	1024	65536
				0	1		4096	262144
				1	0		8192	524288
				1	1		16384	1048576
1	1	1	1	0	0	Divide-by-128	1024	131072
				0	1		4096	524288
				1	0		8192	1048576
				1	1		16384	2097152
0	1	0	1	0	0	Divide-by-256	1024	262144
				0	1		4096	1048576
				1	0		8192	2097152
				1	1		16384	4194304

CKS[3:0] Bits (Clock Divide Ratio Select)

These bits select the IWDTCLK clock divide ratio from among divide-by 1, 16, 32, 64, 128, and 256. Combination with the TOPS[1:0] bit setting, a count period between 1024 and 4194304 cycles of the IWDTCLK clock can be selected for the IWDT.

RPES[1:0] Bits (Window End Position Select)

These bits select 75%, 50%, 25% or 0% of the count period for the window end position of the counter. The window end position should be a value smaller than the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is enabled.
The counter values for the window start and end positions selected by setting the RPSS[1:0] and RPES[1:0] bits change depending on the TOPS[1:0] bit setting.
Table 34.3 lists the counter values for the window start and end positions corresponding to TOPS[1:0] bit values.

Table 34.3 Relationship between Timeout Period and Window Start and End Counter Values

TOPS[1:0] Bits		Timeout Period		Window Start and End Counter Value			
b1	b0	Cycles	Counter Value	100%	75%	50%	25%
0	0	1024	03FFh	03FFh	02FFh	01FFh	00FFh
0	1	4096	0FFFh	0FFFh	0BFFh	07FFh	03FFh
1	0	8192	1FFFh	1FFFh	17FFh	0FFFh	07FFh
1	1	16384	3FFFh	3FFFh	2FFFh	1FFFh	0FFFh

RPSS[1:0] Bits (Window Start Position Select)

These bits select a counter window start position from 100%, 75%, 50%, or 25% of the count period (100% when the count starts and 0% when the counter underflows). The interval between the window start position and window end position is the refresh-permitted period and the other periods are refresh-prohibited periods.
Figure 34.2 shows the relationship between of the RPSS[1:0] and RPES[1:0] bit setting and the refresh-permitted and refresh-prohibited periods.

RPSS[1:0] Bits		RPES[1:0] Bits		Window	
b13	b12	b9	b8	Start (%)	End (%)
1	1	1	1	100	0
		1	0		25
		0	1		50
		0	0		75
1	0	1	1	75	0
		1	0		25
		0	1		50
		0	0		75
0	1	1	1	50	0
		1	0		25
		0	1		50
		0	0		75
0	0	1	1	25	0
		1	0		25
		0	1		50
		0	0		75

Note: If window end setting is greater than or equal to window start setting, the window end setting is set to 0%.

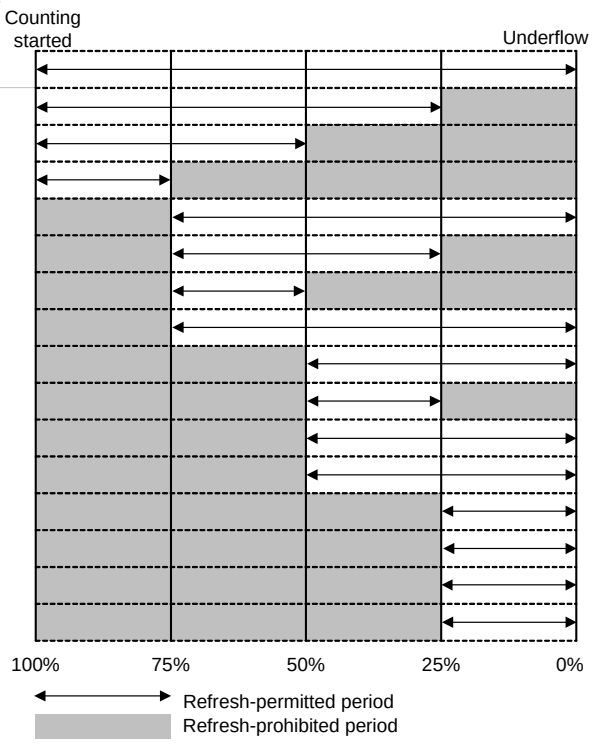

Figure 34.2 RPSS[1:0] and RPES[1:0] Bit Settings and the Refresh-Permitted Period

34.2.3 IWDT Status Register (IWDTSR)

Address(es): IWDT.IWDTSR 0008 8034h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	REFEF	UNDFF	CNTVAL[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b13 to b0	CNTVAL[13:0]	Counter Value	Value counted by the counter	R
b14	UNDFF	Underflow Flag	0: No underflow occurred 1: Underflow occurred	R/(W) *1
b15	REFEF	Refresh Error Flag	0: No refresh error occurred 1: Refresh error occurred	R/(W) *1

Note 1. Only 0 can be written to clear the flag.

The IWDTSR register is initialized by the reset source of the IWDT. The IWDTSR register is not initialized by other reset sources.

CNTVAL[13:0] Bits (Counter Value)

These bits are used to confirm the counter value of the counter, but note that the read value may differ from the actual count by a value of one count.

UNDFF Flag (Underflow Flag)

This bit is used to confirm whether or not an underflow has occurred in the counter.
The value 1 indicates that the counter has underflowed. The value 0 indicates that the counter has not underflowed.
Write 0 to the UNDFF flag to set the value to 0. Writing 1 has no effect.

REFEF Flag (Refresh Error Flag)

This bit is used to confirm whether or not a refresh error (performing a refresh operation during a refresh-prohibited period).
The value 1 indicates that a refresh error has occurred. The value 0 indicates that no refresh error has occurred.
Write 0 to the REFEF flag to set the value to 0. Writing 1 has no effect.

34.2.4 IWDT Reset Control Register (IWDTRCR)

Address(es): IWDT.IWDTRCR 0008 8036h

	b7	b6	b5	b4	b3	b2	b1	b0
	RSTIRQS	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R
b7	RSTIRQS	Reset Interrupt Request Select	0: Non-maskable interrupt request or interrupt request output is enabled. 1: Reset output is enabled.	R/W

There are some restrictions on writing to the IWDTRCR register. For details, refer to section 34.3.2, Control over Writing to the IWDTCR, IWDTRCR, and IWDTCSTPR Registers.

In auto-start mode, the IWDTRCR register setting are disabled, and the settings in option function select register 0 (OFS0) are enabled. The bit setting mode to the IWDTRCR register can also be made in option function select register 0. For details, refer to section 34.3.8, Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers.

34.2.5 IWDT Count Stop Control Register (IWDTCSTPR)

Address(es): IWDT.IWDTCSTPR 0008 8038h

	b7	b6	b5	b4	b3	b2	b1	b0
	SLCSTP	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R
b7	SLCSTP	Sleep Mode Count Stop Control	0: Count stop is disabled. 1: Count is stopped at a transition to sleep mode, software standby mode, deep software standby mode, or all-module clock stop mode.	R/W

The IWDTCSTPR register controls whether to stop the IWDT counter in a low power consumption state. There are some restrictions on writing to the IWDTCSTPR register. For details, refer to section 34.3.2, Control over Writing to the IWDTCR, IWDTRCR, and IWDTCSTPR Registers.

In auto-start mode, the IWDTCSTPR register setting are disabled, and the settings in option function select register 0 (OFS0) are enabled. The bit setting mode to the IWDTCSTPR register can also be made in option function select register 0 (OFS0). For details, refer to section 34.3.8, Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers.

SLCSTP Bit (Sleep Mode Count Stop Control)

This bit selects whether to stop counting at a transition to sleep mode, software standby mode, deep software standby mode, or all-module clock stop mode.

34.2.6 Option Function Select Register 0 (OFS0)

For option function select register 0 (OFS0), refer to section 34.3.8, Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers.

34.3 Operation

34.3.1 Count Operation in Each Start Mode

Select the IWDT start mode by setting the IWDT start mode select bit (OFS0.IWDTSTRT) in option function select register 0.
When the OFS0.IWDTSTRT bit is 1 (register start mode), the IWDT control register (IWDTCR), IWDT reset control register (IWDTRCR), and IWDT count stop control register (IWDTCSTPR) are enabled, and counting is started by refreshing (writing) the IWDT refresh register (IWDTRR). When the OFS0.IWDTSTRT bit is 0 (auto-start mode), the setting of option function select register 0 (OFS0) is enabled, and counting automatically starts after reset.

34.3.1.1 Register Start Mode

When the IWDT start mode select bit (OFS0.IWDTSTRT) in option function select register 0 is 1, register start mode is selected, and the IWDT control register (IWDTCR), IWDT reset control register (IWDTRCR), and IWDT count stop control register (IWDTCSTPR) are enabled.
After the reset state is released, set the clock divide ratio, window start and end positions, and timeout period in the IWDTCR register, the reset output or interrupt request output in the IWDTRCR register, and the counter stop control at transitions to low power consumption states in the IWDTCSTPR register. Then refresh the counter to start counting down from the value selected by setting the timeout period select bits (IWDTCR.TOPS[1:0]).
Thereafter, as long as the program continues normal operation and the counter is refreshed in the refresh-permitted period, the value in the counter is re-set each time the counter is refreshed and counting down continues. The IWDT does not output the reset signal as long as this continues. However, if the counter underflows because the counter cannot be refreshed due to a program runaway, or if a refresh error occurs because the counter was refreshed outside the refresh-permitted period, the IWDT outputs a reset signal or a non-maskable interrupt request/interrupt request (IWUNI). Set the IWDT reset interrupt request select bit (IWDTRCR.RSTIRQS) to select either reset output or interrupt request output.

Figure 34.3 shows an example of operation under the following conditions.

- The IWDT start mode select bit (OFS0.IWDTSTRT) is 1 (register start mode)
- The IWDT reset interrupt request select bit (IWDTRCR.RSTIRQS) is 1 (reset output is enabled)
- The IWDT window start position select bits (IWDTCR.RPSS[1:0]) are 10b (75%)
- The IWDT window end position select bits (IWDTCR.RPES[1:0]) are 10b (25%)

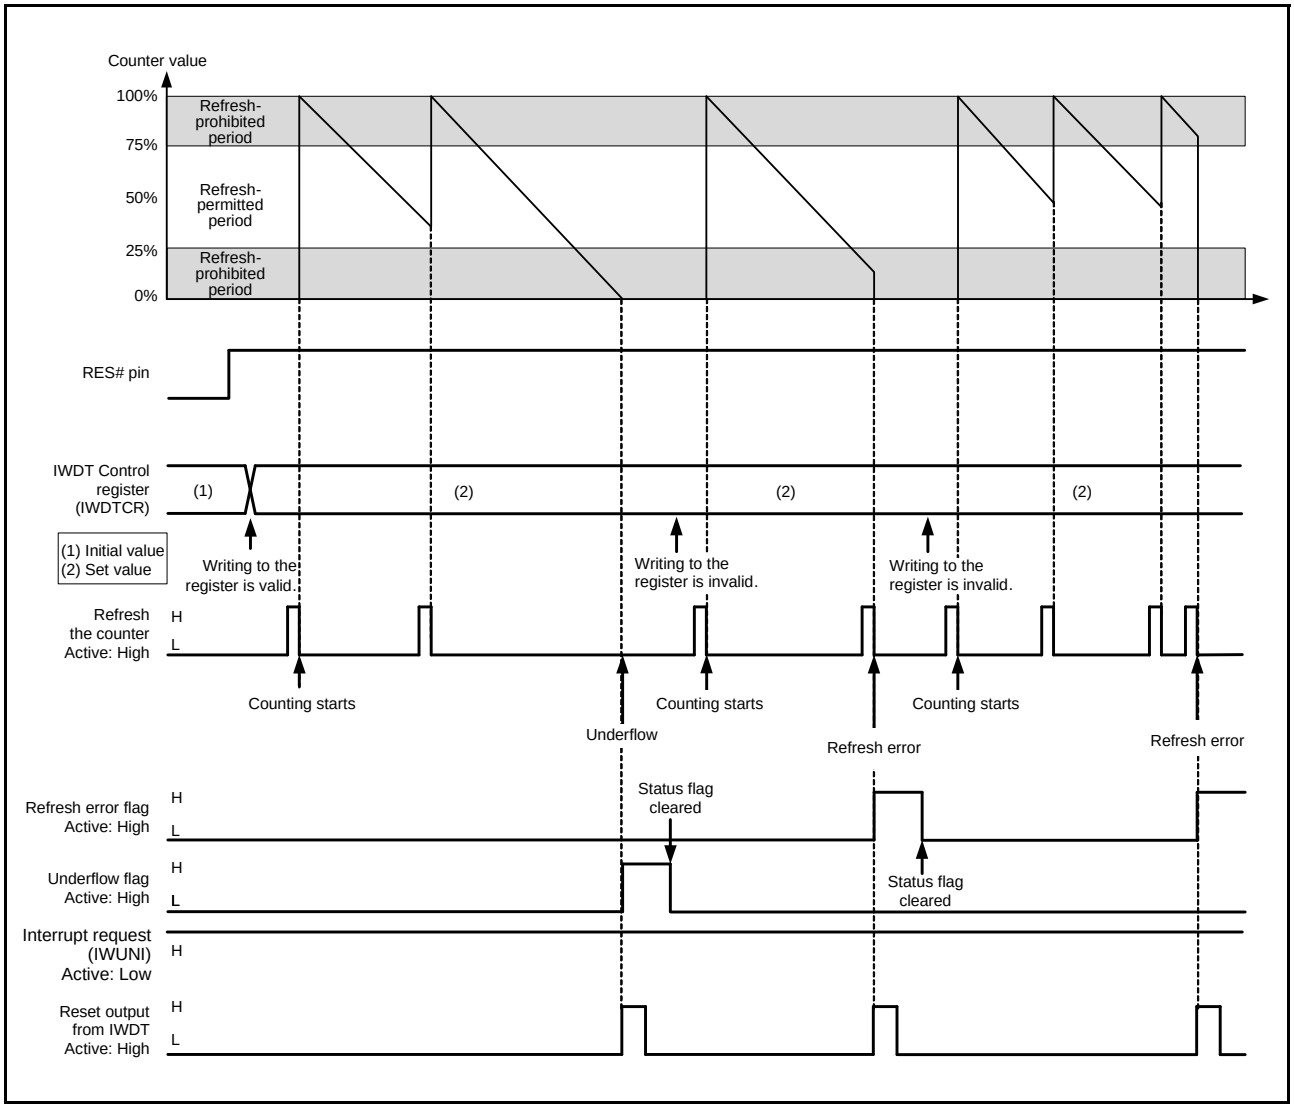

Figure 34.3 Operation Example in Register Start Mode

34.3.1.2 Auto-Start Mode

When the IWDT start mode select bit (OFS0.IWDTSTRT) in option function select register 0 is 0, auto-start mode is selected, and the IWDT control register (IWDTCR), IWDT reset control register (IWDTRCR), and IWDT count stop control register (IWDTCSTPR) are disabled.
Within the reset state, the clock divide ratio, window start and end positions, timeout period, reset output or interrupt request output, and counter stop control at transitions to low power consumption states are set using the values specified in option function select register 0 (OFS0). When the reset state is released, the counter automatically starts counting down from the value selected by the IWDT timeout period select bits (OFS0.IWDTTOPS[1:0]).
After that, as long as the program continues normal operation and the counter is refreshed in the refresh-permitted period, the value in the counter is re-set each time the counter is refreshed and counting down continues. The IWDT does not output the reset signal as long as this continues. However, if the counter underflows because refreshing of the counter is not possible due to the program having entered crashed execution or if a refresh error occurs due to refreshing outside the refresh-permitted period, the IWDT outputs the reset signal or non-maskable interrupt request/interrupt request (IWUNI). After the reset signal or non-maskable interrupt request/interrupt request (IWUNI) is generated, the counter reloads the timeout period after counting for one cycle, and restarts counting. Set the IWDT reset interrupt request select bit (OFS0.IWDTRSTIRQS) to select either reset output or interrupt request output.

Figure 34.4 shows an example of operation under the following conditions.

- The IWDT start mode select bit (OFS0.IWDTSTRT) is 0 (auto-start mode)
- The IWDT reset interrupt request select bit (OFS0.IWDTRSTIRQS) is 0 (non-maskable interrupt request output is enabled)
- The IWDT window start position select bits (OFS0.IWDTRPSS[1:0]) are 10b (75%)
- The IWDT window end position select bits (OFS0.IWDTRPES[1:0]) are 10b (25%)

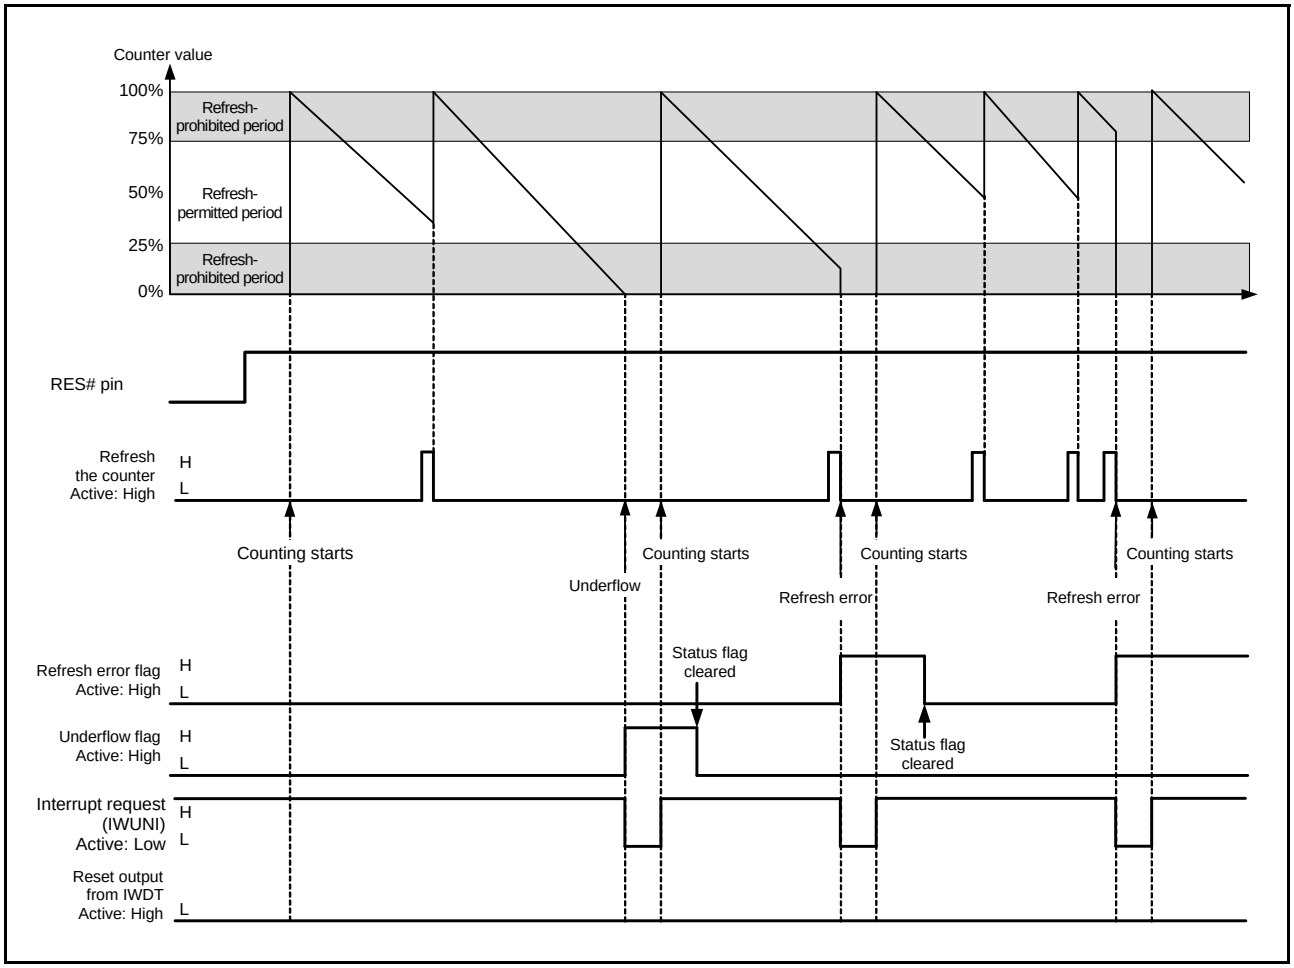

Figure 34.4 Operation Example in Auto-Start Mode

34.3.2 Control over Writing to the IWDTCR, IWDTRCR, and IWDTCSTPR Registers

Writing to the IWDT control register (IWDTCR), IWDT reset control register (IWDTRCR), or IWDT count stop control register (IWDTCSTPR) is only possible once between the release from the reset state and the first refresh operation. After a refresh operation (counting starts) or the IWDTCR, IWDTRCR, or IWDTCSTPR register is written to, the protection signal in the IWDT becomes 1 to protect registers IWDTCR, IWDTRCR, and IWDTCSTPR against subsequent attempts at writing.

This protection is released by the reset source of the IWDT. With other reset sources, the protection is not released.

Figure 34.5 shows control waveforms produced in response to writing to the IWDTCR register.

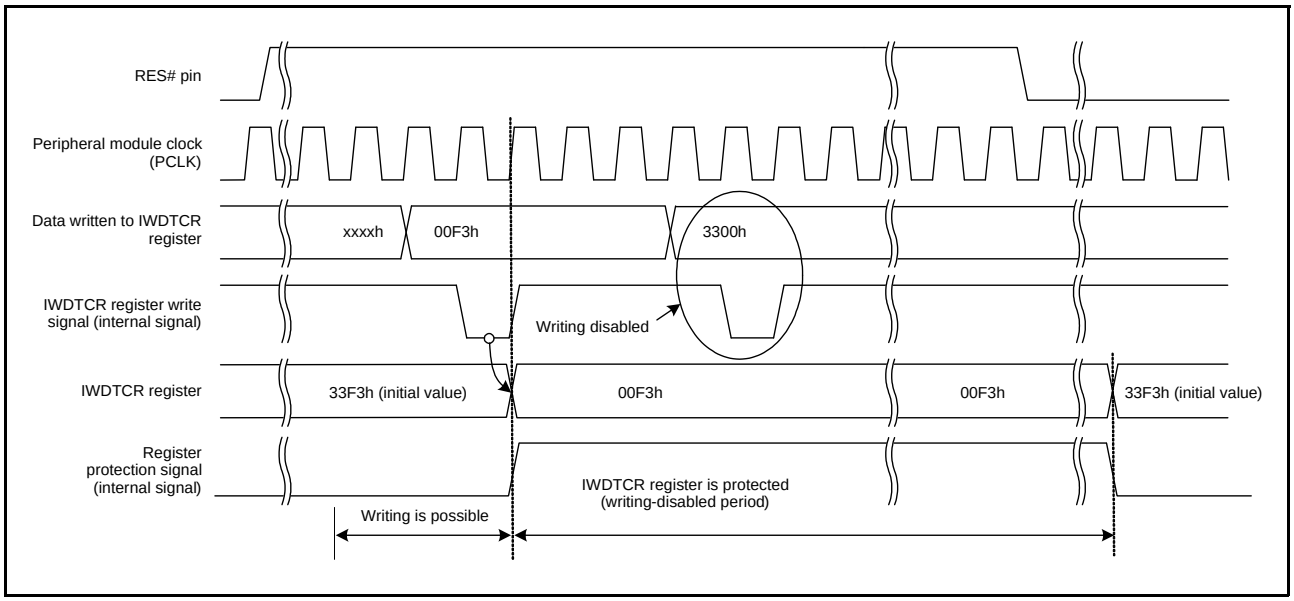

Figure 34.5 Control Waveforms Produced in Response to Writing to the IWDTCR Register

34.3.3 Refresh Operation

The counter is refreshed and starts operation (counting is started by refreshing) by writing the values 00h and then FFh to the IWDT refresh register (IWDTRR). If a value other than FFh is written after 00h, the counter is not refreshed. After such invalid writing, correct refreshing is performed by again writing 00h and then FFh to the IWDT refresh register (IWDTRR).
When writing is done in the order of 00h (first time) → 00h (second time), and if FFh is written after that, the writing order 00h → FFh is satisfied; writing 00h (n–1-th time) → 00h (nth time) → FFh is valid and correct refreshing will be done. Even when the first value written before 00h is not 00h, correct refreshing will be done if the operation contains the set of writing 00h → FFh. Moreover, even if a register other than the IWDTRR register is accessed or the IWDTRR register is read between writing 00h and writing FFh to the IWDTRR register, correct refreshing will be done.

[Sample sequences of writing that are valid for refreshing the counter]

- 00h → FFh
- 00h (n–1-th time) → 00h (nth time) → FFh
- 00h → access to another register or read from the IWDTRR register → FFh

[Sample sequences of writing that are not valid for refreshing the counter]

- 23h (a value other than 00h) → FFh
- 00h → 54h (a value other than FFh)
- 00h → AAh (00h and a value other than FFh) → FFh

Even when 00h is written to the IWDTRR register outside the refresh-permitted period, if FFh is written to the IWDTRR register in the refresh-permitted period, the writing sequence is valid and refreshing will be done.
After FFh is written to the IWDTRR register, refreshing the counter requires up to four cycles of the signal for counting (the clock divide ratio selection bits (IWDTCR.CKS[3:0]) determine how many cycles of the IWDT-dedicated clock (IWDTCLK) make up one cycle for counting). Therefore, writing FFh to the IWDTRR register should be completed four-count cycles before the end position of the refresh-permitted period or a counter underflow. The value of the counter can be checked by the counter bits (IWDTSR.CNTVAL[13:0]).

[Sample refreshing timings]

- When the window start position is set to 1FFFh, even if 00h is written to the IWDTRR register before 1FFFh is reached (2002h, for example), refreshing is done if FFh is written to the IWDTRR register after the value of the IWDTSR.CNTVAL[13:0] bits has reached 1FFFh.
- When the window end position is set to 1FFFh, refreshing is done if 2003h (four-count cycles before 1FFFh) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 00h → FFh to the IWDTRR register.
- When the refresh-permitted period continues until count 0000h, refreshing can be done immediately before an underflow. In this case, if 0003h (four-count cycles before an underflow) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 00h → FFh to the IWDTRR register, no underflow occurs and refreshing is done.

Figure 34.6 shows the IWDT refresh-operation waveforms when PCLK > IWDTCLK and clock divide ratio = IWDTCLK.

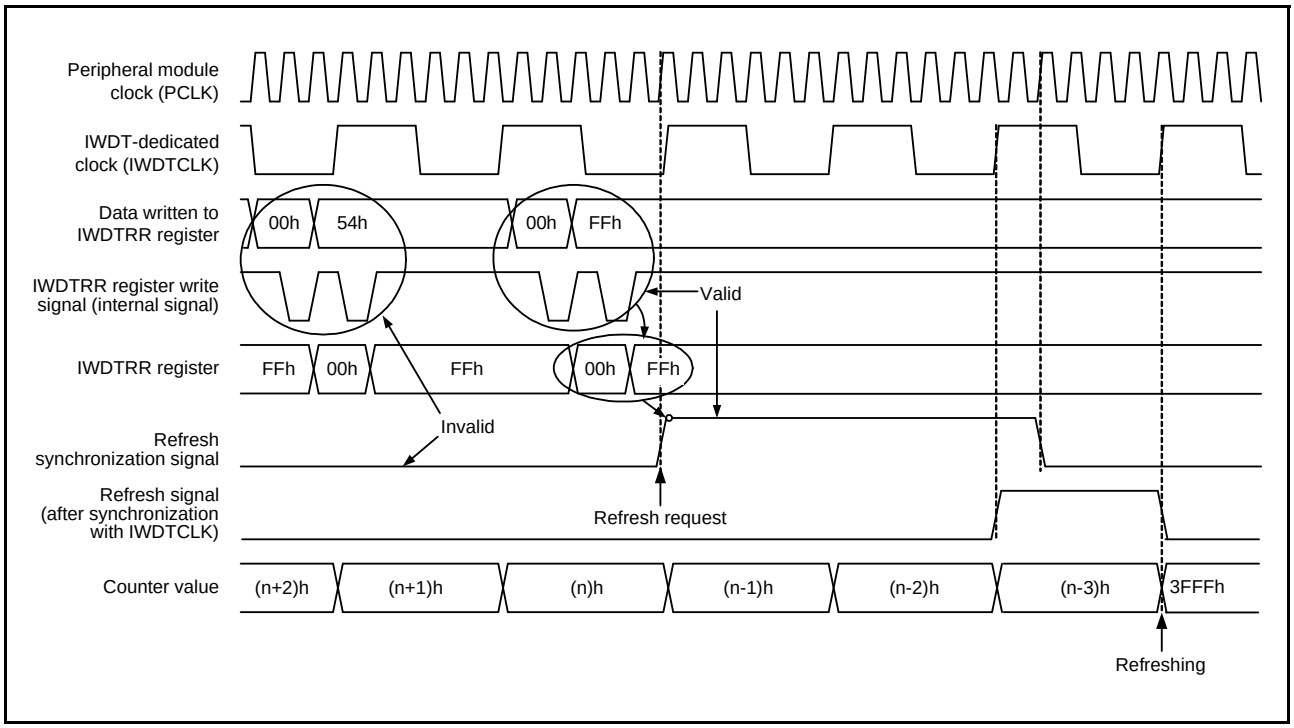

Figure 34.6 IWDT Refresh Operation Waveforms (IWDTCR.CKS[3:0] = 0000b, IWDTCR.TOPS[1:0] = 11b)

34.3.4 Status Flags

The refresh error (IWDTSR.REFEF) and underflow (IWDTSR.UNDFF) flags retain the source of the reset signal output from the IWDT or the source of the interrupt request from the IWDT.
Thus, after release from the reset state or interrupt request generation, read the IWDTSR.REFEF and IWDTSR.UNDFF flags to check for the reset or interrupt source.
For each flag, writing 0 clears the bit and writing 1 has no effect.
Leaving the status flags unchanged does not affect operation. If the flags are not cleared, at the time of the next reset or interrupt request from the IWDT, the earlier reset or interrupt source is cleared and the new reset or interrupt source is written.
After 0 is written to each flag, up to three IWDTCLK cycles and two PCLK cycles are required before the value is reflected.

34.3.5 Reset Output

When the reset interrupt selection bit (IWDTRCR.RSTIRQS) is set to 1 in register start mode or when the IWDT reset interrupt request select bit (OFS0.IWDTRSTIRQS) in option function select register 0 (OFS0) is set to 1 in auto-start mode, a reset signal is output when an underflow in the counter or a refresh error occurs.
In register start mode, the counter is initialized (all bits set to 0) and kept in that state after assertion of the reset signal. After the reset is released and the program is restarted, the counter is set up again and counting down is started by refreshing.
In auto-start mode, counting down automatically starts after the reset output.

34.3.6 Interrupt Sources

When the reset interrupt selection bit (IWDTRCR.RSTIRQS) is set to 0 in register start mode or when the IWDT reset interrupt request select bit (OFS0.IWDTRSTIRQS) in option function select register 0 (OFS0) is set to 0 in auto-start mode, an interrupt (IWUNI) signal is output when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt and an interrupt. For details, refer to section 15, Interrupt Controller (ICUA).

Table 34.4 IWDT Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
IWUNI	Counter underflow Refresh error	Not possible	Not possible

34.3.7 Reading the Counter Value

As the counter in IWDT-dedicated clock (IWDTCLK), the counter value cannot be read directly. The IWDT synchronizes the counter value with the peripheral module clock (PCLK) and stores it in the counter value bits (IWDTSR.CNTVAL[13:0]) of the IWDT status register. Thus, the counter value can be checked indirectly through the IWDTSR.CNTVAL[13:0] bits.

Reading the counter value requires multiple PCLK clock cycles (up to four clock cycles), and the read counter value may differ from the actual counter value by a value of one count.

Figure 34.7 shows the processing for reading the IWDT counter value when PCLK > IWDTCLK and clock divide ratio = IWDTCLK.

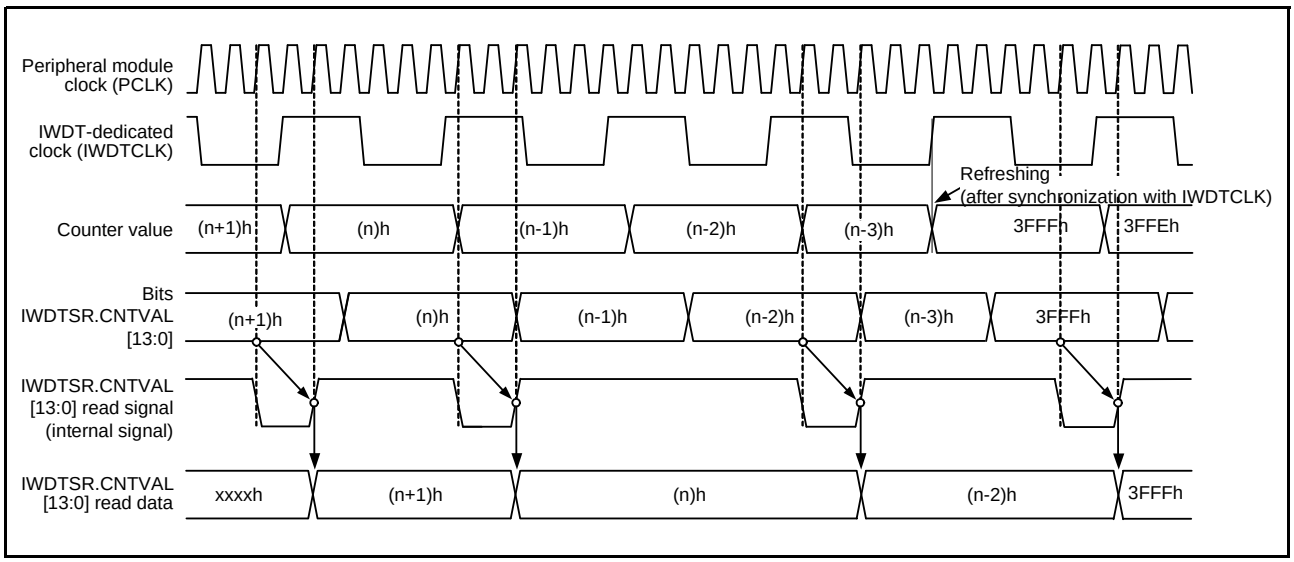

Figure 34.7 Processing for Reading IWDT Counter Value (IWDTCR.CKS[3:0] = 0000b, IWDTCR.TOPS[1:0] = 11b)

34.3.8 Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers

Table 34.5 lists the correspondence between option function select register 0 (OFS0) used in auto-start mode and the registers used in register start mode.
Do not change the OFS0 register setting during IWDT operation.
For details on option function select register 0 (OFS0), refer to section 7.2.3, Option Function Select Register 0 (OFS0).

Table 34.5 Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers

Target of Control	Function	OFS0 Register (Enabled in Auto-Start Mode) OFS0.IWDTSTRT = 0	IWDT Registers (Enabled in Register Start Mode) OFS0.IWDTSTRT = 1
Counter	Timeout period selection	OFS0.IWDTTOPS[1:0]	IWDTCR.TOPS[1:0]
	Clock frequency divide ratio selection	OFS0.IWDTCKS[3:0]	IWDTCR.CKS[3:0]
	Window start position selection	OFS0.IWDTRPSS[1:0]	IWDTCR.RPSS[1:0]
	Window end position selection	OFS0.IWDTRPES[1:0]	IWDTCR.RPES[1:0]
Reset output or interrupt request output	Reset output or interrupt request output selection	OFS0.IWDTRSTIRQS	IWDTRCR.RSTIRQS
Count stop	Sleep mode count stop control	OFS0.IWDTSLCSTP	IWDTCSTPR.SLCSTP

34.4 Link Operation by ELC

The IWDT is capable of link operation for the previously specified module when interrupt request signal is used as an event signal by the event link controller (ELC). The event signal is output by the counter underflow and refresh error. An event signal is output regardless of the setting of the reset interrupt request selection bit (IWDTRCR.RSTIRQS) in register start mode or auto-start mode. An event signal can also be output upon generation of the next interrupt source while the refresh error flag (IWDTSR.REFEF) or underflow flag (IWDTSR.UNDFF) is 1.
For details, see section 21, Event Link Controller (ELC).

34.5 Usage Notes

34.5.1 Refresh Operations

When making the settings to control the timing of refreshing, consider variations in the range of errors due to the accuracy of the PCLK and IWDTCLK and set values which ensure that refreshing is possible.

34.5.2 Clock Divide Ratio Setting

Satisfy the frequency of the peripheral module clock (PCLK) ≥ 4 × (the frequency of the count source after divide).

35. Ethernet Controller (ETHERC)

35.1 Overview

This MCU has a two-channel Ethernet controller (ETHERC) compliant with the Ethernet or IEEE802.3 Media Access Control (MAC) layer protocol. Each ETHERC channel has one channel of the MAC layer interface, and connecting the MCU to the physical layer LSI (PHY-LSI) allows transmission and reception of frames compliant with the Ethernet/IEEE802.3 standard. The ETHERC is connected to the Ethernet controller direct memory access controller (EDMAC), so data can be transferred without using the CPU.

Table 35.1 lists the ETHERC specifications. Figure 35.1 shows the ETHERC configuration. Table 35.2 lists the ETHERC I/O pins.

Figure 35.2 and Figure 35.3 show examples of connecting the MCU to the PHY-LSI.

Table 35.1 ETHERC Specifications

Item	Description
Number of channels	Two channels
Protocol	Flow control compliant with IEEE802.3x
Data transmission/reception	Frames compliant with the Ethernet/IEEE802.3 standard can be transmitted and received.
Bit rate	Supports 10 Mbps and 100 Mbps
Operation modes	Supports full-duplex and half-duplex modes
Interfaces	Media Independent Interface (MII), Reduced Media Independent Interface (RMII), compliant with the IEEE802.3u standard
Functions	Magic Packet™ *1 detection, Wake-On-LAN (WOL) signal output

Note 1. Magic Packet is a trademark of Advanced Micro Devices, Inc.

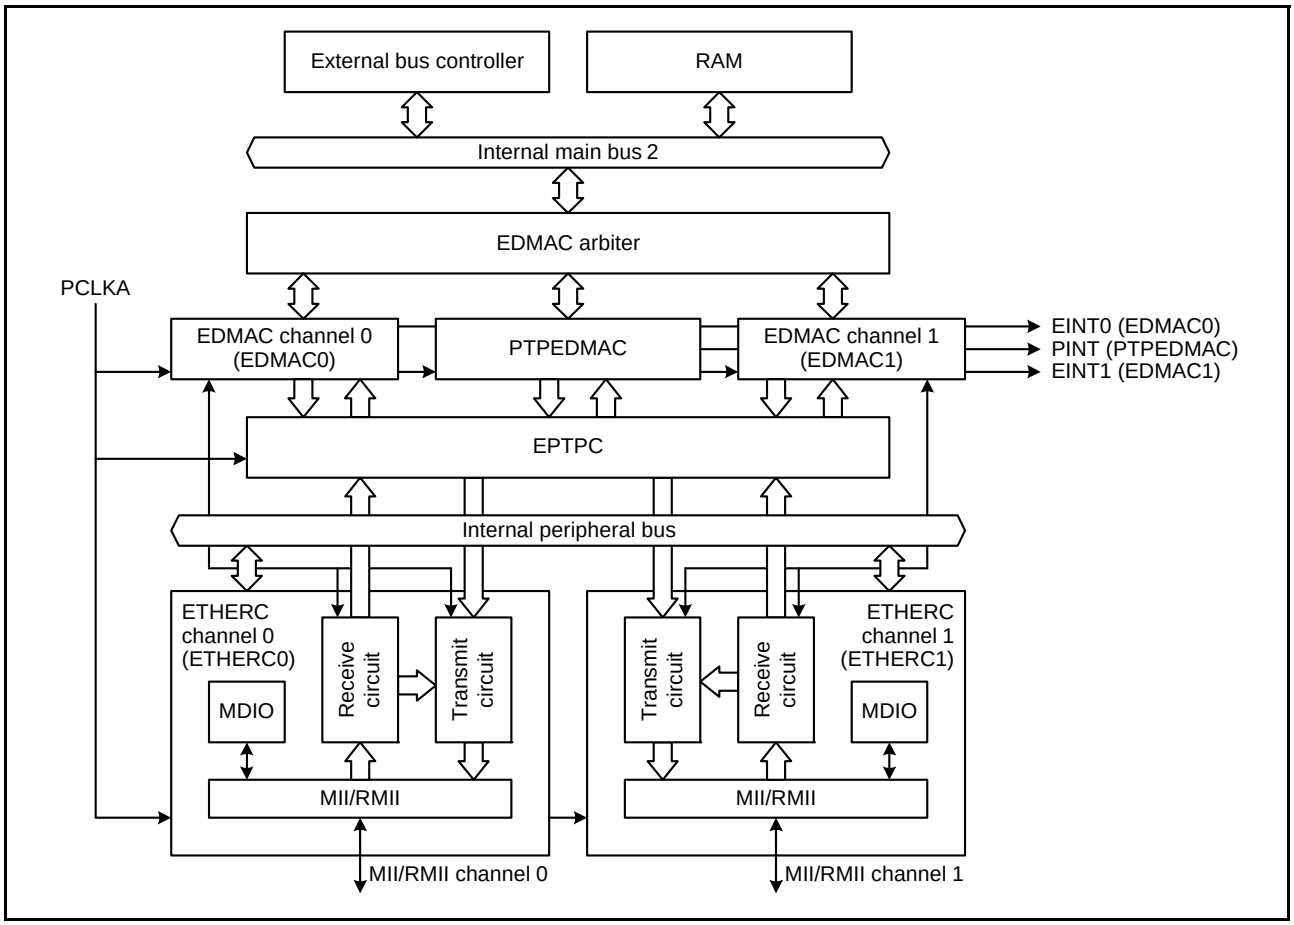

Figure 35.1 ETHERC Configuration

Table 35.2 ETHERC I/O Pins (n = 0, 1)

Operating Mode	Pin Name	I/O	Description
MII	ETn_TX_CLK *1	Input	Transmit clock Timing reference signal for outputting the ETn_TX_EN, ETn_ETXD3 to ETn_ETXD0, and ETn_TX_ER signals.
	ETn_RX_CLK *1	Input	Receive clock Timing reference signal for inputting the ETn_RX_DV, ETn_ERXD3 to ETn_ERXD0, and ETn_RX_ER signals.
	ETn_TX_EN *1	Output	Transmit data valid This signal indicates that valid transmit data has been output on pins ETn_ETXD3 to ETn_ETXD0.
	ETn_ETXD3 to ETn_ETXD0 *1	Output	4-bit transmit data
	ETn_TX_ER *1	Output	Transmit error This signal notifies the PHY-LSI that an error occurred during transmission.
	ETn_RX_DV *1	Input	Receive data valid This signal indicates that valid receive data is on pins ETn_ERXD3 to ETn_ERXD0.
	ETn_ERXD3 to ETn_ERXD0 *1	Input	4-bit receive data
	ETn_RX_ER *1	Input	Receive error This signal indicates that there is an error in a frame that is being transferred from the PHY-LSI to the ETHERC.
	ETn_CRS *1	Input	Carrier sense
	ETn_COL *1	Input	Collision detection signal
	ETn_MDC *1	Output	Management data clock Reference clock signal for transfer of information on the ETn_MDIO pin.
	ETn_MDIO *1	I/O	Management data I/O Bidirectional data signal for exchanging management data with the PHY-LSI.
	ETn_LINKSTA	Input	Link status input from the PHY-LSI
	ETn_EXOUT	Output	General output pin
	ETn_WOL	Output	Wake-On-LAN. This signal indicates that a Magic Packet has been received.
RMII	REF50CKn *2	Input	Reference clock Timing reference signal for pins RMIIn_TXD_EN, RMIIn_TXD1 to RMIIn_TXD0, RMIIn_CRS_DV, RMIIn_RXD1 to RMIIn_RXD0, and RMIIn_RX_ER.
	RMIIn_TXD_EN *2	Output	Transmit data valid This signal indicates that valid transmit data has been output on pins RMIIn_TXD1 and RMIIn_TXD0.
	RMIIn_TXD1 to RMIIn_TXD0 *2	Output	2-bit transmit data
	RMIIn_CRS_DV *2	Input	Carrier sense/receive data valid This signal indicates that valid receive data is on pins RMIIn_RXD1 and RMIIn_RXD0.
	RMIIn_RXD1 to RMIIn_RXD0 *2	Input	2-bit receive data
	RMIIn_RX_ER *2	Input	Receive error This signal indicates that there is an error in a frame that is being transferred from the PHY-LSI to the ETHERC.
	ETn_MDC *2	Output	Management data clock Reference clock signal for transfer of information on the ETn_MDIO pin
	ETn_MDIO *2	I/O	Management data I/O Bidirectional data signal for exchanging management data with the PHY-LSI.
	ETn_LINKSTA	Input	Link status input from the PHY-LSI.
	ETn_EXOUT	Output	General output pin
	ETn_WOL	Output	Wake-On-LAN. This signal indicates that a Magic Packet has been received.

Note 1. MII signal compliant with IEEE802.3u
Note 2. RMII signal compliant with IEEE802.3u

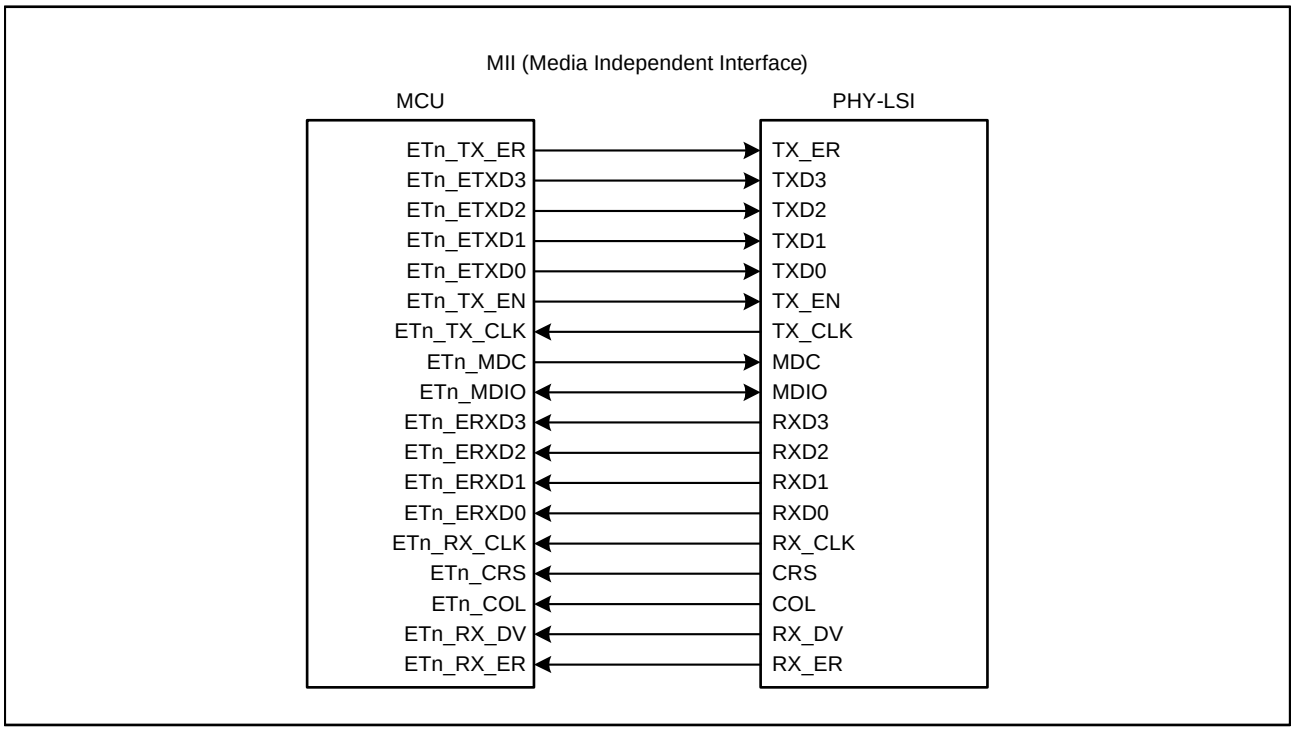

Figure 35.2 Example of Connection with the PHY-LSI for the MII

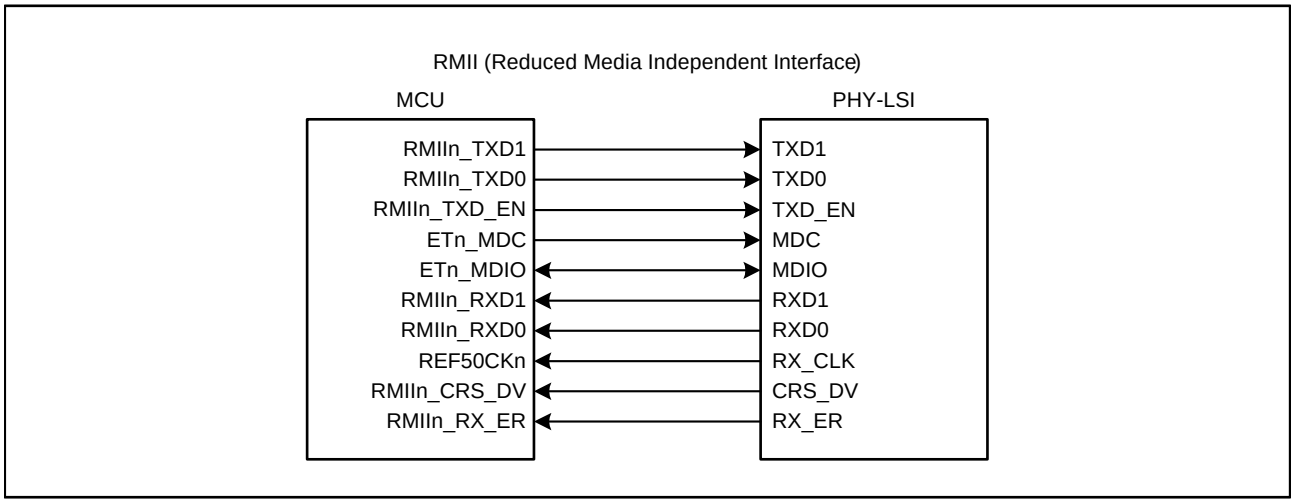

Figure 35.3 Example of Connection with the PHY-LSI for the RMII

35.2 Register Descriptions

35.2.1 ETHERC Mode Register (ECMR)

Address(es): ETHERC0.ECMR 000C 0100h, ETHERC1.ECMR 000C 0300h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	TPC	ZPF	PFR	RXF	TXF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	PRCEF	—	—	MPDE	—	—	RE	TE	—	ILB	RTM	DM	PRM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PRM	Promiscuous Mode	0: Promiscuous mode is disabled. 1: Promiscuous mode is enabled.	R/W
b1	DM	Duplex Mode	0: Half-duplex mode 1: Full-duplex mode	R/W
b2	RTM	Bit Rate	0: 10 Mbps 1: 100 Mbps	R/W
b3	ILB	Internal Loopback Mode	0: Normal data transmission or reception is performed. 1: Data is looped back in the ETHERC when full-duplex mode is selected.	R/W
b4	—	Reserved	The read value is 0. The write value should be 0.	R/W
b5	TE	Transmission Enable	0: Transmit function is disabled. 1: Transmit function is enabled.	R/W
b6	RE	Reception Enable	0: Receive function is disabled. 1: Receive function is enabled.	R/W
b8, b7	—	Reserved	The read value is 0. The write value should be 0.	R/W
b9	MPDE	Magic Packet Detection Enable	0: Magic Packet detection is disabled. 1: Magic Packet detection is enabled.	R/W
b11, b10	—	Reserved	The read value is 0. The write value should be 0.	R/W
b12	PRCEF	CRC Error Frame Receive Mode	0: EDMAC is notified of a CRC error. 1: EDMAC is not notified of a CRC error.	R/W
b15 to b13	—	Reserved	The read value is 0. The write value should be 0.	R/W
b16	TXF	Transmit Flow Control Operating Mode	0: Automatic PAUSE frame transmission is disabled. (PAUSE frame is not automatically transmitted.) 1: Automatic PAUSE frame transmission is enabled. (PAUSE frame is automatically transmitted as required.)	R/W
b17	RXF	Receive Flow Control Operating Mode	0: PAUSE frame detection is disabled. 1: PAUSE frame detection is enabled.	R/W
b18	PFR	PAUSE Frame Receive Mode	0: PAUSE frame is not transferred to the EDMAC. 1: PAUSE frame is transferred to the EDMAC.	R/W
b19	ZPF	0 Time PAUSE Frame Enable	0: PAUSE frame that contains the pause_time parameter of 0 is not used. 1: PAUSE frame that contains the pause_time parameter of 0 is used.	R/W
b20	TPC	PAUSE Frame Transmit	0: PAUSE frame is transmitted even during a PAUSE period. 1: PAUSE frame is not transmitted during a PAUSE period.	R/W
b31 to b21	—	Reserved	The read value is 0. The write value should be 0.	R/W

The ECMR register controls the ETHERC operation.

Set bits in the ECMR register, excluding bits TE and RE, during initialization after a reset. When rewriting this register

outside the initialization process, set the EDMACn.EDMR.SWR bit to 1 to reset the EDMAC and ETHERC, and then set this register again.

PRM Bit (Promiscuous Mode)

When the PRM bit is set to 1, the ETHERC operates in promiscuous mode where all Ethernet frames are received. In promiscuous mode, the ETHERC receives all valid frames regardless of whether or not the address matches the destination address or broadcast address and regardless of the multicast bit setting.

RTM Bit (Bit Rate)

The RTM bit sets the bit rate when the RMII is selected.

ILB Bit (Internal Loopback Mode)

When the ILB bit is set to 1, transmit frames can be looped back in the MCU. Set the DM bit to 1 (full-duplex mode) to perform a loopback test.

TE Bit (Transmission Enable)

When the TE bit is set to 1, the ETHERC transmit function is enabled.
When the TE bit is set to 0, the transmit function is disabled after the frame being processed is completely transmitted.

RE Bit (Reception Enable)

When the RE bit is set to 1, the ETHERC receive function is enabled.
When the RE bit is set to 0, the receive function is disabled after the frame being processed is completely received.

PRCEF Bit (CRC Error Frame Receive Mode)

When the PRCEF bit is set to 1, the EDMAC is not notified that a CRC error has occurred even when the error is detected in a receive frame. Accordingly, the EDMACn.EESR.CERF flag and RFS0 bit in receive descriptor 0 (RD0) do not become 1.

ZPF Bit (0 Time PAUSE Frame Enable)

When the ZPF bit is 1, a PAUSE frame that contains the pause_time parameter of 0 is transmitted when the PAUSE frame transmit request is canceled before the PAUSE time of the previously transmitted PAUSE frame has not elapsed. After the PAUSE frame that contains the pause_time parameter of 0 is received, the ETHERC is ready for transmission. When the ZPF bit is 0, even if the PAUSE frame transmit request from the receive FIFO is canceled, the next PAUSE frame is not transmitted until the PAUSE time of the previously transmitted PAUSE frame has elapsed. When a PAUSE frame that contains the pause_time parameter of 0 is received, the PAUSE frame is discarded.

35.2.2 Receive Frame Maximum Length Register (RFLR)

Address(es): ETHERC0.RFLR 000C 0108h, ETHERC1.RFLR 000C 0308h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	RFL[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	RFL[11:0]	Receive Frame Maximum Length	The set value becomes the maximum frame length. The minimum value that can be set is 1,518 bytes, and the maximum value that can be set is 2,048 bytes. Values that are less than 1,518 bytes are regarded as 1,518 bytes, and values larger than 2,048 bytes are regarded as 2,048 bytes.	R/W
b31 to b12	—	Reserved	The read value is 0. The write value should be 0.	R/W

The RFLR register sets the maximum frame length that can be received by the MCU. Set the length in bytes.
Do not rewrite this register while the ECMR.RE bit is 1 (receive function is enabled).

RFL[11:0] Bits (Receive Frame Maximum Length)

The RFL[11:0] bits set a frame length to be checked. When the number of bytes for fields from the destination address to the frame check sequence (FCS) of the received frame exceeds the RFL[11:0] bit value, the EDMAC is notified of a frame-too-long error.
When the received frame length exceeds the RFL[11:0] bit value, the excess data is discarded.

35.2.3 ETHERC Status Register (ECSR)

Address(es): ETHERC0.ECSR 000C 0110h, ETHERC1.ECSR 000C 0310h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	BFR	PSRTO	—	LCHNG	MPD	ICD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ICD	False Carrier Detect Flag	0: PHY-LSI has not detected a false carrier on the line. 1: PHY-LSI has detected a false carrier on the line.	R/W *1
b1	MPD	Magic Packet Detect Flag	0: Magic Packet has not been detected. 1: Magic Packet has been detected.	R/W *1
b2	LCHNG	Link Signal Change Flag	0: Change in the ETn_LINKSTA signal has not been detected. 1: Change in the ETn_LINKSTA signal has been detected (high to low, or low to high).	R/W *1
b3	—	Reserved	The read value is 0. The write value should be 0.	R/W
b4	PSRTO	PAUSE Frame Retransmit Over Flag	0: PAUSE frame retransmit count has not reached the upper limit. 1: PAUSE frame retransmit count has reached the upper limit.	R/W *1
b5	BFR	Continuous Broadcast Frame Reception Flag	0: The number of continuously received broadcast frames has not exceeded the value set in the BCFRR register. 1: The number of continuously received broadcast frames has exceeded the value set in the BCFRR register.	R/W *1
b31 to b6	—	Reserved	The read value is 0. The write value should be 0.	R/W

Note 1. Write 1 to clear the flag.

The ECSR register indicates the status of the ETHERC.
When any flag in the ECSR register becomes 1 while the corresponding bit in the ECSIPR register is 1 (interrupt is notified), the EDMACn.EESR.ECI flag becomes 1.

ICD Flag (False Carrier Detect Flag)

The ICD flag indicates that the PHY-LSI has detected a false carrier on the line.
The ICD flag becomes 1 when a receive error signal shown in Figure 35.11 is received from the PHY-LSI. Note that the information may not be correct when signals input from the PHY-LSI change faster than software recognizes the change. Check the timing of the PHY-LSI.

LCHNG Flag (Link Signal Change Flag)

The LCHNG flag indicates that ETn_LINKSTA signal input from the PHY-LSI has changed from high to low, or from low to high.
Refer to the PSR.LMON flag for the current link status.

PSRTO Flag (PAUSE Frame Retransmit Over Flag)

The PSRTO flag indicates that the number of retransmissions reaches the value set in the TPAUSER register when retransmitting a PAUSE frame while automatic PAUSE frame transmission is enabled.

35.2.4 ETHERC Interrupt Enable Register (ECSIPR)

Address(es): ETHERC0.ECSIPR 000C 0118h, ETHERC1.ECSIPR 000C 0318h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	BFSIPR	PSRTOIP	—	LCHNGIP	MPDIP	ICDIP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ICDIP	False Carrier Detect Interrupt Enable	0: Notification of the false carrier detect interrupt is disabled. 1: Notification of the false carrier detect interrupt is enabled.	R/W
b1	MPDIP	Magic Packet Detect Interrupt Enable	0: Notification of the Magic Packet detect interrupt is disabled. 1: Notification of the Magic Packet detect interrupt is enabled.	R/W
b2	LCHNGIP	LINK Signal Change Interrupt Enable	0: Notification of ETn_LINKSTA signal change interrupt is disabled. 1: Notification of ETn_LINKSTA signal change interrupt is enabled.	R/W
b3	—	Reserved	The read value is 0. The write value should be 0.	R/W
b4	PSRTOIP	PAUSE Frame Retransmit Over Interrupt Enable	0: Notification of PAUSE frame retransmit over interrupt is disabled. 1: Notification of PAUSE frame retransmit over interrupt is enabled.	R/W
b5	BFSIPR	Continuous Broadcast Frame Reception Interrupt Enable	0: Notification of continuous broadcast frame reception interrupt is disabled. 1: Notification of continuous broadcast frame reception interrupt is enabled.	R/W
b31 to b6	—	Reserved	The read value is 0. The write value should be 0.	R/W

The ECSIPR register selects whether or not to notify the EDMAC of the status indicated by the ECSR register. Each bit corresponds to the flag in the ECSR register that has the same bit number.

35.2.5 PHY Interface Register (PIR)

Address(es): ETHERC0.PIR 000C 0120h, ETHERC1.PIR 000C 0320h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	MDI	MDO	MMD	MDC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	x	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MDC	MII/RMII Management Data Clock	The MDC bit value is output from the ETn_MDC pin to supply the management data clock to the MII or RMII.	R/W
b1	MMD	MII/RMII Management Mode	0: Read 1: Write	R/W
b2	MDO	MII/RMII Management Data-Out	The MDO bit value is output from the ETn_MDIO pin when the MMD bit is 1 (write). The value is not output when the MMD bit is 0 (read).	R/W
b3	MDI	MII/RMII Management Data-In	This bit indicates the level of the ETn_MDIO pin. The write value should be 0.	R/W
b31 to b4	—	Reserved	The read value is 0. The write value should be 0.	R/W

The PIR register is used to access registers in the PHY-LSI via the MII or RMII. The management clock and management data are controlled by software.
Refer to section 35.3.4, Accessing MII/RMII Registers for details on accessing MII and RMII registers.

35.2.6 PHY Status Register (PSR)

Address(es): ETHERC0.PSR 000C 0128h, ETHERC1.PSR 000C 0328h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LMON
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	x

Bit	Symbol	Bit Name	Description	R/W
b0	LMON	ETn_LINKSTA Pin Status Flag	The link status can be read by connecting the link signal output from the PHY-LSI to the ETn_LINKSTA pin. For details on the polarity, refer to the specifications of the connected PHY-LSI.	R
b31 to b1	—	Reserved	The read value is 0. The write value should be 0.	R

The PSR register is used to monitor interface signals from the PHY-LSI.

35.2.7 Random Number Generation Counter Limit Setting Register (RDMLR)

Address(es): ETHERC0.RDMLR 000C 0140h, ETHERC1.RDMLR 000C 0340h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	RMD[19:16]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	RMD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b19 to b0	RMD[19:0]	Random Number Generation Counter	00000h: Normal operation 00001h to FFFFFh: Setting prohibited	R/W
b31 to b20	—	Reserved	The read value is 0. The write value should be 0.	R/W

The RDMLR register sets the maximum value for the counter used in the random number generator.
Do not rewrite this register while the ECMR.TE bit is 1 (transmit function is enabled) or while the ECMR.RE bit is 1 (receive function is enabled).

35.2.8 Interpacket Gap Register (IPGR)

Address(es): ETHERC0.IPGR 000C 0150h, ETHERC1.IPGR 000C 0350h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	IPG[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	IPG[4:0]	Interpacket Gap	00h: 16 bit time 01h: 20 bit time : : 14h: 96 bit time (initial value) : : 1Fh: 140 bit time	R/W
b31 to b5	—	Reserved	The read value is 0. The write value should be 0.	R/W

The IPGR register sets the interpacket gap (IPG) value.
Do not rewrite this register while the ECMR.TE bit is 1 (transmit function is enabled) or while the ECMR.RE bit is 1 (receive function is enabled).
Refer to section 35.3.6, Adjusting Transmission Efficiency by Changing the IPG for details on the IPG.

35.2.9 Automatic PAUSE Frame Register (APR)

Address(es): ETHERC0.APR 000C 0154h, ETHERC1.APR 000C 0354h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	AP[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	AP[15:0]	Automatic PAUSE Time Setting	These bits set the value of the pause_time parameter for a PAUSE frame that is automatically transmitted. Transmission is not performed until the set value multiplied by 512 bit time has elapsed.	R/W
b31 to b16	—	Reserved	The read value is 0. The write value should be 0.	R/W

The APR register sets the PAUSE time of the PAUSE frame that is automatically transmitted. The value set in the APR register is used for the pause_time parameter of the PAUSE frame.
Do not rewrite this register while the ECMR.TE bit is 1 (transmit function is enabled) or while the ECMR.RE bit is 1 (receive function is enabled).

35.2.10 Manual PAUSE Frame Register (MPR)

Address(es): ETHERC0.MPR 000C 0158h, ETHERC1.MPR 000C 0358h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MP[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	MP[15:0]	Manual PAUSE Time Setting	These bits set the value of the pause_time parameter for a PAUSE frame that is manually transmitted. Transmission is not performed until the set value multiplied by 512 bit time has elapsed. The read value is undefined.	R/W
b31 to b16	—	Reserved	The read value is 0. The write value should be 0.	R/W

The MPR register sets the PAUSE time of the PAUSE frame that is manually transmitted. The value set in the MPR register is used for the pause_time parameter of the PAUSE frame.
When a value is set to this register, a PAUSE frame is transmitted. Rewrite this register while the ECMR.TE bit is 1 (transmit function is enabled).

35.2.11 Received PAUSE Frame Counter (RFCF)

Address(es): ETHERC0.RFCF 000C 0160h, ETHERC1.RFCF 000C 0360h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	RPAUSE[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	RPAUSE[7:0]	Received PAUSE Frame Count	Number of received PAUSE frames	R
b31 to b8	—	Reserved	The read value is 0.	R

The RFCF register is a counter indicating the number of received PAUSE frames. The counter is reset after this register is read.

35.2.12 PAUSE Frame Retransmit Count Setting Register (TPAUSER)

Address(es): ETHERC0.TPAUSER 000C 0164h, ETHERC1.TPAUSER 000C 0364h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TPAUSE[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TPAUSE[15:0]	Automatic PAUSE Frame Retransmit Setting	0000h: Number of retransmissions is unlimited 0001h: Maximum number of retransmissions is 1 : : FFFFh: Maximum number of retransmissions is 65,535	R/W
b31 to b16	—	Reserved	The read value is 0. The write value should be 0.	R/W

The TPAUSER register selects the maximum number of times a PAUSE frame is automatically transmitted.
Do not rewrite this register while the ECMR.TE bit is 1 (transmit function is enabled).

35.2.13 PAUSE Frame Retransmit Counter (TPAUSECR)

Address(es): ETHERC0.TPAUSECR 000C 0168h, ETHERC1.TPAUSECR 000C 0368h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TXP[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TXP[7:0]	PAUSE Frame Retransmit Count	Number of times a PAUSE frame was retransmitted	R
b31 to b8	—	Reserved	The read value is 0.	R

The TPAUSECR register is a counter indicating the number of times a PAUSE frame was automatically retransmitted.
The counter is reset after this register is read.

35.2.14 Broadcast Frame Receive Count Setting Register (BCFRR)

Address(es): ETHERC0.BCFRR 000C 016Ch, ETHERC1.BCFRR 000C 036Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BCF[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	BCF[15:0]	Broadcast Frame Continuous Receive Count Setting	0000h: Number of receptions is unlimited. 0001h: Receive 1 frame. : : FFFFh: Receive 65,535 frames.	R/W
b31 to b16	—	Reserved	The read value is 0. The write value should be 0.	R/W

The BCFRR register sets the number of times broadcast frames can be received continuously. When the number of received frames exceeds the BCF[15:0] bit value, the ECSR.BFR flag becomes 1 and the excess broadcast frames are discarded. The internal counter that counts the number of continuously received broadcast frames is reset when receiving any other frame than broadcast frame.
Do not rewrite this register while the ECMR.RE bit is 1 (receive function is enabled).

35.2.15 MAC Address Upper Bit Register (MAHR)

Address(es): ETHERC0.MAHR 000C 01C0h, ETHERC1.MAHR 000C 03C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The MAHR register sets the upper 32 bits (b47 to b16) of the 48-bit MAC address. For example, if the MAC address is 01-23-45-67-89-AB, set the register to 0123 4567h.
Set the MAHR register during initialization after a reset. Do not rewrite this register while the ECMR.TE bit is 1 (transmit function is enabled) or while the ECMR.RE bit is 1 (receive function is enabled). When rewriting this register, set the EDMACn.EDMR.SWR bit to 1 to reset the EDMAC and ETHERC and then set this register again.

35.2.16 MAC Address Lower Bit Register (MALR)

Address(es): ETHERC0.MALR 000C 01C8h, ETHERC1.MALR 000C 03C8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	—	These bits set the lower 16 bits of the MAC address.	R/W
b31 to b16	—	Reserved	The read value is 0. The write value should be 0.	R/W

The MALR register sets the lower 16 bits of the 48-bit MAC address. For example, if the MAC address is 01-23-45-67-89-AB, set the register to 0000 89ABh.
Set the MALR register during initialization after a reset. Do not rewrite this register while the ECMR.TE bit is 1 (transmit function is enabled) or while the ECMR.RE bit is 1 (receive function is enabled). When rewriting this register, set the EDMACn.EDMR.SWR bit to 1 to reset the EDMAC and ETHERC and then set this register again.

35.2.17 Transmit Retry Over Counter Register (TROCR)

Address(es): ETHERC0.TROCR 000C 01D0h, ETHERC1.TROCR 000C 03D0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The TROCR register is a counter indicating the number of frames that fail to be retransmitted.
The TROCR register is incremented by 1 when a frame fails to be retransmitted 15 times. The counter stops when the TROCR register value becomes FFFF FFFFh. The counter value becomes 0 by writing any value to the TROCR register.

35.2.18 Late Collision Detect Counter Register (CDCR)

Address(es): ETHERC0.CDCR 000C 01D4h, ETHERC1.CDCR 000C 03D4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CDCR register is a counter indicating the number of late collisions that have been detected after transmission starts. When the CDCR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the CDCR register.

35.2.19 Lost Carrier Counter Register (LCCR)

Address(es): ETHERC0.LCCR 000C 01D8h, ETHERC1.LCCR 000C 03D8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The LCCR register is a counter indicating the number of times a loss of carrier is detected during frame transmission. When the LCCR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the LCCR register.

35.2.20 Carrier Not Detect Counter Register (CNDCR)

Address(es): ETHERC0.CNDCR 000C 01DCh, ETHERC1.CNDCR 000C 03DCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CNDCR register is a counter indicating the number of times a carrier is not detected during preamble transmission. When the CNDCR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the CNDCR register.

35.2.21 CRC Error Frame Receive Counter Register (CEFCR)

Address(es): ETHERC0.CEFCR 000C 01E4h, ETHERC1.CEFCR 000C 03E4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CEFCR register is a counter indicating the number of received frames where a CRC error has been detected. When the CEFCR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the CEFCR register.

35.2.22 Frame Receive Error Counter Register (FRECR)

Address(es): ETHERC0.FRECR 000C 01E8h, ETHERC1.FRECR 000C 03E8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FRECR register is a counter indicating the number of times a frame receive error has occurred. The PHY-LSI notifies the ETHERC of the frame receive error using the ETn_RX_ER pin.
The FRECR register is incremented each time the ETn_RX_ER pin becomes high. When the FRECR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the FRECR register.
When a frame receive error occurs, the EPTPCn.SYSR.INFABT flag may become 1 regardless of use of the EPTPC. In this case, reset the EPTPC, PTPEDMAC, and the corresponding channels ETHERC and EDMAC. Refer to section 35.5.3, Handling Errors in Control Information for the procedure to reset these modules.

35.2.23 Too-Short Frame Receive Counter Register (TSFRCR)

Address(es): ETHERC0.TSFRCR 000C 01ECh, ETHERC1.TSFRCR 000C 03ECh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The TSFRCR register is a counter indicating the number of times a short frame that is shorter than 64 bytes has been received. When the TSFRCR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the TSFRCR register.

35.2.24 Too-Long Frame Receive Counter Register (TLFRCR)

Address(es): ETHERC0.TLFRCR 000C 01F0h, ETHERC1.TLFRCR 000C 03F0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The TLFRCR register is a counter indicating the number of times a long frame that is longer than the RFLR register value has been received.
When the TLFRCR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the TLFRCR register.
Note that the TLFRCR register is not incremented when a frame is received with the alignment error. In this case, the RFCR register is incremented.

35.2.25 Received Alignment Error Frame Counter Register (RFCR)

Address(es): ETHERC0.RFCR 000C 01F4h, ETHERC1.RFCR 000C 03F4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The RFCR register is a counter indicating the number of times a frame has been received with the alignment error (frame is not an integral number of octets).
When the RFCR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the RFCR register.
When a frame is received with an alignment error, the EPTPCn.SYSR.INFABT flag may become 1 regardless of use of the EPTPC. In this case, reset the EPTPC, PTPEDMAC, and the corresponding channels ETHERC and EDMAC. Refer to section 35.5.3, Handling Errors in Control Information for the procedure to reset these modules.

35.2.26 Multicast Address Frame Receive Counter Register (MAFCR)

Address(es): ETHERC0.MAFCR 000C 01F8h, ETHERC1.MAFCR 000C 03F8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

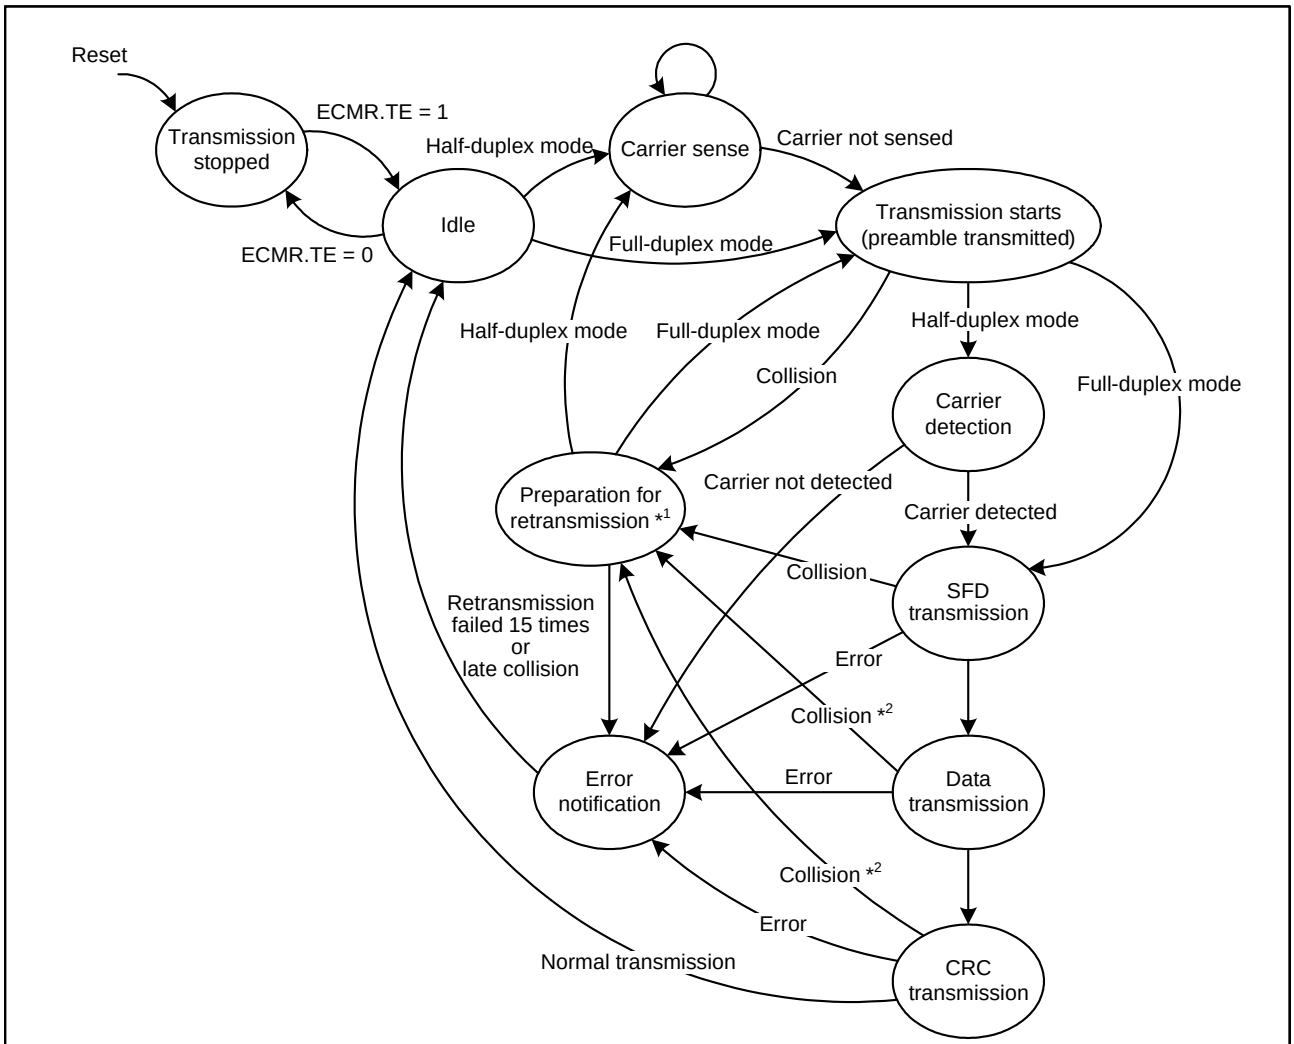
The MAFCR register is a counter indicating the number of times a frame where the multicast address is set has been received.
When the RFCR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the RFCR register.

35.3 Operation

This section is an overview of the ETHERC operations. The ETHERC supports flow control compliant with IEEE802.3x, and can transmit and receive PAUSE frames.

35.3.1 Transmission

The ETHERC transmitter assembles transmit data into a frame and outputs it to the MII/RMII when a transmit request is received from the EDMAC. The frame transmitted via the MII/RMII is transmitted on the line by the PHY-LSI. Figure 35.4 shows the state transitions of the ETHERC transmitter.



Note 1. Preparation for retransmission includes transmitting a jam signal and adjusting transmission time intervals using the backoff algorithm after a collision is detected.

Note 2. Preparation for retransmission is performed only when a collision is detected within 512 bit time after preamble transmission starts. When a collision is detected after 512 bit time, only a jam signal is transmitted and processing using the backoff algorithm is not performed.

Figure 35.4 ETHERC Transmitter State Transitions

1. When setting the ECMR.TE bit to 1, the ETHERC enters the transmit idle state.
2. When a transmit request is received from the EDMAC, the ETHERC enters the carrier sense state. The ETHERC waits for the interpacket gap and then transmits a preamble to the MII/RMII. When full-duplex mode is selected, it is not required to sense a carrier, so the ETHERC transmits a preamble immediately after receiving a transmit request from the EDMAC.

3. The ETHERC transmits the Start Frame Delimiter (SFD), transmit data, and CRC sequentially. When the transmission is completed successfully, the ETHERC notifies the EDMAC of successful completion, and the EDMAC sets the EDMACn.EESR.TC flag to 1. When a late collision or loss of carrier is detected during data transmission, the ETHERC stops the transmission and notifies the EDMAC of the error.
4. After the time for the interpacket gap has elapsed, the ETHERC enters the idle state and continues transmission when transmit data remains.

35.3.2 Reception

The ETHERC receiver separates the frame input from the MII/RMII into the preamble, SFD, receive data, and CRC, and transmits only receive data (destination address, source address, type/length, data/LLC). Figure 35.5 shows the state transitions of the ETHERC receiver.

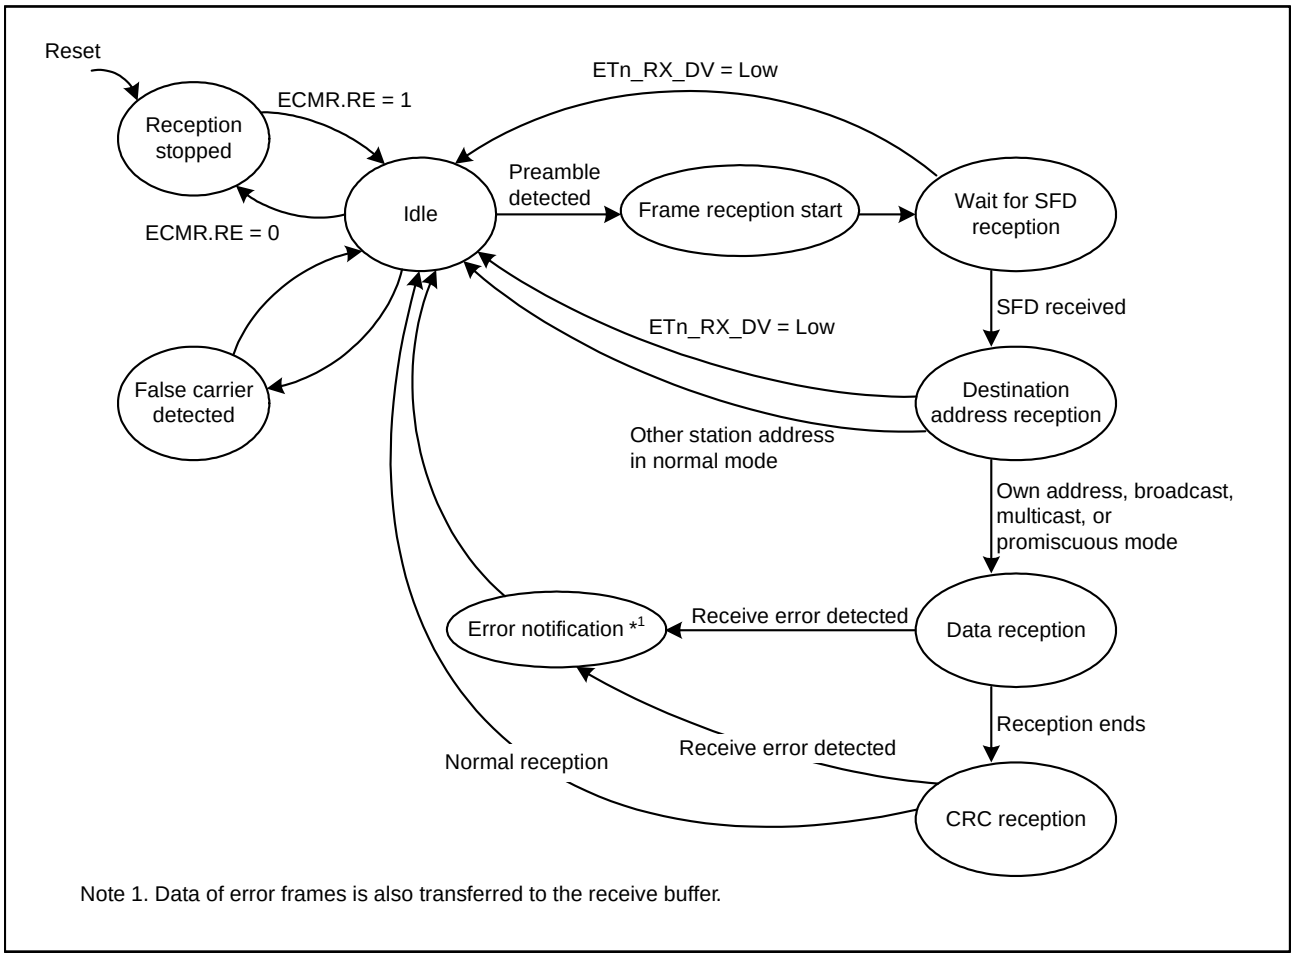


Figure 35.5 ETHERC Receiver State Transitions

1. When setting the ECMR.RE bit to 1, the ETHERC enters the receive idle state.
2. When the SFD following the preamble of the receive packet is detected, the ETHERC starts reception. If the received SFD is invalid, the ETHERC discards the frame.
3. In normal mode, the ETHERC starts data reception when the destination address of the receive frame is the address of the MCU or the receive frame is broadcast frame or multicast frame. In promiscuous mode, the ETHERC starts data reception regardless of the receive frame type.
4. After receiving data from the MII/RMII, the ETHERC performs the CRC check. The ETHERC notifies the EDMAC of the CRC check result. After the received data is transferred to the receive buffer, the CRC check result is written back to the receive descriptor as a status. The result is also reflected in the EDMACn.EESR.CERF flag.
5. When the ECMR.RE bit is 1 after one frame has been received, the ETHERC prepares to receive the next frame.

35.3.3 Frame Timing

35.3.3.1 MII Frame Timing

Figure 35.6 to Figure 35.11 show the MII frame timing.

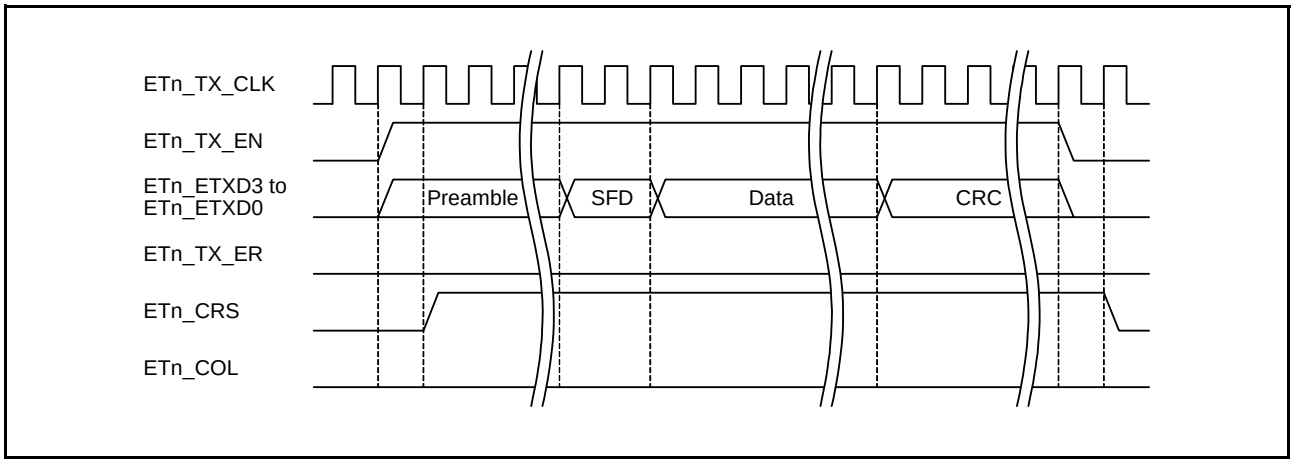

Figure 35.6 MII Frame Transmit Timing During Normal Transmission

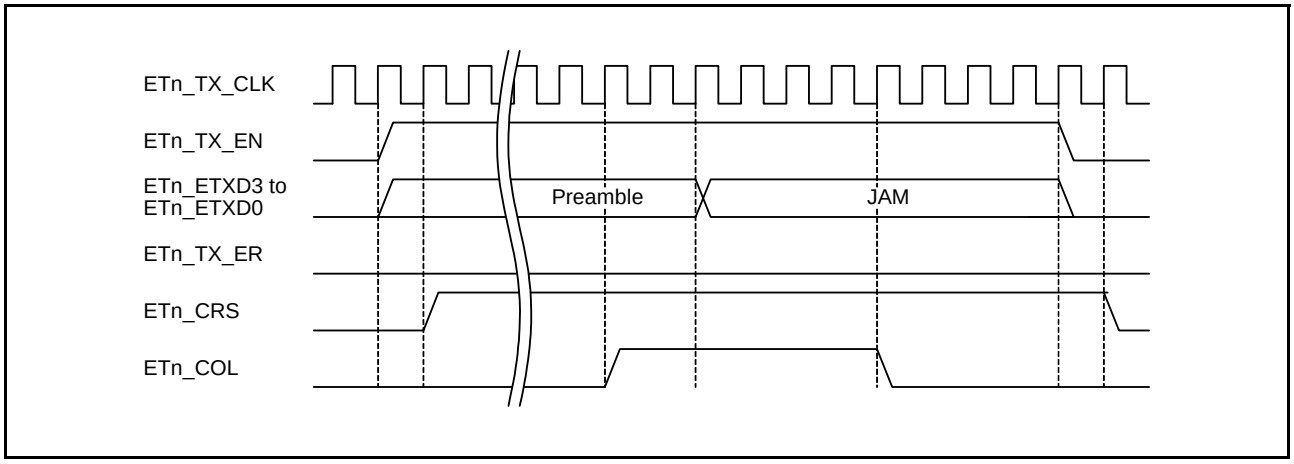

Figure 35.7 MII Frame Transmit Timing When Collision Occurs

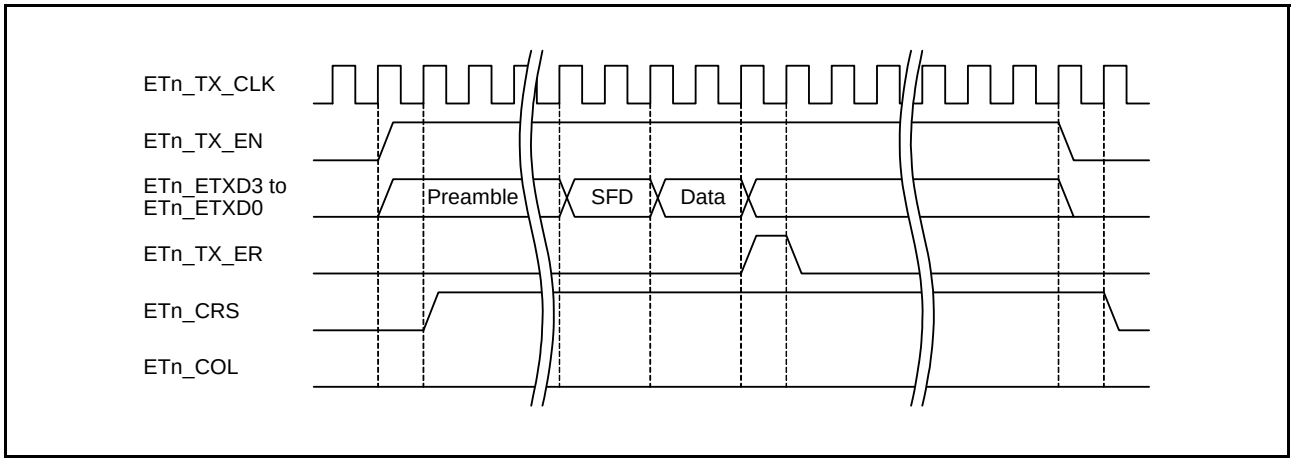

Figure 35.8 MII Frame Transmit Timing When Transmit Error Occurs

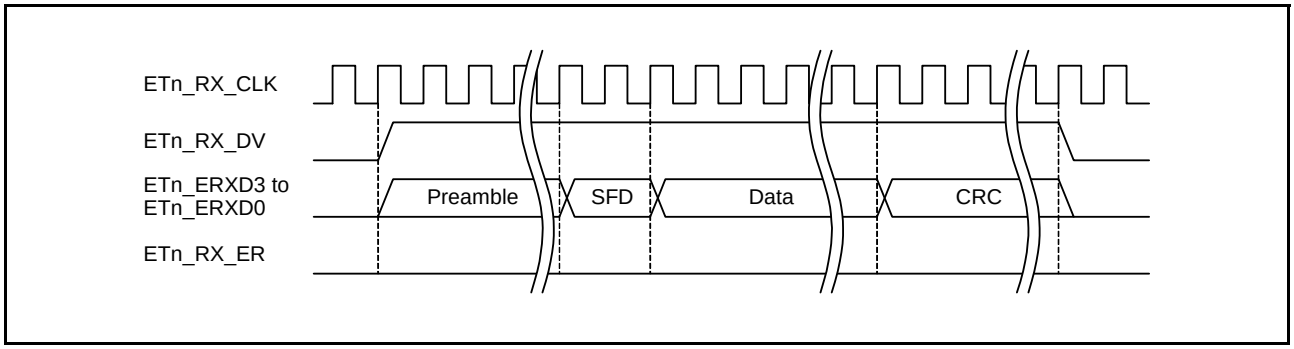

Figure 35.9 MII Frame Receive Timing During Normal Reception

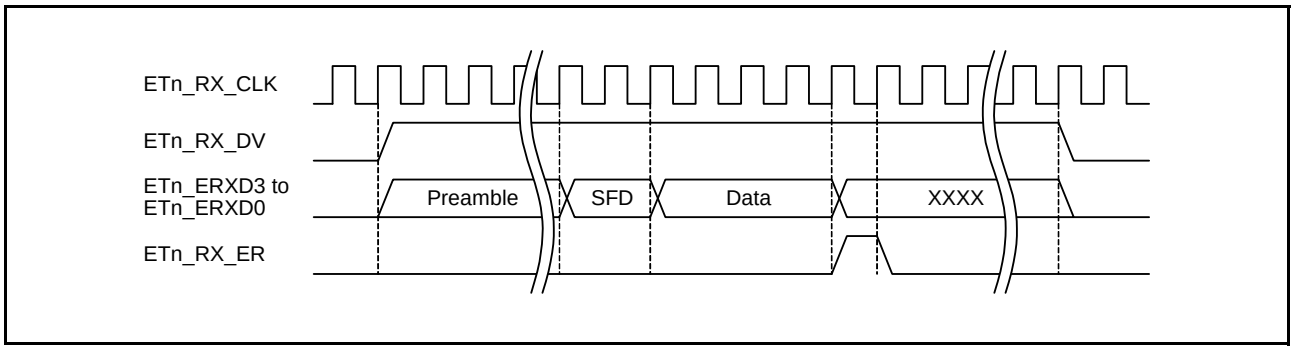

Figure 35.10 MII Frame Receive Timing for Receive Error Notification

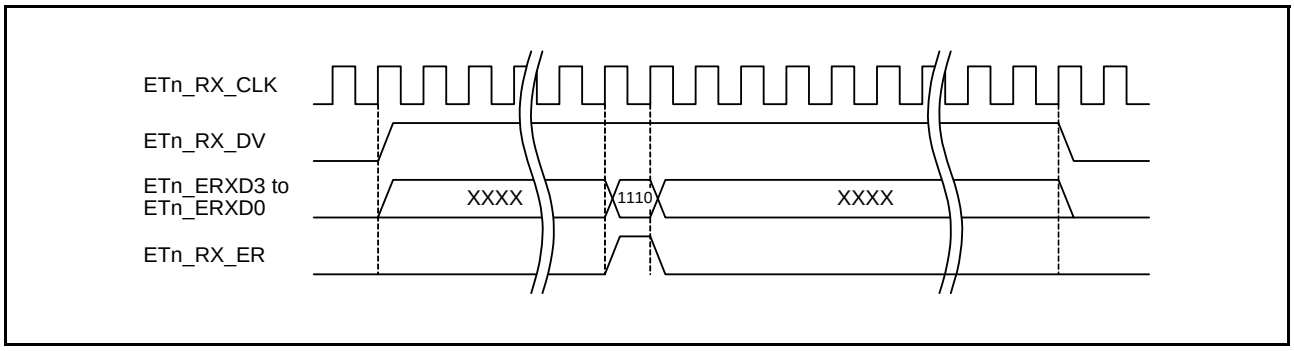

Figure 35.11 MII Fame Receive Timing for False Carrier Notification

35.3.3.2 RMII Frame Timing

The RMII frame timing is shown in Figure 35.12 to Figure 35.14.

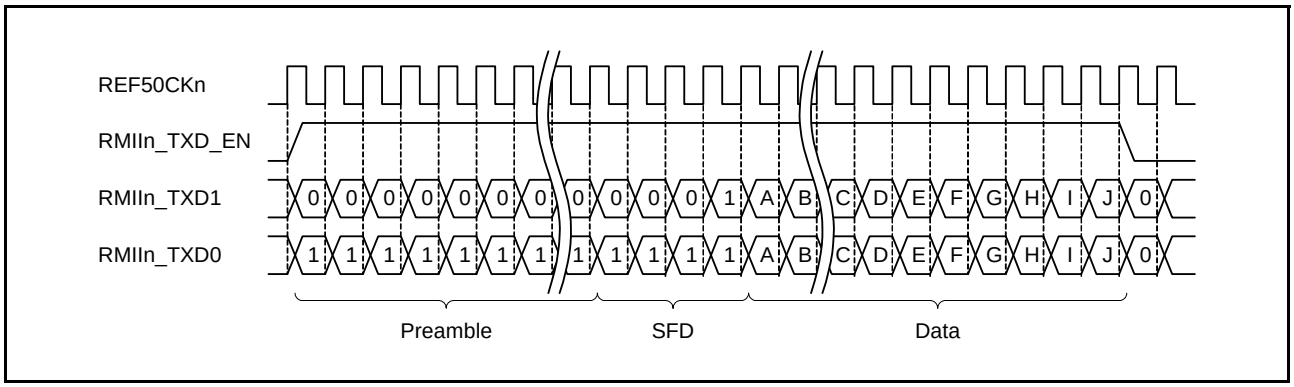

Figure 35.12 RMII Frame Transmit Timing During Normal Transmission

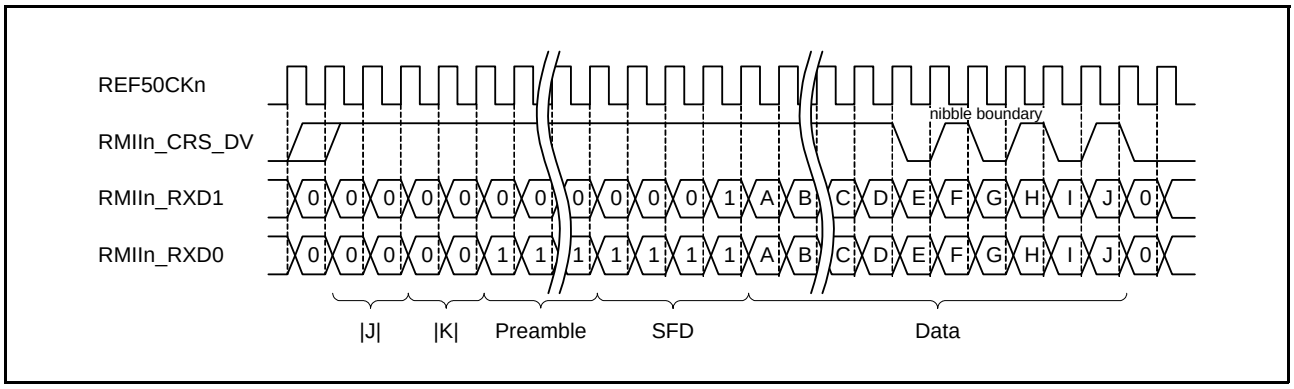

Figure 35.13 RMII Frame Receive Timing During Normal Reception

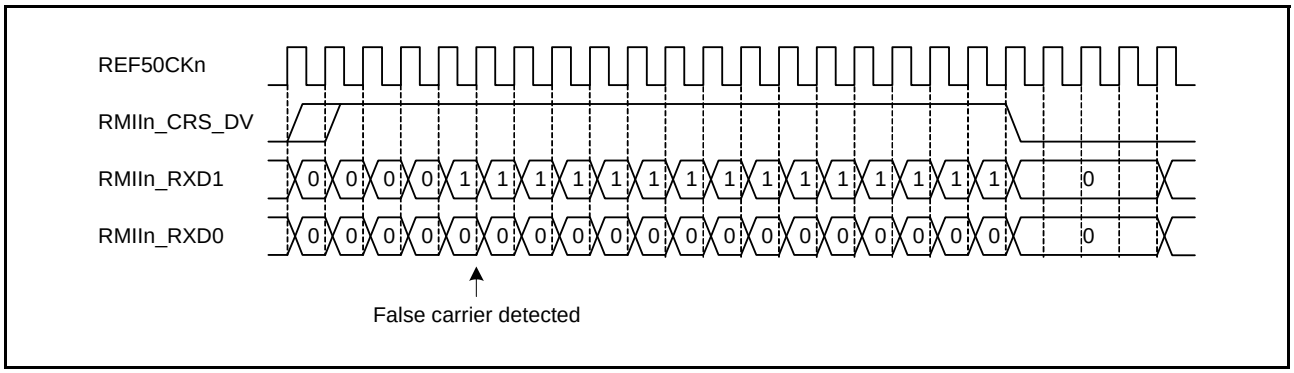

Figure 35.14 RMII Frame Receive Timing When False Carrier Is Detected

35.3.4 Accessing MII/RMII Registers

Use the PIR register to access the MII/RMII registers in the PHY-LSI. Serial data in the MII/RMII management frame format is transmitted and received via the ETn_MDC and ETn_MDIO pins controlled by software.

35.3.4.1 MII/RMII Management Frame Format

Table 35.3 lists the MII/RMII management frame format.

Table 35.3 MII/RMII Management Frame Format

Access Type		MII/RMII Management Frame							
	Item	PRE	ST	OP	PHYAD	REGAD	TA	DATA	IDLE
	Number of bits	32	2	2	5	5	2	16	1
Read		1...1	01	10	00001	RRRRR	Z0	DDDDDDDDDDDDDDDD	Z
Write		1...1	01	01	00001	RRRRR	10	DDDDDDDDDDDDDDDD	Z

PRE (preamble): Send 32 consecutive 1's.
ST (start of frame): Send 01b.
OP (operation code): Send 10b for read or 01b for write.
PHYAD (PHY address): Up to 32 PHY-LSIs can be connected to one MAC. PHY-LSIs are selected with these 5 bits.
When the PHY-LSI address is 1, send 00001b.
REGAD (register address): One register is selected from up to 32 registers in the PHY-LSI.
When the register address is 1, send 00001b.
TA (turnaround): 2-bit turnaround time to avoid contention between the register address and data during a read operation
(a) Send 10b during a write operation.
(b) Release the bus for 1 bit during a read operation (Z is output)
(indicated as Z0 because 0 is output from the PHY-LSI on the next clock cycle).
DATA (data): 16-bit data. Sequentially send or receive starting from the MSB.
IDLE (IDLE condition): Wait time to input the next MII/RMII management format
(a) Release the bus during a write operation (Z is output).
(b) No control is required since a bus has already been released during a read operation.

35.3.4.2 MII/RMII Register Access Procedure

Access to the MII/RMII registers includes writing data in 1-bit units, reading data in 1-bit units, and releasing the bus. Figure 35.15 to Figure 35.18 show examples of the MII/RMII register access timing. The access timing differ with the PHY-LSI type.

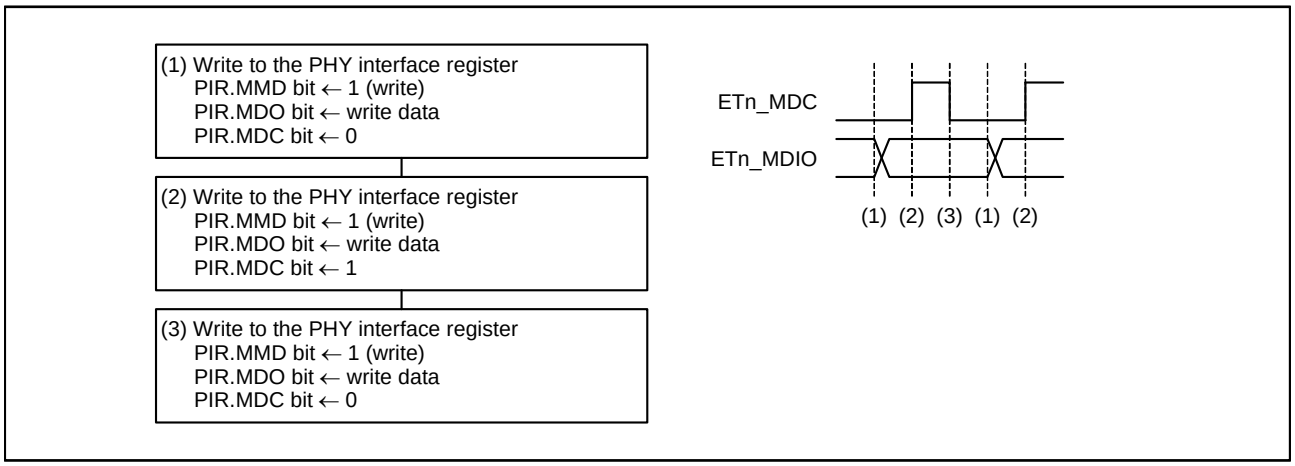

Figure 35.15 1-Bit Data Write Flow

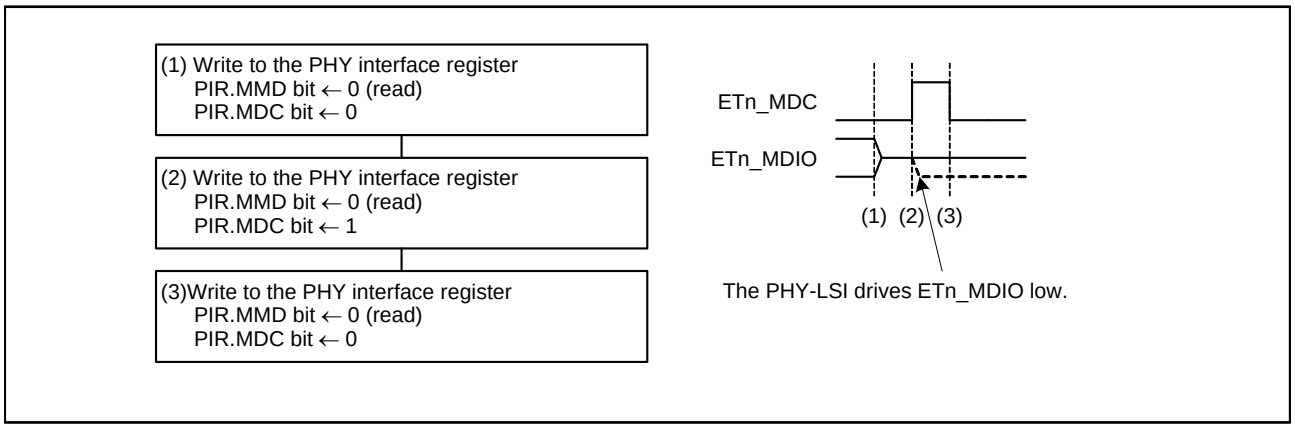

Figure 35.16 Bus Release Flow (TA in Read Operation in Table 35.3)

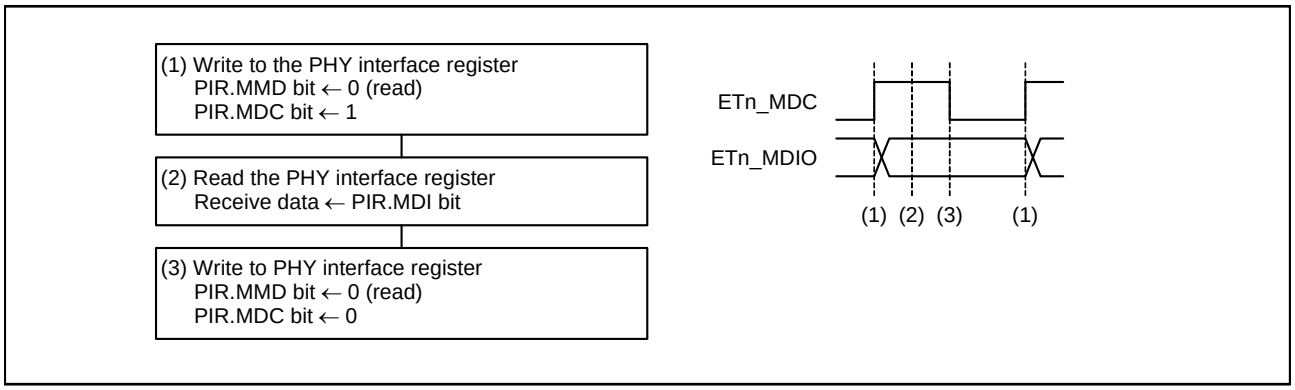

Figure 35.17 1-Bit Data Read Flow

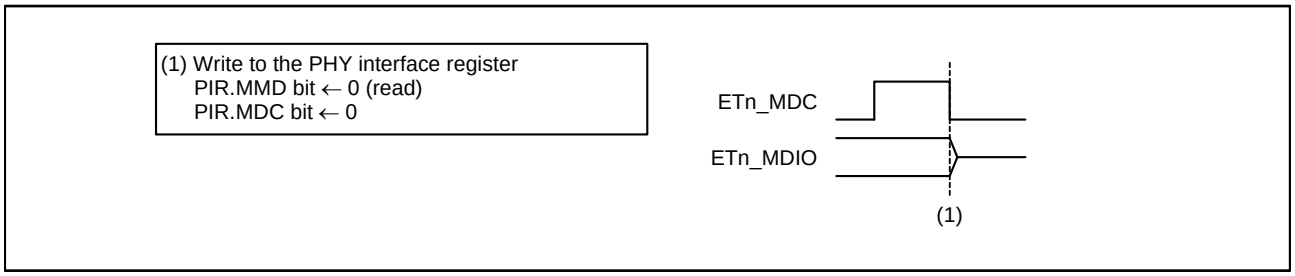

Figure 35.18 Bus Release Flow (IDLE in Write Operation in Table 35.3)

35.3.5 Magic Packet Detection

The ETHERC supports Wake-On-LAN (WOL). WOL is a function to detect a Magic Packet transmitted from a host device or other device and exit a low power consumption state such as sleep mode. When the ETHERC detects a Magic Packet, high is output from the ETn_WOL pin. Write 1 to the EDMACn.EDMR.SWR bit to set the ETn_WOL pin to low.

Since a Magic Packet is transmitted in broadcast mode, the Magic Packet is received regardless of the destination MAC address selected in the format. The ETHERC outputs high from the ETn_WOL pin only when the destination MAC address matches its own MAC address. Refer to the technical documentation provided by Advanced Micro Devices, Inc. for details on the Magic Packet. The following describes an example of the procedure to use WOL in the MCU.

1. Set the ICU to disable the EINTn interrupt request.
2. Set the ECMR.MPDE bit to 1 to enable Magic Packet detection. Set the ECMR.RE bit to 1 to enable reception.
3. Set the ECSIPR.MPDIP bit to 1 to enable notification of the Magic Packet detect interrupt.
4. Set the EDMACn.EESIPR.ECIIP bit to 1 to enable the ETHERC status register source interrupt.
5. Set the ICU to enable the EINTn interrupt request.
6. Change the CPU operating mode to sleep mode or place unused peripherals in the module stop state as needed.
7. When a Magic Packet is detected, an interrupt request is sent to the CPU. High is output from the ETn_WOL pin to notify peripheral devices that the Magic Packet has been detected.

35.3.5.1 Notes on Magic Packet Detection

The ETHERC receives packets, including broadcast packets, even when waiting to receive a Magic Packet. Therefore, receive data may have been stored in the receive FIFO of the EDMAC when a Magic Packet is detected. Also, flags in registers ECSR and EDMACn.EESR may have been changed. When returning to normal operation by detecting a Magic Packet, set the EDMACn.EDMR.SWR bit to 1 to reset the ETHERC and EDMAC.

35.3.6 Adjusting Transmission Efficiency by Changing the IPG

The IPG is a non-transmit period between transmit frames. The ETHERC can change the value of the IPG. Transmission efficiency can be increased or decreased by setting the IPGR register. The typical value of the IPG is specified by the IEEE802.3 standard. When changing the setting, confirm that all devices operate normally in the same network.

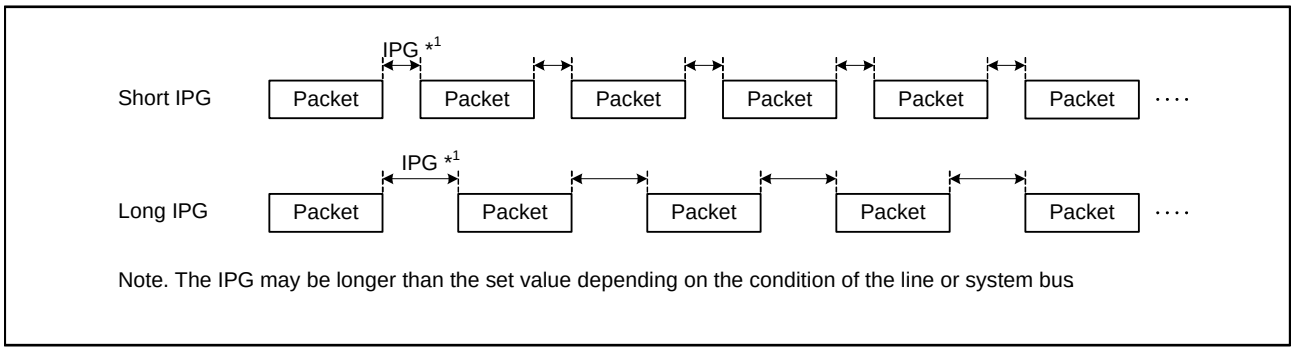

Figure 35.19 Differences in Transmission Efficiency Based on Changes in the IPG

35.3.7 Flow Control

The ETHERC can perform flow control compliant with IEEE802.3x in full-duplex mode, and the receiver and transmitter can be set individually. PAUSE frames can be transmitted automatically or manually.

35.3.7.1 Automatic PAUSE Frame Transmission

When the ECMR.TXF bit is set to 1, automatic PAUSE frame transmission is enabled. A PAUSE frame is automatically transmitted by a PAUSE frame transmit request from the EDMAC. The APR.AP[15:0] bit value is used for the pause_time parameter of the PAUSE frame.

After a PAUSE frame is transmitted, if the EDMAC is still requesting PAUSE frame transmission when the PAUSE time elapses, a PAUSE frame is transmitted again. The maximum number of PAUSE frame retransmissions can be set in the TPAUSER.TPAUSE[15:0] bits. If the maximum number of retransmissions is reached, subsequent PAUSE frames are not transmitted.

Figure 35.20 shows the procedure to set automatic PAUSE frame transmission.

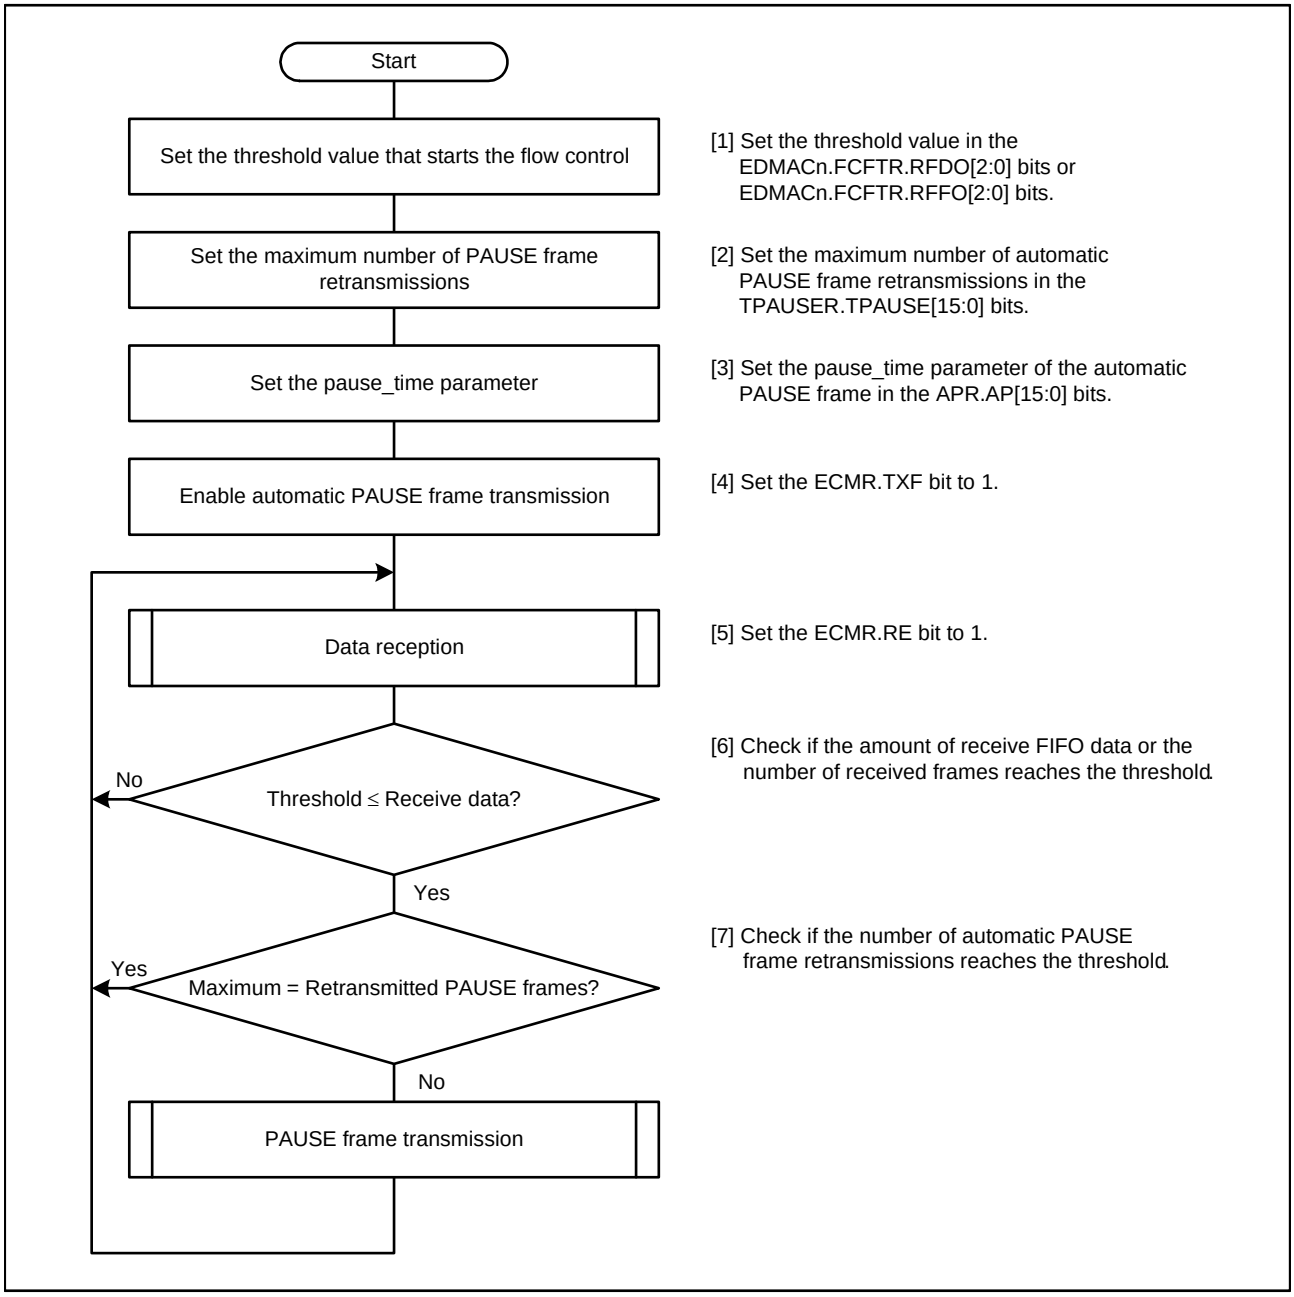

Figure 35.20 Example of Procedure to Set Automatic PAUSE Frame Transmission

35.3.7.2 Manual PAUSE Frame Transmission

A PAUSE frame can be manually transmitted at any time. When writing the pause_time parameter of the PAUSE frame to the MPR.MP[15:0] bits by software, the ETHERC transmits a PAUSE frame once. When transmitting a PAUSE frame more than once, write to the MPR.MP[15:0] bits for each transmission.

35.3.7.3 PAUSE Frame Reception

When setting the ECMR.RXF bit to 1, PAUSE frame detection is enabled. After a PAUSE frame is received, the ETHERC completes transmitting the current frame and waits for the PAUSE time of the received PAUSE frame to elapse before the next frame can be transmitted. Also, the ETHERC increments the RFCF.RPAUSE[7:0] bit value.
However, while waiting for the PAUSE time to elapse, if a PAUSE frame that contains a pause_time parameter of 0 is received and the ECMR.ZPF bit is 1, the ETHERC becomes ready to transmit.

35.4 Interrupts

When a flag in the ECSR register becomes 1 and the corresponding bit in the ECSIPR register is 1, the ETHERC notifies the EDMAC of the status as an interrupt source. After receiving the notification, the EDMAC sets the EDMACn.EESR.ECI flag to 1. When the EDMACn.EESIPR.ECIIP bit is 1, the EDMAC sends an EINTn interrupt request to the CPU. Refer to section 37, DMA Controller for the Ethernet Controller (EDMACa) for details.

35.5 Usage Notes

35.5.1 Conditions for the LCHNG Flag to Become 1

The ECSR.LCHNG flag may become 1 even when the input level of the ETn_LINKSTA pin remains the same. In this case, high is input to the ETn_LINKSTA pin when setting the MPC.PmnPFS register to assign the ETn_LINKSTA signal to a port or when releasing the ETHERC and EDMAC software reset using the EDMACn.EDMR.SWR bit. The ECSR.LCHNG flag becomes 1 because the ETn_LINKSTA signal in the ETHERC is fixed low regardless of the input level to the external pin while the MPC does not assign the ETn_LINKSTA signal or during the ETHERC and EDMAC software reset.
To avoid wrongly generating a link signal change interrupt, clear the ECSR.LCHNG flag and then set the ECSIPR.LCHNGIP bit to 1.

35.5.2 Input to the RMIIn_RX_ER Pin While the RMII is Selected

When the width of a reception error signal received from the PHY-LSI is only one cycle of the REF50CKn clock (50 MHz) while the RMII is selected, the signal is not recognized as an error signal.

35.5.3 Handling Errors in Control Information

When a frame is received with an alignment error or a frame receive error occurs, the EPTPCn.SYSR.INFABT flag may become 1 regardless of use of the EPTPC. In this case, reset the EPTPC, PTPEDMAC, and the corresponding channels ETHERC and EDMAC.

Follow the procedure below to reset these modules:

(1) Write 0000 0001h to the EPTPC.PTRSTR register.
(2) Write 0000 0001h to the PTPEDMAC.EDMR register.
(3) Write 0000 0001h to the EDMACn.EDMR register of the corresponding channels.
(4) Wait for 64 cycles of the PCLKA until initialization is completed.
(5) Write 0000 0000h to the EPTPC.PTRSTR register.

Refer to sections section 36.2.83, PTP Reset Register (PTRSTR) and section 37.2.1, EDMAC Mode Register (EDMR) for details of resets.

36. PTP Module for the Ethernet Controller (EPTPC)

36.1 Overview

This MCU has an on-chip Precision Time Protocol (PTP) module for the Ethernet controller (EPTPC). The module applies the PTP defined in version 2 of the IEEE 1588-2008 standard to handle timing and synchronization between devices. The EPTPC is composed of synchronization frame processing units (SYNFP0 and SYNFP1), a packet relation controller unit (PRC-TC), and a statistical time correction algorithm unit (STCA).
Use the EPTPC in combination with the on-chip Ethernet controller (ETHERC) and the DMA controller for the PTP Ethernet controller (PTPEDMAC).
Table 36.1 lists the EPTPC specifications, and Figure 36.1 shows the EPTPC configuration.

Table 36.1 EPTPC Specifications

Item	Description
Protocol	Compliant with the Precision Time Protocol (PTP) defined in IEEE 1588
Synchronization frame processing units (SYNFP0 and SYNFP1)	• Transmits and receives PTP messages as a master or slave. • The following four clock devices are supported: Ordinary clock (OC) Boundary clock (BC) End-to-end transparent clock (E2E TC) Peer-to-peer transparent clock (P2P TC) • Calculates the meanPathDelay and offsetFromMaster values defined in IEEE 1588. • Capable of generating a master clock. • Hardware filtering of received multicast packets with a MAC address • Capable of hardware filtering in accord with the type of PTP message • Supports PTP message frames in layer 4 (IPv4 and UDP) and layer 2 (Ethernet frames). • Can be used as a normal Ethernet port when time synchronization is not in use.
Packet relation controller unit (PRC-TC)	• Relaying of received data between Ethernet ports 0 and 1 • Setting the same MAC address for Ethernet ports 0 and 1 allows transmission of data from the two ports or from only one of them. • Store-and-forward method or cut-through method selectable for the relaying of packets
Statistical time correction algorithm unit (STCA)	• Frequency of the clock signal supplied to the statistical time correction algorithm unit is selectable as 20, 25, 50, or 100 MHz. • In slave operation, the synchronized state can be indicated from the offsetFromMaster value staying below a previously specified threshold. Additionally, the threshold can be calculated statistically from collected positive and negative gradient values (worst-10 acquisition). • The local clock counter holds corrected time information obtained from a master clock. • The STCA clock can be used as the clock source for generating pulse signals from pulse output timer m (m = 0 to 5). • Peripheral modules such as MTU3 and GPT can be started or stopped on the edge of pulses synchronized with the master clock in response to interrupt requests by the pulse output timer or the output of event signals to the ELC.
Interrupt sources	MINT interrupt • Requested when the state of the individual modules is changed. • Requested on rising edges of the pulse signal generated by the pulse output timer. IPLS interrupt • Requested on rising or falling edges of the pulse signal generated by the previously selected pulse output timer group. • Can be requested on every edge or only once.
Event linking	• An event signal is output to the ELC on a rising or falling edge of the pulse signal generated by the pulse output timer. • An event signal can be output on every edge or only once.

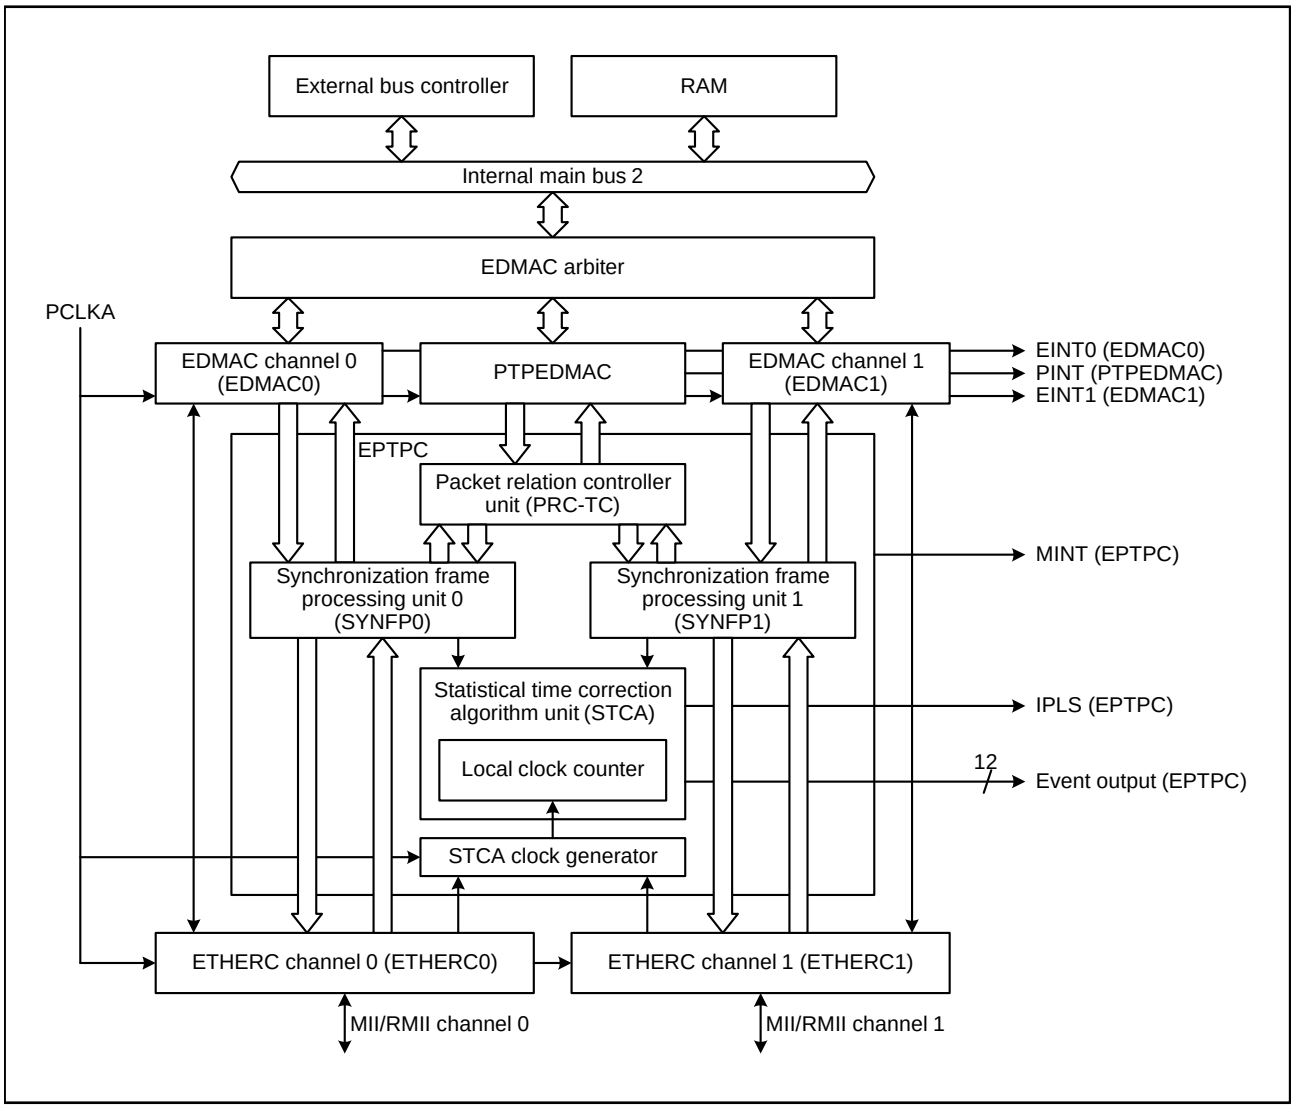

Figure 36.1 EPTPC Configuration

In this section, channels may not be mentioned in overall descriptions of modules that have multiple channels. Examples of the notation are listed in Table 36.2.

Table 36.2 Examples of the Notation

Module Name	Channel	Meaning
SYNFPn module	n = 0, 1	Synchronization processing units 0 and 1 (SYNFP0 and SYNFP1)
Pulse output timer m	m = 0 to 5	Pulse output timer channels 0 to 5

36.1.1 Combination of Clock Device and Ethernet Port

The EPTPC supports operation as three types of clock device: an ordinary clock (OC), boundary clock (BC), or transparent clock (TC). Furthermore, it supports both end-to-end (E2E) and peer-to-peer (P2P) operation for all three clock devices.
Available combinations for usage of Ethernet ports 0 and 1 are listed in Table 36.3.

Table 36.3 Combination of Clock Device and Ethernet Port

Clock Device	Ethernet Port 0		Ethernet Port 1	
No control by EPTPC	PTP packets are not handled.			
Ordinary Clock (OC) Only Ethernet port 0 is used for handling PTP packets	Master	End-to-end (E2E)	PTP packets are not handled.	
		Peer-to-peer (P2P)		
	Slave	E2E		
		P2P		
Ordinary Clock (OC) Only Ethernet port 1 is used for handling PTP packets	PTP packets are not handled.		Master	E2E
				P2P
			Slave	E2E
				P2P
Boundary clock (OC)	Master	E2E	Master	E2E
		E2E		P2P
		P2P		E2E
		P2P		P2P
	Master	E2E	Slave	E2E
		E2E		P2P
		P2P		E2E
		P2P		P2P
	Slave	E2E	Master	E2E
		E2E		P2P
		P2P		E2E
		P2P		P2P
Transparent clock (TC)	E2E TC			
	P2P TC			

36.1.2 Frame Format of PTP Messages

The frame format of PTP messages can be selected from the two types by setting the FORM0 and FORM1 bits in the SYNFP frame format setting register (SYFORMR).
Figure 36.2 shows the PTP message formats for transmission and reception by the EPTPC.

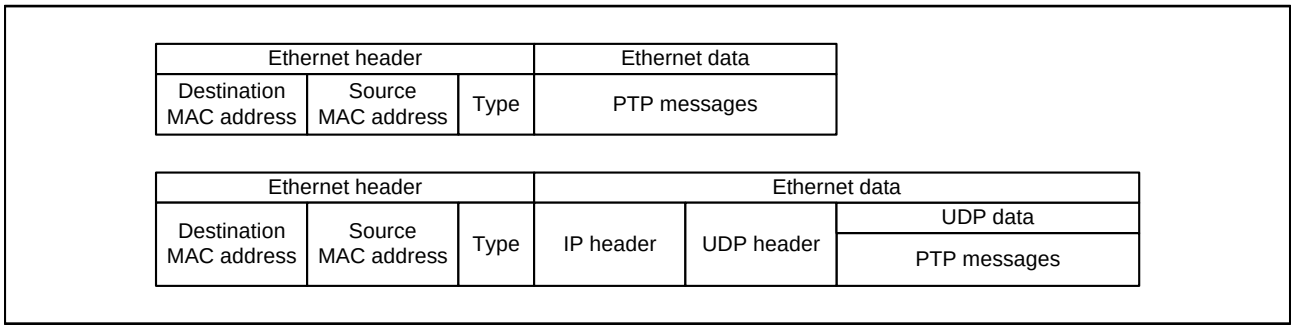

Figure 36.2 Frame Format of PTP Messages

The EPTPC module is capable of transmitting PTP messages. When it sends a PTP message, multicast addresses defined by IEEE 1588 are normally specified as the destination MAC address and IP address, depending on the type of the PTP message to be sent.
Furthermore, the port number when a PTP message is encapsulated for use with the UDP must also be specified in accord with the type of message as stipulated by IEEE 1588.
Table 36.4 gives a summary of the information to specify the Ethernet frame format for PTP messages.

Table 36.4 Type of PTP Message for Multicast and Information to Specify the Ethernet Frame Format

Type of PTP Message			Ethernet II Frame Format (SYFORMR.FORM0 Bit = 0)		IP Address (IPv4)	UDP Port No. *1
			MAC Address	Ethertype		
PTP-primary	Event messages	Sync	01-1B-19-00-00-00	88F7h	224.0.1.129	319
		Delay_Req				
PTP-pdelay		Pdelay_Req	01-80-C2-00-00-0E		224.0.0.107	
		Pdelay_Resp				
	General messages	Pdelay_Resp_Follow_Up				320
PTP-primary		Announce	01-1B-19-00-00-00		224.0.1.129	
		Follow_Up				
		Delay_Resp				
		Signaling				
		Management				

Note 1. The port number must be specified only when a PTP message is encapsulated for use with the UDP (i.e. the SYFORMR.FORM1 bit = 1).

36.1.3 Type of PTP Message and Details of Processing

Table 36.5 and Table 36.6 respectively give details of processing by the EPTPC for receiving and transmitting PTP messages.

Table 36.5 List of PTP Messages for Reception by the EPTPC

Message Type	Message	Details of Processing
Event	Sync	Calculates the value of offsetFromMaster if twoStepFlag in flagField is FALSE.
	Delay_Req	Responds to Delay_Resp.
	Pdelay_Req	Responds to Pdelay_Resp.
	Pdelay_Resp	Calculates the value of meanPathDelay if twoStepFlag in flagField is FALSE.
General	Announce	—
	Follow_Up	Calculates the value of offsetFromMaster if twoStepFlag in flagField of the most recently received Sync message was TRUE and the value of meanPathDelay is fixed.
	Delay_Resp	Calculates the value of meanPathDelay.
	Pdelay_Resp_Follow_Up	Calculates the value of meanPathDelay if twoStepFlag in flagField of the most recently received Pdelay_Resp message was TRUE.
	Management	—
	Signaling	—

Table 36.6 List of PTP Messages for Transmission by the EPTPC

Message Type	Message	Details of Processing
Event	Sync	Sync messages are transmitted at the fixed interval specified by the SYTLIR.SYNC[7:0] bits.
	Delay_Req	Transmission proceeds with an interval from 0 to twice the interval set by the value of the SYTLIR.DREQ[7:0] bits and determined by a random number.
	Pdelay_Req	Pdelay_Req messages are transmitted at the fixed interval specified by the SYTLIR.DREQ[7:0] bits.
	Pdelay_Resp	Transmission of responses to Pdelay_Req.
General	Announce	Announce messages are transmitted at the fixed interval specified by the SYTLIR.ANCE[7:0] bits.
	Follow_Up	—
	Delay_Resp	Transmission of responses to Delay_Req
	Pdelay_Resp_Follow_Up	—
	Management	—
	Signaling	—

36.2 Register Descriptions

36.2.1 MINT Interrupt Source Status Register (MIESR)

Address(es): EPTPC.MIESR 000C 4000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	CYC5	CYC4	CYC3	CYC2	CYC1	CYC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	PRC	SY1	SY0	ST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ST	STCA Status Flag	0: No change in the state of the STCA module 1: A change in the state of the STCA module	R
b1	SY0	SYNFP0 Status Flag	0: No change in the state of the SYNFP0 module 1: A change in the state of the SYNFP0 module	R
b2	SY1	SYNFP1 Status Flag	0: No change in the state of the SYNFP1 module 1: A change in the state of the SYNFP1 module	R
b3	PRC	PRC-TC Status Flag	0: No change in the state of the PRC-TC module 1: A change in the state of the PRC-TC module	R
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	CYC0	Pulse Output Timer 0 Rising Edge Detection Flag	0: A rising edge in the periodic pulse signal from pulse output timer 0 is not detected. 1: A rising edge in the periodic pulse signal from pulse output timer 0 is detected.	R/W*1
b17	CYC1	Pulse Output Timer 1 Rising Edge Detection Flag	0: A rising edge in the periodic pulse signal from pulse output timer 1 is not detected. 1: A rising edge in the periodic pulse signal from pulse output timer 1 is detected.	R/W*1
b18	CYC2	Pulse Output Timer 2 Rising Edge Detection Flag	0: A rising edge in the periodic pulse signal from pulse output timer 2 is not detected. 1: A rising edge in the periodic pulse signal from pulse output timer 2 is detected.	R/W*1
b19	CYC3	Pulse Output Timer 3 Rising Edge Detection Flag	0: A rising edge in the periodic pulse signal from pulse output timer 3 is not detected. 1: A rising edge in the periodic pulse signal from pulse output timer 3 is detected.	R/W*1
b20	CYC4	Pulse Output Timer 4 Rising Edge Detection Flag	0: A rising edge in the periodic pulse signal from pulse output timer 4 is not detected. 1: A rising edge in the periodic pulse signal from pulse output timer 4 is detected.	R/W*1
b21	CYC5	Pulse Output Timer 5 Rising Edge Detection Flag	0: A rising edge in the periodic pulse signal from pulse output timer 5 is not detected. 1: A rising edge in the periodic pulse signal from pulse output timer 5 is detected.	R/W*1
b31 to b22	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writing 1 clears the flag. Writing 0 does not affect the flag value.

The MIESR register indicates changes in the states of the STCA, SYNFPn, and PRC-TC modules which act as sources of MINT interrupts and the detection of rising edges of pulse output timers m (m = 0 to 5).

For the MINT interrupt, see section 36.4, Interrupts.

ST Flag (STCA Status Flag)

This flag indicates changes in the state of the STCA module.
[Setting condition]

- A change in the state of a flag of the STSR register for which the setting in the STIPR register enables notification

[Clearing conditions]
When any of the following conditions is met:

- The flags in the STSR register are all 0.
- The bits in the STIPR register are all 0.
- There is a bit set to 1 in the STIPR register, but the corresponding flag in the STSR register is 0.

SYn Flag (SYNFPn Status Flag)

This flag indicates changes in the state of the SYNFPn module.
[Setting condition]

- A change in the state of a flag of the SYSR register for which the setting in the SYIPR register enables notification

[Clearing conditions]
When any of the following conditions is met:

- The flags in the SYSR register are all 0.
- The bits in the SYIPR register are all 0.
- There is a bit set to 1 in the SYIPR register, but the corresponding flag in the SYSR register is 0.

PRC Flag (PRC-TC Status Flag)

This flag indicates changes in the state of the PRC-TC module.
[Setting condition]

- A change in the state of a flag of the PRSR register for which the setting in the PRIPR register enables notification

[Clearing conditions]
When any of the following conditions is met:

- The flags in the PRSR register are all 0.
- The bits in the PRIPR register are all 0.
- There is a bit set to 1 in the PRIPR register, but the corresponding bit in the PRSR register is 0.

CYCm Flag (Pulse Output Timer m Rising Edge Detection Flag)

This flag indicates detection of a rising edge in the periodic pulse signal produced by the corresponding pulse output timer m (m = 0 to 5).
[Setting condition]

- Detection of a rising edge in the periodic pulse signal produced by a pulse output timer for which the setting in the MITSELR register enables notification

[Clearing condition]

- 1 being written to this flag.
  After the flag is cleared to 0, it is set to 1 again on detection of a rising edge in the periodic pulse signal from the corresponding pulse output timer.

36.2.2 MINT Interrupt Request Enable Register (MIEIPR)

Address(es): EPTPC.MIEIPR 000C 4004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	CYC5	CYC4	CYC3	CYC2	CYC1	CYC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	PR	SY1	SY0	ST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ST	STCA Status Interrupt Request Enable	0: Disables the generation of MINT interrupt requests by the STCA status flag. 1: Enables the generation of MINT interrupt requests by the STCA status flag.	R/W
b1	SY0	SYNFP0 Status Interrupt Request Enable	0: Disables the generation of MINT interrupt requests by the SYNFP0 status flag. 1: Enables the generation of MINT interrupt requests by the SYNFP0 status flag.	R/W
b2	SY1	SYNFP1 Status Interrupt Request Enable	0: Disables the generation of MINT interrupt requests by the SYNFP1 status flag. 1: Enables the generation of MINT interrupt requests by the SYNFP1 status flag.	R/W
b3	PR	PRC-TC Status Interrupt Request Enable	0: Disables the generation of MINT interrupt requests by the PRC-TC status flag. 1: Enables the generation of MINT interrupt requests by the PRC-TC status flag.	R/W
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	CYC0	Pulse Output Timer 0 Rising Edge Detection Interrupt Request Enable	0: Disables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 0. 1: Enables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 0.	R/W
b17	CYC1	Pulse Output Timer 1 Rising Edge Detection Interrupt Request Enable	0: Disables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 1. 1: Enables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 1.	R/W
b18	CYC2	Pulse Output Timer 2 Rising Edge Detection Interrupt Request Enable	0: Disables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 2. 1: Enables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 2.	R/W
b19	CYC3	Pulse Output Timer 3 Rising Edge Detection Interrupt Request Enable	0: Disables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 3. 1: Enables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 3.	R/W
b20	CYC4	Pulse Output Timer 4 Rising Edge Detection Interrupt Request Enable	0: Disables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 4. 1: Enables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 4.	R/W
b21	CYC5	Pulse Output Timer 5 Rising Edge Detection Interrupt Request Enable	0: Disables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 5. 1: Enables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 5.	R/W
b31 to b22	—	Reserved	These bits are read as 0. The write value should be 0.	R

The MIEIPR register is used to enable or disable the generation of MINT interrupt requests when MINT interrupt source conditions are satisfied.

36.2.3 ELC Output/IPLS Interrupt Request Enable Register (ELIPPR)

Address(es): EPTPC.ELIPPR 000C 4010h

Bit	Symbol	Bit Name	Description	R/W
b0	CYCP0	Pulse Output Timer 0 Rising Edge Detection Event Output Enable	0: Rising edges of the signal from pulse output timer 0 are not conveyed to the ELC as event signals. 1: Rising edges of the signal from pulse output timer 0 are conveyed to the ELC as event signals.	R/W
b1	CYCP1	Pulse Output Timer 1 Rising Edge Detection Event Output Enable	0: Rising edges of the signal from pulse output timer 1 are not conveyed to the ELC as event signals. 1: Rising edges of the signal from pulse output timer 1 are conveyed to the ELC as event signals.	R/W
b2	CYCP2	Pulse Output Timer 2 Rising Edge Detection Event Output Enable	0: Rising edges of the signal from pulse output timer 2 are not conveyed to the ELC as event signals. 1: Rising edges of the signal from pulse output timer 2 are conveyed to the ELC as event signals.	R/W
b3	CYCP3	Pulse Output Timer 3 Rising Edge Detection Event Output Enable	0: Rising edges of the signal from pulse output timer 3 are not conveyed to the ELC as event signals. 1: Rising edges of the signal from pulse output timer 3 are conveyed to the ELC as event signals.	R/W
b4	CYCP4	Pulse Output Timer 4 Rising Edge Detection Event Output Enable	0: Rising edges of the signal from pulse output timer 4 are not conveyed to the ELC as event signals. 1: Rising edges of the signal from pulse output timer 4 are conveyed to the ELC as event signals.	R/W
b5	CYCP5	Pulse Output Timer 5 Rising Edge Detection Event Output Enable	0: Rising edges of the signal from pulse output timer 5 are not conveyed to the ELC as event signals. 1: Rising edges of the signal from pulse output timer 5 are conveyed to the ELC as event signals.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	CYCN0	Pulse Output Timer 0 Falling Edge Detection Event Output Enable	0: Falling edges of the signal from pulse output timer 0 are not conveyed to the ELC as event signals. 1: Falling edges of the signal from pulse output timer 0 are conveyed to the ELC as event signals.	R/W
b9	CYCN1	Pulse Output Timer 1 Falling Edge Detection Event Output Enable	0: Falling edges of the signal from pulse output timer 1 are not conveyed to the ELC as event signals. 1: Falling edges of the signal from pulse output timer 1 are conveyed to the ELC as event signals.	R/W
b10	CYCN2	Pulse Output Timer 2 Falling Edge Detection Event Output Enable	0: Falling edges of the signal from pulse output timer 2 are not conveyed to the ELC as event signals. 1: Falling edges of the signal from pulse output timer 2 are conveyed to the ELC as event signals.	R/W

Bit	Symbol	Bit Name	Description	R/W
b11	CYCN3	Pulse Output Timer 3 Falling Edge Detection Event Output Enable	0: Falling edges of the signal from pulse output timer 3 are not conveyed to the ELC as event signals. 1: Falling edges of the signal from pulse output timer 3 are conveyed to the ELC as event signals.	R/W
b12	CYCN4	Pulse Output Timer 4 Falling Edge Detection Event Output Enable	0: Falling edges of the signal from pulse output timer 4 are not conveyed to the ELC as event signals. 1: Falling edges of the signal from pulse output timer 4 are conveyed to the ELC as event signals.	R/W
b13	CYCN5	Pulse Output Timer 5 Falling Edge Detection Event Output Enable	0: Falling edges of the signal from pulse output timer 5 are not conveyed to the ELC as event signals. 1: Falling edges of the signal from pulse output timer 5 are conveyed to the ELC as event signals.	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	PLSP	Pulse Output Timer Rising Edge Detection IPLS Interrupt Request Enable	0: Disables IPLS interrupt requests due to rising edges of signals from the selected pulse output timer. 1: Enables IPLS interrupt requests due to rising edges of signals from the selected pulse output timer.	R/W
b23 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R
b24	PLSN	Pulse Output Timer Falling Edge Detection IPLS Interrupt Request Enable	0: Disables IPLS interrupt requests due to falling edges of signals from the selected pulse output timer. 1: Enables IPLS interrupt requests due to falling edges of signals from the selected pulse output timer.	R/W
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R

The ELIPPR register determines whether or not rising and falling edges of the periodic pulse signals produced by pulse output timers m are output to the ELC. The register also enables and disables IPLS interrupts due to rising or falling edges of signals from the pulse output timer selected in the IPTSELR register.

Peripheral modules such as the MTU3 or GPT can be controlled with the clock synchronized by the PTP by using the ELC linking function to set a periodic pulse generated by pulse output timer m as a trigger for operations of the peripheral module.

The ELIPACR register can be used to set up the one-time-only output of event signals to the ELC or of IPLS interrupt requests.

For the IPLS interrupt, see section 36.4, Interrupts.

36.2.4 ELC Output/IPLS Interrupt Enable Automatic Clearing Register (ELIPACR)

Address(es): EPTPC.ELIPACR 000C 4014h

Bit	Symbol	Bit Name	Description	R/W
b12	CYCN4	ELIPPR.CYCN4 Bit Automatic Clearing	0: Disables automatic clearing of the enable bit for the output of falling edges of pulse output timer 4. 1: Enables automatic clearing of the enable bit for the output of falling edges of pulse output timer 4.	R/W
b13	CYCN5	ELIPPR.CYCN5 Bit Automatic Clearing	0: Disables automatic clearing of the enable bit for the output of falling edges of pulse output timer 5. 1: Enables automatic clearing of the enable bit for the output of falling edges of pulse output timer 5.	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	PLSP	ELIPPR.PLSP Bit Automatic Clearing	0: Disables automatic clearing of the enable bit for IPLS interrupt requests in response to detection of rising edges of the pulse output timer. 1: Enables automatic clearing of the enable bit for IPLS interrupt requests in response to detection of rising edges of the pulse output timer.	R/W
b23 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R
b24	PLSN	ELIPPR.PLSN Bit Automatic Clearing	0: Disables automatic clearing of the enable bit for IPLS interrupt requests in response to detection of falling edges of the pulse output timer. 1: Enables automatic clearing of the enable bit for IPLS interrupt requests in response to detection of falling edges of the pulse output timer.	R/W
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R

The ELIPACR register is used to enable one-time output of each event to the ELC or each IPLS interrupt request triggered by detecting edges of the periodic pulses of pulse output timer m.
Normally, an event is output to the ELC or an IPLS interrupt request is generated at each edge of the periodic pulses of pulse output timer m while the corresponding bit in the ELIPPR register is 1 (enabled),
When a bit in the ELIPPR register is 1 while the corresponding bit in the ELIPACR register is also 1, the bit in the ELIPPR register automatically becomes 0 when the event signal for the ELC or IPLS interrupt request is generated.
For the IPLS interrupt, see section 36.4, Interrupts.

36.2.5 STCA Status Register (STSR)

Address(es): EPTPC.STSR 000C 4040h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	W10D	SYNTOUT	—	SYNCOUT	SYNC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SYNC	Synchronized State Detection Flag	0: Synchronization is not detected. 1: Synchronization is detected.	R/W*1
b1	SYNCOUT	Synchronization Loss Detection Flag	0: A loss of synchronization is not detected. 1: A loss of synchronization is detected.	R/W*1
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R
b3	SYNTOUT	Sync Message Reception Timeout Detection Flag	0: A Sync message reception timeout is not detected. 1: A Sync message reception timeout is detected.	R/W*1
b4	W10D	Worst 10 Acquisition Completion Flag	0: The worst 10 values have not been acquired yet. 1: The worst 10 values have been acquired.	R/W*1
b31 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: When the SYNSTARTR.STR bit is 0, the value of the corresponding flag remains.
Note 1. Writing 1 clears the flag. Writing 0 does not affect the flag value.

The STSR register indicates the state of the STCA module.

SYNC Flag (Synchronized State Detection Flag)

This flag indicates that synchronization has occurred more than the number of times specified by the STMR.SYTH[3:0] bits in succession when the STMR.ALEN0 bit is 1. When the STMR.ALEN0 bit is 0, the SYNC flag is not set to 1 even if synchronization has occurred more than the specified number of times in succession.

SYNCOUT Flag (Synchronization Loss Detection Flag)

This flag indicates that loss of synchronization has occurred more than the number of times specified by the STMR.DVTH[3:0] bits in succession when the STMR.ALEN0 bit is 1.
Since the time is not synchronized immediately after time synchronization is started (SYNSTARTR.STR bit is set to 1), the SYNCOUT becomes 1 regardless of the STMR.ALEN0 bit setting. When using the SYNTOUT flag, set the SYNTOUT flag to 0 immediately after starting time synchronization.
When the STMR.ALEN0 bit is 0, the SYNCOUT flag does not become 1 even if loss of synchronization has occurred more than the specified number of times in succession after time synchronization is started and the SYNTOUT flag is immediately set to 0.

SYNTOUT Flag (Sync Message Reception Timeout Detection Flag)

This flag indicates that a Sync message has not been received during the period specified by the SYNTOR register when the STMR.ALEN1 bit is 1. The SYNTOUT flag becomes 1 immediately if time synchronization is started (SYNSTARTR.STR bit is set to 1) when no Sync message has been received after the EPTPC starts. When using the SYNTOUT flag, set the SYNTOUT flag to 0 immediately after starting time synchronization.

W10D Flag (Worst 10 Acquisition Completion Flag)

This flag indicates that acquisition of the worst 10 has been completed.

36.2.6 STCA Status Notification Enable Register (STIPR)

Address(es): EPTPC.STIPR 000C 4044h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	W10D	SYNTOUT	—	SYNCOUT	SYNC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SYNC	SYNC Status Notification Enable	0: Disables notification of the state of STSR.SYNC. 1: Enables notification of the state of STSR.SYNC.	R/W
b1	SYNCOUT	SYNCOUT Status Notification Enable	0: Disables notification of the state of STSR.SYNCOUT. 1: Enables notification of the state of STSR.SYNCOUT.	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R
b3	SYNTOUT	SYNTOUT Status Notification Enable	0: Disables notification of the state of STSR.SYNTOUT. 1: Enables notification of the state of STSR.SYNTOUT.	R/W
b4	W10D	W10D Status Notification Enable	0: Disables notification of the state of STSR.W10D. 1: Enables notification of the state of STSR.W10D.	R/W
b31 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R

The STIPR register specifies whether the MIESR.ST flag does or does not reflect changes in the state of the STCA module.

36.2.7 STCA Clock Frequency Setting Register (STCFR)

Address(es): EPTPC.STCFR 000C 4050h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STCF[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	STCF[1:0]	STCA Clock Frequency	b1 b0 0 0: 20 MHz 0 1: 25 MHz 1 0: 50 MHz 1 1: 100 MHz	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: Set a value in this register before starting the EDMAC, ETHERC, and PTPEDMAC. Do not change the settings during operations.

The STCFR register is used to select the frequency of the clock source for the STCA module (STCA clock).
The setting in the STCFR register must be for the same frequency as that selected by the setting of the STCSELR register.

STCF[1:0] Bits (STCA Clock Frequency)

These bits select the frequency of the STCA clock.
To enable synchronous control in compliance with IEEE 1588, the STCA clock frequency must be selected from 20 MHz, 25 MHz, 50 MHz, or 100 MHz. If the frequency selected by these bits differs from the clock frequency actually input to the STCA module, operation is not guaranteed.

36.2.8 STCA Operating Mode Register (STMR)

Address(es): EPTPC.STMR 000C 4054h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	ALEN1	ALEN0	—	—	—	—	DVTH[3:0]				SYTH[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	W10S	—	CMOD	—	—	—	—	—	WINT[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	WINT[7:0]	Worst 10 Acquisition Time	00h: The worst 10 values are not acquired. 01h: Sync message reception: 1 time : FFh: Sync message reception: 255 times	R/W
b12 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R
b13	CMOD	Time Synchronization Correction Mode	0: Mode 1 1: Mode 2	R/W
b14	—	Reserved	This bit is read as 0. The write value should be 0.	R
b15	W10S	Worst 10 Acquisition Control Select	0: Measurement is started by hardware and the value acquired in the PW10VR or MW10R register is used as the limit for filtering. 1: Measurement is started by the GETW10R.GW10 bit. Also, the value set in the PLIMITR or MLIMITR register is used as the limit for filtering.	R/W
b19 to b16	SYTH[3:0]	Synchronized State Detection Threshold Setting	0h: None *1 1h: 1 time : Fh: 15 times	R/W
b23 to b20	DVTH[3:0]	Synchronization Loss Detection Threshold Setting	0h: None *2 1h: 1 time : Fh: 15 times	R/W
b27 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R
b28	ALEN0	Alarm Detection Enable 0	0: The STSR.SYNC or SYNCOUT flag is not set to 1 on detection of synchronization or loss of synchronization. 1: The STSR.SYNC or SYNCOUT flag is set to 1 on detection of synchronization or loss of synchronization.	R/W
b29	ALEN1	Alarm Detection Enable 1	0: The STSR.SYNTOUT flag is not set to 1 on detection of the Sync message reception timeout interrupt. 1: The STSR.SYNTOUT flag is not set to 1 on detection of the Sync message reception timeout interrupt.	R/W
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. The STSR.SYNC flag does not become 1 regardless of the ALEN0 bit setting.
Note 2. The STSR.SYNCOUT flag does not become 1 regardless of the ALEN0 bit setting.

The STMR register is used to set the operating mode of the STCA module.

WINT[7:0] Bits (Worst 10 Acquisition Time)

These bits set the time for acquiring the worst 10 gradients (the number of times Sync messages are received). Usually, it is recommended to set the number of times of Sync message receptions to 32 or more.

CMOD Bit (Time Synchronization Correction Mode)

Mode 1 or mode 2 can be selected to correct the local time information when the EPTPC operates as a slave clock. Select the appropriate mode in consideration of system configuration, etc.
Table 36.7 is a summary of the two individual correction modes.

Table 36.7 Types and Features of Correction Mode

Correction Mode	Function	Features	Notes
Mode 1	Mode for correcting the counter every Sync message reception by using the current offsetFromMaster (operation is in mode 1 after the start of correction, and then shifts to the specified mode).	The time information of the master clock is set as the local time information at a time.	Synchronization cannot be guaranteed if calculating offsetFromMaster is not possible (e.g. packets are temporarily being discarded due to a failure of communications).
Mode 2	Mode where the gradient value calculated from offsetFromMaster (worst-10 control) is retained and used in correcting the local time information so that it approximates the time information of the master clock.	Even if calculating offsetFromMaster is not possible, a certain level of synchronization can be guaranteed in this mode (the counter is still corrected from the gradient information).	Establishing synchronization takes longer.

W10S Bit (Worst 10 Acquisition Control Select)

This bit selects the value used for measurement and filtering of worst 10 gradients. When this bit is set to 0, the values acquired in registers PW10VRU, PW10VRM, and PW10VRL and registers MW10RU, MW10RM, and MW10RL are used as the limit for the filter. When the bit is set to 1, the values set in registers PLIMITRU, PLIMITRM, and PLIMITRL and registers MLIMITRU, MLIMITRM, and MLIMITRL are used as the limit for the filter.

SYTH[3:0] Bits (Synchronized State Detection Threshold Setting)

These bits specify a value for the number of consecutive times being within the thresholds will be judged as synchronization. Specifically, the value falling within the thresholds set in registers SYNTDBRU and SYNTDBRL as many times as the value of these bits indicates the synchronized state. When the ALEN0 bit is 1, the STSR.SYNCOUT flag becomes 1.

DVTH[3:0] Bits (Synchronization Loss Detection Threshold Setting)

These bits specify a value for the number of consecutive times exceeding a threshold will be judged as a loss of synchronization. Specifically, synchronization is judged to have been lost when the value in registers SYNTDARU and SYNTDARL is consecutively exceeded as many times as the value of these bits. When the ALEN0 bit is 1, the STSR.SYNCOUT flag becomes 1.

ALEN0 Bit (Alarm Detection Enable 0)

When this bit is 1, the STSR.SYNC or SYNCOUT flag is set to 1 on detection of synchronization or loss of synchronization. When this bit is 0, the SYNC or SYNCOUT flag is not set to 1 even if synchronization or loss of synchronization is detected.

ALEN1 Bit (Alarm Detection Enable 1)

When this bit is 1, the STSR.SYNTOUT flag is set to 1 if a Sync message is not received within the time specified by the SYNTOR register. When this bit is 0, the SYNTOUT flag is not set to 1 even if the reception timeout has occurred.

36.2.9 Sync Message Reception Timeout Register (SYNTOR)

Address(es): EPTPC.SYNTOR 000C 4058h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	A Sync message not being received within 1024 × n (ns), where n is the setting, leads to a timeout for reception of Sync messages, leading to the STSR.SYNTOUT flag being set to 1.	R/W

The SYNTOR register is used to specify the timeout period for reception of Sync messages. The timeout period is 1024 times the setting of these bits, in units of nanoseconds.

A Sync message not being received within the period specified by these bits is judged to represent a timeout.

When the SYNTOR register is 0, the STSR.SYNTOUT flag does not become 1.

36.2.10 IPLS Interrupt Request Timer Select Register (IPTSELR)

Address(es): EPTPC.IPTSELR 000C 4060h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	IPTSEL5	IPTSEL4	IPTSEL3	IPTSEL2	IPTSEL1	IPTSEL0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IPTSEL0	Pulse Output Timer 0 Select	0: Pulse output timer 0 is not selected as a source of IPLS interrupt requests. 1: Pulse output timer 0 is selected as a source of IPLS interrupt requests.	R/W
b1	IPTSEL1	Pulse Output Timer 1 Select	0: Pulse output timer 1 is not selected as a source of IPLS interrupt requests. 1: Pulse output timer 1 is selected as a source of IPLS interrupt requests.	R/W
b2	IPTSEL2	Pulse Output Timer 2 Select	0: Pulse output timer 2 is not selected as a source of IPLS interrupt requests. 1: Pulse output timer 2 is selected as a source of IPLS interrupt requests.	R/W
b3	IPTSEL3	Pulse Output Timer 3 Select	0: Pulse output timer 3 is not selected as a source of IPLS interrupt requests. 1: Pulse output timer 3 is selected as a source of IPLS interrupt requests.	R/W
b4	IPTSEL4	Pulse Output Timer 4 Select	0: Pulse output timer 4 is not selected as a source of IPLS interrupt requests. 1: Pulse output timer 4 is selected as a source of IPLS interrupt requests.	R/W
b5	IPTSEL5	Pulse Output Timer 5 Select	0: Pulse output timer 5 is not selected as a source of IPLS interrupt requests. 1: Pulse output timer 5 is selected as a source of IPLS interrupt requests.	R/W
b31 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R

The IPTSELR register is used to select the pulse output timer that generates IPLS interrupt requests.
Each pulse output timer m (m = 0 to 5) takes the clock signal from the STCA as its clock source and produces pulses with a specified period and duty cycle. An IPLS interrupt is requested on rising edges if the ELIPPR.PLSP bit is set to 1 and on falling edges if the PLSN bit in the same register is set to 1. The interrupt request signal becomes the logical OR of the interrupt requests from the given channels when bits for multiple channels in register IPTSELR are set to 1. For the IPLS interrupt, see section 36.4, Interrupts.

36.2.11 MINT Interrupt Request Timer Select Register (MITSELR)

Address(es): EPTPC.MITSELR 000C 4064h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit Name	Description	R/W
b0	MINTEN0	Pulse Output Timer 0 MINT Interrupt Output Enable	0: Output of rising edges by pulse output timer 0 is not reflected by the MIESR.CYC0 flag as a MINT interrupt source. 1: Output of rising edges by pulse output timer 0 is reflected by the MIESR.CYC0 flag as a MINT interrupt source.	R/W
b1	MINTEN1	Pulse Output Timer 1 MINT Interrupt Output Enable	0: Output of rising edges by pulse output timer 1 is not reflected by the MIESR.CYC1 flag as a MINT interrupt source. 1: Output of rising edges by pulse output timer 1 is reflected by the MIESR.CYC1 flag as a MINT interrupt source.	R/W
b2	MINTEN2	Pulse Output Timer 2 MINT Interrupt Output Enable	0: Output of rising edges by pulse output timer 2 is not reflected by the MIESR.CYC2 flag as a MINT interrupt source. 1: Output of rising edges by pulse output timer 2 is reflected by the MIESR.CYC2 flag as a MINT interrupt source.	R/W
b3	MINTEN3	Pulse Output Timer 3 MINT Interrupt Output Enable	0: Output of rising edges by pulse output timer 3 is not reflected by the MIESR.CYC3 flag as a MINT interrupt source. 1: Output of rising edges by pulse output timer 3 is reflected by the MIESR.CYC3 flag as a MINT interrupt source.	R/W
b4	MINTEN4	Pulse Output Timer 4 MINT Interrupt Output Enable	0: Output of rising edges by pulse output timer 4 is not reflected by the MIESR.CYC4 flag as a MINT interrupt source. 1: Output of rising edges by pulse output timer 4 is reflected by the MIESR.CYC4 flag as a MINT interrupt source.	R/W
b5	MINTEN5	Pulse Output Timer 5 MINT Interrupt Output Enable	0: Output of rising edges by pulse output timer 5 is not reflected by the MIESR.CYC5 flag as a MINT interrupt source. 1: Output of rising edges by pulse output timer 5 is reflected by the MIESR.CYC5 flag as a MINT interrupt source.	R/W
b31 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R

The MITSELR register is used to select pulse output timer m that generates MINT interrupt requests.
Each pulse output timer m (m = 0 to 5) takes the clock signal from the STCA as its clock source and produces pulses with a specified period and duty cycle. A MINT interrupt is requested on rising edges of the pulse signal from the corresponding pulse output timer m if the setting of the MIEIPR.CYCm bit is 1.
For the MINT interrupt, see section 36.4, Interrupts.

36.2.12 ELC Output Timer Select Register (ELTSELR)

Address(es): EPTPC.ELTSELR 000C 4068h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	ELTDIS5	ELTDIS4	ELTDIS3	ELTDIS2	ELTDIS1	ELTDIS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ELTDIS0	Pulse Output Timer 0 Event Generation Disable	0: Pulse output timer 0 is used for the generation of event signals for the ELC. 1: Pulse output timer 0 is not used for the generation of event signals for the ELC.	R/W
b1	ELTDIS1	Pulse Output Timer 1 Event Generation Disable	0: Pulse output timer 1 is used for the generation of event signals for the ELC. 1: Pulse output timer 1 is not used for the generation of event signals for the ELC.	R/W
b2	ELTDIS2	Pulse Output Timer 2 Event Generation Disable	0: Pulse output timer 2 is used for the generation of event signals for the ELC. 1: Pulse output timer 2 is not used for the generation of event signals for the ELC.	R/W
b3	ELTDIS3	Pulse Output Timer 3 Event Generation Disable	0: Pulse output timer 3 is used for the generation of event signals for the ELC. 1: Pulse output timer 3 is not used for the generation of event signals for the ELC.	R/W
b4	ELTDIS4	Pulse Output Timer 4 Event Generation Disable	0: Pulse output timer 4 is used for the generation of event signals for the ELC. 1: Pulse output timer 4 is not used for the generation of event signals for the ELC.	R/W
b5	ELTDIS5	Pulse Output Timer 5 Event Generation Disable	0: Pulse output timer 5 is used for the generation of event signals for the ELC. 1: Pulse output timer 5 is not used for the generation of event signals for the ELC.	R/W
b31 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R

The ELTSELR register is used to select pulse output timer m that outputs event signals to the ELC.
Each pulse output timer m (m = 0 to 5) takes the clock signal from the STCA as its clock source and produces pulses with a specified period and duty cycle. An event signal is output to the ELC on rising edges if the ELIPPR.CYCPm bit is set to 1 and on falling edges if the CYCNm bit in the same register is set to 1.
For the output of event signals to the ELC, see section 36.4, Interrupts.

36.2.13 Time Synchronization Channel Select Register (STCHSELR)

Address(es): EPTPC.STCHSELR 000C 406Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SYSEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SYSEL	Timer Information Input Select	0: Time information from the SYNFP0 module is used. 1: Time information from the SYNFP1 module is used.	R/W*1
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Do not change the value of this bit while the SYNSTARTR.STR bit is 1.

The STCHSELR register selects the time information input to the STCA module.

36.2.14 Slave Time Synchronization Start Register (SYNSTARTR)

Address(es): EPTPC.SYNSTARTR 000C 4080h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STR	Slave Time Synchronization Control	0: Slave time synchronization is stopped. 1: Slave time synchronization is started.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SYNSTARTR register is used to start or stop time synchronization. This register is used when the EPTPC is operating as a slave node.

36.2.15 Local Clock Counter Initial Value Load Directive Register (LCIVLDR)

Address(es): EPTPC.LCIVLDR 000C 4084h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LOAD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	LOAD	Local Clock Counter Initial Value Load Directive	0: The initial value is not loaded into the local clock counter. 1: The initial value is loaded into the local clock counter.	W*1
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Do not change the value of this bit while the SYNSTARTR.STR bit is 1.

The LCIVLDR register is used to set the value of registers LCIVRU, LCIVRM, and LCIVRL as the initial value of the local clock counter.

36.2.16 Synchronization Loss Detection Threshold Registers (SYNTDARU, SYNTDARL)

Address(es): EPTPC.SYNTDARU 000C 4090h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the higher-order 32 bits of the threshold for detection of loss of synchronization.	R/W

Address(es): EPTPC.SYNTDARL 000C 4094h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the lower-order 32 bits of the threshold for detection of loss of synchronization.	R/W

The settings of the SYNTDARU and SYNTDARL registers specify the threshold value for offsetFromMaster to be used in judging loss of synchronization. When setting a threshold value, write the higher-order 32 bits to SYNTDARU and the lower-order 32 bits to SYNTDARL, in that order and in consecutive operations.

If the offsetFromMaster value exceeds the value specified in SYNTDARU and SYNTDARL, a loss of synchronization is detected. Set a value in SYNTDARU and SYNTDARL in units of nanoseconds.

SYNTDARU and SYNTDARL are not used when the device is operating as a master clock.

36.2.17 Synchronization Detection Threshold Registers (SYNTDBRU, SYNTDBRL)

Address(es): EPTPC.SYNTDBRU 000C 4098h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the higher-order 32 bits of the threshold for detection of synchronization.	R/W

Address(es): EPTPC.SYNTDBRL 000C 409Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the lower-order 32 bits of the threshold for detection of synchronization.	R/W

The settings of the SYNTDBRU and SYNTDBRL registers specify the threshold value for offsetFromMaster to be used in judging synchronization. When setting a threshold value, write the higher-order 32 bits to SYNTDBRU and the lower-order 32 bits to SYNTDBRL, in that order and in consecutive operations.
If the offsetFromMaster value is less than the value specified in SYNTDBRU and SYNTDBRL, synchronization is detected. Set a value in SYNTDBRU and SYNTDBRL in units of nanoseconds.
SYNTDBRU and SYNTDBRL are not used when the device is operating as a master clock.

36.2.18 Local Clock Counter Initial Value Registers (LCIVRU, LCIVRM, LCIVRL)

Address(es): EPTPC.LCIVRU 000C 40B0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	—	These bits hold the setting for the higher-order 16 bits of the integer portion of the initial value for the local clock counter.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Address(es): EPTPC.LCIVRM 000C 40B4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the lower-order 32 bits of the integer portion of the initial value for the clock counter.	R/W

Address(es): EPTPC.LCIVRL 000C 40B8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the fractional portion of the initial value of the clock counter in nanoseconds.	R/W

Registers LCIVRU, LCIVRM, and LCIVRL specify the initial value in seconds of the clock counter. When setting an initial value, write the higher-order 16 bits of the integer portion to LCIVRU, the lower-order 32 bits of the integer portion to LCIVRM, and the fractional portion in nanoseconds to LCIVRL, in that order and in consecutive operations. The value of registers LCIVRU, LCIVRM, and LCIVRL can be used as the initial value of the local clock counter. When setting the value of registers LCIVRU, LCIVRM, and LCIVRL in the local clock counter, set the LCIVLDR.LOAD bit to 1.

Example) When 2.000000025s is to be set as the initial value, write the following values to each of the registers.
LCIVRU: 0000 0000h
LCIVRM: 0000 0002h
LCIVRL: 0000 0019h

36.2.19 Worst 10 Acquisition Directive Register (GETW10R)

Address(es): EPTPC.GETW10R 000C 4124h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	GW10
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	GW10	Worst 10 Acquisition Directive	0: The worst-10 values are not acquired. 1: Starts acquisition of the worst-10 values.	R/W*1
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Do not set this bit to 1 while the STMR.W10S bit is 0.

The GETW10R register is used in software control to start calculation of gradient values for use in selecting the worst-10 values.
A gradient value is the amount by which the timer counter of a slave is incremented when a given interval elapses. Setting the GW10 bit to 1 while the value of the STMR.W10S bit is 1 selects calculation of a gradient value by the EPTPC each time it receives a Sync message. Gradient values are calculated the number of times specified by the STMR.WINT[7:0] bits. The GW10 bit is cleared to 0 on completion of this number of calculations. The GETW10R register is not used in operation as a master clock.

36.2.20 Positive Gradient Limit Registers (PLIMITRU, PLIMITRM, PLIMITRL)

Address(es): EPTPC.PLIMITRU 000C 4128h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the middle-order 32 bits of the limit for the positive gradient.	R/W

Address(es): EPTPC.PLIMITRL 000C 4130h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the lower-order 32 bits of the limit for the positive gradient.	R/W

Registers PLIMITRU, PLIMITRM, and PLIMITRL are used to specify an upper limit on gradient (= positive gradient) for use in time synchronization. When setting an upper limit, write values consecutively to PLIMITRU, PLIMITRM, and PLIMITRL in that order.
The gradients that exceed the value specified in registers PLIMITRU, PLIMITRM, and PLIMITRL are not used in time synchronization. Registers PLIMITRU, PLIMITRM, PLIMITRL are not used when the device is operating as a master clock. Registers PLIMITRU, PLIMITRM, and PLIMITRL are effective while the STMR.CMOD and W10S bits are 1.

The gradient value to be set in the register is calculated by using the following expression.

PLIMITRU, PLIMITRM, and PLIMITRL register values = A (s)/T (s) × 2^{32}

A: The time (s) by which the slave local clock counter advances during the interval between received Sync messages

T: The actual time (s) between received Sync messages

For example, if the interval between Sync messages is 0.5 seconds and the local clock counter advances by 0.7 seconds during that time, and this is to be set as the limit, then the setting for PLIMITR = 0.7/0.5 × 2^{32} = 6 012 954 214 = 1 6666 6666h,
and the settings for the individual registers are as follows: PLIMITRU = 0000 0000h, PLIMITRM = 0000 0001h, and PLIMITRL = 6666 6666h.

The minimum setting depends on the STCA clock frequency as the clock source for counting by the local clock counter. For example, if the STCA clock frequency is 50 MHz, then the minimum allowable setting for registers PLIMITRU, PLIMITRM, and PLIMITRL = (1/50 (MHz)) (s)/0.5 (s) × 2^{32} = 172 = ACh,
and the settings for the individual registers are as follows: PLIMITRU = 0000 0000h, PLIMITRM = 0000 0000h, and PLIMITRL = 0000 00ACh.
The gradient limit values to be set are valid when time synchronization correction mode is mode 2 (the STMR.CMOD bit is 1) and the gradient is controlled by software (the STMR.W10S bit is 1).

36.2.21 Negative Gradient Limit Registers (MLIMITRU, MLIMITRM, MLIMITRL)

Address(es): EPTPC.MLIMITRU 000C 4134h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the lower-order 32 bits of the limit for the negative gradient.	R/W

Registers MLIMITRU, MLIMITRM, and MLIMITRL are used to specify a lower limit for the gradient (= negative gradient) for use in time synchronization. Use two's complement to set a lower limit. When setting a lower limit, write values consecutively to MLIMITRU, MLIMITRM, and MLIMITRL in that order.
The gradients that are less than the value specified in registers MLIMITRU, MLIMITRM, and MLIMITRL are not used in time synchronization. Registers MLIMITRU, MLIMITRM, and MLIMITRL are not used when the device is operating as a master clock. Registers MLIMITRU, MLIMITRM, and MLIMITRL are effective while the STMR.CMOD and W10S bits are 1.
The procedure for setting a value and the minimum value that can be set are the same as for registers PLIMITRU, PLIMITRM, and PLIMITRL.

36.2.22 Statistical Information Retention Control Register (GETINFOR)

Address(es): EPTPC.GETINFOR 000C 4140h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	INFO
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	INFO	Information Retention Control	[When written] 0: Has no effects. 1: Information is retained. [When read] 0: Information retention is completed. 1: Processing for information retention is in progress. Once information fetching is directed, values of various statistical information read before completion of information fetching are not guaranteed.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

The GETINFOR register controls retention of the following statistical information.

- Registers LCCVRU, LCCVRM, and LCCVRL
- Registers PW10VRU, PW10VRM, and PW10VRL
- Registers MW10RU, MW10RM, and MW10RL

The only value that is writable to the INFO bit is 1. When setting a value in registers PW10VRU, PW10VRM, and PW10VRL, or registers MW10RU, MW10RM, and MW10RL, set the INFO bit to 1 only while the STMR.W10S bit is 1. If the INFO bit is set to 1 before acquisition of the worst-10 values is completed, whether the information retained in registers PW10VRU, PW10VRM, and PW10VRL and registers MW10RU, MW10RM, MW10RL is correct or not is not guaranteed. Use the GETW10R.GW10 bit to confirm that acquisition has been completed before setting the INFO bit to 1. The INFO bit is automatically returned to 0 on completion of information fetching.

36.2.23 Local Clock Counters (LCCVRU, LCCVRM, LCCVRL)

Address(es): EPTPC.LCCVRU 000C 4170h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits are for reading the lower-order 32 bits of the integer portion of the local clock counter's value.	R

Address(es): EPTPC.LCCVRL 000C 4178h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits are for reading the fractional portion of the local clock counter's value (in nanoseconds).	R

Registers LCCVRU, LCCVRM, and LCCVRL indicate the local clock counter's value.
When the GETINFOR.INFO bit is set to 1, the value of the local clock counter at that time is stored in registers LCCVRU, LCCVRM, and LCCVRL. The higher-order 16 bits of the integer portion in seconds are saved in LCCVRU, the lower-order 32 bits of the integer portion in seconds are saved in LCCVRM, and the fractional portion in nanoseconds is saved in LCCVRL.
For example, if the local time information is 14:25, 44 seconds, 10 milliseconds, 23 microseconds, and 39 nanoseconds, registers LCCVRU, LCCVRM, and LCCVRL have $14 \times 3600 + 25 \times 60 + 44 = 51944$ (s) = 0000 0000 CAE8h as the setting of the higher-order 48 bits and $10 \times 10^6 + 23 \times 10^3 + 39 = 10023039$ (ns) = 0098 F07Fh as the setting of the lower-order 32 bits.

36.2.24 Positive Gradient Worst 10 Value Registers (PW10VRU, PW10VRM, PW10VRL)

Address(es): EPTPC.PW10VRU 000C 4210h

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the lower-order 32 bits of the start time of the pulse output timer in nanoseconds.	R/W

Registers TMSTTRUm and TMSTTRLm are used to set the start time of pulse output timer m.

Set the start time of pulse output timer m (64 bits) in units of nanoseconds. Though the setting is in units of nanoseconds, the start time of pulse output timer m depends on the resolution of the STCA clock.

For example, if the STCA clock is running at 50 MHz, one cycle takes 20 ns, so the time at which the timer starts may differ from the time set in registers TMSTTRUm and TMSTTRLm by up to 20 ns.

When writing to registers TMSTTRUm and TMSTTRLm, write values consecutively in order of TMSTTRUm and then TMSTTRLm while the TMSTARTR.ENm bit is 0.

Note, however, that the format for setting times in registers TMSTTRUm and TMSTTRLm differs from that described in section 36.2.23, Local Clock Counters (LCCVRU, LCCVRM, LCCVRL).

36.2.27 Timer Cycle Setting Registers m (TMCYCRm) (m = 0 to 5)

Address(es): EPTPC.TMCYCR0 000C 4308h, EPTPC.TMCYCR1 000C 4318h, EPTPC.TMCYCR2 000C 4328h, EPTPC.TMCYCR3 000C 4338h, EPTPC.TMCYCR4 000C 4348h, EPTPC.TMCYCR5 000C 4358h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b29 to b0	—	—	These bits set the cycle of the pulse output timer in nanoseconds. Set a value that is equivalent to at least four cycles of the STCA clock.	R/W
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R

A TMCYCRm register specifies the period of the output signal generated by the corresponding pulse output timer m. Set a value in nanoseconds that is equivalent to at least four cycles of the STCA clock while the value of the TMSTARTR.ENm bit is 0.

Though the settings of TMCYCRm registers are in units of nanoseconds, the period of the output signal generated by pulse output timer m and the time at which the timer starts depend on the period of the STCA clock. For example, one cycle of the STCA clock running at 50 MHz takes 20 ns, so the clock source for counting by pulse output timer m may differ from the period set in the TMCYCRm registers by up to 19 ns. The SYNFP module handles calculations to correct this difference.

For example, if the setting for the timer period is 81 ns and the STCA clock is running at 50 MHz, the only available settings close to the actual timer period are for 80 ns or 100 ns. By setting the timer period in the SYNFP module to 80 ns for 19 and to 100 ns for 1 of every 20 cycles, we are able to adjust the average period to 81 ns.

(80 (ns) × 19 + 100 (ns) × 1)/20 = 81 (ns)

The minimum value that can be set in a TMCYCRm register is four cycles of the STCA clock. For example, if the STCA clock is running at 50 MHz, the minimum setting corresponds to 80 ns. Timer operation is not guaranteed if a value set in one of these registers is less than this value.

36.2.28 Timer Pulse Width Setting Register m (TMPLSRm) (m = 0 to 5)

Address(es): EPTPC.TMPLSR0 000C 430Ch, EPTPC.TMPLSR1 000C 431Ch, EPTPC.TMPLSR2 000C 432Ch, EPTPC.TMPLSR3 000C 433Ch, EPTPC.TMPLSR4 000C 434Ch, EPTPC.TMPLSR5 000C 435Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	—	—	These bits set the width at high level of the pulse signal from the timer in nanoseconds. Set a value that is equivalent to at least two cycles of the STCA clock.	R/W
b31 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R

A TMPLSRm register specifies the width at high level of the output signal generated by the corresponding pulse output timer m.

When the TMSTARTR.ENm bit is 0, set a value corresponding to a time no shorter than two cycles of the STCA clock in units of nanoseconds.

The higher-order 3 bits of the TMPLSRm register are reserved. These bits are read as 000b. When writing, write 000b to these bits.

Though the settings of the TMPLSRm register are in units of nanoseconds, the width at high level of the signal from the timer depends on the period of the STCA clock. The method for correcting the width at high level of the signal from the timer is the same as that for correcting the timer periods set by the TMCYCRm register.

36.2.29 Timer Start Register (TMSTARTR)

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	OVRE0	Relay Packet Overflow Detection Flag 0	0: No overflow in transfer of data from SYNFP1 to PTPEDMAC 1: An overflow has been detected in transfer of data from SYNFP1 to PTPEDMAC.	R/W*1
b1	OVRE1	Relay Packet Overflow Detection Flag 1	0: No overflow in transfer of data from SYNFP0 to PTPEDMAC 1: An overflow has been detected in transfer of data from SYNFP0 to PTPEDMAC.	R/W*1
b2	OVRE2	Relay Packet Overflow Detection Flag 2	0: No overflow in transfer of data from SYNFP1 to SYNFP0 1: An overflow has been detected in transfer of data from SYNFP1 to SYNFP0.	R/W*1
b3	OVRE3	Relay Packet Overflow Detection Flag 3	0: No overflow in transfer of data from SYNFP0 to SYNFP1 1: An overflow has been detected in transfer of data from SYNFP0 to SYNFP1.	R/W*1
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	MACE	Source MAC Address Mismatch Detection Flag	0: A MAC address mismatch has not been detected. 1: A MAC address mismatch has been detected.	R/W*1
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R
b27 to b16	—	Reserved	These bits are read as undefined. The write value should be 0.	R/W
b28	URE0	Relay Packet Underflow Detection Flag 0	0: No underflow in transfer of data from SYNFP1 to SYNFP0 1: An underflow has been detected in transfer of data from SYNFP1 to SYNFP0.	R/W*1
b29	URE1	Relay Packet Underflow Detection Flag 1	0: No underflow in transfer of data from SYNFP0 to SYNFP1 1: An underflow has been detected in transfer of data from SYNFP0 to SYNFP1.	R/W*1
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writing 1 clears the flag. Writing 0 does not affect the flag value.

The PRSR register indicates the state of the PRC-TC module.
The PRC-TC module transmits and receives Ethernet packets through Ethernet port 0, Ethernet port 1, and the PTPEDMAC.
The PRSR register indicates the states as overflows, underflows, and non-matching MAC addresses in the transmission and reception of Ethernet packets.

OVRE0 Flag (Relay Packet Overflow Detection Flag 0)

This flag indicates that the FIFO buffer has overflowed while packets were being transferred from the SYNFP1 module to the PTPEDMAC. The data received in the PTPEDMAC may be incorrect if the setting of the OVRE0 flag is 1.

OVRE1 Flag (Relay Packet Overflow Detection Flag 1)

This flag indicates that the FIFO buffer has overflowed while packets were being transferred from the SYNFP0 module to the PTPEDMAC. The data received in the PTPEDMAC may be incorrect if the setting of the OVRE1 flag is 1.

OVRE2 Flag (Relay Packet Overflow Detection Flag 2)

This flag indicates that the FIFO buffer has overflowed while packets were being transferred from the SYNFP1 module to the SYNFP0 module.

OVRE3 Flag (Relay Packet Overflow Detection Flag 3)

This flag indicates that the FIFO buffer has overflowed while packets were being transferred from the SYNFP0 module to the SYNFP1 module.

MACE Flag (Source MAC Address Mismatch Detection Flag)

This flag becomes 1 if the source MAC address of a packet for transmission from the PTPEDMAC matches none of registers PRMACRU0, PRMACRL0, PRMACRU1, and PRMACRL1.

URE0 Flag (Relay Packet Underflow Detection Flag 0)

This flag indicates that the FIFO buffer has underflowed while packets were being transferred from the SYNFP1 module to the SYNFP0 module.

URE1 Flag (Relay Packet Underflow Detection Flag 1)

This flag indicates that the FIFO buffer has underflowed while packets were being transferred from the SYNFP0 module to the SYNFP1 module.

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b23 to b0	—	—	These bits hold the setting for the lower-order 24 bits of the local MAC address for Ethernet port 0.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R

Registers PRMACRU0 and PRMACRL0 are used to set the local MAC address for Ethernet port 0. Set the higher-order 24 bits and the lower-order 24 bits of the MAC address in PRMACRU0 and PRMACRL0, respectively.
These registers are used in transmission from the PTPEDMAC to send frames from transmission sources with MAC addresses matching the value of this register to Ethernet port 0. Set registers PRMACRU0 and PRMACRL0 to the same value as registers SYMACRU and SYMACRL for the EPTPC0 module.
Rewrite registers PRMACRU0 and PRMACRL0 before starting the EDMAC, ETHERC, and PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.33 Channel 1 Local MAC Address Registers (PRMACRU1, PRMACRL1)

Address(es): EPTPC.PRMACRU1 000C 4418h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit Name	Description	R/W
b23 to b0	—	—	These bits hold the setting for the higher-order 24 bits of the local MAC address for Ethernet port 1.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R

Address(es): EPTPC.PRMACRL1 000C 441Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b23 to b0	—	—	These bits hold the setting for the lower-order 24 bits of the local MAC address for Ethernet port 1.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R

Registers PRMACRU1 and PRMACRL1 are used to set the local MAC address for Ethernet port 1. Set the higher-order 24 bits and the lower-order 24 bits of the MAC address in registers PRMACRU1 and PRMACRL1, respectively.
These registers are used in transmission from the PTPEDMAC to send frames from transmission sources with MAC addresses matching the value of this register to Ethernet port 1. Set registers PRMACRU1 and PRMACRL1 to the same value as registers SYMACRU and SYMACRL for the EPTPC1 module.
Rewrite registers PRMACRU1 and PRMACRL1 before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.34 Packet Transmission Control Register (TRNDISR)

Address(es): EPTPC.TRNDISR 000C 4420h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TDIS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	TDIS[1:0]	Packet Transmission Control	b1 b0 0 0: PTP packets are transmitted through both Ethernet port 0 and Ethernet port 1. 0 1: PTP packets are only transmitted through Ethernet port 0. 1 0: PTP packets are only transmitted through Ethernet port 1. 1 1: Setting prohibited	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R

The TRNDISR register controls transmission of PTP packets when Ethernet port 0 and Ethernet port 1 have the same local MAC address.

When registers PRMACRU0 and PRMACRL0 and registers PRMACRU1 and PRMACRL1 have the same local MAC address setting, the EPTPC can selects whether PTP packets with the matching address are transmitted through both ports or are only transmitted through one port or the other.

If Ethernet port 0 and Ethernet port 1 have different local MAC address settings, set the TDIS[1:0] bits to 00b. If the setting is other than 00b, the transmission of frames with an source MAC address matching that of the Ethernet port may be blocked.

Rewrite the TRNDISR register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.35 Relay Mode Register (TRNMR)

Address(es): EPTPC.TRNMR 000C 4430h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	FWD1	FWD0	—	—	—	—	—	—	—	MOD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MOD	Cut-Through Mode	0: Store-and-forward 1: Cut-through	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	FWD0	Channel 0 Relay Enable	0: Unicast, multicast (other than PTP packets), and broadcast messages from the other node are not relayed from port 0 to port 1. 1: Unicast, multicast (other than PTP packets), and broadcast messages from the other node are relayed from port 0 to port 1.	R/W
b9	FWD1	Channel 1 Relay Enable	0: Unicast, multicast (other than PTP packets), and broadcast messages from the other node are not relayed from port 1 to port 0. 1: Unicast, multicast (other than PTP packets), and broadcast messages from the other node are relayed from port 1 to port 0.	R/W
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R

The TRNMR register is used to control relaying of packets between Ethernet port 0 and Ethernet port 1 by the PRC-TC module. For example, as Figure 36.3 shows, if the network is in a daisy-chain configuration, packets can be transferred through all three devices by enabling relaying of packets between Ethernet port 0 and Ethernet port 1 in the center of the figure.

For recalculating the CRC value in packet transfer, in the case of cut-through mode, a packet that had an abnormal CRC value may be transferred with a normal CRC value. Use store-and-forward mode when abnormal packets need to be discarded. There is no difference in the latency of transfer in cut-through mode and store-and-forward mode when the length of the packets is shorter than 96 bytes.

Rewrite the TRNMR register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

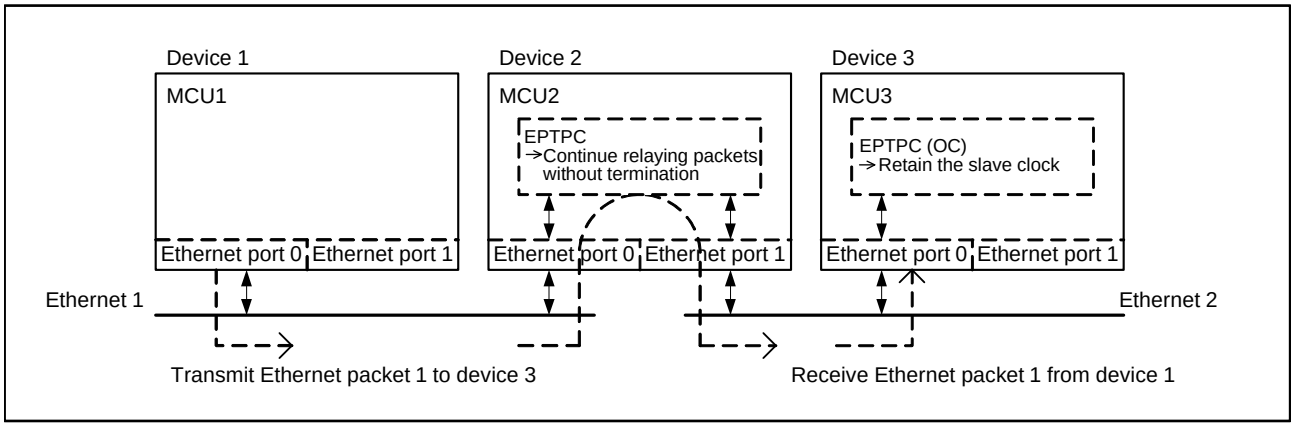

Figure 36.3 Network Configuration Example

36.2.36 Cut-Through Transfer Start Threshold Register (TRNCTTDR)

Address(es): EPTPC.TRNCTTDR 000C 4434h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	THVAL[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	THVAL[10:0]	FIFO Read Start Threshold	Threshold for starting to read data from the relay FIFO in cut-through mode (specified as the number of bytes)*1, *2	R
b10 to b2				R/W
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. A value cannot be set in the lower-order 2 bits. These bits are fixed to 0.
Note 2. A value of less than 96 bytes cannot be set.

The TRNCTTDR register is used to set the threshold for the transmitting port starting to read data from the relay FIFO when the cut-through method is selected for relaying between the Ethernet ports.
When the TRNMR.MOD bit is 1, data transfer can start without waiting for all frame data to be stored in the relay FIFO. The setting of the THVAL[10:0] bits is the amount of data, in bytes, that must be stored in the relay FIFO before transmission starts. Set a multiple of four as the threshold value.
Reading from the relay FIFO starts when either of the following conditions is met.

- The relay FIFO holds at least as much data as the number of bytes specified by the THVAL[10:0] bits.
- The relay FIFO holds at least one frame.

Rewrite the TRNCTTDR register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.37 SYNFP Status Register (SYSR)

Address(es): EPTPC0.SYSR 000C 4800h, EPTPC1.SYSR 000C 4C00h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	GENDN	RESDN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	OFMUD	offsetFromMaster Value Update Flag	0: The offsetFromMaster value has not been updated. 1: The offsetFromMaster value has been updated.	R/W*1
b1	INTCHG	Receive logMessageInterval Value Change Detection Flag	0: No change in the received logMessageInterval value. 1: A change in the received logMessageInterval value.	R/W*1
b2	MPDUD	meanPathDelay Value Update Flag	0: The meanPathDelay value has not been updated. 1: The meanPathDelay value has been updated.	R/W*1
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R
b4	DRPTO	Delay_Resp/Pdelay_Resp Reception Timeout Detection Flag	0: A Delay_Resp/Pdelay_Resp timeout has not occurred. 1: A Delay_Resp/Pdelay_Resp timeout has occurred.	R/W*1
b5	INTDEV	Receive logMessageInterval Value Out-of-Range Flag	0: The received logMessageInterval value is within the range. 1: The received logMessageInterval value is out of the range.	R/W*1
b6	DRQOVR	Delay_Req Reception FIFO Overflow Detection Flag	0: The received Delay_Req has not caused the reception FIFO to overflow. 1: The received Delay_Req has caused the reception FIFO to overflow.	R/W*1
b11 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R
b12	RECLP	Loop Reception Detection Flag	0: A received message has not returned through a loop. 1: A received message has returned through a loop.	R/W*1
b13	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b14	INFABT	Control Information Abnormality Detection Flag	0: No abnormality in control information 1: Abnormality in control information	R/W*1
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R
b16	RESDN	Response Stop Completion Detection Flag	0: Stopping responses has not been completed. 1: Stopping responses has been completed.	R/W*1
b17	GENDN	Generation Stop Completion Detection Flag	0: Stopping generation has not been completed. 1: Stopping generation has been completed.	R/W*1
b23 to b18	—	Reserved	These bits are read as undefined. The write value should be 0.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writing 1 clears the flag. Writing 0 does not affect the flag value.

The SYSR register indicates the state of the SYNFP module.

OFMUD Flag (offsetFromMaster Value Update Flag)

This flag indicates that the value of offsetFromMaster has been updated.

INTCHG Flag (Receive logMessageInterval Value Change Detection Flag)

This flag indicates that the logMessageInterval value of the Delay_Resp, Sync or Announce message differs from the previously received value.

MPDUD Flag (meanPathDelay Value Update Flag)

This flag indicates that the value of meanPathDelay has been updated.

DRPTO Flag (Delay_Resp/Pdelay_Resp Reception Timeout Detection Flag)

This flag indicates that a Delay_Resp or Pdelay_Resp message has not been received within the period set in the RSTOUTR register.

INTDEV Flag (Receive logMessageInterval Value Out-of-Range Flag)

This flag indicates the reception of a Delay_Resp message with a logMessageInterval value outside the range -7 to 6.

DRQOVR Flag (Delay_Req Reception FIFO Overflow Detection Flag)

This flag indicates that the FIFO buffer for storing information from received Delay_Req messages holds 32 or more entries.

RECLP Flag (Loop Reception Detection Flag)

This flag indicates that the value of the sourcePortIdentity field in a received PTP message matches the local PortIdentity (as set by registers SYCIDRU, SYCIDRL, and SYPNUMR).

INFABT Flag (Control Information Abnormality Detection Flag)

This flag indicates that the control information included a mismatch.
When this bit becomes 1, reset the EPTPC, PTPEDMAC, and the corresponding channels ETHERC and EDMAC.
Follow the procedure below to reset these modules:

(1) Write 0000 0001h to the EPTPC.PTRSTR register.
(2) Write 0000 0001h to the PTPEDMAC.EDMR register.
(3) Write 0000 0001h to the EDMACn.EDMR register of the corresponding channels.
(4) Wait for 64 cycles of the PCLKA until initialization is completed.
(5) Write 0000 0000h to the EPTPC.PTRSTR register.

Refer to section 36.2.83, PTP Reset Register (PTRSTR) and section 37.2.1, EDMAC Mode Register (EDMR) for details of resets.

RESDN Flag (Response Stop Completion Detection Flag)

This flag indicates the end of processing for transmission of a Delay_Resp or Pdelay_Resp as response messages when the handling of a received Delay_Req or Pdelay_Req by the SYNFP module has been disabled by the setting of the SYRFL1R or SYRVLDR register.

GENDN Flag (Generation Stop Completion Detection Flag)

This flag indicates the end of processing for transmission of messages of a type disabled in the SYTRENR or SYRVLDR register.

36.2.38 SYNFP Status Notification Enable Register (SYIPR)

b1	INTCHG	SYSR.INTCHG Status Notification Enable	0: Disables notification of the state of SYSR.INTCHG. 1: Enables notification of the state of SYSR.INTCHG.	R/W
b2	MPDUD	SYSR.MPDUD Status Notification Enable	0: Disables notification of the state of SYSR.MPDUD. 1: Enables notification of the state of SYSR.MPDUD.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R
b4	DRPTO	SYSR.DRPTO Status Notification Enable	0: Disables notification of the state of SYSR.DRPTO. 1: Enables notification of the state of SYSR.DRPTO.	R/W
b5	INTDEV	SYSR.INTDEV Status Notification Enable	0: Disables notification of the state of SYSR.INTDEV. 1: Enables notification of the state of SYSR.INTDEV.	R/W
b6	DRQOVR	SYSR.DRQOVR Status Notification Enable	0: Disables notification of the state of SYSR.DRQOVR. 1: Enables notification of the state of SYSR.DRQOVR.	R/W
b11 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R
b12	RECLP	SYSR.RECLP Status Notification Enable	0: Disables notification of the state of SYSR.RECLP. 1: Enables notification of the state of SYSR.RECLP.	R/W
b13	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b14	INFABT	SYSR.INFABT Status Notification Enable	0: Disables notification of the state of SYSR.INFABT. 1: Enables notification of the state of SYSR.INFABT.	R/W
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R
b16	RESDN	SYSR.RESDN Status Notification Enable	0: Disables notification of the state of SYSR.RESDN. 1: Enables notification of the state of SYSR.RESDN.	R/W
b17	GENDN	SYSR.GENDN Status Notification Enable	0: Disables notification of the state of SYSR.GENDN. 1: Enables notification of the state of SYSR.GENDN.	R/W
b23 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SYIPR register specifies whether the MIESR.SYn flag does or does not reflect changes in the state of the SYNFPn module.

36.2.39 SYNFP MAC Address Registers (SYMACRU, SYMACRL)

Address(es): EPTPC0.SYMACRU 000C 4810h, EPTPC1.SYMACRU 000C 4C10h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b23 to b0	—	—	These bits hold the setting for the higher-order 24 bits of the local MAC address.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Address(es): EPTPC0.SYMACRL 000C 4814h, EPTPC1.SYMACRL 000C 4C14h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b23 to b0	—	—	These bits hold the setting for the lower-order 24 bits of the local MAC address.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Registers SYMACRU and SYMACRL are used to specify the local MAC address for Ethernet ports 0 and 1. Rewrite registers SYMACRU and SYMACRL before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.40 SYNFP Local IP Address Register (SYIPADDRR)

Address(es): EPTPC0.SYIPADDRR 000C 481Ch, EPTPC1.SYIPADDRR 000C 4C1Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the local IP address.	R/W

The SYIPADDRR register is used to specify the local IP address for Ethernet ports 0 and 1.
Rewrite the SYIPADDRR register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.41 SYNFP Specification Version Setting Register (SYSPVRR)

Address(es): EPTPC0.SYSPVRR 000C 4840h, EPTPC1.SYSPVRR 000C 4C40h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TRSP[3:0]				VER[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	VER[3:0]	versionPTP Field Value	These bits are used to set the versionPTP field value of the PTP v2 header. When a message is received, this value is compared with the versionPTP field of the received frame. In generating messages, the value is used for the versionPTP field of the frame for transmission. Set these bits to 0010b (PTP v2).	R/W
b7 to b4	TRSP[3:0]	transportSpecific Field Value	These bits are used to set the transportSpecific field value of the PTP v2 header. When a message is received, this value is compared with the transportSpecific field of the received frame. In generating messages, the value is used for the transportSpecific field of the frame for transmission. Set these bits to 0000b (IEEE 1588).	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SYSPVRR register is used to set the transportSpecific and versionPTP field values of the PTP v2 message header. The value should not be modified while reception or transmission of PTP messages is enabled.

36.2.42 SYNFP Domain Number Setting Register (SYDOMR)

Address(es): EPTPC0.SYDOMR 000C 4844h, EPTPC1.SYDOMR 000C 4C44h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	DNUM[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	DNUM[7:0]	domainNumber Field Value Setting	These bits are used to set the domainNumber field value of the PTP v2 header. When a message is received, this value is compared with the domainNumber field of the received frame as a condition for PTP reception processing. In generating messages, the value is used for the domainNumber field of the frame for transmission.	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SYDOMR register is used to set the domainNumber field value of the PTP v2 message header. The value should not be modified while reception or transmission of PTP messages is enabled.

36.2.43 Announce Message Flag Field Setting Register (ANFR)

Address(es): EPTPC0.ANFR 000C 4850h, EPTPC1.ANFR 000C 4C50h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	FLAG14	FLAG13	—	—	FLAG10	—	FLAG8	—	—	FLAG5	FLAG4	FLAG3	FLAG2	FLAG1	FLAG0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FLAG0	leap61	This bit is used to set the logical value of the leap61 member of timePropertiesDS. 0: leap61 is set to FALSE. 1: leap61 is set to TRUE.	R/W
b1	FLAG1	leap59	This bit is used to set the logical value of the leap59 member of timePropertiesDS. 0: leap59 is set to FALSE. 1: leap59 is set to TRUE.	R/W
b2	FLAG2	currentUtcOffsetValid	This bit is used to set the logical value of the currentUtcOffsetValid member of timePropertiesDS. 0: currentUtcOffsetValid is set to FALSE. 1: currentUtcOffsetValid is set to TRUE.	R/W
b3	FLAG3	ptpTimescale	This bit is used to set the logical value of the ptpTimescale member of timePropertiesDS. 0: ptpTimescale is set to FALSE. 1: ptpTimescale is set to TRUE.	R/W
b4	FLAG4	timeTraceable	This bit is used to set the logical value of the timeTraceable member of timePropertiesDS. 0: timeTraceable is set to FALSE. 1: timeTraceable is set to TRUE.	R/W
b5	FLAG5	frequencyTraceable	This bit is used to set the logical value of the frequencyTraceable member of timePropertiesDS. 0: frequencyTraceable is set to FALSE. 1: frequencyTraceable is set to TRUE.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	FLAG8	alternateMasterFlag	0: alternateMasterFlag is set to FALSE. 1: alternateMasterFlag is set to TRUE.	R/W
b9	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b10	FLAG10	unicastFlag	0: unicastFlag is set to FALSE. 1: unicastFlag is set to TRUE.	R/W
b12, b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13	FLAG13	PTP profile Specific 1	0: PTP profile Specific 1 is set to FALSE. 1: PTP profile Specific 1 is set to TRUE.	R/W
b14	FLAG14	PTP profile Specific 2	0: PTP profile Specific 2 is set to FALSE. 1: PTP profile Specific 2 is set to TRUE.	R/W
b31 to b15	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ANFR register is used to set the flagField section of the header when the SYNFP module is to generate an Announce message.

The value specified by the ANFR register is only reflected in the SYNFP module after the SYRVLDR.ANUP bit is set to 1.

36.2.44 Sync Message Flag Field Setting Register (SYNFR)

Address(es): EPTPC0.SYNFR 000C 4854h, EPTPC1.SYNFR 000C 4C54h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	FLAG14	FLAG13	—	—	FLAG10	FLAG9	FLAG8	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	FLAG8	alternateMasterFlag	0: alternateMasterFlag is set to FALSE. 1: alternateMasterFlag is set to TRUE.	R/W
b9	FLAG9	twoStepFlag	Set this bit to 0 (FALSE).	R/W
b10	FLAG10	unicastFlag	0: unicastFlag is set to FALSE. 1: unicastFlag is set to TRUE.	R/W
b12, b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13	FLAG13	PTP profile Specific 1	0: PTP profile Specific 1 is set to FALSE. 1: PTP profile Specific 1 is set to TRUE.	R/W
b14	FLAG14	PTP profile Specific 2	0: PTP profile Specific 2 is set to FALSE. 1: PTP profile Specific 2 is set to TRUE.	R/W
b31 to b15	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SYNFR register is used to set the flagField section of the header when the SYNFP module is to generate a Sync message.

The value specified by the SYNFR register is only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

36.2.45 Delay_Req Message Flag Field Setting Register (DYRQFR)

Address(es): EPTPC0.DYRQFR 000C 4858h, EPTPC1.DYRQFR 000C 4C58h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	FLAG14	FLAG13	—	—	FLAG10	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b10	FLAG10	unicastFlag	0: unicastFlag is set to FALSE. 1: unicastFlag is set to TRULE.	R/W
b12, b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13	FLAG13	PTP profile Specific 1	0: PTP profile Specific 1 is set to FALSE. 1: PTP profile Specific 1 is set to TRULE.	R/W
b14	FLAG14	PTP profile Specific 2	0: PTP profile Specific 2 is set to FALSE. 1: PTP profile Specific 2 is set to TRULE.	R/W
b31 to b15	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Register DYRQFR is used to set the flagField section of the header when the SYNFP module is to generate a Delay_Req or Pdelay_Req message.
The value specified by DYRQFR is only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

36.2.46 Delay_Resp Message Flag Field Setting Register (DYRPFR)

Address(es): EPTPC0.DYRPFR 000C 485Ch, EPTPC1.DYRPFR 000C 4C5Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	FLAG14	FLAG13	—	—	FLAG10	FLAG9	FLAG8	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	FLAG8	alternateMasterFlag*1	0: alternateMasterFlag is set to FALSE. 1: alternateMasterFlag is set to TRUE.	R/W
b9	FLAG9	twoStepFlag*2	Set this bit to 0 (FALSE).	R/W
b10	FLAG10	unicastFlag	0: unicastFlag is set to FALSE. 1: unicastFlag is set to TRUE.	R/W
b12, b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13	FLAG13	PTP profile Specific 1	0: PTP profile Specific 1 is set to FALSE. 1: PTP profile Specific 1 is set to TRUE.	R/W
b14	FLAG14	PTP profile Specific 2	0: PTP profile Specific 2 is set to FALSE. 1: PTP profile Specific 2 is set to TRUE.	R/W
b31 to b15	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. This bit is reserved for Pdelay_Resp messages. Set the bit to 0.
Note 2. This bit is reserved for Delay_Resp messages.

The DYRPFR register is used to set the flagField section of the header when the SYNFP module is to generate a Delay_Resp or PDelay_Resp message.
The value specified by the DYRPFR register is only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.
Do not change the value of the DYRPFR register while processing for the transmission of Delay_Resp or Pdelay_Resp messages is enabled. Furthermore, after disabling this processing for transmission, do not change the value of the DYRPFR register until the SYSR.RESDN flag becomes 1.

36.2.47 SYNFP Local Clock ID Registers (SYCIDRU, SYCIDRL)

Address(es): EPTPC0.SYCIDRU 000C 4860h, EPTPC1.SYCIDRU 000C 4C60h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the higher-order 32 bits of the clock-ID of the local port.	R/W

Address(es): EPTPC0.SYCIDRL 000C 4864h, EPTPC1.SYCIDRL 000C 4C64h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the lower-order 32 bits of the clock-ID of the local port.	R/W

The SYCIDR registers are used to set the clock-ID of the local port.
The registers are used for the clockIdentity section in the sourcePortIdentity field of the header when the SYNFP module is to generate a PTP message.
When a PTP message is received, the value of these registers is compared with the clockIdentity section in the sourcePortIdentity field of the PTP message to determine whether the message is one that was transmitted by you.
Usually, the setting should be the same as the value of portDS.portIdentity.clockIdentity.
Do not change the value of these registers while processing for the reception or transmission of PTP messages is enabled.

36.2.48 SYNFP Local Port Number Register (SYPNUMR)

Address(es): EPTPC0.SYPNUMR 000C 4868h, EPTPC1.SYPNUMR 000C 4C68h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PNUM[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	PNUM[15:0]	Local Port Number Setting	These bits hold the setting for the port number of the local port.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SYPNUMR register is used to set the port number of the local port.
This register is used for the portNumber section in the sourcePortIdentity field of the header when the SYNFP module is to generate a PTP message.
When a PTP message is received, the value of this register is compared with the portNumber section in the sourcePortIdentity field of the PTP message to determine whether the message is one that was transmitted by the local device.
Usually, the setting should be the same as the value of portDS.portIdentity.portNumber.
Do not change the value of this register while processing for the reception or transmission of PTP messages is enabled.

36.2.49 SYNFP Register Value Load Directive Register (SYRVLDR)

Address(es): EPTPC0.SYRVLDR 000C 4880h, EPTPC1.SYRVLDR 000C 4C80h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	ANUP	STUP	BMUP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BMUP	BMC Update	When this bit is set to 1, the SYNFP module simultaneously reflects values of registers storing the MasterClock identifying information.	W
b1	STUP	State Update	When this bit is set to 1, the SYNFP module simultaneously reflects register values for PTP message reception and transmission.	W
b2	ANUP	Announce Message Generation Information Update	When this bit is set to 1, the Announce message generation block simultaneously reflects register values required for generating Announce messages.	W
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SYRVLDR register is used for simultaneously updating multiple register values in the SYNFP module.

BMUP Bit (BMC Update)

When the BMUP bit is set to 1, the SYNFP module simultaneously reflects the values of registers storing the MasterClock identifying information listed below.

- Registers MTCIDU and MTCIDL
- MTPID register

STUP Bit (State Update)

When the STUP bit is set to 1, the SYNFP module simultaneously reflects the values of registers and bits for PTP message reception and transmission listed below.

- SYNFR register
- DYRQFR register
- SYTLIR.DREQ[7:0] bits
- RSTOUTR register
- SYRFL1R register
- SYRFL2R register
- SYTRENR register

ANUP Bit (Announce Message Generation Information Update)

When the ANUP bit is set to 1, the Announce message generation block simultaneously reflects the values of registers and bits required for generating Announce messages listed below.

- ANFR register
- SYTLIR.ANCE[7:0] bits
- GMPR register
- GMCQR register
- Registers GMIDRU and GMIDRL
- CUOTSR register
- SRR register

36.2.50 SYNFP Reception Filter Register 1 (SYRFL1R)

Address(es): EPTPC0.SYRFL1R 000C 4890h, EPTPC1.SYRFL1R 000C 4C90h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	PDFUP[2:0]			—	PDRP[2:0]			—	PDRQ[2:0]			—	DRP[2:0]

b17			0: The PRC-TC does not relay messages between ports 0 and 1. 1: The PRC-TC relays messages between ports 0 and 1.	R/W
b18			0: The SYNFP does not process messages. 1: The SYNFP processes messages.	R/W
b19	—	Reserved	This bit is read as 0. The write value should be 0.	R
b20	PDRQ[2:0]	Pdelay_Req Message Processing	0: Messages are not transferred to the PTPEDMAC. 1: Messages are transferred to the PTPEDMAC.	R/W
b21			0: The PRC-TC does not relay messages between ports 0 and 1. 1: The PRC-TC relays messages between ports 0 and 1.	R/W
b22			0: The SYNFP does not process messages. 1: The SYNFP processes messages.	R/W

Bit	Symbol	Bit Name	Description	R/W
b23	—	Reserved	This bit is read as 0. The write value should be 0.	R
b24	PDRP[2:0]	Pdelay_Resp Message Processing	0: Messages are not transferred to the PTPEDMAC. 1: Messages are transferred to the PTPEDMAC.	R/W
b25			0: The PRC-TC does not relay messages between ports 0 and 1. 1: The PRC-TC relays messages between ports 0 and 1.	R/W
b26			0: The SYNFP does not process messages. 1: The SYNFP processes messages.	R/W
b27	—	Reserved	This bit is read as 0. The write value should be 0.	R
b28	PDFUP[2:0]	Pdelay_Resp_Follow_Up Message Processing	0: Messages are not transferred to the PTPEDMAC. 1: Messages are transferred to the PTPEDMAC.	R/W
b29			0: The PRC-TC does not relay messages between ports 0 and 1. 1: The PRC-TC relays messages between ports 0 and 1.	R/W
b30			0: The SYNFP does not process messages. 1: The SYNFP processes messages.	R/W
b31	—	Reserved	This bit is read as 0. The write value should be 0.	R

The SYRFL1R register is used to set up filtering for the reception of PTP messages.
Multiple bits corresponding to different types of messages can be set to 1. Setting all bits for a type of message to 0 leads to all messages of the given type being discarded.
The value specified by the SYRFL1R register is only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

36.2.51 SYNFP Reception Filter Register 2 (SYRFL2R)

Address(es): EPTPC0.SYRFL2R 000C 4894h, EPTPC1.SYRFL2R 000C 4C94h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	ILL[1:0]		—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	SIG[1:0]		—	—	MAN[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MAN[1:0]	Management Message Processing Setting	0: Messages are not transferred to the PTPEDMAC. 1: Messages are transferred to the PTPEDMAC.	R/W
b1			0: The PRC-TC does not relay messages between ports 0 and 1. 1: The PRC-TC relays messages between ports 0 and 1.	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	SIG[1:0]	Signaling Message Processing Setting	0: Messages are not transferred to the PTPEDMAC. 1: Messages are transferred to the PTPEDMAC.	R/W
b5			0: The PRC-TC does not relay messages between ports 0 and 1. 1: The PRC-TC relays messages between ports 0 and 1.	R/W
b27 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R
b28	ILL[1:0]	Illegal Message Processing Setting*1	0: Messages are not transferred to the PTPEDMAC. 1: Messages are transferred to the PTPEDMAC.	R/W
b29			0: The PRC-TC does not relay messages between ports 0 and 1. 1: The PRC-TC relays messages between ports 0 and 1.	R/W
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. PTP messages other than PTP v2 messages and messages of undefined type are handled as illegal messages.

The SYRFL2R register is used to set up filtering for the reception of PTP messages.
Multiple bits corresponding to different types of messages can be set to 1. Setting all bits for a type of message to 0 leads to all messages of the given type being discarded.
The value specified by the SYRFL2R register is only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

36.2.52 SYNFP Transmission Enable Register (SYTRENR)

Address(es): EPTPC0.SYTRENR 000C 4898h, EPTPC1.SYTRENR 000C 4C98h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	PDRQ	—	—	—	DRQ	—	—	—	SYNC	—	—	—	ANCE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ANCE	Announce Message Transmission Enable	0: Announce messages are not transmitted. 1: Announce messages are transmitted.	R/W
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	SYNC	Sync Message Transmission Enable	0: Sync messages are not transmitted. 1: Sync messages are transmitted.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	DRQ	Delay_Req Message Transmission Enable	0: Delay_Req messages are not transmitted. 1: Delay_Req messages are transmitted.	R/W
b11 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R
b12	PDRQ	Pdelay_Req Message Transmission Enable	0: Pdelay_Req messages are not transmitted. 1: Pdelay_Req messages are transmitted.	R/W
b31 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SYTRENR register is used to enable or disable transmission of PTP messages.
The PDRQ and DRQ bits should not be set to 1 at the same time. Operation is not guaranteed when both bits are set to 1.
The value specified by the SYTRENR register is only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

36.2.53 Master Clock ID Registers (MTCIDU, MTCIDL)

Address(es): EPTPC0.MTCIDU 000C 48A0h, EPTPC1.MTCIDU 000C 4CA0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the higher-order 32 bits of the clock-ID of the master clock.	R/W

Address(es): EPTPC0.MTCIDL 000C 48A4h, EPTPC1.MTCIDL 000C 4CA4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the lower-order 32 bits of the clock-ID of the master clock.	R/W

Registers MTCIDU and MTCIDL are used to set the clock-ID of the master for synchronization.
The value specified by registers MTCIDU and MTCIDL is only reflected in the SYNFP module after the SYRVLDR.BMUP bit is set to 1.

36.2.54 Master Clock Port Number Register (MTPID)

Address(es): EPTPC0.MTPID 000C 48A8h, EPTPC1.MTPID 000C 4CA8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PNUM[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	PNUM[15:0]	Master Clock Port Number Setting	These bits hold the setting for the port number of the master clock.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

The MTPID register is used to set the port number of the master for synchronization.
The value specified by the MTPID register is only reflected in the SYNFP module after the SYRVLDR.BMUP bit is set to 1.
In normal usage, set the value of parentDS.parentPortIdentity.portNumber in this register.

36.2.55 SYNFP Transmission Interval Setting Register (SYTLIR)

Address(es): EPTPC0.SYTLIR 000C 48C0h, EPTPC1.SYTLIR 000C 4CC0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	DREQ[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SYNC[7:0]								ANCE[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	ANCE[7:0]	Announce Message Transmission Interval Setting	These bits set the interval for the transmission of Announce messages.	R/W
b15 to b8	SYNC[7:0]	Sync Message Transmission Interval Setting	These bits set the interval for the transmission of Sync messages. The setting is also placed in the logMessageInterval field of transmitted Sync messages.	R/W
b23 to b16	DREQ[7:0]	Delay_Req Transmission Interval Average Value/ Pdelay_Req Transmission Interval Setting	The bits set the average interval for the transmission of Delay_Req messages and the interval for the transmission of Pdelay_Req messages. The setting is also placed in the logMessageInterval field of Delay_Resp messages.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SYTLIR register is used to set the interval for the transmission of messages generated by the SYNFP module. The setting is an integer logarithm in base 2 ($\log_2(x)$) and determines a value x in seconds.
In other words, the interval for transmission is 2^n (s), where n is the setting. The available settings are from -7 (F9h) to +6 (06h).
Example:
If the setting is 06h, then the interval for transmission is $2^6 = 64$ (s).
If the setting is 00h, then the interval for transmission is $2^0 = 1$ (s).
If the setting is FFh, then the interval for transmission is $2^{-1} = 0.5$ (s) = 500 (ms).
If the setting is F9h, then the interval for transmission is $2^{-7} = 0.0078125$ (s) = 7.8125 (ms).

The value set in the ANCE[7:0] bits is only reflected in the SYNFP module after the SYRVLDR.ANUP bit is set to 1.
The value set in the DREQ[7:0] and SYNC[7:0] bits is only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

36.2.56 SYNFP Received logMessageInterval Value Indication Register (SYRLIR)

Address(es): EPTPC0.SYRLIR 000C 48C4h, EPTPC1.SYRLIR 000C 4CC4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	DRESP[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SYNC[7:0]								ANCE[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	ANCE[7:0]	Announce Message logMessageInterval Field Indication Flag	These bits indicate the logMessageInterval field value of a received Announce message.	R
b15 to b8	SYNC[7:0]	Sync Message logMessageInterval Field Indication Flag	These bits indicate the logMessageInterval field value of a received Sync message.	R
b23 to b16	DRESP[7:0]	Delay_Resp Message logMessageInterval Field Indication Flag	These bits indicate the logMessageInterval field value of a received Delay_Resp message.	R
b31 to b24	—	Reserved	These bits are read as 0.	R

The SYRLIR register indicates the logMessageInterval field values of received PTP messages.

36.2.57 offsetFromMaster Value Registers (OFMRU, OFMRL)

Address(es): EPTPC0.OFMRU 000C 48C8h, EPTPC1.OFMRU 000C 4CC8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits indicate the higher-order 32 bits of the calculated offsetFromMaster value.	R

Address(es): EPTPC0.OFMRL 000C 48CCh, EPTPC1.OFMRL 000C 4CCCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits indicate the lower-order 32 bits of the calculated offsetFromMaster value.	R

Registers OFMRU and OFMRL indicate the calculated offsetFromMaster value.
The value is expressed as two's complements in units of nanoseconds. Note that the numeric representation*1 differs from that of the offsetFromMaster member of the current data set (currentDS).
When read, access to the registers should be in order of OFMRU and then OFMRL.

Note 1. The value of currentDS.offsetFromMaster is multiplied by 2^{16}.
Example: 2.5 (ns) = 00000000_00028000h

36.2.58 meanPathDelay Value Registers (MPDRU, MPDRL)

Address(es): EPTPC0.MPDRU 000C 48D0h, EPTPC1.MPDRU 000C 4CD0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits indicate the higher-order 32 bits of the calculated meanPathDelay value.	R

Address(es): EPTPC0.MPDRL 000C 48D4h, EPTPC1.MPDRL 000C 4CD4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits indicate the lower-order 32 bits of the calculated meanPathDelay value.	R

Registers MPDRU and MPDRL indicate the calculated meanPathDelay value.
The value is expressed as two's complements in units of nanoseconds. Note that the numeric representation*1 differs from that of the meanPathDelay member of the current data set (currentDS).
When read, access to the registers should be in order of MPDRU and then MPDRL.

Note 1. The value of currentDS.meanPathDelay is multiplied by 2^{16}.
Example: 2.5 (ns) = 00000000_00028000h

36.2.59 grandmasterPriority Field Setting Register (GMPR)

Address(es): EPTPC0.GMPR 000C 48E0h, EPTPC1.GMPR 000C 4CE0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	GMPR1[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	GMPR2[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	GMPR2[7:0]	grandmasterPriority2 Field Value Setting	These bits are used to set the value of the grandmasterPriority2 fields of Announce messages.	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R
b23 to b16	GMPR1[7:0]	grandmasterPriority1 Field Value Setting	These bits are used to set the value of the grandmasterPriority1 fields of Announce messages.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R

The GMPR register is used to specify the grandmasterPriority1 and grandmasterPriority2 field values of Announce messages generated by the SYNFP module.
The value specified by the GMPR register is only reflected in the SYNFP module after the SYRVLDR.ANUP bit is set to 1.

36.2.60 grandmasterClockQuality Field Setting Register (GMCQR)

Address(es): EPTPC0.GMCQR 000C 48E4h, EPTPC1.GMCQR 000C 4CE4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits are used to set the value of the grandmasterClockQuality fields of Announce messages. The correspondence between bits and the grandmasterClockQuality fields is as listed below. b31 to b24: clockClass b23 to b16: clockAccuracy b15 to b0: offsetScaledLogVariance	R/W

The GMCQR register is used to specify the grandmasterClockQuality field value of Announce messages generated by the SYNFP module.

The value specified by the GMCQR register is only reflected in the SYNFP module after the SYRVLDR.ANUP bit is set to 1.

36.2.61 grandmasterIdentity Field Setting Registers (GMIDRU, GMIDRL)

Address(es): EPTPC0.GMIDRU 000C 48E8h, EPTPC1.GMIDRU 000C 4CE8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the higher-order 32 bits of the value of the grandmasterIdentity fields of Announce messages.	R/W

Address(es): EPTPC0.GMIDRL 000C 48ECh, EPTPC1.GMIDRL 000C 4CECh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the lower-order 32 bits of the value of the grandmasterIdentity fields of Announce messages.	R/W

Registers GMIDRU and GMIDRL are used to specify the grandmasterIdentity field value of Announce messages generated by the SYNFP module.
The value specified by registers GMIDRU and GMIDRL is only reflected in the SYNFP module after the SYRVLDR.ANUP bit is set to 1.

36.2.62 currentUtcOffset/timeSource Field Setting Register (CUOTSR)

Address(es): EPTPC0.CUOTSR 000C 48F0h, EPTPC1.CUOTSR 000C 4CF0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	CUTO[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TSRC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TSRC[7:0]	timeSource Field Setting	These bits set the value of the timeSource fields of Announce messages.	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R
b31 to b16	CUTO[15:0]	currentUtcOffset Field Setting	These bits set the value of the currentUtcOffset fields of Announce messages.	R/W

The CUOTSR register is used to specify the currentUtcOffset and timeSource field values of Announce messages generated by the SYNFP module.
The value specified by the CUOTSR register is only reflected in the SYNFP module after the SYRVLDR.ANUP bit is set to 1.

36.2.63 stepsRemoved Field Setting Register (SRR)

Address(es): EPTPC0.SRR 000C 48F4h, EPTPC1.SRR 000C 4CF4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SRMV[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	SRMV[15:0]	stepsRemoved Field Value Setting	These bits set the value of the stepsRemoved fields of Announce messages.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SRR register is used to specify the stepsRemoved field value of Announce messages generated by the SYNFP module.
The value specified by the SRR register is only reflected in the SYNFP module after the SYRVLDR.ANUP bit is set to 1.

36.2.64 PTP-primary Message Destination MAC Address Setting Registers (PPMACRU, PPMACRL)

Address(es): EPTPC0.PPMACRU 000C 4900h, EPTPC1.PPMACRU 000C 4D00h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	1	1	0	1	1	0	0	0	1	1	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b23 to b0	—	—	These bits hold the setting for the higher-order 24 bits of the destination MAC address for PTP-primary messages.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R

Address(es): EPTPC0.PPMACRL 000C 4904h, EPTPC1.PPMACRL 000C 4D04h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b23 to b0	—	—	These bits hold the setting for the lower-order 24 bits of the destination MAC address for PTP-primary messages.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R

The PPMACR registers are used to specify the destination MAC address for PTP-primary messages. In normal usage, set 01:1B:19:00:00:00 in these registers.

The value is used in the destination MAC address field when generating an Ethernet frame for a PTP-primary message. It is also used as a determining condition for received frames carrying PTP messages.

Set a value in these registers before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.65 PTP-pdelay Message MAC Address Setting Registers (PDMACRU, PDMACRL)

Address(es): EPTPC0.PDMACRU 000C 4908h, EPTPC1.PDMACRU 000C 4D08h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	0	0	0	0	0	0	0	1	1	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b23 to b0	—	—	These bits hold the setting for the higher-order 24 bits of the destination MAC address for PTP-pdelay messages.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R

Address(es): EPTPC0.PDMACRL 000C 490Ch, EPTPC1.PDMACRL 000C 4D0Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	0

Bit	Symbol	Bit Name	Description	R/W
b23 to b0	—	—	These bits hold the setting for the lower-order 24 bits of the destination MAC address for PTP-pdelay messages.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R

The PDMACR registers are used to specify the destination MAC address for PTP-pdelay messages. In normal usage, set 01:80:C2:00:00:0E in these registers.

The value is used in the destination MAC address field when generating frames carrying PTP-pdelay messages in the Ethernet format. It is also used as a determining condition for received frames carrying PTP messages.

Set a value in these registers before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.66 PTP Message Ethertype Setting Register (PETYPER)

Address(es): EPTPC0.PETYPER 000C 4910h, EPTPC1.PETYPER 000C 4D10h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TYPE[15:0]															
Value after reset:	1	0	0	0	1	0	0	0	1	1	1	1	0	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TYPE[15:0]	PTP Message Ethertype Value Setting	These bits hold the setting for the Ethertype field value for frames in the Ethernet II format.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

The PETYPER register is used to specify the Ethertype field for frames carrying the PTP messages. In normal usage, set 0000 88F7h in this register.

The value is used in the Ethertype field when generating frames carrying PTP messages in the Ethernet II format. It is also used as a determining condition for received frames carrying PTP messages.

Set a value in these registers before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.67 PTP-primary Message Destination IP Address Setting Register (PPIPR)

Address(es): EPTPC0.PPIPR 000C 4920h, EPTPC1.PPIPR 000C 4D20h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the destination IP address for PTP-primary messages.	R/W

The PPIPR register is used to specify the destination IP address for PTP messages. In normal usage, set E000 0181h (224.0.1.129) in this register.

The value is used in the destination IP address field when generating frames carrying PTP-primary messages in the IPv4 format. The lower-order 23 bits are also used in the destination MAC address field for Ethernet frames. The value is also used as a determining condition for received frames carrying PTP messages.

Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.68 PTP-pdelay Message Destination IP Address Setting Register (PDIPR)

Address(es): EPTPC0.PDIPR 000C 4924h, EPTPC1.PDIPR 000C 4D24h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	1	1	0	1	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the destination IP address for PTP-pdelay messages.	R/W

The PDIPR register is used to specify the destination IP address for PTP-pdelay messages. In normal usage, set E000 006Bh (224.0.0.107) in this register.
The value is used in the destination IP address field when generating frames carrying PTP-pdelay messages in the IPv4 format. The lower-order 23 bits are also used in the destination MAC address field for Ethernet frames. The value is also used as a determining condition for received frames carrying PTP messages.
Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.69 PTP Event Message TOS Setting Register (PETOSR)

Address(es): EPTPC0.PETOSR 000C 4928h, EPTPC1.PETOSR 000C 4D28h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	EVTO[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	EVTO[7:0]	PTP Event Message TOS Field Value Setting	These bits hold the setting for the value of the TOS field within the IPv4 headers of PTP event messages.	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

The PETOSR register is used to set the TOS (type of service) field value within the IPv4 headers of PTP event messages. Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.70 PTP general Message TOS Setting Register (PGTOSR)

Address(es): EPTPC0.PGTOSR 000C 492Ch, EPTPC1.PGTOSR 000C 4D2Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	GETO[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	GETO[7:0]	PTP general Message TOS Field Value Setting	These bits hold the setting for the value of the TOS field within the IPv4 headers of PTP general messages.	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

The PGTOSR register is used to set the TOS (type of service) field value within the IPv4 headers of PTP general messages.
Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.71 PTP-primary Message TTL Setting Register (PPTTLR)

Address(es): EPTPC0.PPTTLR 000C 4930h, EPTPC1.PPTTLR 000C 4D30h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	PRTL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	PRTL[7:0]	PTP-primary Message TTL Field Value Setting	These bits hold the setting for the value of the TTL field within the IPv4 headers of PTP-primary messages.	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

The PPTTLR register is used to set the TTL (time to live) field value within the IPv4 headers of PTP-primary messages. Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.72 PTP-pdelay Message TTL Setting Register (PDTTLR)

Address(es): EPTPC0.PDTTLR 000C 4934h, EPTPC1.PDTTLR 000C 4D34h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	PDTL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	PDTL[7:0]	PTP-pdelay Message TTL Field Value	These bits hold the setting for the value of the TTL field within the IPv4 headers of PTP-pdelay messages.	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

The PDTTLR register is used to set the TTL field value within the IPv4 headers of PTP-pdelay messages.
Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.73 PTP Event Message UDP Destination Port Number Setting Register (PEUDPR)

Address(es): EPTPC0.PEUDPR 000C 4938h, EPTPC1.PEUDPR 000C 4D38h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	EVUPT[15:0]															
Value after reset:	0	0	0	0	0	0	0	1	0	0	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	EVUPT[15:0]	PTP Event Message Destination Port Number Setting	These bits hold the setting for the value of the destination port number field within the UDP headers of PTP event messages.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

The PEUDPR register is used to set the destination port number field value within the UDP headers of PTP event messages. In normal usage, set 013Fh (319) in this register.
Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.74 PTP general Message UDP Destination Port Number Setting Register (PGUDPR)

Address(es): EPTPC0.PGUDPR 000C 493Ch, EPTPC1.PGUDPR 000C 4D3Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	GEUPT[15:0]															
Value after reset:	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	GEUPT[15:0]	PTP general Message Destination Port Number	These bits hold the setting for the value of the destination port number field within the UDP headers of PTP general messages.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

The PGUDPR register is used to set the destination port number field value within the UDP headers of PTP general messages. In normal usage, set 0140h (320) in this register.

Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.75 Frame Reception Filter Setting Register (FFLTR)

Address(es): EPTPC0.FFLTR 000C 4940h, EPTPC1.FFLTR 000C 4D40h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EXTPRM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	ENB	PRT	SEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SEL	Receive MAC Address Select*1	These bits select how filtering is handled when multicast frames other than PTP messages are received. b2 b1 b0 0 0 0: Filtering is disabled (all multicast frames are received). 0 0 1: Filtering is disabled (all multicast frames are received). 0 1 0: Filtering is disabled (all multicast frames are received). 0 1 1: Filtering is disabled (all multicast frames are received). 1 0 0: Do not receive multicast frames. 1 0 1: Do not receive multicast frames. 1 1 0: Only receive multicast frames matching the MAC address setting in registers FMAC0RU and FMAC0RL. 1 1 1: Only receive multicast frames matching the MAC address setting in registers FMAC1RU and FMAC1RL).	R/W
b1	PRT	Frame Reception Enable*1		R/W
b2	ENB	Reception Filter Enable*1		R/W
b15 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	EXTPRM	Extended Promiscuous Mode Setting	0: Normal operation (unicast frames addressed to the EPTPC are received, filtering of PTP frames is applied, multicast filtering is applied, and all broadcast frames are received). 1: Extended promiscuous mode (all frames are received)	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. The setting of these bits is only effective when the EXTPRM bit is 0.

The FFLTR register is used to switch extended promiscuous mode on or off and to select how filtering is handled when multicast frames other than PTP messages are received.

The filter for the reception of multicast frames other than PTP messages is enabled by setting the ENB, PRT, and SEL bits to 110b or 111b. Frames passed by the filter are then transferred by EDMACn.

Relaying of multicast frames other than PTP messages is in accord with the TRNMR register and relaying and reception of PTP messages is in accord with the setting of registers SYRFL1R and SYRFL2R.

Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.76 Frame Reception Filter MAC Address 0 Setting Registers (FMAC0RU, FMAC0RL)

Address(es): EPTPC0.FMAC0RU 000C 4960h, EPTPC1.FMAC0RU 000C 4D60h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	—	These bits hold the setting for the higher-order 16 bits of the asymmetric delay value. Set them to 0000h in this MCU.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

Address(es): EPTPC0.DASYMRL 000C 49C4h, EPTPC1.DASYMRL 000C 4DC4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	These bits hold the setting for the lower-order 32 bits of the asymmetric delay value. Set them to 0000 0000h in this MCU.	R/W

Registers DASYMRU and DASYMRL are used to set the asymmetric delay value (delayAsymmetry).
Set the registers DASYMRU and DASYMRL to 0000 0000h in this MCU.

36.2.79 Timestamp Latency Setting Register (TSLATR)

Address(es): EPTPC0.TSLATR 000C 49C8h, EPTPC1.TSLATR 000C 4DC8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	INGP[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	EGP[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	EGP[15:0]	Output Port Timestamp Latency Setting	These bits hold the setting for the time stamp latency (ns) for the output ports.	R/W
b31 to b16	INGP[15:0]	Input Port Timestamp Latency Setting	These bits hold the setting for the time stamp latency (ns) for the input ports.	R/W

The TSLATR register is used to set the amount of latency in timestamp acquisition in nanoseconds.
The value should not be modified while reception or transmission of PTP messages is enabled.

EGP[15:0] Bits (Output Port Timestamp Latency Setting)

Set the corresponding fixed value in Table 36.8. The timestamp latency differs with the link transfer rate (100 Mbps or 10 Mbps) and the frequency of the STCA clock (20, 25, 50, or 100 MHz).

Table 36.8 Settings of the EGP[15:0] Bits (ns)

		STCA Clock Frequency			
Link Transfer Rate		**20 MHz**	**25 MHz**	**50 MHz**	**100 MHz**
MII	100 Mbps	590	625	695	730
	10 Mbps	7430	7465	7535	7570
RMII	100 Mbps	770	805	875	910
	10 Mbps	9230	9265	9335	9370

INGP[15:0] Bits (Input Port Timestamp Latency Setting)

Set the corresponding fixed value in Table 36.9. The timestamp latency differs with the link transfer rate (100 Mbps or 10 Mbps) and the frequency of the STCA clock (20, 25, 50, or 100 MHz).

Table 36.9 Settings of the INGP[15:0] Bits (ns)

		STCA Clock Frequency			
Link Transfer Rate		**20 MHz**	**25 MHz**	**50 MHz**	**100 MHz**
MII	100 Mbps	980	945	875	840
	10 Mbps	8180	8145	8075	8015
RMII	100 Mbps	1060	1025	955	920
	10 Mbps	8980	8945	8875	8815

36.2.80 SYNFP Operation Setting Register (SYCONFR)

Address(es): EPTPC0.SYCONFR 000C 49CCh, EPTPC1.SYCONFR 000C 4DCCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	TCMOD	—	—	—	FILDIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	SBDIS	—	—	—	—	TCYC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TCYC[7:0]	PTP Message Transmission Interval Setting	These bits are used to set the time from the completion of one transmission to the start of the next in cycles of the transmission clock. A value n in these bits means that a transmission interval of n cycles will be secured. No interval is secured if the setting is 00h. The recommended value is 28h (40 cycles).	R/W
b11 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R
b12	SBDIS	Sync Message Transmission Bandwidth Securing Disable	0: Securing of the bandwidth for the transmission of SYNC messages is enabled (transfer by the EDMAC is given lower priority). 1: Securing of the bandwidth for the transmission of SYNC messages is disabled (transfer by the EDMAC is given higher priority).	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	FILDIS	Receive Message domainNumber Filter Disable	0: Filtering conditions for the reception of PTP messages include comparison with the domainNumber field. 1: Filtering conditions for the reception of PTP messages do not include comparison with the domainNumber field.	R/W
b19 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	TCMOD	TC Mode Setting	0: E2E TC 1: P2P TC	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SYCONFR register controls operation of the SYNFP module.
Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

TCYC[7:0] Bits (PTP Message Transmission Interval Setting)

The TCYC[7:0] bits are used to secure the waiting time between packets to keep a fixed transmission delay time.
The setting defines the interval from input of the transmission completed signal from the ETHERC to output of the next transmission request as a number of cycles of the transmission clock (which runs at 2.5 MHz if the link transfer rate is 10 Mbps and at 25 MHz if the rate is 100 Mbps).

SBDIS Bit (Sync Message Transmission Bandwidth Securing Disable)

This bit disables securing of bandwidth to increase accuracy of the interval for the transmission of SYNC messages.

TCMOD Bit (TC Mode Setting)

This bit sets the delay mechanism for operation as a transparent clock (TC). The bit setting changes the method of calculating the values used in the correctionField field during operation as a TC.

36.2.81 SYNFP Frame Format Setting Register (SYFORMR)

Address(es): EPTPC0.SYFORMR 000C 49D0h, EPTPC1.SYFORMR 000C 4DD0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FORM1	FORM0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FORM0	Ethernet Frame Format Setting	Set this bit to 0 (Ethernet II frame format).	R/W
b1	FORM1	Ethernet/UDP Encapsulation	0: PTP directly over Ethernet 1: PTP over UDP/IPv4	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SYFORMR register is used to set the format for frame generation by the SYNFP module.
Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

36.2.82 Response Message Reception Timeout Register (RSTOUTR)

Address(es): EPTPC0.RSTOUTR 000C 49D4h, EPTPC1.RSTOUTR 000C 4DD4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	Response Message Reception Timeout Time Setting	A response message not being received within n × 1024 (ns), where n is the setting, is judged to represent a timeout.	R/W

The RSTOUTR register is used to set the time for detection of a timeout in the reception of PTP response messages (Delay_Resp and Pdelay_Resp).
If a Delay_Resp or Pdelay_Resp message is not received within the time specified by this register after transmission of a Delay_Req or Pdelay_Req message, the SYSR.DRPTO flag becomes 1.
The value specified by this register is only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

36.2.83 PTP Reset Register (PTRSTR)

Address(es): EPTPC.PTRSTR 000C 0500h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RESET
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RESET	EPTPC Software Reset	0: The EPTPC is not reset. 1: The EPTPC is reset.*1	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Do not access the EPTPC-related registers other than this register while a software reset is being issued.

The PTRSTR register is used to reset the EPTPC.
It takes 64 cycles of the peripheral module clock (PCLKA) until initialization of the EPTPC is completed. After the RESET bit is set to 1, wait for 64 cycles of the PCLKA before setting its value back to 0.

36.2.84 STCA Clock Select Register (STCSELR)

Address(es): EPTPC.STCSELR 000C 0504h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SCLKSEL[2:0]			—	—	—	—	—	SCLKDIV[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SCLKDIV[2:0]	PCLKA Clock Frequency Division	b2 b0 0 0 1: 1 0 1 0: 1/2 0 1 1: 1/3 1 0 0: 1/4 1 0 1: 1/5 1 1 0: 1/6 Settings other than above are prohibited.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R
b10 to b8	SCLKSEL[2:0]	STCA Clock Select	b10 b8 0 0 0: PCLKA clock divided by 1 to 6 0 1 0: Input clock from the REF50CK0 pin 0 1 1: Input clock from the REF50CK1 pin Settings other than above are prohibited.	R/W
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R

The STCSELR register selects the STCA clock signal for use in the EPTPC.
Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

SCLKDIV[2:0] Bits (PCLKA Clock Frequency Division)

These bits set the division ratio of PCLKA.
When the setting of the SCLKSEL[2:0] bits is 000b, the frequency-divided PCLKA is used as the STCA clock signal.

SCLKSEL[2:0] Bits (STCA Clock Select)

These bits select the STCA clock signal for use in the EPTPC.

36.3 Operation

The EPTPC is set not to receive (analyze) and transmit (generate) PTP messages after release from the reset state. Accordingly, the EPTPC has no effect on the transmission and reception of frames by the ETHERC and EDMAC at that time.

Settings of the EPTPC registers are required for the ETHERC and EDMAC to be able to use packet filtering by MAC address in the SYNFP modules and for relaying between Ethernet ports by the PRC-TC module. That is, the transmission and reception of PTP messages requires setting of the EPTPC.

Figure 36.4 is a block diagram of the modules involved in transferring and relaying frames.

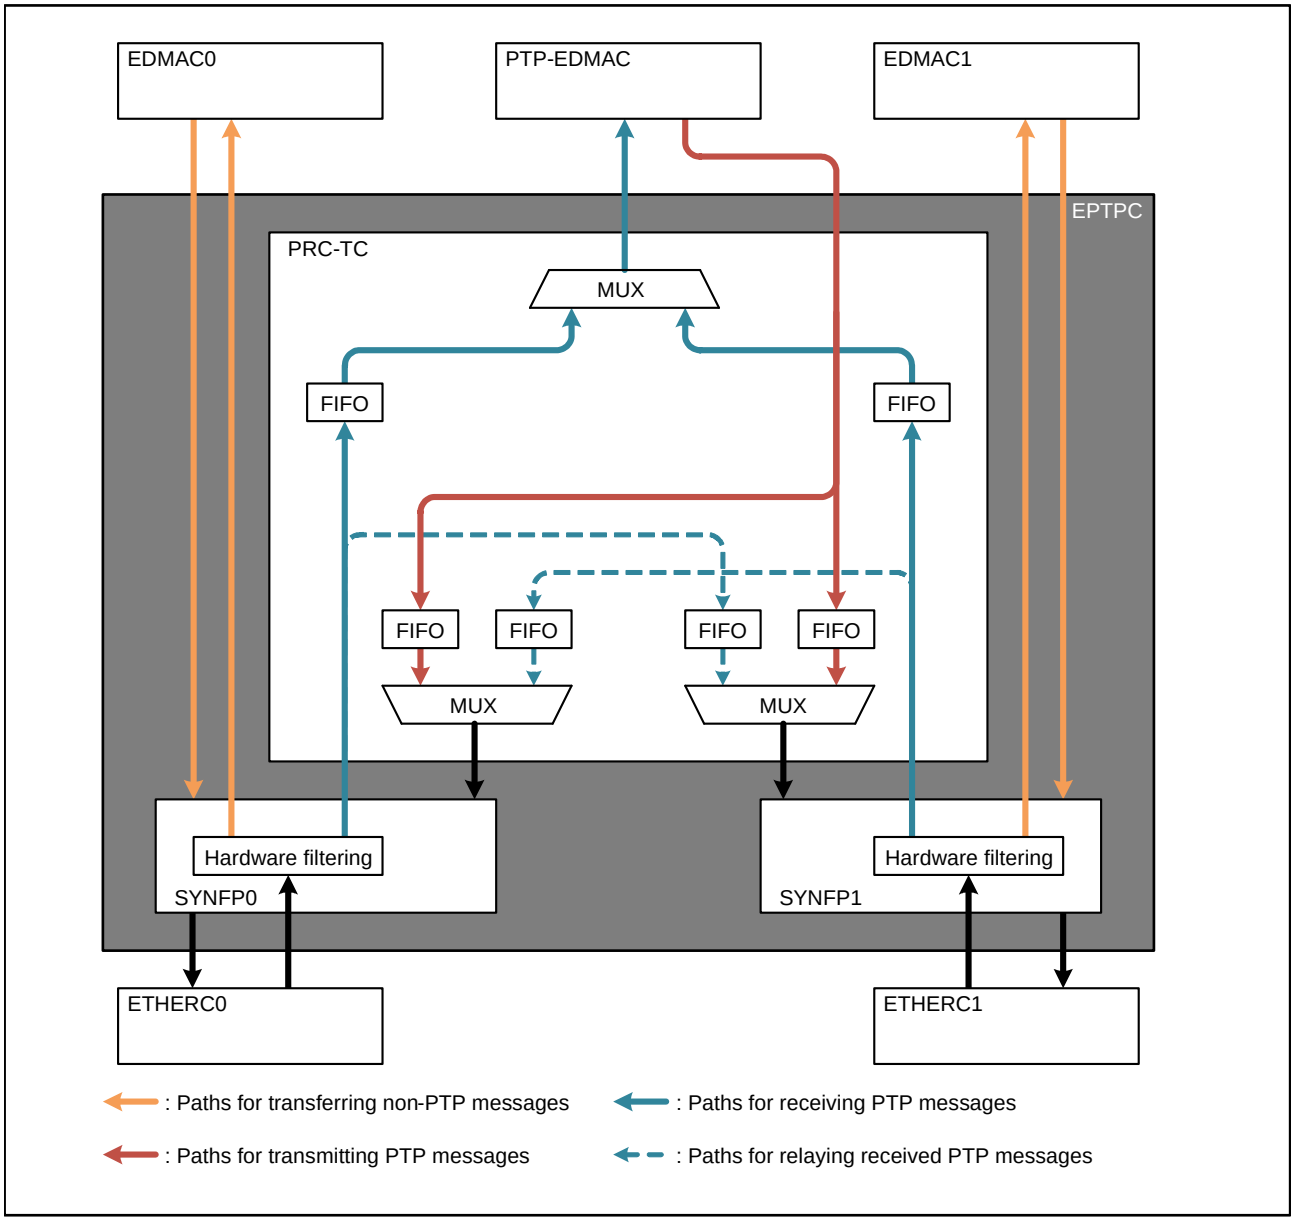

Figure 36.4 Block Diagram of the Modules Involved in Transferring and Relaying Frames

36.3.1 Transmission and Reception and Relaying of Non-PTP Messages

The EPTPC operates in extended promiscuous mode if the setting of the FFLTR.EXTPRM bit is 1 (extended promiscuous mode). In this mode, all frames received by the Ethernet ports are transferred to the EDMAC without filtering.
The EPTPC operates in normal mode if the setting of the FFLTR.EXTPRM bit is 0 (normal operation). In this mode, the SYNFP module applies its hardware filtering function to filter frames received by the Ethernet ports.
Frames for the other node can also be relayed to the Ethernet port on the other side in accord with the settings of the TRNMR.FWD0 and FWD1 bits.
The EPTPC and EDMAC transfer received unicast frames if they are for the given node. When a received frame is for the other node, the EPTPC is able to relay received frames to the other port if relaying between Ethernet ports is enabled.

Operation when multicast frames are received can be selected from the following: frames are transferred to the EDMAC, frames are not transferred to the EDMAC, or frames are transferred to the EDMAC only when the address matches the specified MAC address. The EPTPC also relays multicast frames to the other Ethernet port if relaying between Ethernet ports is enabled.
The EPTPC transfers received broadcast frames to the EDMAC for the receiving Ethernet port. The EPTPC also relays broadcast frames to the other Ethernet port if relaying between Ethernet ports is enabled.
The PRC-TC module, which handles the relaying of frames received by one Ethernet port to the other Ethernet port, has a relaying FIFO buffer for use in this process. Either of two methods for reading out from the relaying FIFO is selectable: store and forward or cut-through. With the cut-through method, reading out from the relaying FIFO starts when it holds more than one frame or more data than a specified threshold value, or when both of these conditions are satisfied. The TRNCTTDR.THVAL[10:0] bits specify the threshold value for reading out from the relaying FIFO.
With the cut-through method, when a frame is handled as an error frame due to a fault (such as malformed data being read) after a read operation starts, there is no procedure for notifying the ETHERC module of the error. Accordingly, the ETHERC may send such error frames over the line as if they were normal frames. Avoid situations of this kind by using the store-and-forward method with the relaying FIFO. With the store-and-forward method, the PRC-TC module internally discards error frames.

36.3.2 Paths for the Transfer of Non-PTP Messages

Messages received through the Ethernet port are transferred to the EDMAC. The PRC-TC module is capable of relaying messages between the Ethernet ports.

Figure 36.5 is a diagram of paths for the transmission and reception and relaying of non-PTP messages.

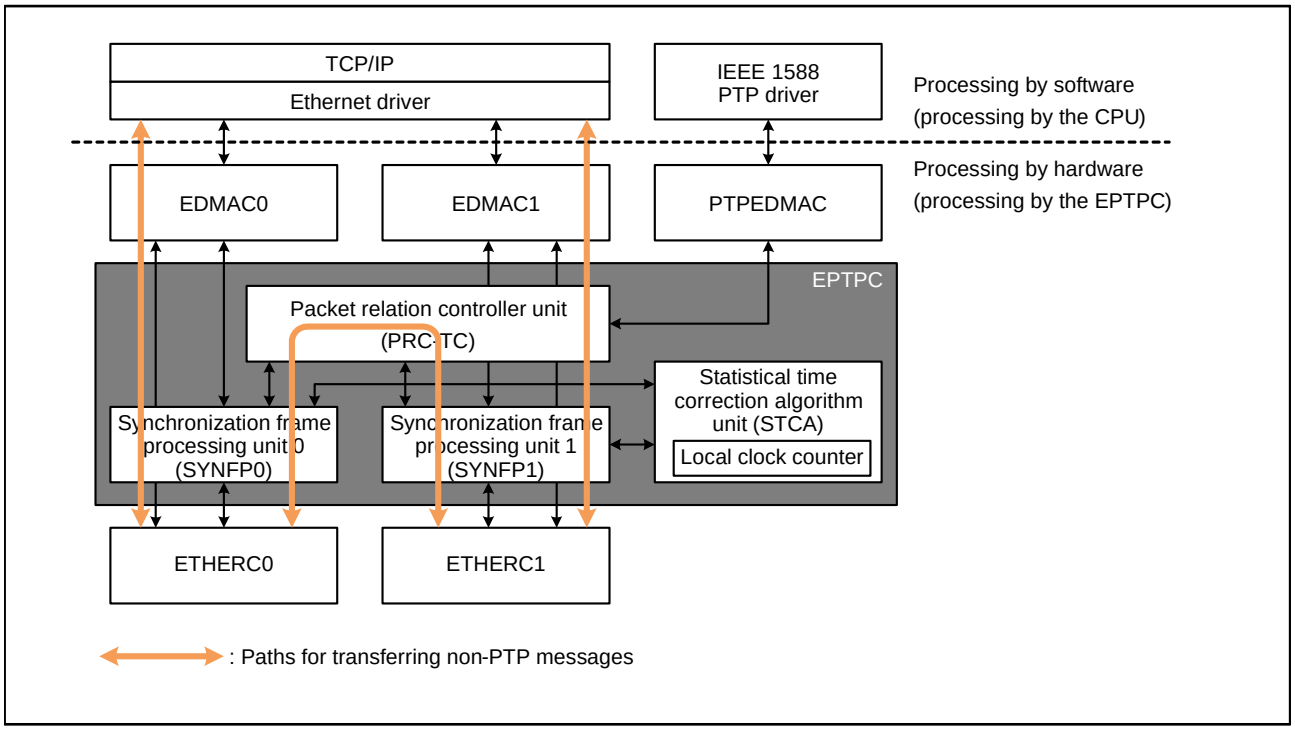

Figure 36.5 Paths for the Transmission and Reception and Relaying of Non-PTP Messages

36.3.3 Transmission and Reception and Relaying of PTP Messages

Hardware of the EPTPC automatically handles analysis of and the extraction of fields from received PTP messages, and generation and transmission of PTP messages. However, software must still handle the transmission of certain PTP messages. Table 36.10 shows the specifications for control over the transmission and reception of the various PTP messages.

Table 36.10 Control over the Transmission and Reception of PTP Messages

Message Type	Message	OC (Ordinary Clock)/BC (Boundary Clock)		TC (Transparent Clock)
		Master	Slave	
Event	Sync	Generation (automatic)	Reception (automatic)	Relaying (automatic)
	Delay_Req	Generation (automatic)	Reception (automatic)	Relaying (automatic)
	Pdelay_Req	Generation and reception (automatic)	Generation and reception (automatic)	Generation and reception (automatic)
	Pdelay_Resp	Generation and reception (automatic)	Generation and reception (automatic)	Generation and reception (automatic)
General	Announce	Generation (automatic)	Reception (software)	Reception (software)
	Follow_Up	—*1	Reception (automatic)	Relaying (automatic)
	Delay_Resp	Packet generation	Reception (automatic)	Relaying (automatic)
	Pdelay_Resp_Follow_Up	—*1	Reception (automatic)	Relaying (automatic)
	Management	Transmission and reception (software)		Transmission and reception (software) Relaying (automatic)
	Signaling	Transmission and reception (software)		Transmission and reception (software) Relaying (automatic)

Note 1. Control is not required as the clock in this case is a one-step clock.

36.3.4 Paths for the Transfer of PTP Messages

Paths for the transfer of PTP messages differ according to whether transfer requires processing by software or is automatically processed by hardware.

36.3.4.1 Paths for the Transfer of PTP Messages Requiring Processing by Software

Paths for the transfer of PTP messages where transfer requires processing by software are shown in Figure 36.6. The figure shows paths for message, clock-type, and process combinations for which “(software)” is indicated in Table 36.10.

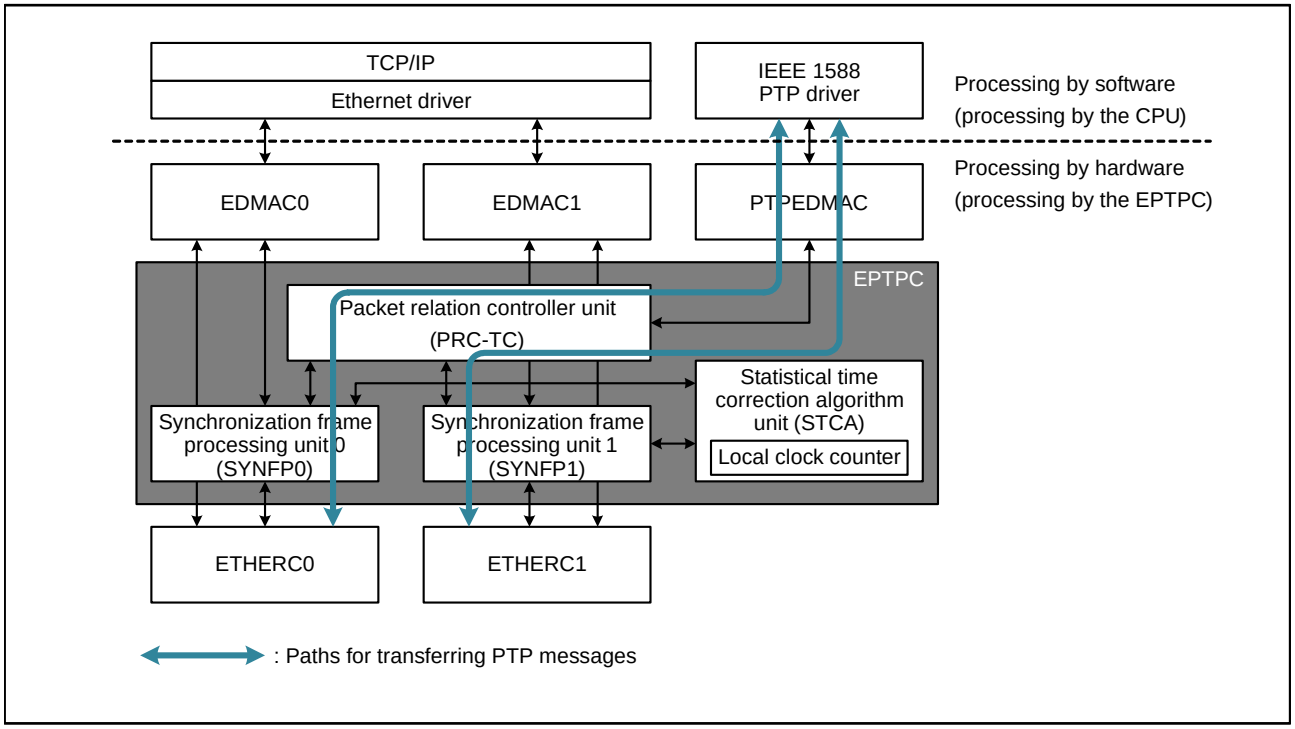

Figure 36.6 Paths for the Transfer of PTP Messages Requiring Processing by Software

36.3.4.2 Paths for the Transfer of PTP Messages Automatically Handled by Hardware

In the case of PTP messages for which hardware automatically handles the processing, the SYNFP modules handle transmission and reception, and the PRC-TC module handles relaying.

(1) Generation of and Response to PTP Messages by Hardware

Paths for transfer in the automatic generation of and response to PTP messages by the SYNFP modules are shown in Figure 36.7. The paths in the figure are used for operations “Generation (automatic)”, “Reception (automatic)”, and “Generation and reception (automatic)” indicated in Table 36.10.

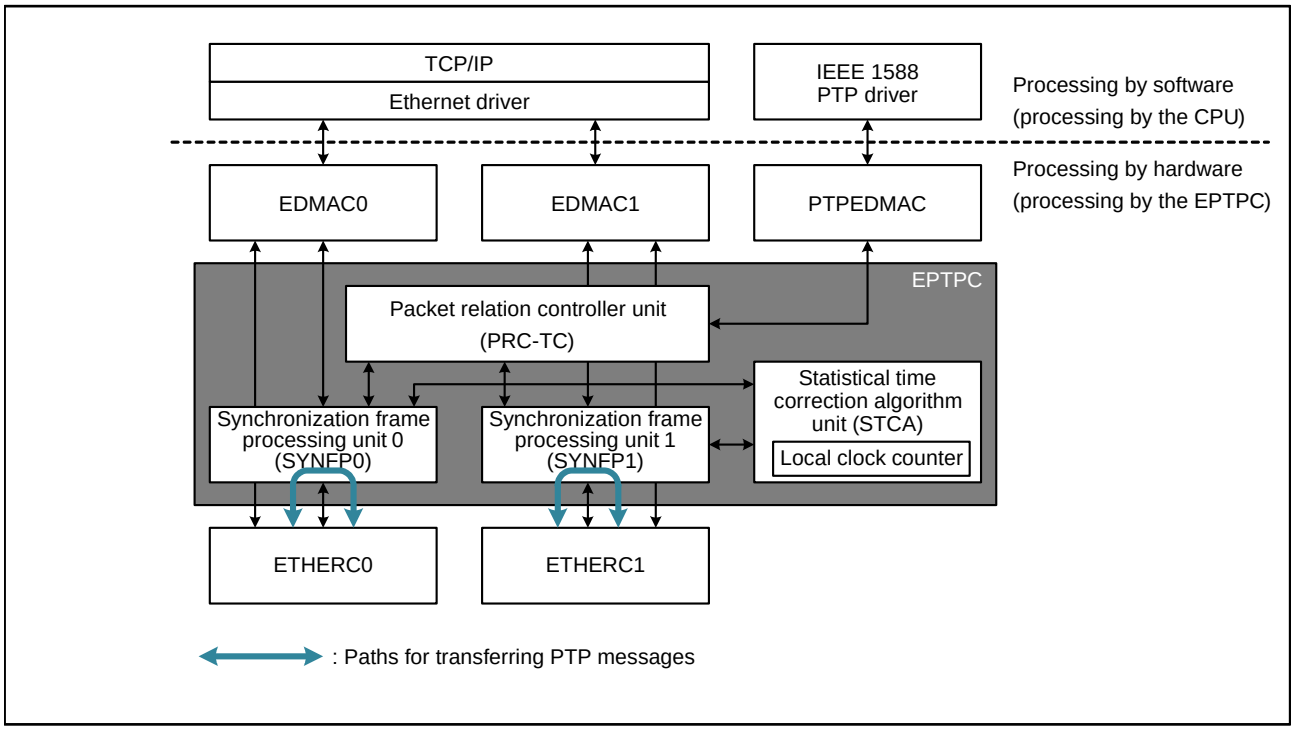

Figure 36.7 Paths for the Generation of and Response to PTP Messages by Hardware

(2) Relaying of PTP Messages by Hardware

Figure 36.8 shows paths for the relaying of PTP messages by the PRC-TC module. The paths in the figure are used for the “Relaying” operation indicated in Table 36.10.

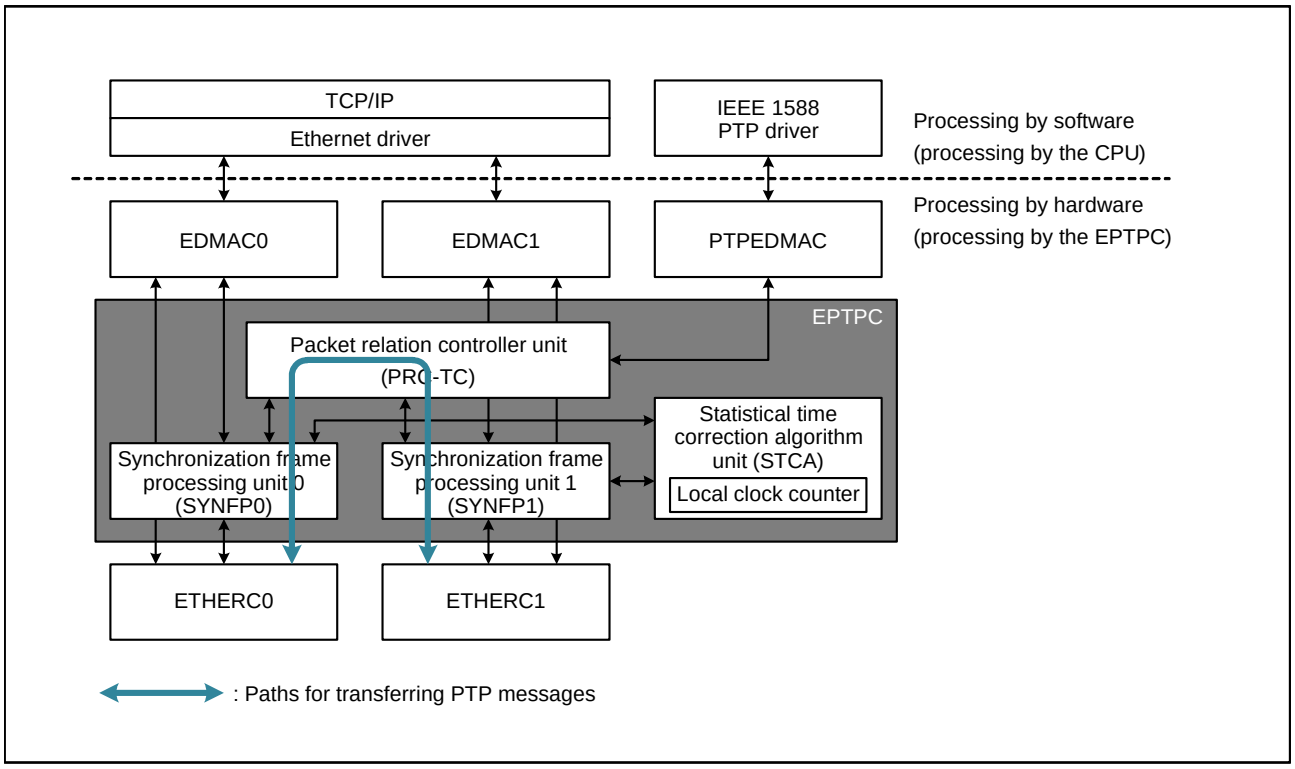

Figure 36.8 Paths for the Relaying of PTP Messages by Hardware

36.3.5 Clock Devices

The EPTPC can operate as the clock device defined in IEEE 1588.

36.3.5.1 End-to-End (E2E)

(1) Master

PTP messages are transmitted and received as listed below in operation as an end-to-end (E2E) master.

Table 36.11 List of PTP Message Processing (by an E2E Master)

Message Type	Message	Details of Processing
Event	Sync	Sync messages are transmitted at the fixed interval specified by the SYTLIR.SYNC[7:0] bits.
	Delay_Req	When this message is received, a Delay_Resp message is transmitted in response.
	Pdelay_Req	—
	Pdelay_Resp	—
General	Announce	Announce messages are transmitted at the fixed interval specified by the SYTLIR.ANCE[7:0] bits.
	Follow_Up	—
	Delay_Resp	This is transmitted as the response to a received Delay_Req messages.
	Pdelay_Resp_Follow_Up	—
	Management	Management messages are transmitted and received by software via the PTPEDMAC.
	Signaling	Signaling messages are transmitted and received by software via the PTPEDMAC.

(2) Slave

PTP messages are transmitted and received as listed below in operation as an E2E slave, and the calculated offsetFromMaster is used to correct the local time information.

Table 36.12 List of PTP Message Processing (by an E2E Slave)

Message Type	Message	Details of Processing
Event	Sync	The offsetFromMaster value is calculated when this message is received if twoStepFlag in flagField was FALSE (one-step clock).
	Delay_Req	Delay_Req messages are transmitted at random intervals from 0 to the time specified by the SYTLIR.DREQ[7:0] bits × 2.
	Pdelay_Req	—
	Pdelay_Resp	—
General	Announce	Announce messages are transmitted by software via the PTPEDMAC.
	Follow_Up	The offsetFromMaster value is calculated when this message is received if twoStepFlag in flagField of the most recently received Sync message was TRUE (two-step clock).
	Delay_Resp	The meanPathDelay value is calculated when this message is received.
	Pdelay_Resp_Follow_Up	—
	Management	Management messages are transmitted and received by software via the PTPEDMAC.
	Signaling	Signaling messages are transmitted and received by software via the PTPEDMAC.

36.3.5.2 Peer-to-Peer (P2P)

(1) Master

PTP messages are transmitted and received as listed below in operation as a peer-to-peer (P2P) master.

Table 36.13 List of PTP Message Processing (by a P2P Master)

Packet Type	Message	Details of Processing
Event	Sync	Timestamps for transmission are transmitted at the fixed interval specified by the SYTLIR.SYNC[7:0] bits.
	Delay_Req	—
	Pdelay_Req	Pdelay_Req messages are transmitted at the fixed interval specified by the SYTLIR.DREQ[7:0] bits. When this message is received, a Pdelay_Resp message is transmitted in response.
	Pdelay_Resp	This is transmitted as the response to a received Pdelay_Req messages. The meanPathDelay value is calculated when this message is received if twoStepFlag in flagField was FALSE (one-step clock).
General	Announce	Announce messages are transmitted at the fixed interval specified by the SYTLIR.ANCE[7:0] bits.
	Follow_Up	—
	Delay_Resp	—
	Pdelay_Resp_Follow_Up	The meanPathDelay value is calculated when this message is received if twoStepFlag in flagField of the most recently received Pdelay_Resp message was TRUE (two-step clock).
	Management	Management messages are transmitted by software via the PTPEDMAC.
	Signaling	Signaling messages are transmitted by software via the PTPEDMAC.

(2) Slave

PTP messages are transmitted and received as listed below in operation as a P2P slave, and the calculated offsetFromMaster is used to correct the local time information.

Table 36.14 List of PTP Message Processing (by a P2P Slave)

Packet Type	Message	Details of Processing
Event	Sync	The offsetFromMaster value is calculated when this message is received if twoStepFlag in flagField was FALSE (one-step clock).
	Delay_Req	—
	Pdelay_Req	Pdelay_Req messages are transmitted at the fixed interval specified by the SYTLIR.DREQ[7:0] bits. When this message is received, a Pdelay_Resp message is transmitted in response.
	Pdelay_Resp	This is transmitted as the response to a received Pdelay_Req messages. The meanPathDelay value is calculated when this message is received if twoStepFlag in flagField was FALSE (one-step clock).
General	Announce	Announce messages are transmitted by software via the PTPEDMAC.
	Follow_Up	The offsetFromMaster value is calculated when this message is received if twoStepFlag in flagField of the most recently received Sync message was TRUE (two-step clock).
	Delay_Resp	—
	Pdelay_Resp_Follow_Up	The meanPathDelay value is calculated when this message is received if twoStepFlag in flagField of the most recently received Pdelay_Resp message was TRUE (two-step clock).
	Management	Management messages are transmitted and received by software via the PTPEDMAC.
	Signaling	Signaling messages are transmitted and received by software via the PTPEDMAC.

36.3.5.3 Ordinary Clock (OC)

PTP messages are transmitted and received through one Ethernet port in operation as an ordinary clock.
An ordinary clock operates as the grand master clock or as a slave clock in the master-slave hierarchy.
For operation as an E2E master, E2E slave, P2P master, or P2P slave, see section 36.3.7, Operation as an E2E Master, section 36.3.8, Operation as an E2E Slave, section 36.3.10, Operation as a P2P Master, and section 36.3.11, Operation as a P2P Slave.

36.3.5.4 Boundary Clock (BC)

PTP messages are transmitted and received through both ports in operation as a boundary clock.
One port operates as a slave in synchronization with the root master clock and the other operates as the master that delivers time information synchronized with the master clock.
Both ports can also operate as masters.
For operation as an E2E master, E2E slave, P2P master, or P2P slave, see section 36.3.7, Operation as an E2E Master, section 36.3.8, Operation as an E2E Slave, section 36.3.10, Operation as a P2P Master, and section 36.3.11, Operation as a P2P Slave.

36.3.5.5 Transparent Clock (TC)

(1) E2E TC

In operation as an E2E transparent clock, received PTP-primary and PTP-pdelay messages are relayed.

Table 36.15 List of Packet Processing (by an E2E TC)

Message Type	Message	Details of Processing
Event	Sync	The packet residence time in the clock device is added when these messages are relayed.
	Delay_Req	
	Pdelay_Req	
	Pdelay_Resp	
General	Announce	These messages are relayed.
	Follow_Up	
	Delay_Resp	
	Pdelay_Resp_Follow_Up	
	Management	These messages are relayed. Messages are also transmitted and received by software via the PTPEDMAC.
	Signaling	

(2) P2P TC

In operation as a P2P transparent clock, PTP-primary messages other than Delay_Req and Delay_Resp are relayed.

Table 36.16 List of Packet Processing (by a P2P TC)

Message Type	Message	Details of Processing
Event	Sync	The packet residence time in the clock device is added when this message is relayed.
	Delay_Req	—
	Pdelay_Req	Pdelay_Req messages are transmitted at the fixed interval specified by the SYTLIR.DREQ[7:0] bits. When this message is received, a Pdelay_Resp message is transmitted in response.
	Pdelay_Resp	This is transmitted as the response to a received Pdelay_Req messages. The meanPathDelay value is calculated when this message is received if twoStepFlag in flagField was FALSE (one-step clock).
General	Announce	These messages are relayed.
	Follow_Up	
	Delay_Resp	—
	Pdelay_Resp_Follow_Up	The meanPathDelay value is calculated when this message is received if twoStepFlag in flagField of the most recently received Pdelay_Resp message was TRUE (two-step clock).
	Management	These messages are relayed. Messages are also transmitted and received by software via the PTPEDMAC.
	Signaling	

36.3.6 EPTPC Initialization

Transmitting and receiving PTP messages requires settings in various registers of the EPTPC.
Table 36.17 is a list of the registers for which settings are required. Set the registers corresponding to the Ethernet port used. Also set the registers listed in Table 36.18 if the UDP and IPv4 are used for the frame format of the PTP messages.

Table 36.17 List of the Registers for which Settings are Required

Register Name	Settings	Description
STCFR	Example: 0x00000002	The value for 50 MHz is given as an example. Three other settings are also available.
PRMACRU0, PRMACRL0	As desired	This setting is not required If Ethernet port 0 is not used.
PRMACRU1, PRMACRL1	As desired	This setting is not required If Ethernet port 1 is not used.
SYCONFR	Example: 0x00000002	The setting differs with the type of PTP clock operation.
SYMACRU, SYMACRL	As desired	
SYSPVRR	0x0000002	transportSpecific and version fields
SYDOMR	As desired	
SYCIDRU, SYCIDRL	As desired	Set the same value for Ethernet ports 0 and 1.
SYPNUMR	0x00000001 or 0x00000002	If the PTP clock operates as an OC, the setting is 0x00000001. If it operates as a BC or TC, set 0x00000001 for one port and 0x00000002 for the other.
PPMACRU, PPMACRL	01:1B:19:00:00:00	MAC address for PTP-primary messages
PDMACRU, PDMACRL	01:80:C2:00:00:0E	MAC address for PTP-pdelay messages
DASYMRU, DASYMRL	0x00000000	
TSLATR	As desired	Depends on the link transfer rate and STCA clock frequency.
SYFORMR	As desired	Two settings are available.
PETYPER	0x000088F7	Ethertype for PTP messages

Table 36.18 List of the Registers for which Settings are Required (Additional Settings Required when UDP or IPv4 is to be Used)

Register Name	Settings	Description
SYIPADDRR	As desired	Local IP address
PRIPR	0xE0000181	IP address for PTP-primary messages
PETOSR	As desired	Set the highest allowable traffic class selector codepoint as the value for the differentiated service (DS) field.
PGTOSR	As desired	
PPTTLR	As desired	TTL field value for PTP-primary messages
PEUDPR	0x0000013F	UDP port number for event messages
PGUDPR	0x00000140	UDP port number for general messages
PDIPR	0xE000006B	IP address for PTP-pdelay messages
PDTTLR	0x00000001	TTL field value for PTP-pdelay messages

In operation as an OC or BC, set registers as shown below in order to transfer received Announce, Management, and Signaling messages to the PTPEDMAC.

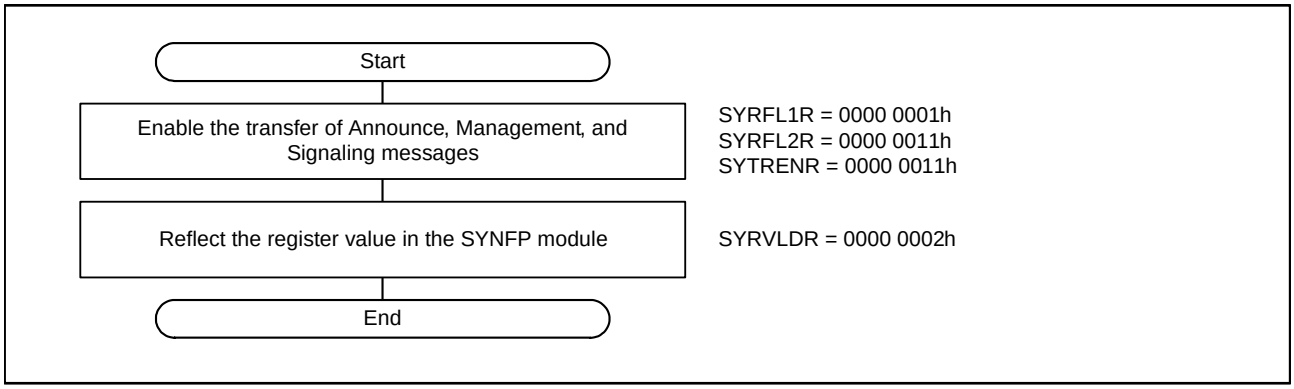

Figure 36.9 Common Settings for PTP Devices

36.3.7 Operation as an E2E Master

36.3.7.1 Preparatory Setting

Table 36.19 lists the registers for use in operation as an E2E master.
If the EPTPC operates as an OC or as a BC with both ports serving as masters, set the initial value of the time information in advance. Refer to section 36.2.18, Local Clock Counter Initial Value Registers (LCIVRU, LCIVRM, LCIVRL) for the initial value of the time information. Reflecting the values set in the registers requires setting the SYRVLDR.STUP or ANUP bit to 1.

Table 36.19 Registers for Use in Operation as an E2E Master

Register Name	SYRVLDR Register Bits Used for Loading Direction	Settings	Description
SYNFR	STUP	0x00000000	flagField for Sync messages
SYTLIR	STUP ANUP	Example: 0x00000001	Delay_Resp: 1 s Sync: 1 s Announce: 2 s
ANFR	ANUP	0x00000000	flagField for Announce messages
GMPR	ANUP	As desired	
GMCQR	ANUP	As desired	
GMIDR	ANUP	As desired	
CUOTSR	ANUP	As desired	timeSource: Internal Oscillator
SRR	ANUP	As desired	If the EPTPC operates as an OC or as a BC with both ports serving as masters, set this register to 0x00000000. If the EPTPC operates as a BC in the combination of a slave and master, set this register to the StepsRemoved field value of Announce messages received by the slave plus one.
SYRFL1R	STUP	0x00004001	This enables the processing of Delay_Req messages by the SYNFP module.
SYRFL2R	STUP	0x00000011	This enables the transfer of Signaling and Management messages to the PTPEDMAC.
SYTRENR	STUP	0x00000011	This enables the transmission of Sync and Announce messages.

36.3.7.2 Procedure for Starting Operations

Figure 36.10 shows the procedure for settings to start operation as an E2E master.

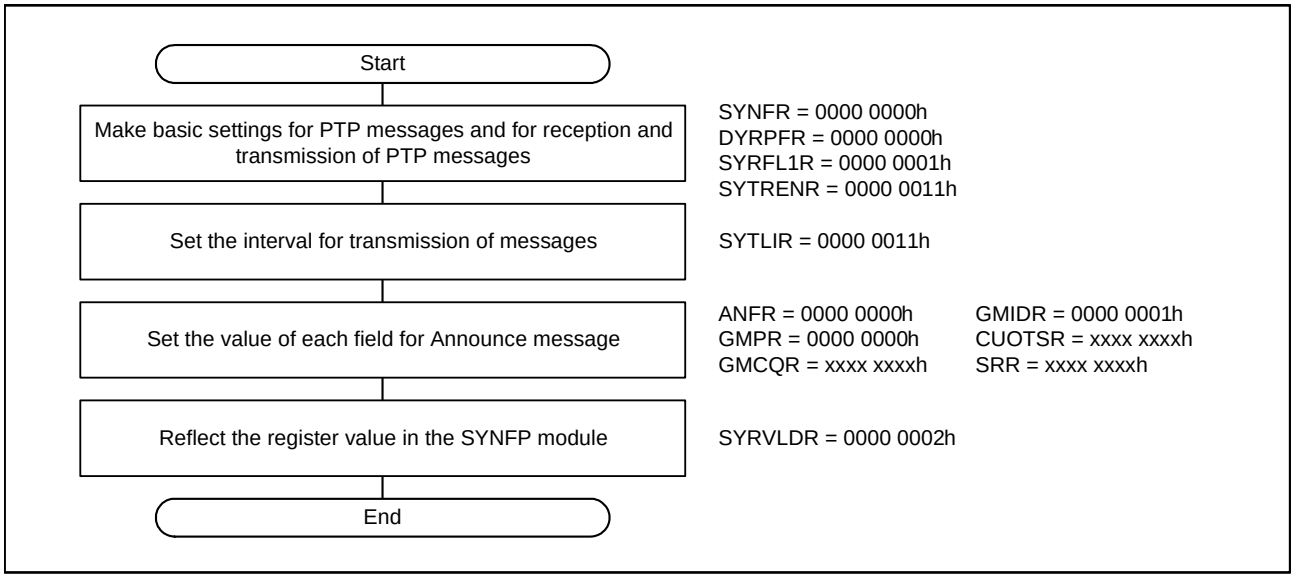

Figure 36.10 Procedure for Starting Operation as an E2E Master

36.3.7.3 Procedure for Changing the Settings

Increases in the frequency of receiving Delay_Req messages due to network conditions may lead to an overflow of the FIFO buffer which is receiving the Delay_Req messages. In such cases, change the value of the logMessageInterval field of Delay_Resp messages so that the slave sending the Delay_Req messages lengthens the interval between the messages. Figure 36.11 shows the procedure for changing the value of the logMessageInterval field.

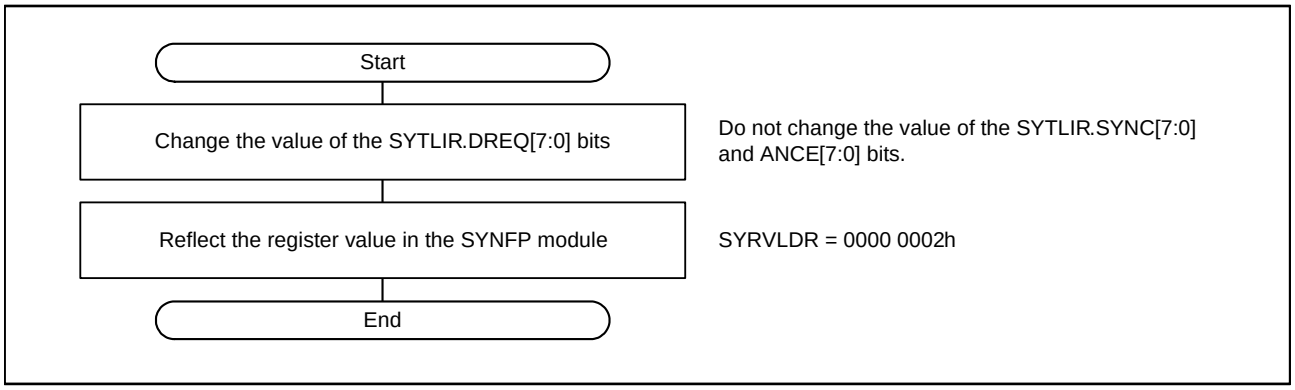

Figure 36.11 Procedure for Changing the Value of the logMessageInterval Field for Delay_Resp Messages

36.3.7.4 Procedure for Stopping Operations

Figure 36.12 shows the procedure for stopping operation as an E2E master. To confirm that the operation as the E2E master is completely stopped, read the SYSR.GENDN flag and RESDN flag to check that generating messages and sending responses are completely stopped.

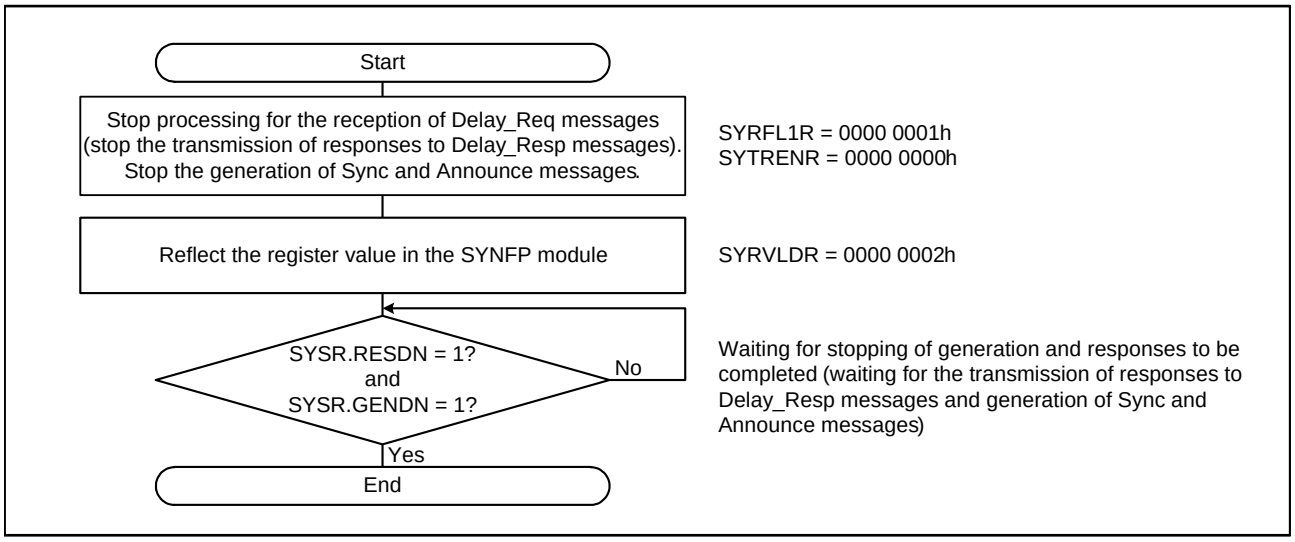

Figure 36.12 Procedure for Stopping Operation as an E2E Master

36.3.8 Operation as an E2E Slave

36.3.8.1 Preparatory Setting

Table 36.20 lists the registers for use in operation as an E2E slave.
Reflecting the value set in the register in SYNFP operations requires setting the SYRVLDR.STUP, ANUP, or BMUP bit to 1.

Table 36.20 Registers for Use in Operation as an E2E Slave

Register Name	SYRVLDR Register Bits Used for Loading Direction	Settings	Description
MTCID	BMUP	As desired	This is the clockIdentity value of the master clock that provides synchronization.
MTPID	BMUP	As desired	This is the portNumber value of the master clock that provides synchronization.
SYTLIR	ANUP BMUP	0x00000000	Delay_Resp: 1 s*1
RSTOUTR	STUP	As desired	
SYNTOR	—	As desired	
SYRFL1R	STUP	0x00040441	This enables the reception of Delay_Resp, Follow_Up, and Sync messages and the transfer of Announce messages to the PTPEDMAC.
SYRFL2R	STUP	0x00000011	This enables the transfer of Signaling and Management messages to the PTPEDMAC.
SYTRENR	STUP	0x00000100	This enables the generation of Delay_Req messages.

Note 1. In the reception of Delay_Resp messages by an E2E slave, the SYTLIR.DREQ[7:0] bits must be adjusted if the value of the SYRLIR.DRESP[7:0] flags is to be altered. The SYTLIR.DREQ[7:0] bits specify a value in the range from -7 to 6. Set the SYTLIR.DREQ[7:0] bits to -7 if the value indicated by the SYRLIR.DRESP[7:0] flags is less than or equal to -8 and to 6 if the value indicated by the SYRLIR.DRESP[7:0] flags is greater than or equal to 7.

36.3.8.2 Procedure for Starting Operations

Figure 36.13 shows the procedure for settings to start operation as an E2E slave.

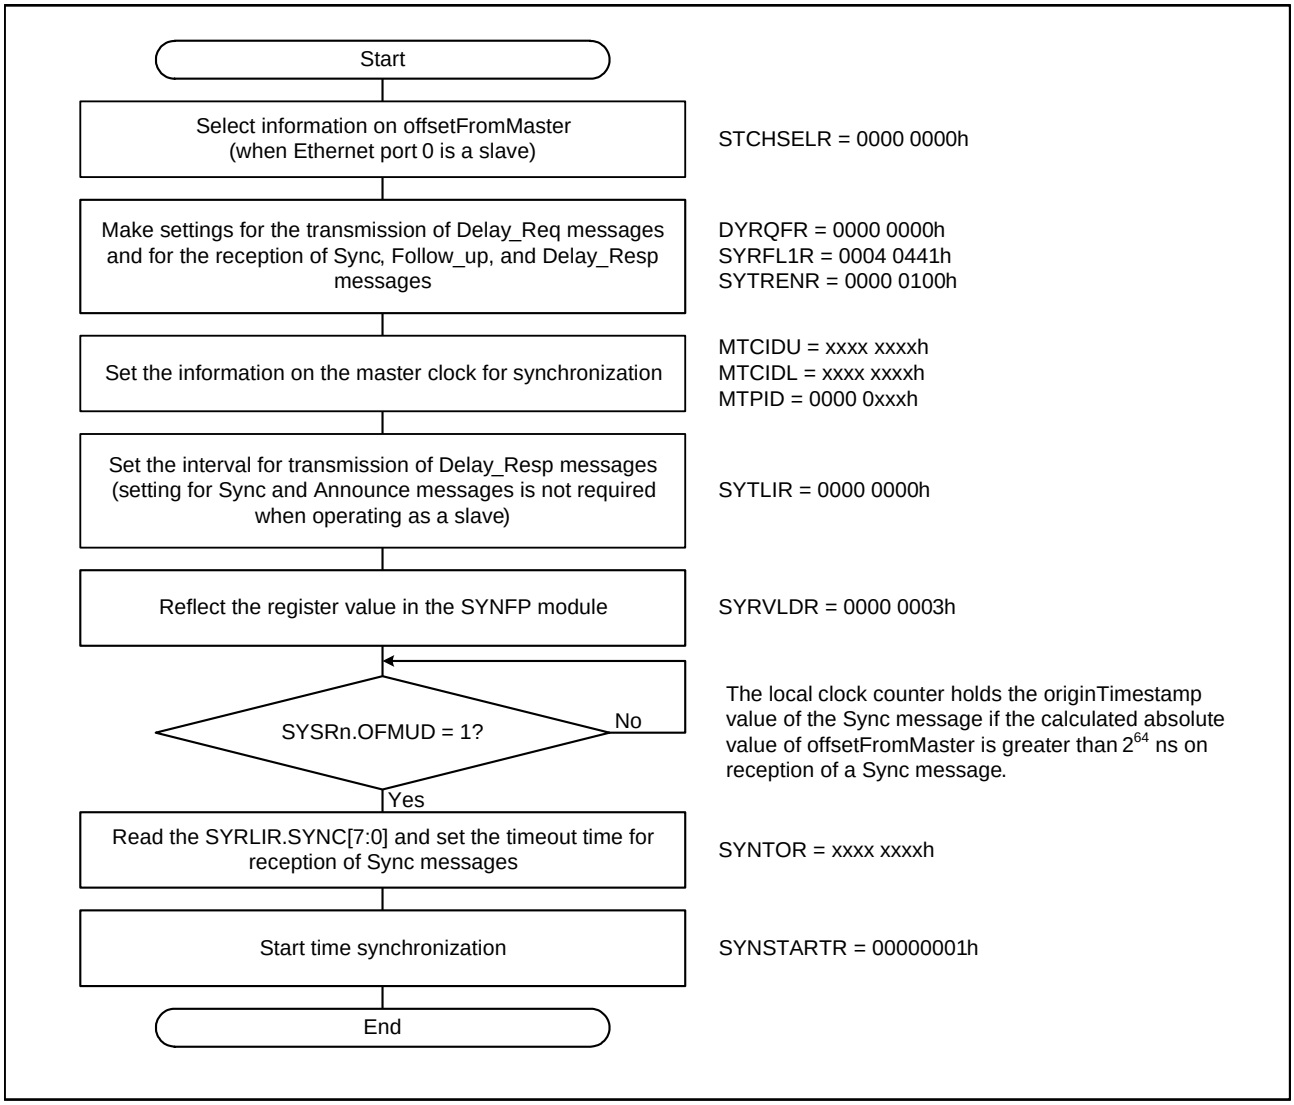

Figure 36.13 Procedure for Starting Operation as an E2E Slave

36.3.8.3 Procedure for Changing the Settings

IEEE 1588 stipulates that the average interval for the transmission of Delay_Req messages must be adjusted in response to changes in the value of the logMessageInterval field of received Delay_Resp messages. The EPTPC sets the SYSR.INTCHG flag to 1 if the logMessageInterval value of a received message differs from that of the previous message.

When this happens, set the SYTLIR.DREQ[7:0] bits to the value of the SYRLIR.DRESP[7:0] bits.

The SYTLIR.DREQ[7:0] bits specify a value in the range from -7 to 6. Set the SYTLIR.DREQ[7:0] bits to -7 if the value indicated by the SYRLIR.DRESP[7:0] flags is less than or equal to -8 and to 6 if the value indicated by the SYRLIR.DRESP[7:0] bits is greater than or equal to 7.

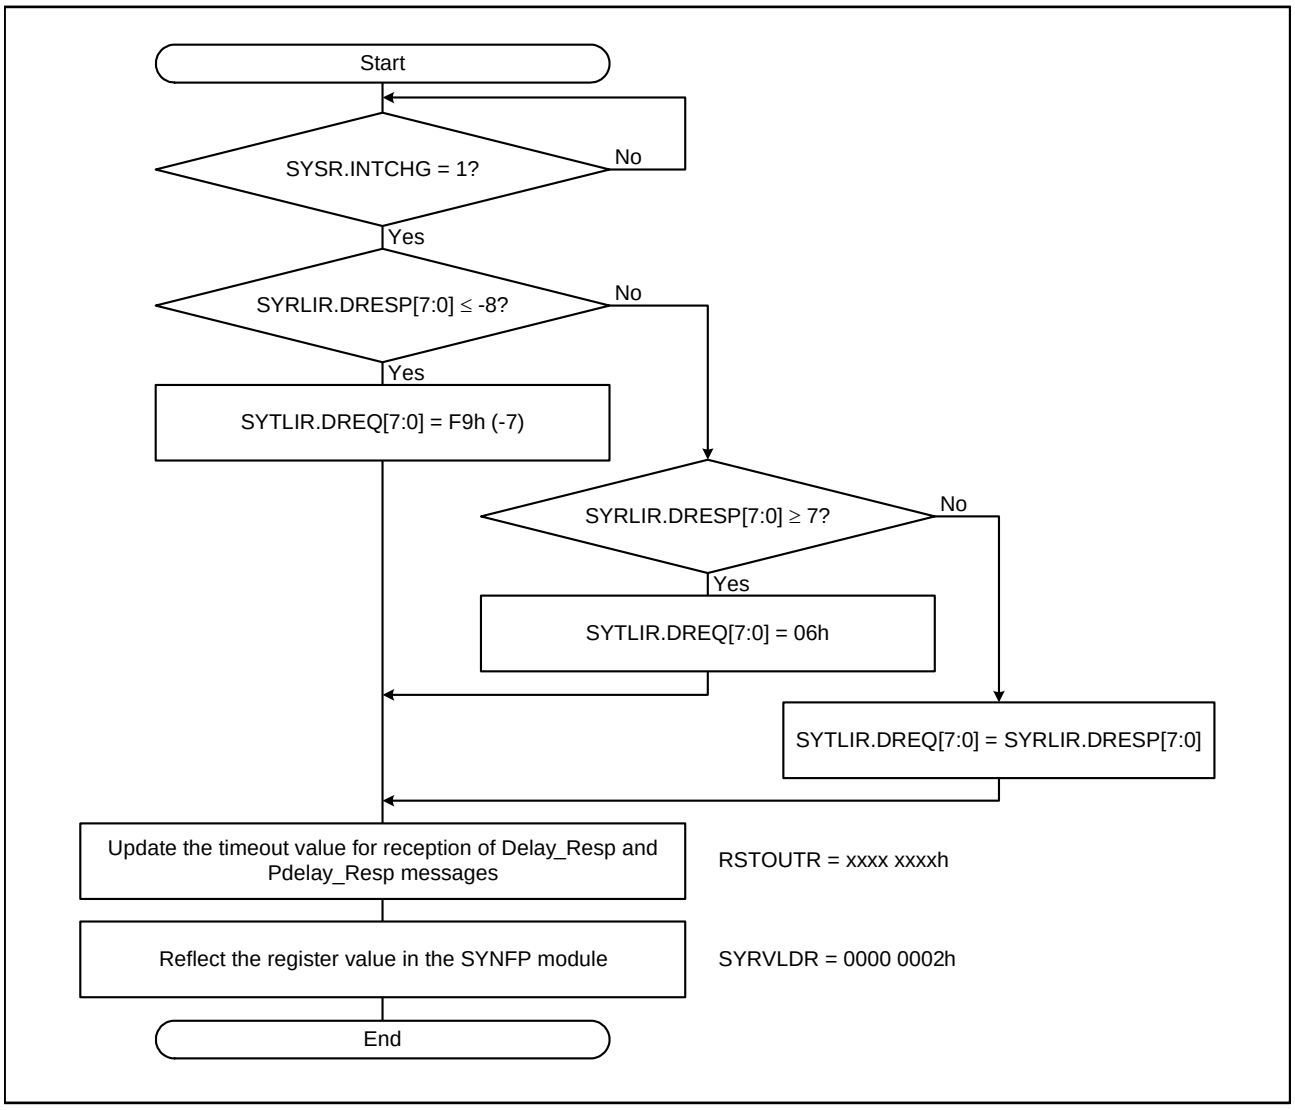

Figure 36.14 Procedure for Changing the Interval for Transmission of Delay_Req Messages

36.3.8.4 Procedure for Stopping Operations

Figure 36.15 shows the procedure for stopping operation as an E2E slave. To confirm that operation as an E2E slave is completely stopped, read the SYSR.GENDN flag to check that generation is completely stopped.

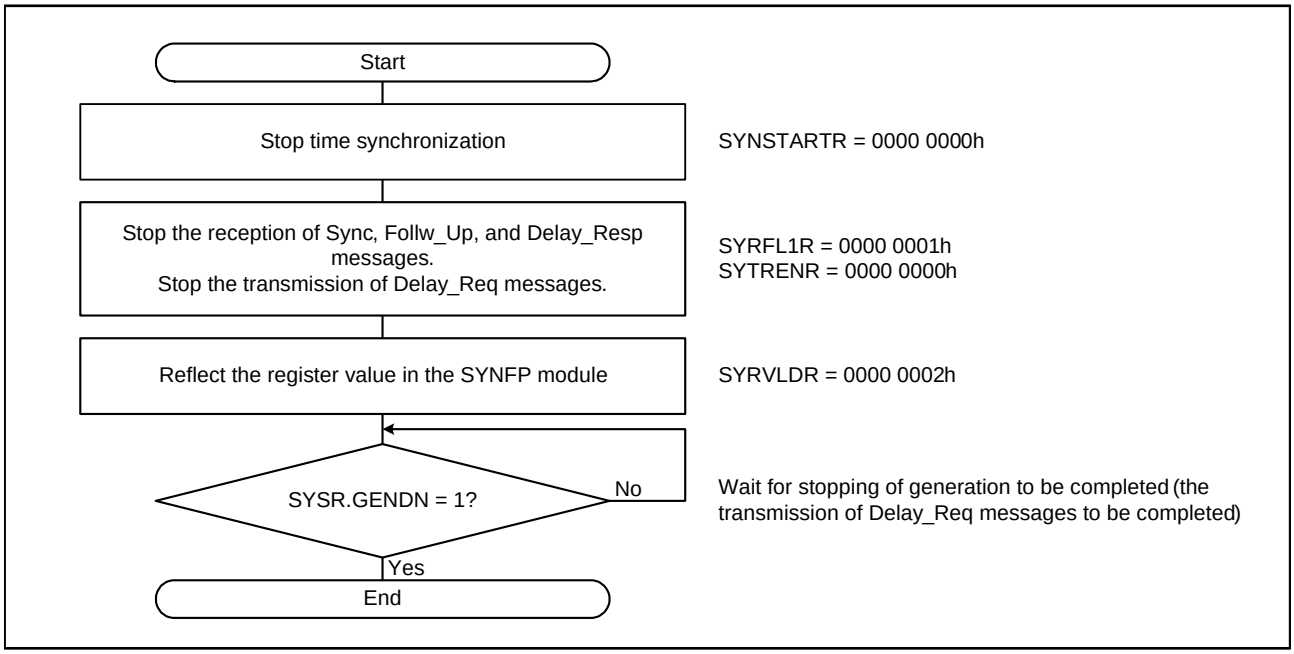

Figure 36.15 Procedure for Stopping Operation as an E2E Slave

36.3.9 P2P Operation (Common to Master and Slave)

If the EPTPC is to be operated as a P2P, the SYNFP module handles the processing of PTP-pdelay messages regardless of whether operation is to be as a master or slave. The interval for Pdelay_Req transmission and the parameters for monitoring of Pdelay_Resp messages must be set at the same time. Registers for use in operation as a P2P are listed in Table 36.21.

Table 36.21 Registers for Use in Operation as a P2P

Register Name	SYRVLDR Register Bits Used for Loading Direction	Settings	Description
MTCID	BMUP	As desired	This is the clockIdentity value of the synchronized master clock.
MTPID	BMUP	As desired	This is the portNumber value of the synchronized master clock.
SYTLIR	ANUP STUP	0x00000000	Announce: — Sync: — Pdelay_Req: 1 s
RSTOUTR	STUP	As desired	
SYRFL1R	STUP	0x44400001	This enables the reception of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages and the transfer of Announce messages to the PTPEDMAC.
SYRFL2R	STUP	0x00000011	This enables the transfer of Signaling and Management messages to the PTPEDMAC.
SYTRENR	STUP	0x00001000	This enables the generation of Pdelay_Req messages.

36.3.9.1 Procedure for Starting Operations

Figure 36.16 shows the procedure for starting operation as a P2P (sending and receiving PTP-pdelay messages).

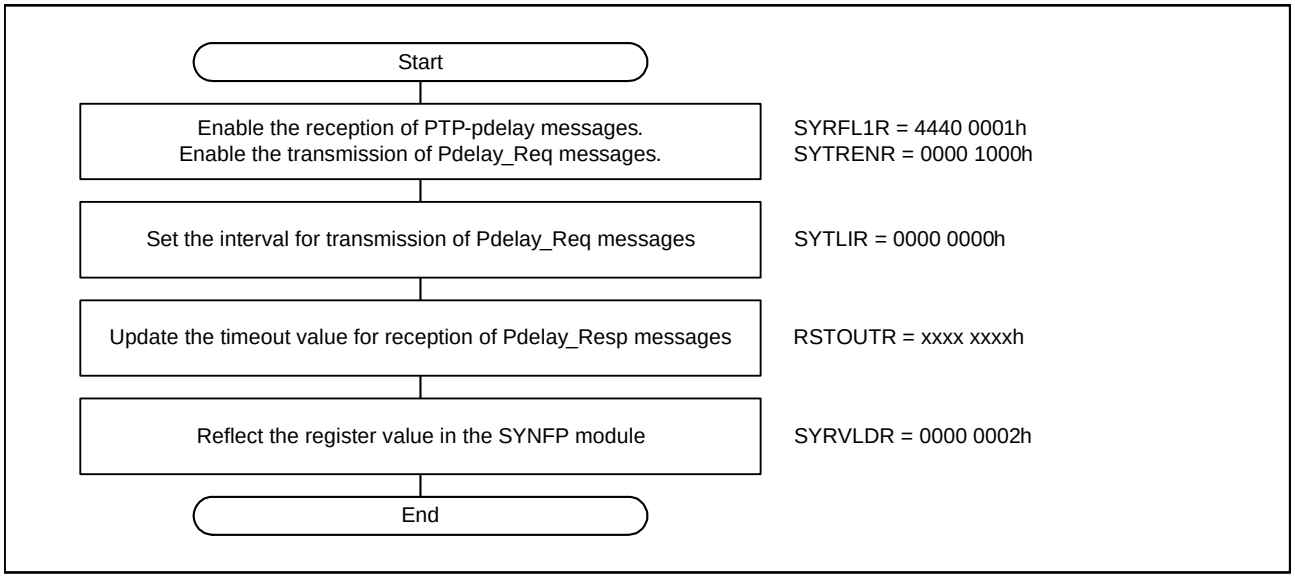

Figure 36.16 Procedure for Starting Operation as a P2P

36.3.9.2 Procedure for Stopping Operations

Figure 36.17 shows the procedure for stopping operation as a P2P (sending and receiving PTP-pdelay messages).

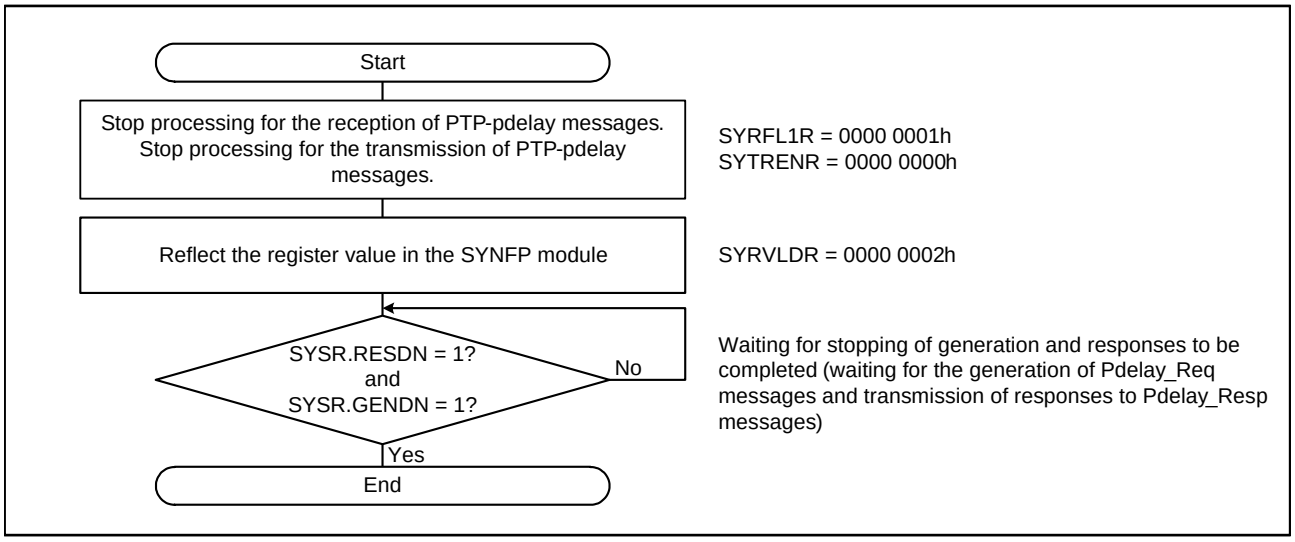

Figure 36.17 Procedure for Stopping Operation as a P2P

36.3.10 Operation as a P2P Master

When the EPTPC operates as OC or BC that uses both ports as the master, set the initial value of time information in advance as required. Refer to section 36.2.18, Local Clock Counter Initial Value Registers (LCIVRU, LCIVRM, LCIVRL) for the initial value of time information. Registers for use in operation as a P2P master are listed in Table 36.22.

Table 36.22 Registers for Use in Operation as a P2P Master

Register Name	SYRVLDR Register Bits Used for Loading Direction	Settings	Description
SYCONFR	—	0x00000028	
ANFR	ANUP	0x00000000	flagField for Announce messages
SYNFR	STUP	0x00000000	flagField for Sync messages
SYTLIR	ANUP STUP	0x00000001	Announce: 2 s Sync: 1 s Pdelay_Req: 1 s
GMPR	ANUP	As desired	Grandmaster Priority1 and Priority2
GMCQR	ANUP	As desired	Grandmaster Quality
GMIDR	ANUP	As desired	Grandmaster Identity
CUOTSR	ANUP	As desired	currentUtcOffset, timeSource
SRR	ANUP	As desired	StepsRemoved
RSTOUTR	STUP	As desired	
SYRFL1R	STUP	0x44400000	This enables the reception of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages.
SYRFL2R	STUP	0x00000011	This enables the transfer of Signaling and Management messages to the PTPEDMAC.
SYTRENR	STUP	0x00001011	This enables the transmission of Pdelay_Req, Sync, and Announce messages.

36.3.10.1 Procedure for Starting Operations

When transmission of Sync and Announce messages is started during operation as a P2P (sending and receiving PTP-pdelay messages), the EPTPC operates as a P2P master. Figure 36.18 shows the procedure for starting operation as a P2P master.

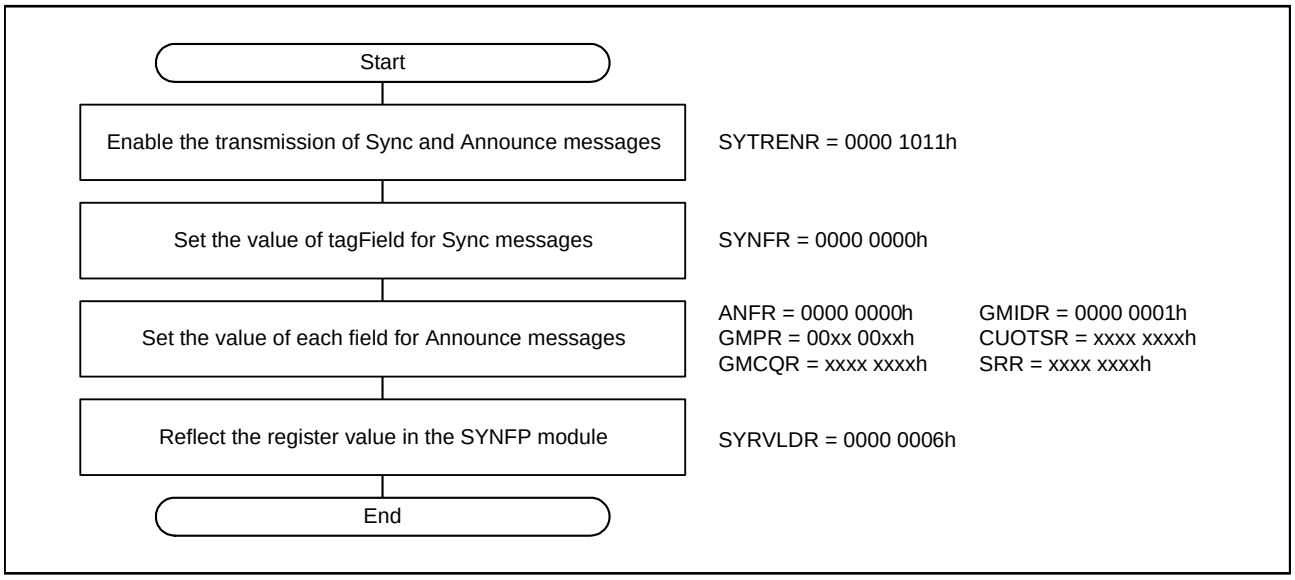

Figure 36.18 Procedure for Starting Operation as a P2P Master

36.3.10.2 Procedure for Stopping Operations

Figure 36.19 shows the procedure for stopping the transmission of Sync and Announce messages to stop operation as a P2P master.

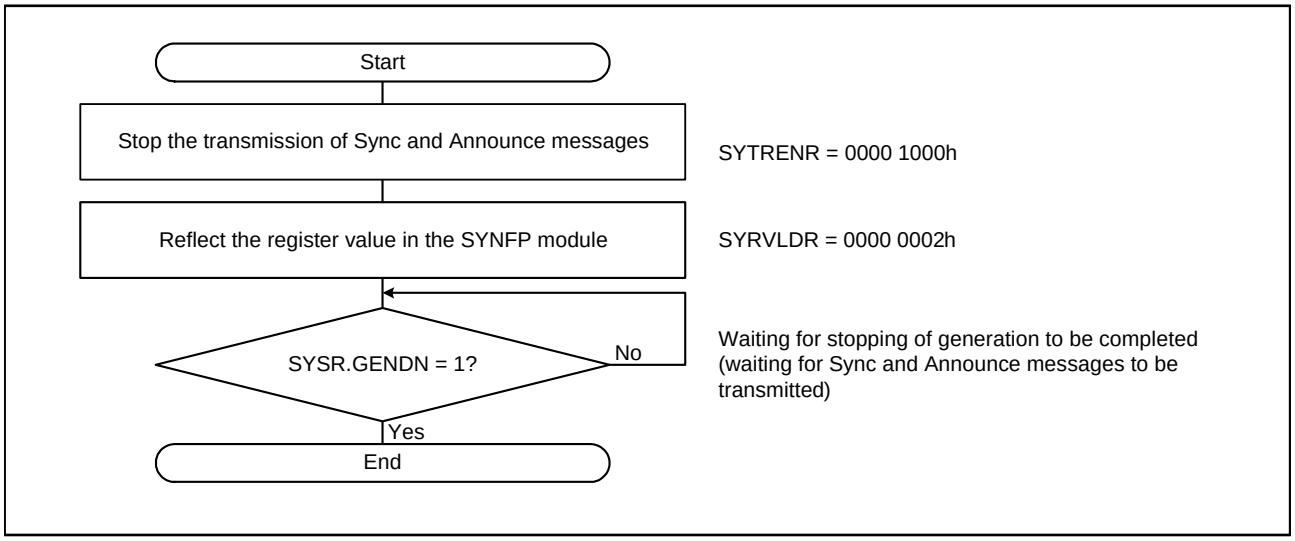

Figure 36.19 Procedure for Stopping Operation as a P2P Master

36.3.11 Operation as a P2P Slave

Setting a SYNFP module to receive Sync messages and Follow_Up messages during P2P operation obtains operation as a P2P slave. Information on the master clock for synchronization must be specified.
Table 36.23 lists the registers for use in operation as a P2P slave.

Table 36.23 Registers for Use in Operation as a P2P Slave

Register Name	SYRVLDR Register Bits Used for Loading Direction	Settings	Description
MTCID	BMUP	As desired	This is the clockIdentity value of the synchronized master clock.
MTPID	BMUP	As desired	This is the portNumber value of the synchronized master clock.
RSTOUTR	STUP	As desired	
SYRFL1R	STUP	0x44400441	This enables the reception of Pdelay_Req, Pdelay_Resp, Pdelay_Resp_Follow_Up, Follow_Up, and Sync messages and the transfer of Announce messages to the PTPEDMAC.

36.3.11.1 Procedure for Starting Operations

Figure 36.20 shows the procedure for making the additional settings for shifting to operation as a slave during operation as a P2P (sending and receiving PTP-pdelay messages).

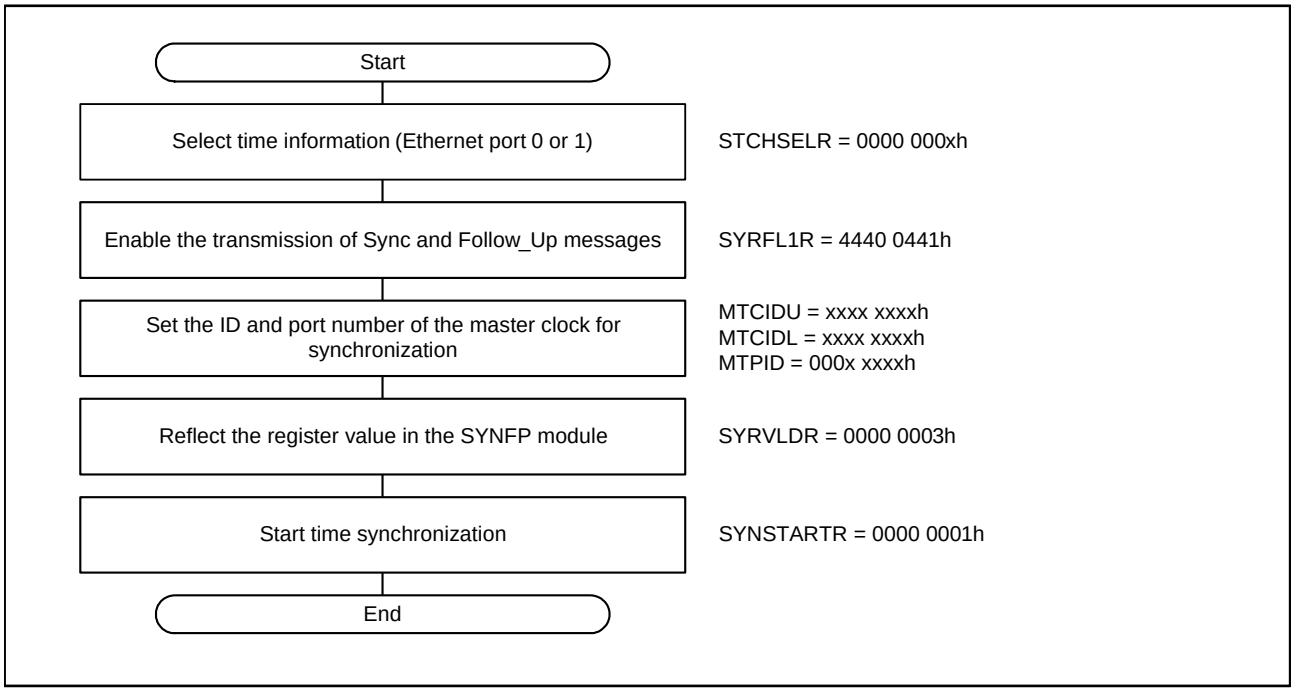

Figure 36.20 Procedure for Starting Operation as a P2P Slave

36.3.11.2 Procedure for Stopping Operations

Figure 36.21 shows the procedure for stopping the reception of Sync and Follow_Up messages to stop operation as a P2P slave.

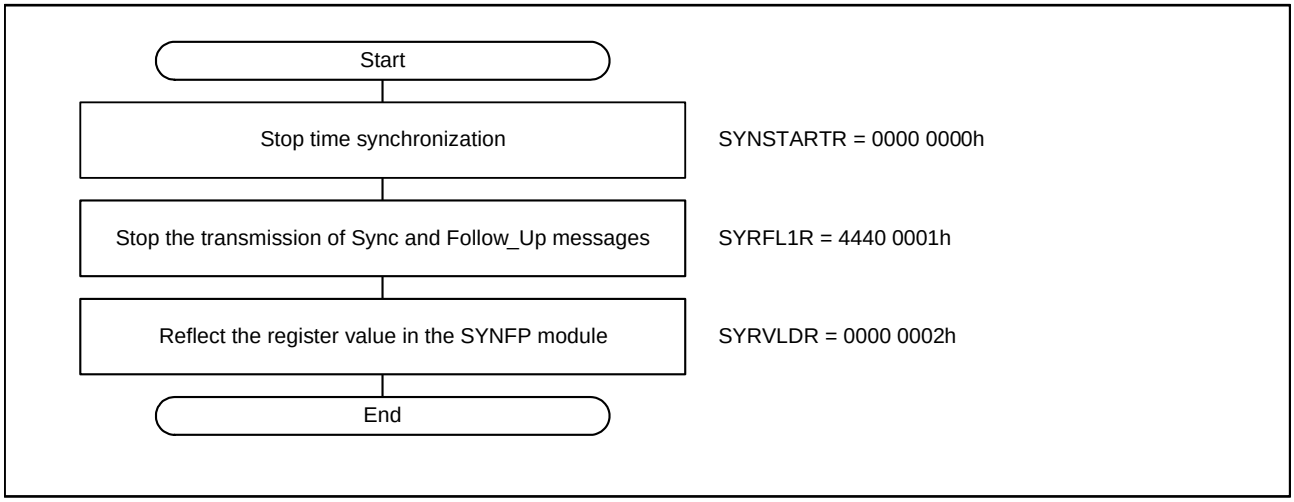

Figure 36.21 Procedure for Stopping Operation as a P2P Slave

36.3.12 Operation as an E2E TC

36.3.12.1 Preparatory Setting

Table 36.24 lists the registers for use in operation as an E2E TC.
Make the settings for both the SYNFP0 and SYNFP1 modules.

Table 36.24 Registers for Use in Operation as an E2E TC

Register Name	SYRVLDR Register Bits Used for Loading Direction	Settings	Description
SYCONFR	—	Example: 0x00000028	Set the TCMOD bit to 0 as a preparatory setting for the PTP device.
SYRFL1R	STUP	0x22222222	This enables the relaying of messages by the PRC-TC.
SYRFL2R	STUP	0x20000033	This enables the transfer of Signaling and Management messages to the PTPEDMAC and the relaying of these messages by the PRC-TC.
SYTRENR	STUP	0x00000000	No generation of messages

36.3.12.2 Procedure for Starting Operations

Figure 36.22 shows the procedure for starting operation as an E2E TC.

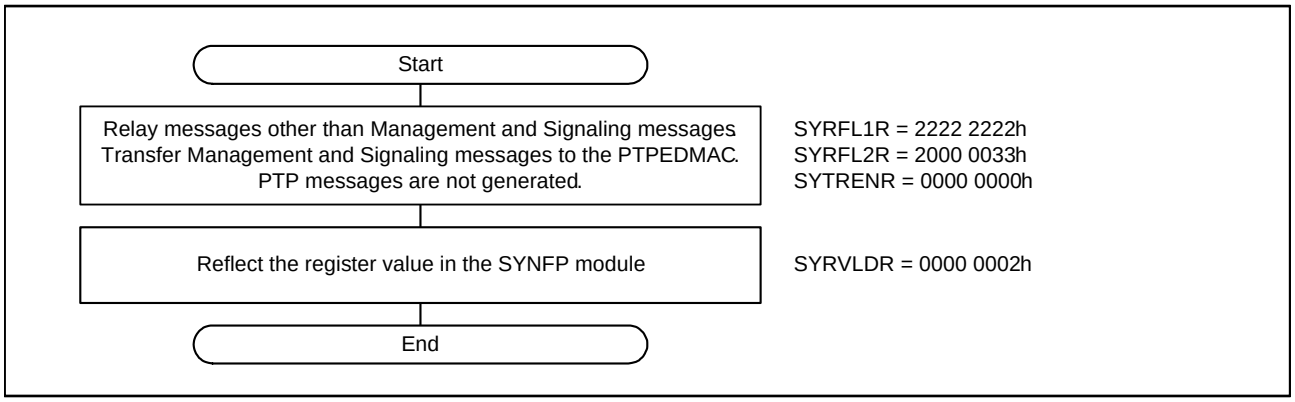

Figure 36.22 Procedure for Starting Operation as an E2E TC

36.3.13 Operation as a P2P TC

Table 36.25 lists the registers for use in operation a P2P TC.
Make the settings for both the SYNFP0 and SYNFP1 modules.

Table 36.25 Registers for Use in Operation as a P2P TC

Register Name	SYRVLDR Register Bits Used for Loading Direction	Settings	Description
SYCONFR	—	Example: 0x00100028	Set the TCMOD bit to 1 as a preparatory setting for the PTP device.
RSTOUTR	STUP	As desired	
SYTLIR	STUP	Example: 0x00000000	Pdelay_Req: 1 s
SYRFL1R	STUP	0x44400222	This enables the discarding of Delay_Req and Delay_Resp messages and the relaying of Sync, Follow_Up, and Announce messages by the PRC-TC.
SYRFL2R	STUP	0x20000033	This enables the transfer of Signaling and Management messages to the PTPEDMAC and the relaying of these messages by the PRC-TC
SYTRENR	STUP	0x00001000	This enables the generation of Pdelay_Req messages.

36.3.13.1 Procedure for Starting Operations

Figure 36.23 shows the procedure for starting operation as a P2P TC.

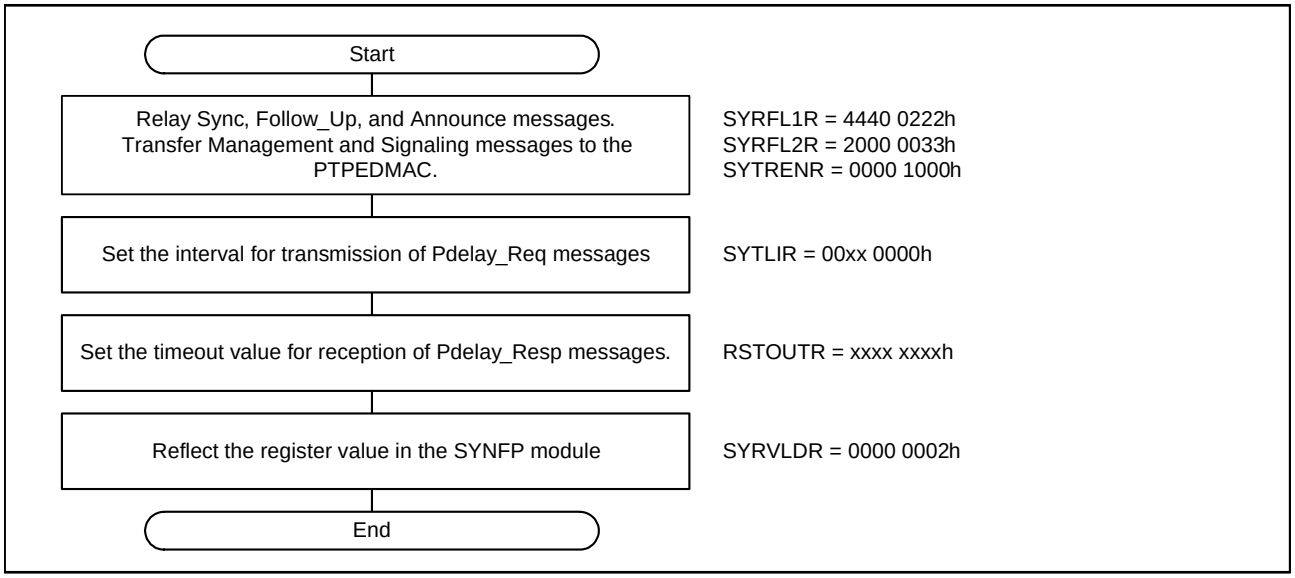

Figure 36.23 Procedure for Starting Operation as a P2P TC

36.3.14 Monitoring of Received Messages

36.3.14.1 Reception of Announce Messages

The EPTPC does not detect timeouts in the reception of Announce messages. To detect timeouts in the reception of these messages, monitor the reception of Announce messages by software.

36.3.14.2 Reception of Sync Messages

The STSR.SYNTOUT flag becomes 1 when a timeout in the reception of a Sync message occurs during the correction of time synchronization.
The SYSR.OFMUD flag becomes 1 when a Sync message is received, regardless of whether time synchronization is being corrected. Accordingly, the reception of Sync messages is detectable by reference to the SYSR.OFMUD flag even if the correction of time synchronization stops due to a timeout in the reception of a Sync message.

36.3.14.3 Reception of Delay_Resp and Pdelay_Resp Messages

The SYSR.DRPTO flag becomes 1 when a timeout in the reception of a Delay_Resp message occurs after the transmission of a Delay_Req message during operation as an E2E slave, or when a timeout in the reception of a Pdelay_Resp message occurs after the transmission of a Pdelay_Req message during operation as a P2P.
The SYSR.MPDUD flag becomes 1 when a Delay_Resp or Pdelay_Resp message is received, so the reception of these messages is still detectable in the case of a timeout in reception.

36.3.15 Correcting Time Synchronization

A slave detects differences in the clock gradient relative to the master clock. The offsetFromMaster values calculated by using the standard IEEE 1588 algorithm are used to calculate the clock gradient, so the result includes elements of network fluctuation besides frequency differences. The EPTPC has a “worst 10” function to eliminate fluctuations due to network load, etc. With these functions, the time is corrected from the calculated gradient difference values and results of correction are obtained as shown in Figure 36.25.

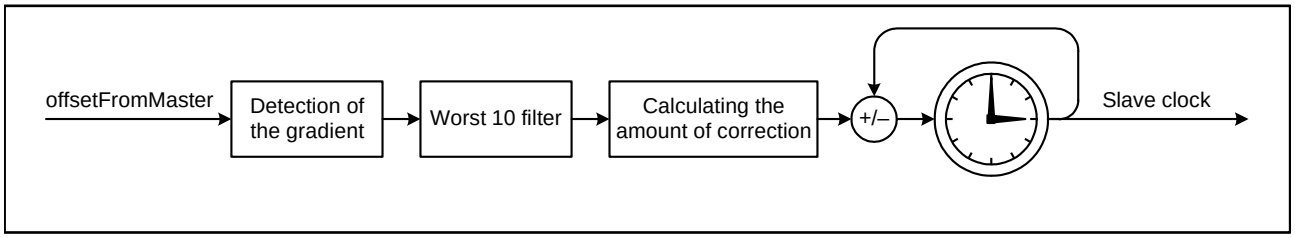

Figure 36.24 Configuration of the Time Correction Circuit

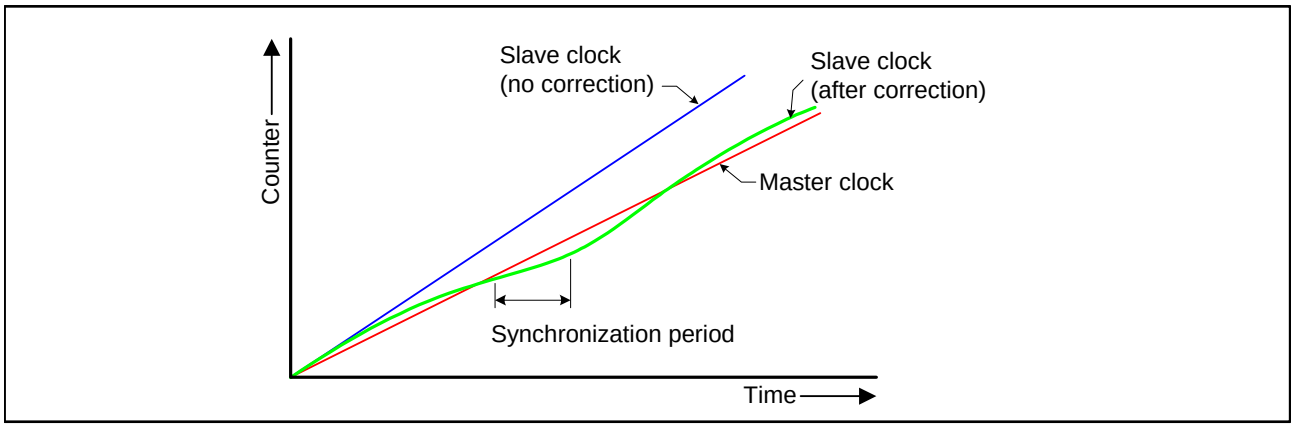

Figure 36.25 Overview of Time Correction

36.3.15.1 Judging Synchronization and Loss of Synchronization

The absolute value of offsetFromMaster reaching or exceeding the value specified in the SYNTDARU or SYNTDARL register is considered a loss of synchronization. The absolute value of offsetFromMaster being less than the absolute values of the synchronization detection threshold registers (SYNTDBRU and SYNTDBRL) is considered synchronization.

The values of the STSR.SYNCOUT and SYNC flags become 1 when synchronization is lost and obtained, respectively. Hysteresis can be obtained by setting the respective threshold registers to appropriate different values. Furthermore, the STMR.DVTH[3:0] and SYTH[3:0] bits can be used to set the consecutive number of times detection must occur for the judgment of loss of synchronization and of synchronization.

Set registers SYNTDARU and SYNTDARL to low values and the number of times detection is required to judge loss of synchronization to one in systems where control must be aborted if synchronization is lost due to fluctuations in network conditions. Set registers SYNTDARU and SYNTDARL and the number of times detection is required to large values in systems where the above condition does not apply.

Figure 36.26 shows an example of a situation where synchronization is being lost and regained. In this example, the number of consecutive times detection is required is three for both synchronization and loss of synchronization.

Note: The setting of the STSR.SYNCOUT flag is 1 when time synchronization starts, even though the condition for judging loss of synchronization has not been satisfied at this stage. For this reason, detection of loss of synchronization must be ignored immediately after time synchronization starts.

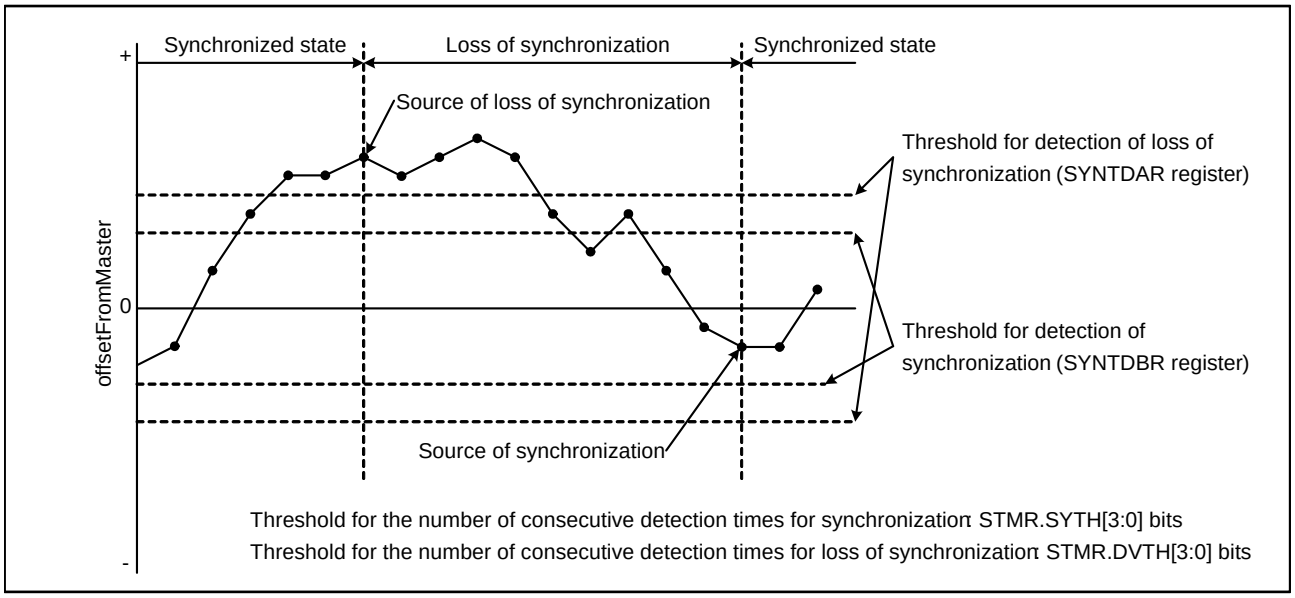

Figure 36.26 Example of a Situation where Synchronization is being Lost and Regained (the number of consecutive detection times is specified as three by the STMR.DVTH[3:0] and SYTH[3:0] bits)

36.3.15.2 Worst 10 Function

The worst 10 function is for imposing limits with regard to exceedingly large and small values among the calculated values for differences in clock gradient.

Values for difference in clock gradient are collected by observing the state of transfer over a specified interval and threshold values to impose limits are extracted from the observed values. With regard to differences in gradient, not only errors in the clock but also fluctuations in network conditions must be considered, and differences in both the positive and negative directions as shown in Figure 36.27 are collected

From among the collected values for positive and negative gradient difference, the largest values for gradient, from the first to the tenth place (worst to tenth worst), are acquired and the tenth worst is used as a threshold value. Fluctuations in the time kept by a slave clock can be suppressed by continually overwriting the tenth worst value for gradient difference with new values large enough to exceed the threshold. Furthermore, periodic collections of gradient values can also be made for updating the threshold values during operations or for the method of setting threshold values from previously measured results

However, note that while fluctuations in the time kept by a slave clock can be suppressed by the effective filtering of values for gradient difference (collecting the worst 10 values and using the tenth worst), following of the time kept by a master clock also becomes slower.

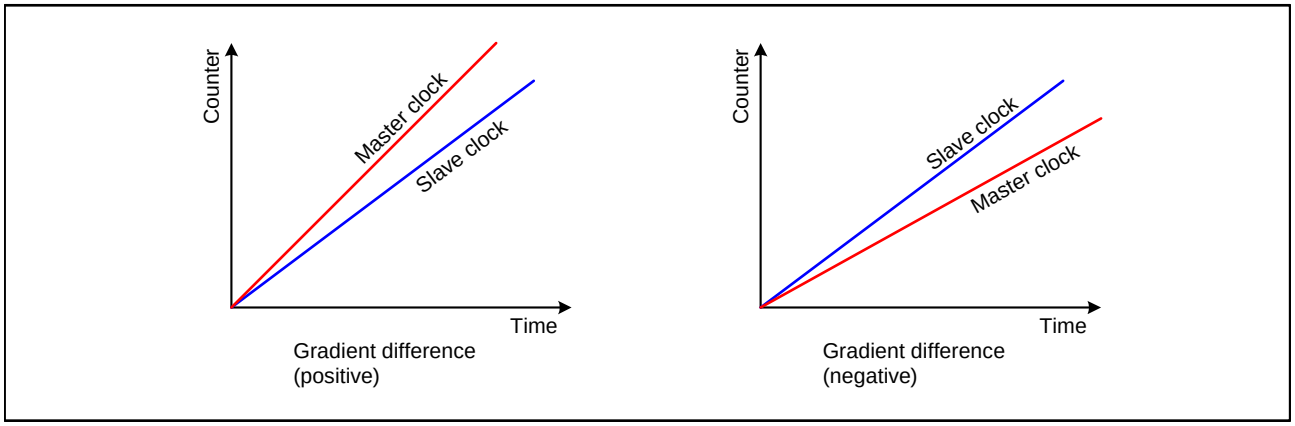

Figure 36.27 Overview of Gradient Differences

36.3.15.3 Collecting Differences in Clock Gradient and Extracting the Worst Ten Values

During slave operation, the EPTPC is capable of calculating the offsetFromMaster values from received messages and then calculating gradient differences between the local clock (acting as a slave clock) and master clock from those values. Specifically, the worst ten values are extracted from the sets of collected values for gradient difference. Either automatic filtering by the hardware or software-triggered filtering can be designated for acquisition of the sets of worst-10 values.

Figure 36.28 gives an overview of the collection of values for gradient difference.

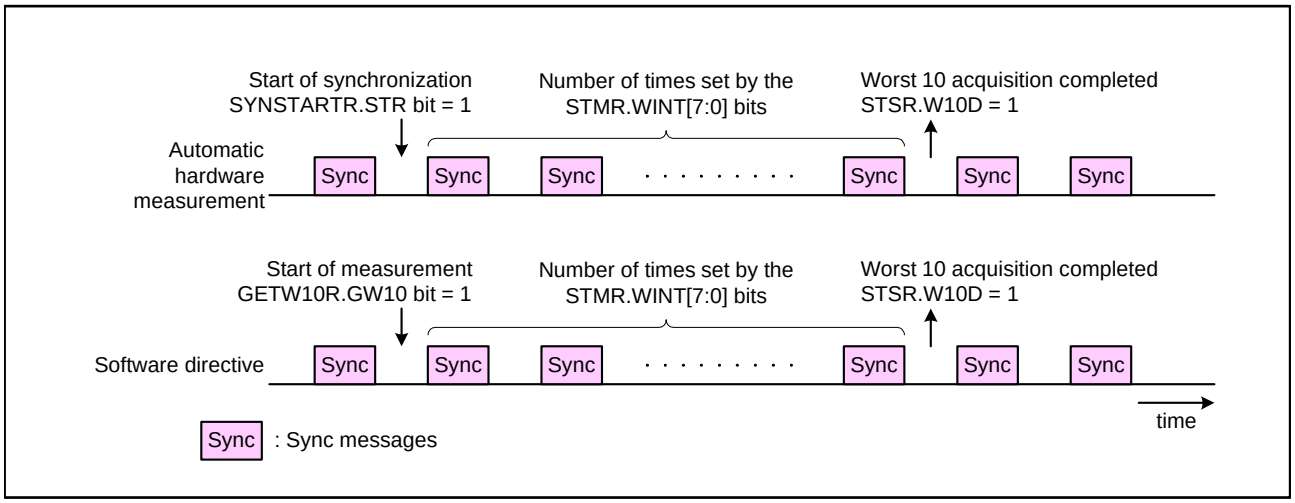

Figure 36.28 Overview of the Collection of Values for Gradient Differences

(1) Collecting Gradient Differences and Extracting the Worst Ten Values by Hardware

The EPTPC automatically collects the values of gradient difference by hardware if the STMR.W10S bit is 0.

When the SYNSTARTR.STR bit is set to 1 (starting slave time synchronization), the EPTPC collects gradient difference values for the number of times set by the STMR.WINT[7:0] bits. When the collection of gradient difference values is finished, the tenth largest values on the positive and negative gradient difference sides are stored as the tenth worst values in registers PW10VRU, PW10VRM, and PW10VRL and registers MW10RU, MW10RM, and MW10RL. When acquisition of the worst 10 values is complete, the STSR.W10D flag becomes 1.

Filtering of gradient difference values by using the stored tenth worst values then proceeds automatically.

Note that if the number of times set by STMR.WINT[7:0] bits are fewer than ten times, the double of the best of the collected values on the positive side is stored in registers PW10VRU, PW10VRM, and PW10VRL, and the half of the best of the collected values on the negative side is stored in registers MW10RU, MW10RM, and MW10RL.

(2) Collecting Gradient Differences and Extracting the Worst Ten Values by Software

The EPTPC collects values of gradient differences by software if the STMR.W10S bit is 1.
When the GETW10R.GW10 bit is set to 1 after time synchronization has started, the EPTPC collects gradient difference values for the number of times set by the STMR.WINT[7:0] bits. When the collection of gradient difference values is finished, the tenth largest values on the positive and negative gradient difference sides are stored as the tenth worst values in registers PW10VRU, PW10VRM, and PW10VRL and registers MW10RU, MW10RM, and MW10RL. When acquisition of the worst 10 values is complete, the STSR.W10D flag becomes 1.
Since filtering of gradient difference values proceeds with the values set in registers PLIMITRU, PLIMITRM, and PLIMITRL and registers MLIMITRU, MLIMITRM, and MLIMITRL as the upper and lower limits for filtering, the values stored in registers PW10VRU, PW10VRM, and PW10VRL and registers MW10RU, MW10RM, and MW10RL must be written to the PLIMITRU, PLIMITRM, and PLIMITRL and registers MLIMITRU, MLIMITRM, and MLIMITRL, respectively.
Note that if the number of times set by the STMR.WINT[7:0] bits is fewer than ten or times, the double of the best of the collected values on the positive is stored in registers PW10VRU, PW10VRM, and PW10VRL, and the half of the best of the collected values on the negative side is stored in registers MW10RU, MW10RM, and MW10RL.
The flowchart in Figure 36.29 shows an example of the procedure for software-triggered acquisition of the worst 10 values.

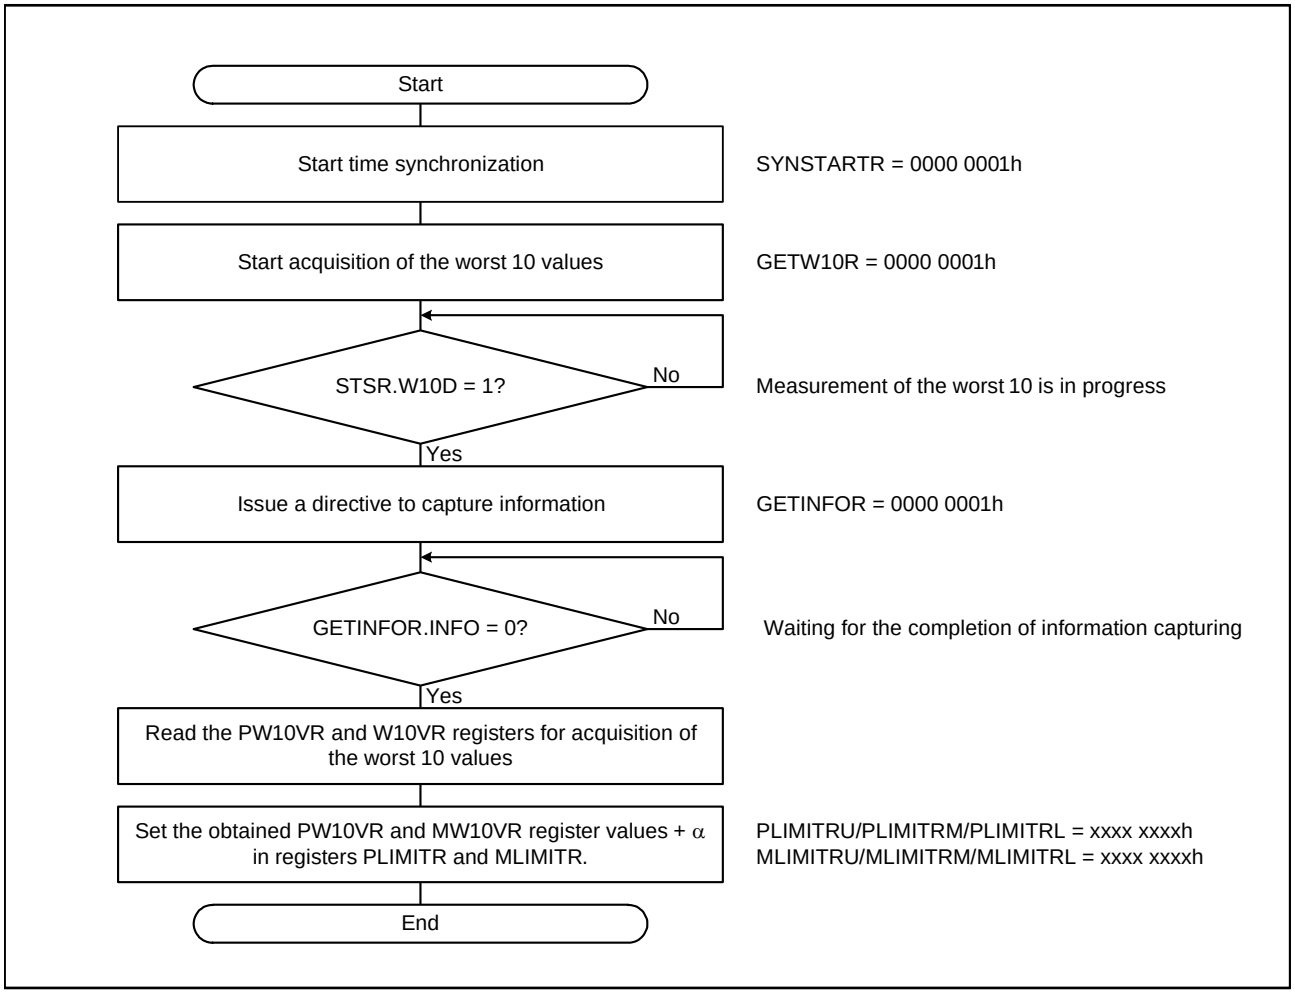

Figure 36.29 Example of the Procedure for Software-Triggered Acquisition of the Worst 10 Values

36.3.16 Local Clock Counter

The local clock counter retains the synchronized time information. The counter starts counting from 0 after the ETHERC is released from the module stop state or the EPTPC is released from the software reset state. The local clock counter can then be set to any desired value. The procedure for setting the initial value in the local clock counter is shown in Figure 36.30.

The time information kept by the local clock counter is also readable. Figure 36.31 shows the procedure for reading the time information kept by the local clock counter.

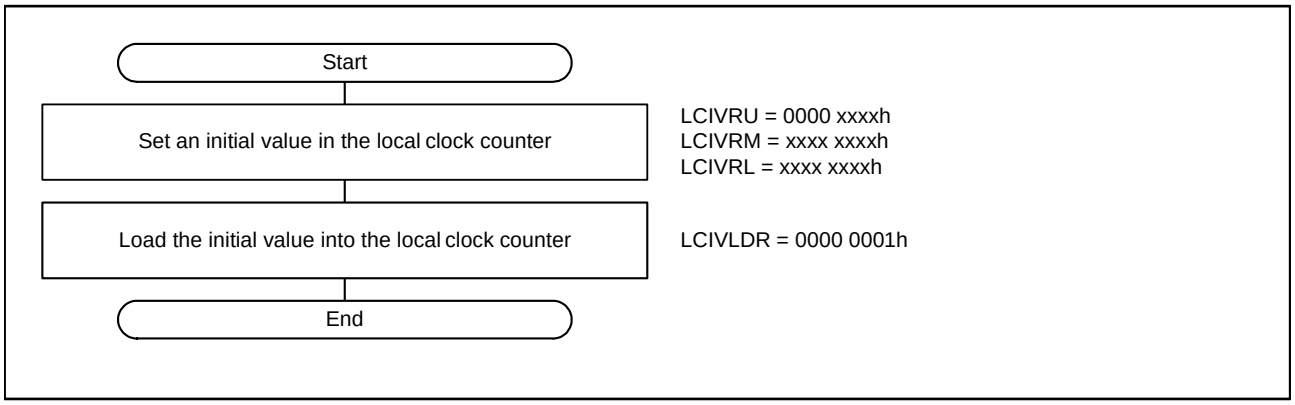

Figure 36.30 Procedure for Setting a New Initial Value in the Local Clock Counter

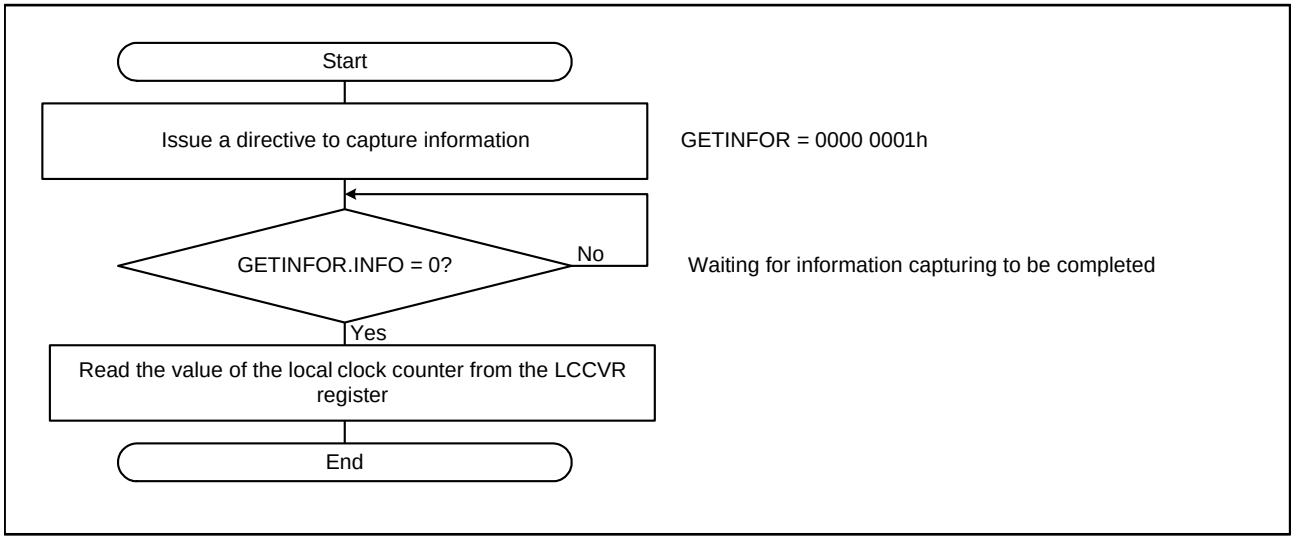

Figure 36.31 Procedure for Reading the Time Kept by the Local Clock Counter

36.3.17 Pulse Output Timer

The STCA module of the EPTPC incorporates six timers (pulse output timers 0 to 5) which operate independently of each other.

The pulse output timers produce periodic pulses, and the rising or falling edges of these pulses can be used as interrupt requests or output to the ELC as event signals. The time at which a pulse output timer starts operating (t_{start}), and the period (t_C) and pulse width (t_W) of the output pulses, can be specified.

The timing of pulse output timer operation is shown in Figure 36.32, and limits on the settings are listed in Table 36.26.

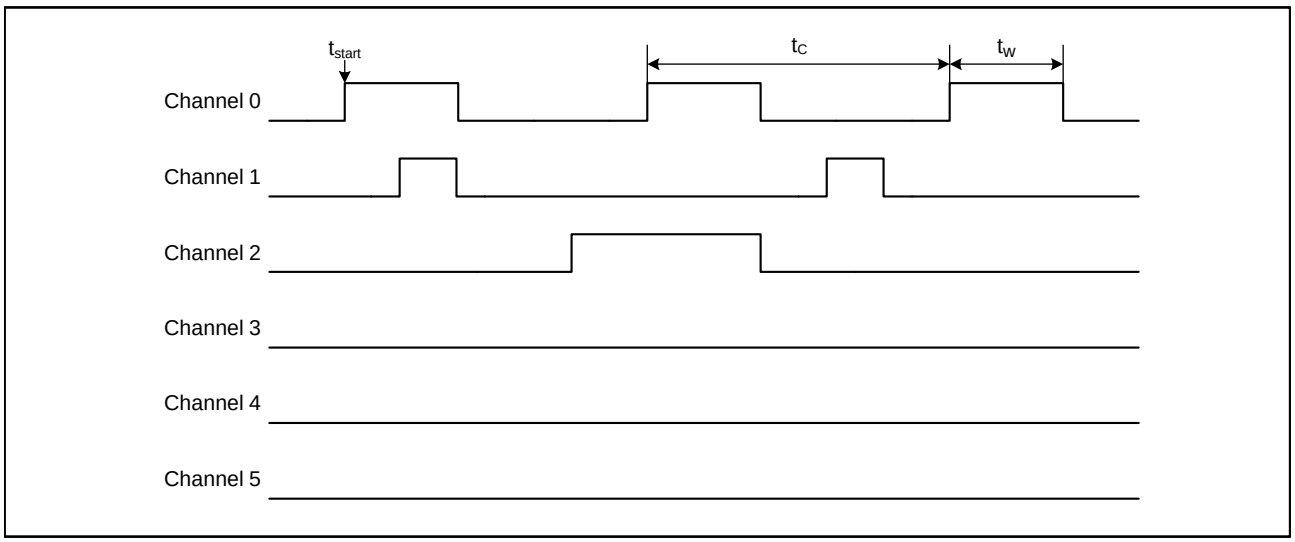

Figure 36.32 Time at which a Pulse Output Timer Starts Operating

Table 36.26 Limits on the Values that can be Specified for a Pulse Output Timer

Item	Description
Cycle (t_C)	From four cycles of the STCA clock to 1 s
Resolution of the cycle	Set in units of nanoseconds. However, the timing of rising edges is rounded by the period of the system clock (50 ns, 40 ns, 20 ns, or 10 ns).
Pulse width (t_W)	From two cycles of the STCA clock to 500 ms
Resolution of the pulse width	Set in units of nanoseconds. However, the timing of falling edges is rounded by the period of the system clock (50 ns, 40 ns, 20 ns, or 10 ns).

36.3.17.1 Procedure for Setting a Pulse Output Timer

Figure 36.33 shows the procedure for setting a pulse output timer.
Note that a timer does not produce periodic pulses if the time set in registers TMSTTRUm and TMSTTRLm (m = 0 to 5) has already passed. Set the time for a pulse output timer to start to a later time than the time when the timer is being set.

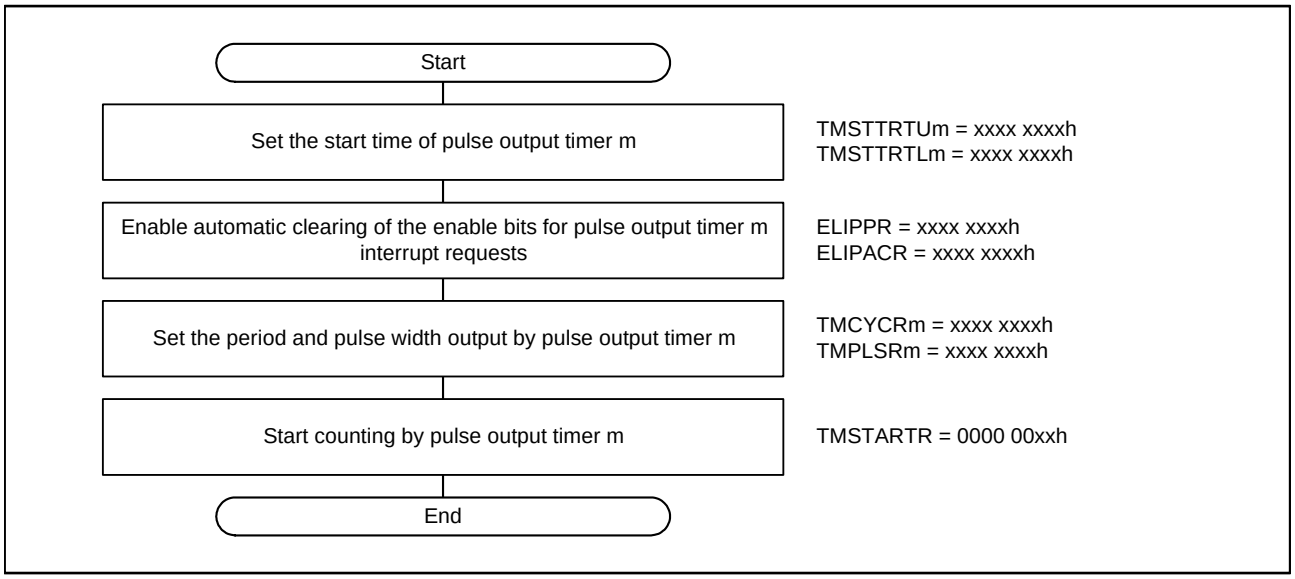

Figure 36.33 Procedure for Setting a Pulse Output Timer

36.3.17.2 Output of periodic pulses as interrupt requests or event signals

MINT interrupt requests, IPLS interrupt requests, or event output signals for the ELC can be generated by detecting rising or falling edges of the periodic pulses from the pulse output timer. The edge for detection and pulse output timer to use can be selected, and automatic clearing of enable bits for the IPLS interrupt or event output can be set. Make the required settings before setting the TMSTARTR.ENm bit to 1 (starting pulse output timer m).

(1) MINT Interrupt Request

Rising edges of the periodic pulses from the pulse output timers can be detected to generate MINT interrupt requests. Falling edges cannot be used in this way. The pulse output timers for use in generating MINT interrupt requests are selected by the MITSELR.MINTENm bits.
Automatic clearing of the enable bits for MINT interrupt requests is not available.

(2) IPLS Interrupt Request

Rising or falling edges of the periodic pulses from the pulse output timers can be detected to generate IPLS interrupt requests. The pulse output timers for use in generating IPLS interrupt requests are selected by the IPTSELR.IPTSELm bits.
Setting the ELIPACR.PLSP or PLSN bit enables automatic clearing of the enable bits for IPLS interrupt requests.

(3) Output of Event Signals to the ELC

Rising or falling edges of the periodic pulses from the pulse output timers can be detected to output event signals to the ELC. The pulse output timers for use in outputting event signals and the edge are selected by the ELIPPR.CYCPm or CYCNm bits.
Setting the ELIPACR.CYCPm or CYCNm bits enables automatic clearing of the event output enable bits.

36.3.18 Priority Control in Transmission

36.3.18.1 Arbitration

In cases of contention between a message for transmission from the PTPEDMAC and a request for relaying from another channel, the PRC-TC module gives priority to the request for relaying from the other channel.
Cases of contention between multiple requests for the transmission of messages by the SYNFP module are also arbitrated in the order of priority shown in Table 36.27.

Table 36.27 Priority in Arbitration for Messages for Transmission

Messages for Transmission	Priority Order	Remark
Sync	1 Highest priority	
Delay_Req, Pdelay_Req	2	There is no device type that simultaneously transmits Delay_Req and Pdelay_Req messages.
Delay_Resp, Pdelay_Resp	3	There is no device type that simultaneously transmits Delay_Resp and Pdelay_Resp messages.
Announce	4	
Relay messages from another channel	5	The PRC-TC module determines the order of priority for these two items.
Messages for transmission from the PTPEDMAC	5	
Messages for transmission from the EDMAC	6	

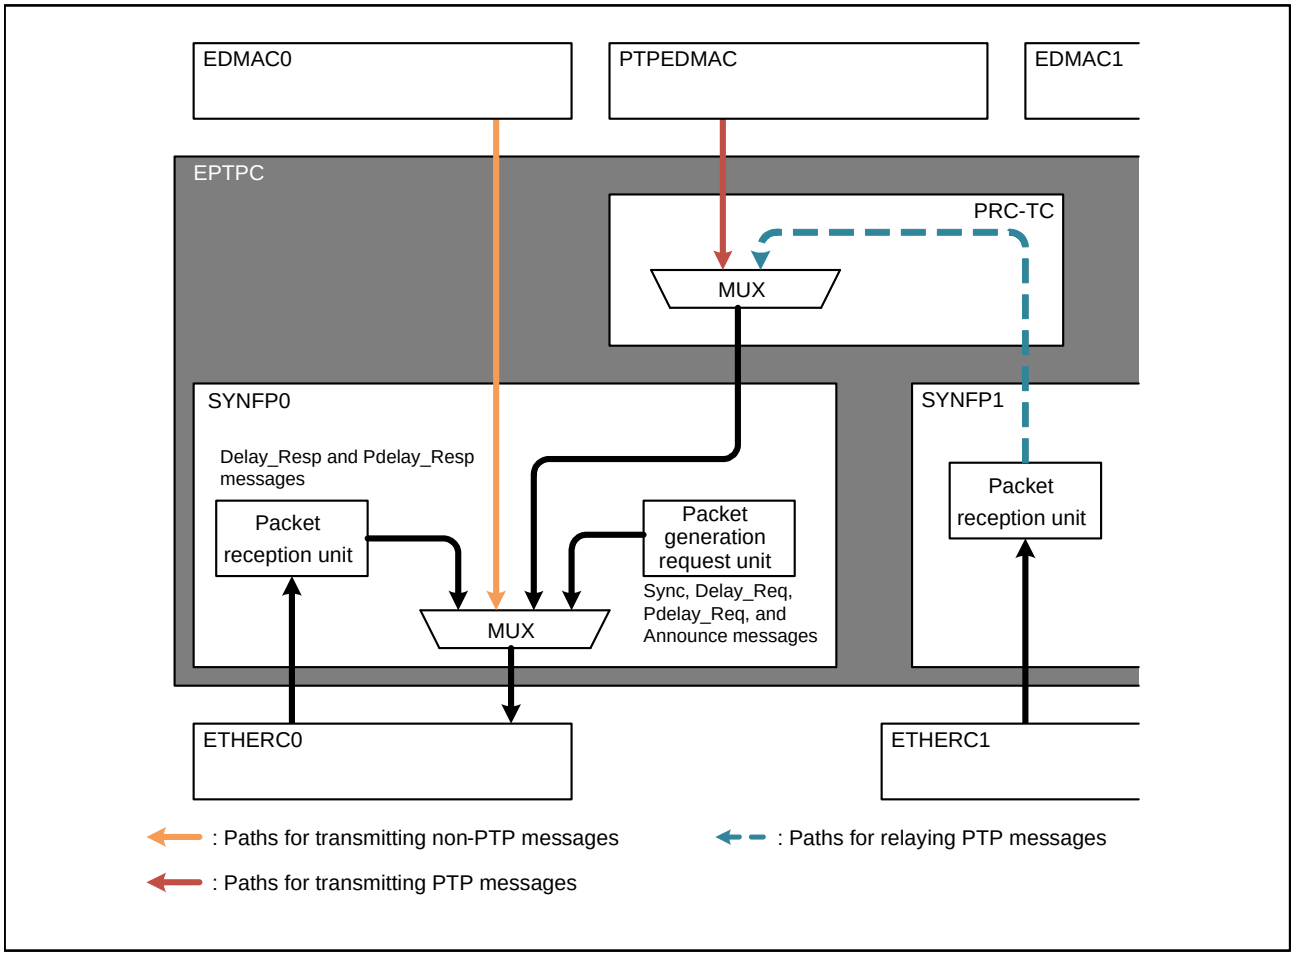

Figure 36.34 Arbitration in Message Transmission

36.3.18.2 Securing of Bandwidth for the Transmission of Sync Messages

The EPTPC secures bandwidth for the transmission of Sync messages, and is capable of handling transmission at very precise intervals.

If the transmission of a Sync message at a fixed interval proceeds at the same time as transmission by the PTPEDMAC or the relaying of messages by another channel is in progress, because transmission of the Sync message proceeds when the other processing is complete, the interval for transmission will no longer be fixed.

By securing bandwidth for the transmission of Sync messages, the transmission of messages from EDMAC0, EDMAC1, and the PTPEDMAC is limited, and the transmission of Sync messages can be handled without fluctuations. Securing of bandwidth for the transmission of Sync messages can be disabled by setting the SYCONFR.SBDIS bit to 1. Figure 36.35 gives a schematic view of securing bandwidth for the transmission of Sync messages.

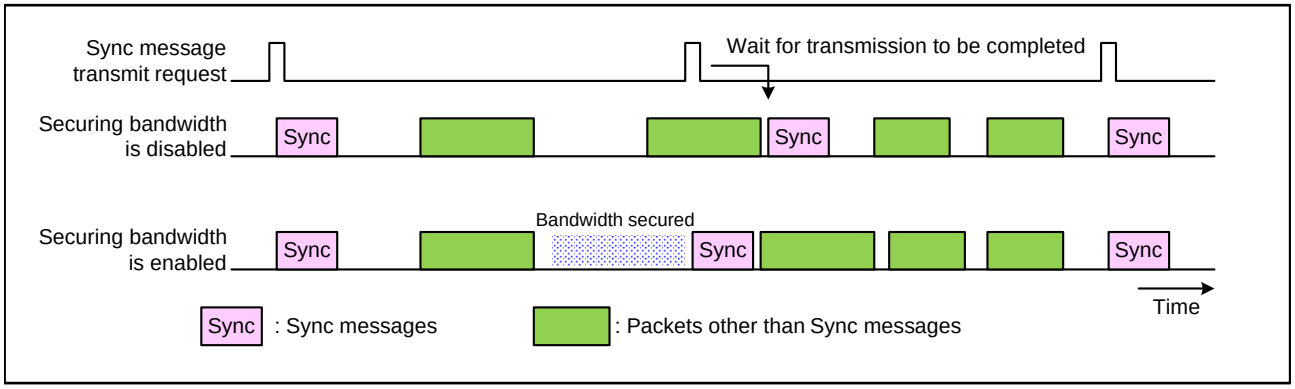

Figure 36.35 Securing of Bandwidth for the Transmission of Sync Messages

36.3.18.3 Securing of Transmission Interval

In the transmission of messages by the ETHERC, if there is a fixed delay from the time of a request for transmission to the time of transmission on the MII of Ethernet port 0 or 1, time stamp values of PTP messages can be used for accurately obtaining the size of the delay during operation as a slave. However, in the case of continuous transfer and so on, in situations where processing of messages to wait for interpacket gap times is required, delay times may fluctuate. Specifying an interval for frame transmission in SYCONFR.TCYC[7:0] bits to control the interval between the completion of transmission and the next request for transmission makes the ETHERC able to secure the reliability of time stamp values, thus avoiding the effects of interpacket gap times and obtaining a fixed delay for transmission.

36.4 Interrupts

The EPTPC has the MINT interrupt request and IPLS interrupt request.
Figure 36.36 shows the relation between the MINT interrupt request and IPLS interrupt request. Figure 36.37 shows the details on interrupt requests of the pulse output timer.

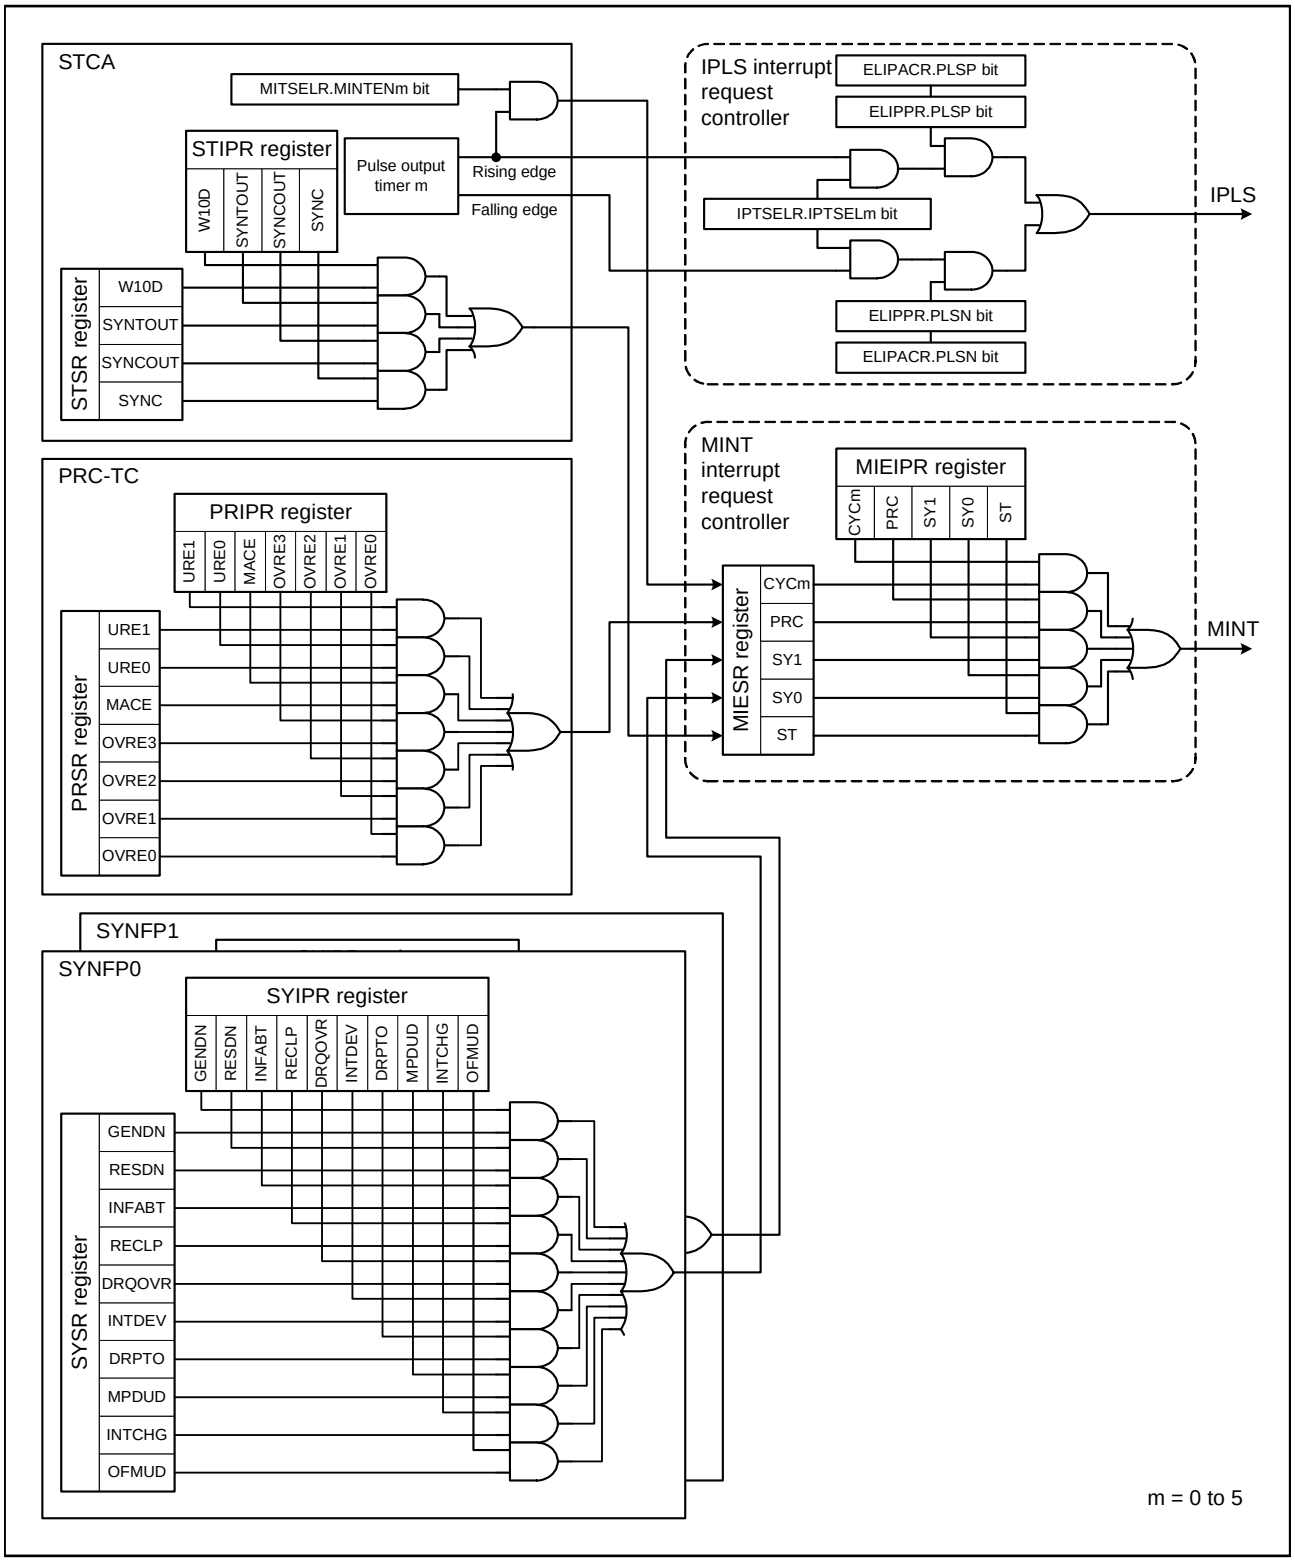

Figure 36.36 MINT Interrupt Request and IPLS Interrupt Request

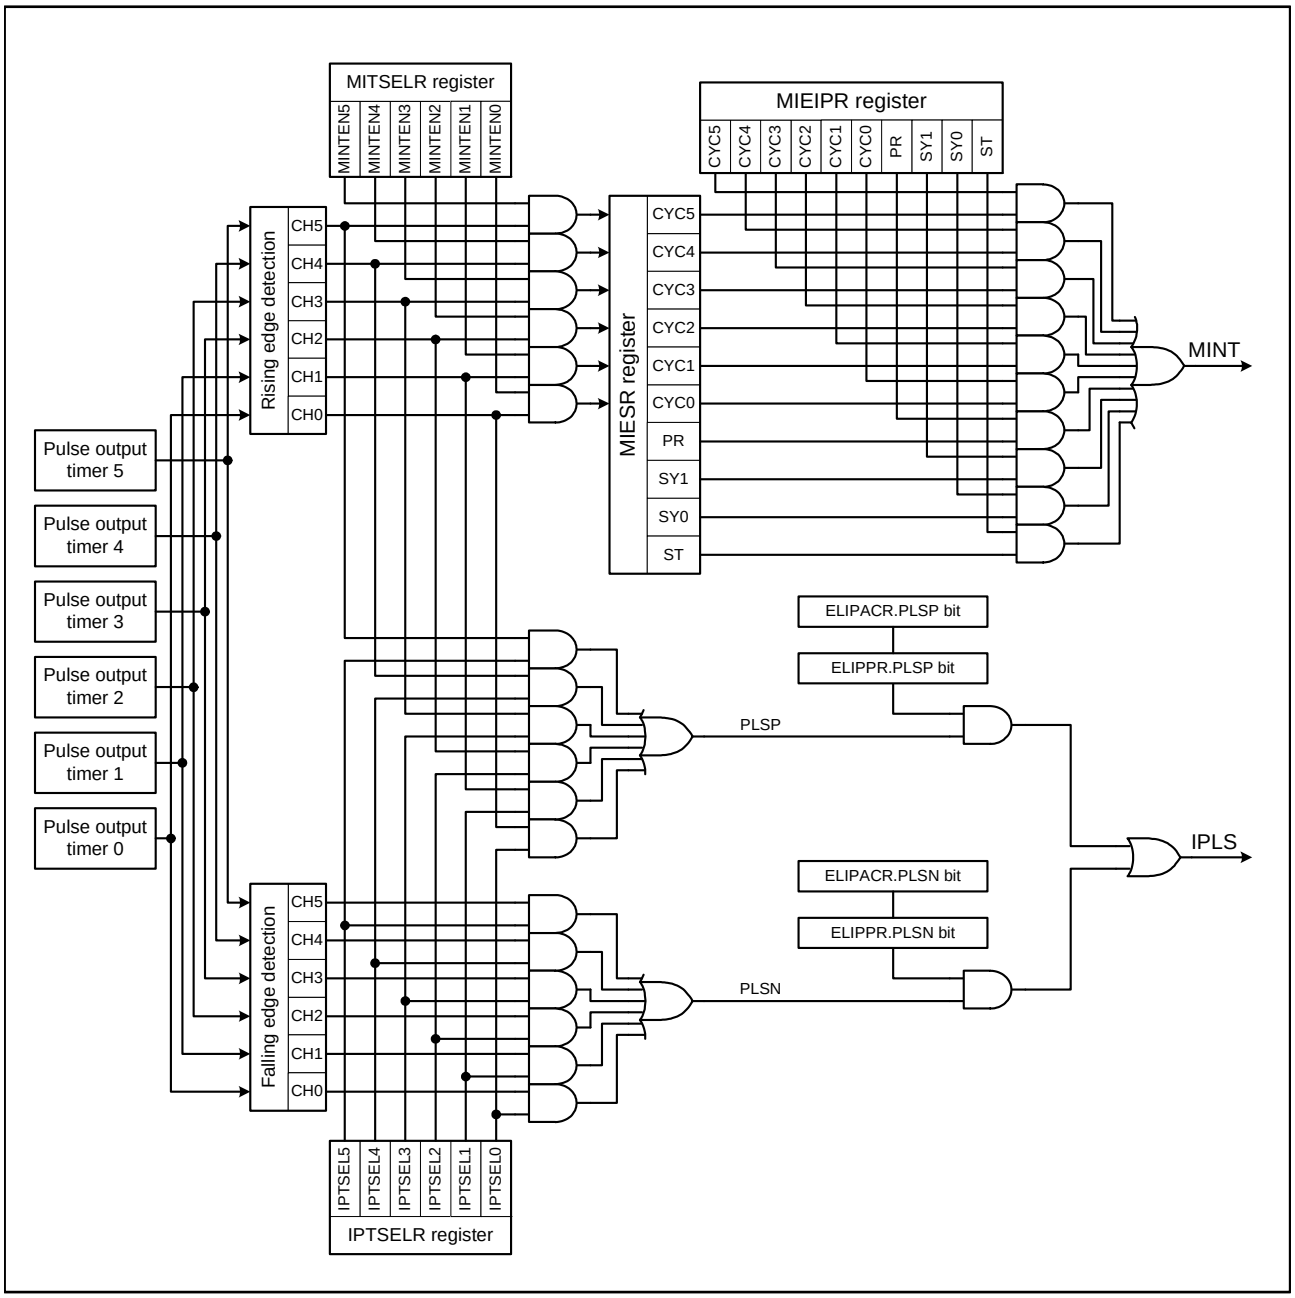

Figure 36.37 Details on Interrupt Requests of the Pulse Output Timer

36.5 Event Link (Output)

The EPTPC can output an event to the ELC by detecting the rising edge or falling edge of the pulse that the pulse output timer outputs.

Figure 36.37 shows the relation between the pulse output timer and the ELC.

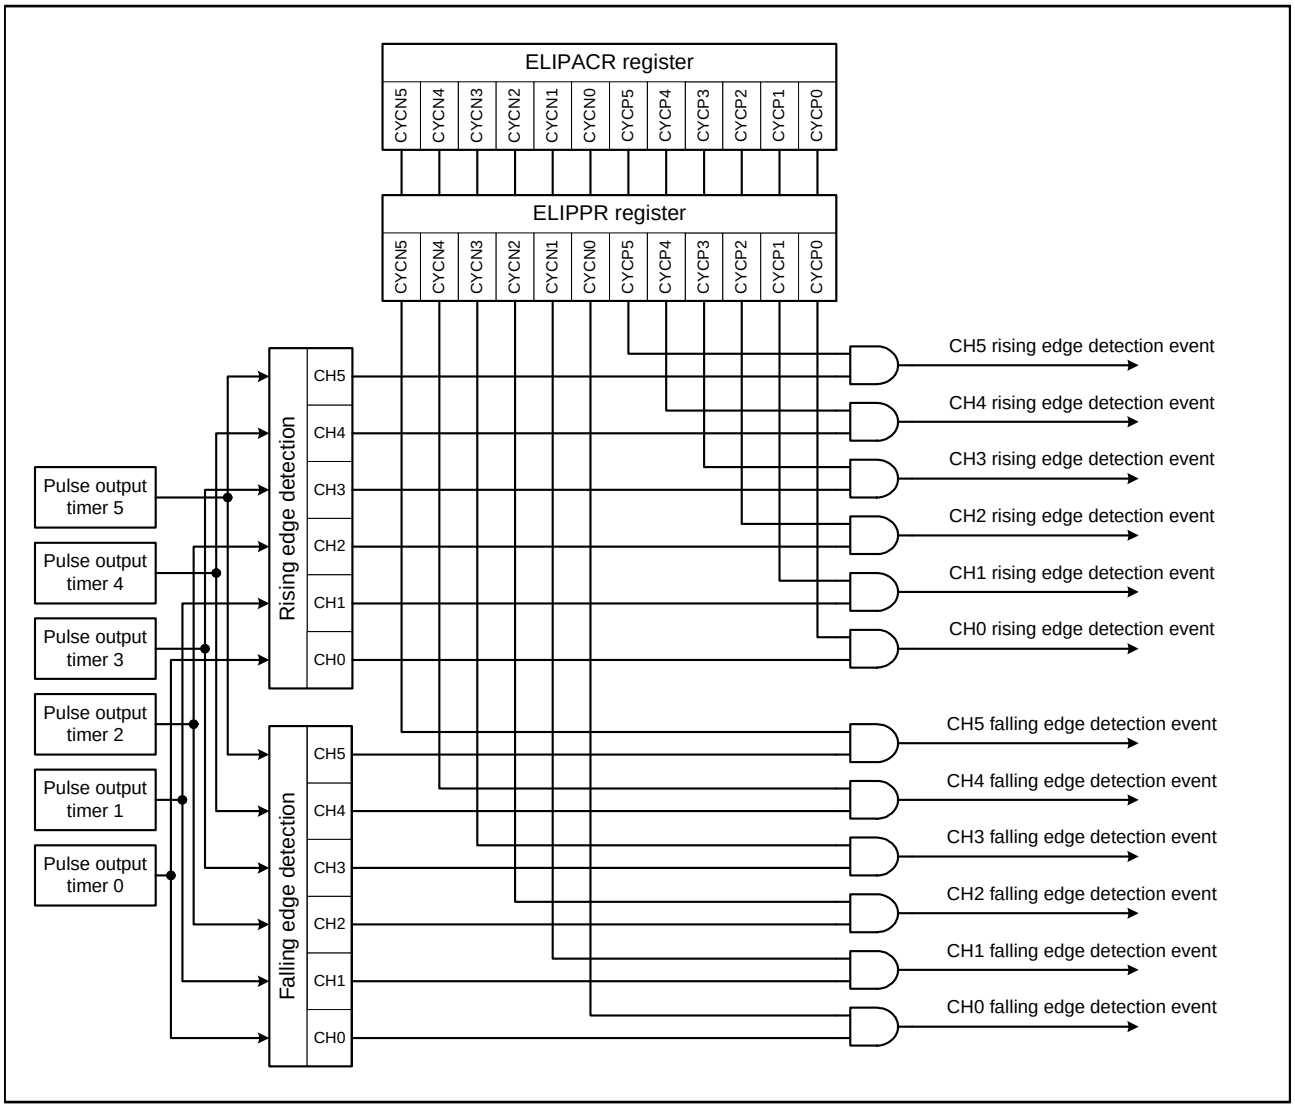

Figure 36.38 Relation between the Pulse Output Timer and ELC

36.6 Usage Notes

36.6.1 Restrictions on Access to Registers

Even if the EPTPC does not handle time synchronization, multicast filtering and so on can still be applied in the internal operation of the module. However, if Ethernet port 0 or Ethernet port 1 is stopped, some registers in the EPTPC module become inaccessible because supply of the clock signal from the corresponding EDMAC stops.
Table 36.28 summarizes the restrictions on access to registers.

Table 36.28 Restrictions on Register Access

Usage of Ethernet Ports		Allocation of Register Addresses for Access					
Ethernet Port 0 (EDMAC0)	**Ethernet Port 1 (EDMAC1)**	**000C 0500h to 000C 05FFh**	**000C 4000h to 000C 403Fh**	**000C 4040h to 000C 43FFh (STCA)**	**000C 4400h to 000C 47FFh (PRC-TC)**	**000C 4800h to 000C 4BFFh (SYNFP0)**	**000C 4C00h to 000C 4FFFh (SYNFP1)**
In use	In use	Accessible	Accessible	Accessible	Accessible	Accessible	Accessible
In use	Not in use	Accessible	Accessible	Accessible	Accessible	Accessible	Access prohibited
Not in use	In use	Accessible	Accessible	Accessible	Accessible	Access prohibited	Accessible
Not in use	Not in use	Accessible	Access prohibited	Access prohibited	Access prohibited	Access prohibited	Access prohibited

Access to an access-prohibited register can lead to a bus timeout error. If a bus timeout error occurs, use the PTRSTR.RESET bit to reset the EPTPC by software. Refer to section 16.7.1.2, Timeout for details on the bus timeout error.

36.6.2 Wait Cycles for Register Access

Access to registers in the EPTPC involves the arbitration of different clock signals, specifically the peripheral module clock signal (PCLKA), the STCA clock signal, and the MII clock signals such as TX_CLK. Accordingly, numbers of wait cycles for register access differ with the combination of the frequency settings of the peripheral module clock signal, of the STCA clock signal, and of the MII clock signals.

Table 36.29 gives examples of numbers of wait cycles for different combinations of clock frequency. Add 1 to 2 cycles to these values to obtain the number of access cycles.

Table 36.29 Wait Cycles for Register Access (when the frequency of the STCA clock is 20 MHz)

	STCA Clock = 20 MHz							
	Peripheral Module Clock PCLKA = 120 MHz				Peripheral Module Clock PCLKA = 20 MHz			
	MII Clock 25 MHz (100 Mbps)		MII Clock 2.5 MHz (10 Mbps)		MII Clock 25 MHz (100 Mbps)		MII Clock 2.5 MHz (10 Mbps)	
Address Range	Read	Write	Read	Write	Read	Write	Read	Write
000C 0500h to 000C 05FFh	2	2	2	2	2	2	2	2
000C 4000h to 000C 403Fh	4	4	4	4	4	4	4	4
000C 4040h to 000C 43FFh (STCA)	7	27 to 41*1	7	27 to 41*1	7	15 to 17*1	7	15 to 17*1
000C 4400h to 000C 47FFh (PRC-TC)	8	8	8	8	8	8	8	8
000C 4800h to 000C 4BFFh (SYNFP0)	8	23 to 33*2	8	111 to 209*2	8	15 to 17*2	8	31 to 49*2
000C 4C00h to 000C 4FFFh (SYNFP1)	8	23 to 33*2	8	111 to 209*2	8	15 to 17*2	8	31 to 49*2

Note 1. The number of wait cycles in access to the STCA-related registers (Wstca) can be calculated to be in the following range from the periods of the peripheral module clock ($t_{c(PCLKA)}$) and STCA clock ($t_{c(STCA)}$).

The minimum value of Wstca = Int ($t_{c(STCA)}/t_{c(PCLKA)}$) × 2 + 15 ($t_{c(PCLKA)} \leq t_{c(STCA)}$)
= 15 ($t_{c(PCLKA)} > t_{c(STCA)}$)

The maximum value of Wstca = Int ($t_{c(STCA)}/t_{c(PCLKA)}$) × 4 + 17 ($t_{c(PCLKA)} \leq t_{c(STCA)}$)
= 17 ($t_{c(PCLKA)} > t_{c(STCA)}$)

- Int(A) is the calculation of the largest integer not greater than A.
- This calculation presumes that the CPU clock and peripheral module clock have the same periods.

For example, if the frequency of the peripheral module clock is 120 MHz and that of the STCA clock is 1/6 that of the peripheral module clock (= 20 MHz),
the minimum value of Wstca = Int (50 [ns]/8.3 [ns]) × 2 + 15 = 27, and
the maximum value of Wstca = Int (50 [ns]/8.3 [ns]) × 4 + 17 = 41.
If REF50CK0 or REF50CK1 is used as the STCA clock, the frequency of the STCA clock is 25 MHz.

Note 2. The number of wait cycles in access to the SYNFP-related registers (Wsynf) can be calculated to be in the following range from the periods of the peripheral module clock ($t_{c(PCLKA)}$) and MII clock ($t_{c(MII)}$).

The minimum value of Wsynf = Int ($t_{c(MII)}/t_{c(PCLKA)}$) × 2 + 15 ($t_{c(PCLKA)} \leq t_{c(MII)}$)
= 15 ($t_{c(PCLKA)} > t_{c(MII)}$)

The maximum value of Wsynf = Int ($t_{c(MII)}/t_{c(PCLKA)}$) × 4 + 17 ($t_{c(PCLKA)} \leq t_{c(MII)}$)
= 17 ($t_{c(PCLKA)} > t_{c(MII)}$)

- Int(A) is the calculation of the largest integer not greater than A.
- This calculation presumes that the CPU clock and peripheral module clock have the same periods.

For example, if the frequency of the peripheral module clock is 120 MHz and the transmission rate is 10 Mbps (so the MII clock is running at 2.5 MHz),
the minimum value of Wsynf = Int (400 [ns]/8.3 [ns]) × 2 + 15 = 111, and
the maximum value of Wsynf = Int (400 [ns]/8.3 [ns]) × 4 + 17 = 209.

37. DMA Controller for the Ethernet Controller (EDMACa)

37.1 Overview

This MCU has three channels for the ethernet controller direct memory access controller (EDMAC): two channels for the ethernet controller (ETHERC) and one channel for the PTP controller (EPTPC). EDMAC0 and EDMAC1 control data transmission and reception for ETHERC0 and ETHERC1, respectively. The PTPEDMAC controls data transmission and reception for ETHERC0 and ETHERC1 according to the EPTPC settings. In this chapter, channel numbers are indicated as n (n = 0, 1).

The EDMAC controls most of the transmit/receive buffer management for communications. This reduces the load on the CPU and allows efficient data transmission and reception. The data transfers are controlled according to the information (referred to as descriptors) on the memory.

Table 37.1 lists the EDMAC specifications. Figure 37.1 shows the EDMAC configuration, and Figure 37.2 shows the configuration of descriptors and transmit/receive buffers on the memory.

Table 37.1 EDMAC Specifications

Item	Description
Data transmission and reception	• Controls data transmission and reception according to descriptors • Supports single buffer frame transmission and reception (1 buffer per frame), and multi-buffer frame transmission and reception (multiple buffers per frame)
Functions	• Minimizes system bus occupation time using block transfer (32-byte units) • Writes back the transmit/receive frame state to descriptors • Inserts padding in receive data
Low power consumption function	The EDMAC can be set to the module-stop state to reduce power consumption.

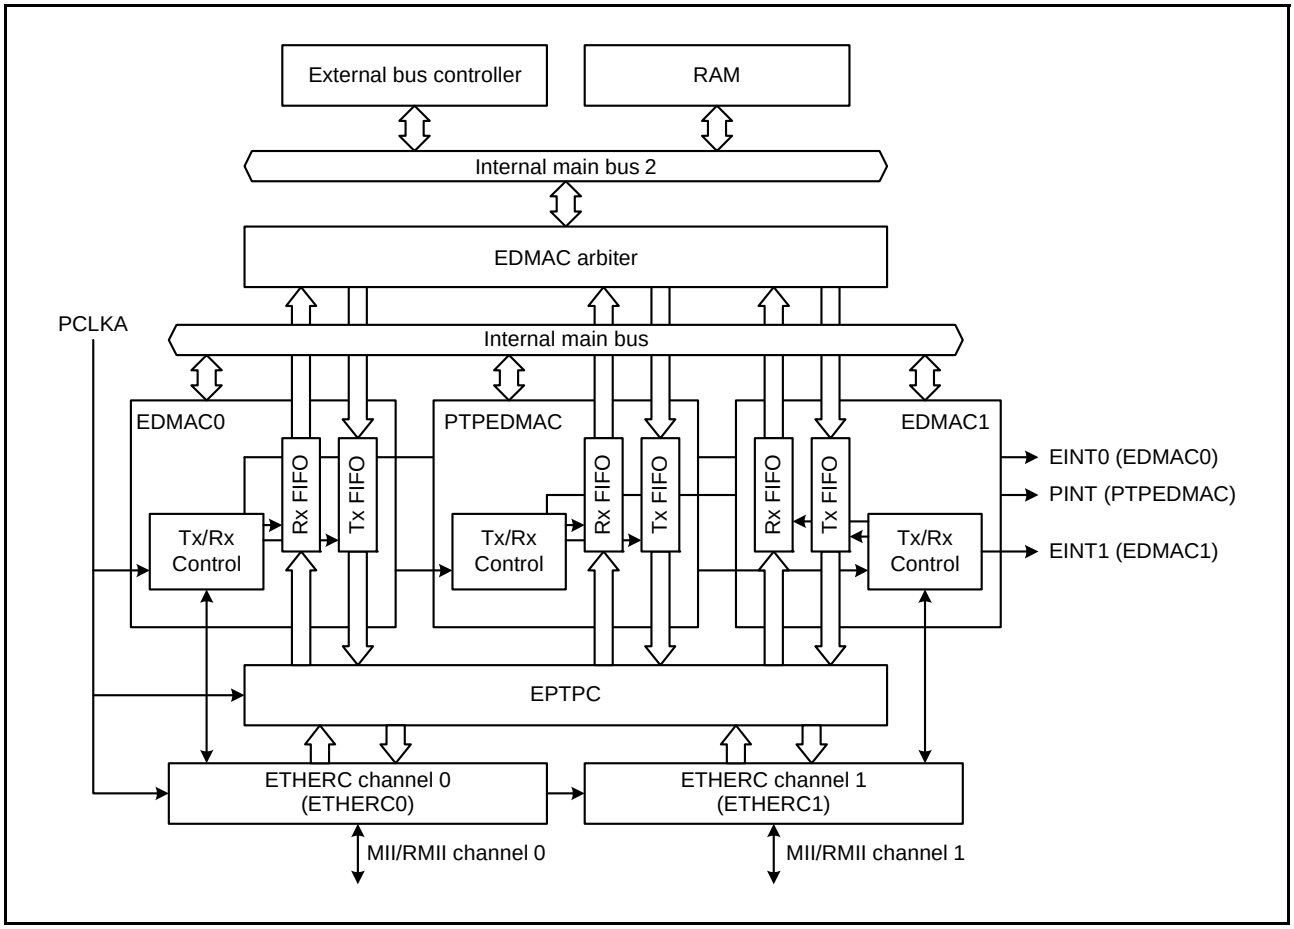

Figure 37.1 EDMAC Configuration

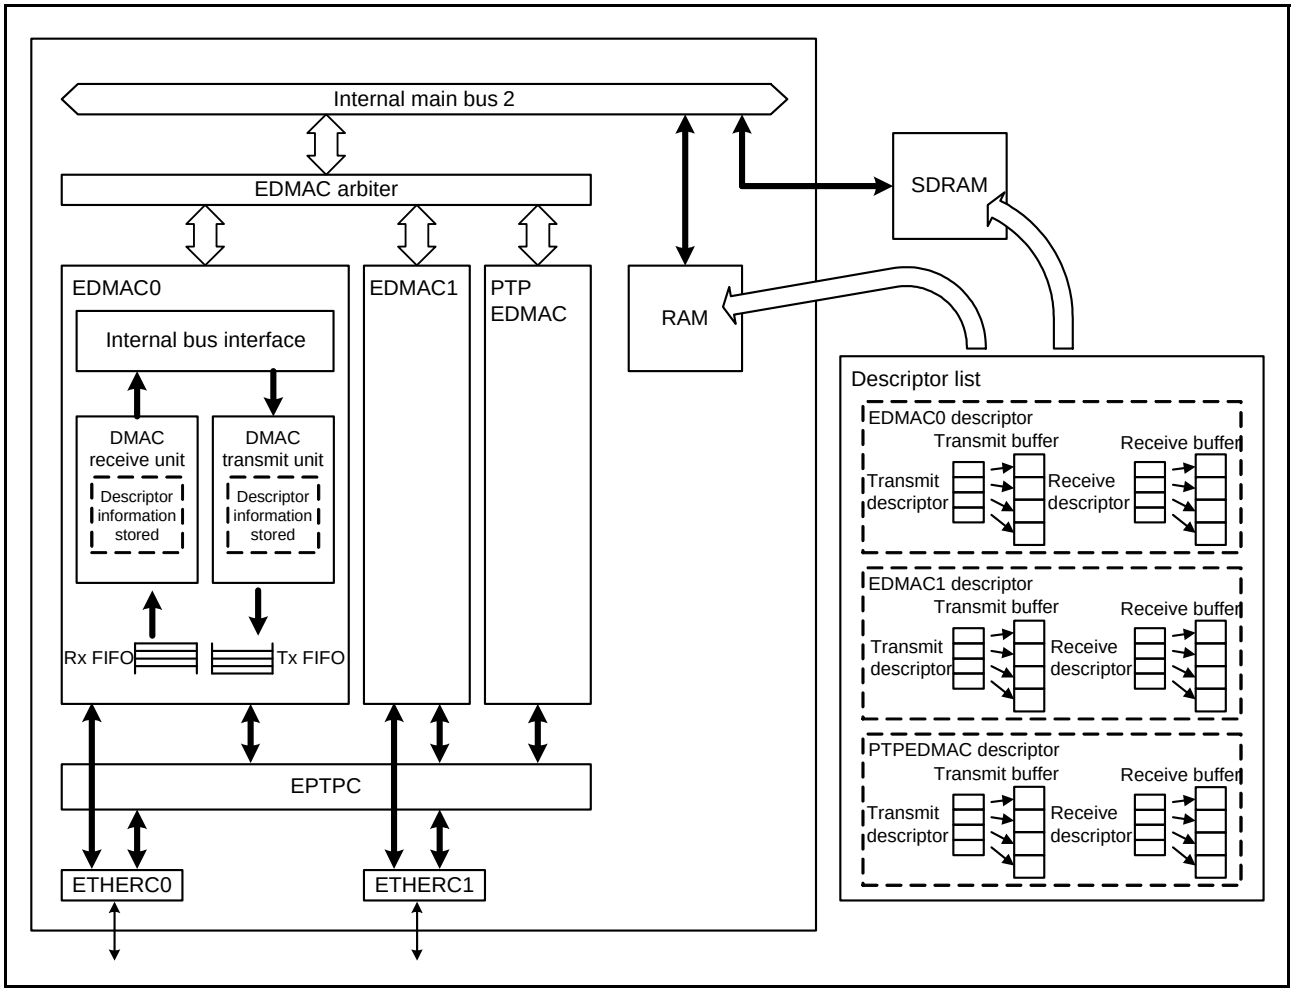

Figure 37.2 Configuration of Descriptors and Transmit/Receive Buffers on the Memory

37.2 Register Descriptions

37.2.1 EDMAC Mode Register (EDMR)

Address(es): EDMAC0.EDMR 000C 0000h, EDMAC1.EDMR 000C 0200h, PTPEDMAC.EDMR 000C 0400h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	DE	DL[1:0]		—	—	—	SWR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SWR	Software Reset	When 1 is written, the corresponding channels of the EDMAC and ETHERC are reset. Note that for the PTPEDMAC, the ETHERC are not reset. Registers TDLAR, RDLAR, RMFCR, TFUCR, and RFOCR are not reset with this bit. The read value is 0.	R/W
b3 to b1	—	Reserved	The read value is 0. The write value should be 0.	R/W
b5, b4	DL[1:0]	Transmit/Receive Descriptor Length	b5 b4 0 0: 16 bytes 0 1: 32 bytes 1 0: 64 bytes 1 1: 16 bytes	R/W
b6	DE	Big Endian Mode/Little Endian Mode *1	0: Big endian mode 1: Little endian mode	R/W
b31 to b7	—	Reserved	The read value is 0. The write value should be 0.	R/W

Note 1. This setting applies to data for the transmit/receive buffer. It does not apply to transmit/receive descriptors and registers.

The EDMR register controls EDMAC operation.

Set the EDMR register during the initialization process after a reset. When rewriting this register outside of the initialization process, set the SWR bit to 1 to reset the EDMAC and ETHERC, and then set this register again. If the ETHERC and EDMAC are reset during data transmission or reception, abnormal data may be sent on the line. Do not rewrite this register while the ETHERC transmit or receive function is enabled. It takes 64 cycles of the peripheral module clock (PCLKA) to initialize the ETHERC and EDMAC. Complete the initialization process before accessing registers in the ETHERC and EDMAC.

37.2.2 EDMAC Transmit Request Register (EDTRR)

Address(es): EDMAC0.EDTRR 000C 0008h, EDMAC1.EDTRR 000C 0208h, PTPEDMAC.EDTRR 000C 0408h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TR	Transmit Request	When 1 is written, the EDMAC reads the corresponding descriptor and transmits frames where the TD0.TACT bit is 1. The TR bit becomes 0 after all the valid frames are transmitted. Writing 0 to this bit has no effect.	R/W
b31 to b1	—	Reserved	The read value is 0. The write value should be 0.	R/W

The EDTRR register controls EDMAC transmission.
After the EDMAC has transmitted one frame, it reads the next descriptor. When the TD0.TACT bit in the descriptor is 1, the EDMAC continues transmission. When the TD0.TACT bit is 0, the EDMAC sets the TR bit to 0 and stops transmission.

37.2.3 EDMAC Receive Request Register (EDRRR)

Address(es): EDMAC0.EDRRR 000C 0010h, EDMAC1.EDRRR 000C 0210h, PTPEDMAC.EDRRR 000C 0410h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RR	Receive Request	0: Receive function is disabled. *1 1: Receive descriptor is read, and the receive function is enabled.	R/W
b31 to b1	—	Reserved	The read value is 0. The write value should be 0.	R/W

Note 1. If the receive function is disabled during frame reception, write-back to the receive descriptor is not performed successfully. Subsequent pointers for reading a receive descriptor become abnormal and the EDMAC cannot operate normally. In this case, to enable the EDMAC receive function again, execute a software reset by setting the EDMR.SWR bit to 1.
To disable the EDMAC receive function without resetting the EDMAC, set the ETHERCn.ECMR.RE bit to 0. Next, after the EDMAC has completed reception and write-back to the receive descriptor has been confirmed, set the RR bit to 0.

The EDRRR register controls EDMAC reception.

When the RR bit becomes 1, the EDMAC reads the receive descriptor. When the RD0.RACT bit is 1, the EDMAC waits for a receive request from the ETHERC.

When the EDMAC has received data for the receive buffer size, it reads the next descriptor and waits to receive a frame. If the RD0.RACT bit is 0, the EDMAC sets the RR bit to 0 and stops reception.

37.2.4 Transmit Descriptor List Start Address Register (TDLAR)

Address(es): EDMAC0.TDLAR 000C 0018h, EDMAC1.TDLAR 000C 0218h, PTPEDMAC.TDLAR 000C 0418h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	The start address of the transmit descriptor list is set. Set the start address according to the descriptor length selected by the EDMR.DL[1:0] bits. 16-byte boundary: Lower 4 bits = 0000b 32-byte boundary: Lower 5 bits = 00000b 64-byte boundary: Lower 6 bits = 000000b	R/W

The TDLAR register sets the start address of the transmit descriptor list.
Align each descriptor on the corresponding boundary to the descriptor length selected by the EDMR.DL[1:0] bits.
Do not rewrite the TDLAR register during transmission. Rewrite the TDLAR register while the EDTRR.TR bit is 0.

37.2.5 Receive Descriptor List Start Address Register (RDLAR)

Address(es): EDMAC0.RDLAR 000C 0020h, EDMAC1.RDLAR 000C 0220h, PTPEDMAC.RDLAR 000C 0420h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	—	The start address of the receive descriptor list is set. Set the start address according to the descriptor length selected by the EDMR.DL[1:0] bits. 16-byte boundary: Lower 4 bits = 0000b 32-byte boundary: Lower 5 bits = 00000b 64-byte boundary: Lower 6 bits = 000000b	R/W

The RDLAR register sets the start address of the receive descriptor list.
Align each descriptor on the corresponding boundary to the descriptor length selected by the EDMR.DL[1:0] bits.
Do not rewrite the RDLAR register during reception. Rewrite the RDLAR register while the EDRRR.RR bit is 0.

37.2.6 ETHERC/EDMAC Status Register (EDMACn.EESR)

Address(es): EDMAC0.EESR 000C 0028h, EDMAC1.EESR 000C 0228h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	CND	DLC	CD	TRO	RMAF	—	—	RRF	RTLF	RTSF	PRE	CERF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CERF	CRC Error Flag	0: CRC error has not been detected. 1: CRC error has been detected.	R/W
b1	PRE	PHY-LSI Receive Error Flag	0: PHY-LSI receive error has not been detected. 1: PHY-LSI receive error has been detected.	R/W
b2	RTSF	Frame-Too-Short Error Flag	0: Frame-too-short error has not been detected. 1: Frame-too-short error has been detected.	R/W
b3	RTLF	Frame-Too-Long Error Flag	0: Frame-too-long error has not been detected. 1: Frame-too-long error has been detected.	R/W
b4	RRF	Alignment Error Flag	0: Alignment error has not been detected. 1: Alignment error has been detected.	R/W
b6, b5	—	Reserved	The read value is 0. The write value should be 0.	R/W
b7	RMAF	Multicast Address Frame Receive Flag	0: Multicast address frame has not been received. 1: Multicast address frame has been received.	R/W
b8	TRO	Transmit Retry Over Flag	0: Transmit retry-over condition has not been detected. 1: Transmit retry-over condition has been detected.	R/W
b9	CD	Late Collision Detect Flag	0: Late collision has not been detected. 1: Late collision has been detected during frame transmission.	R/W
b10	DLC	Loss of Carrier Detect Flag	0: Loss of carrier has not been detected. 1: Loss of carrier has been detected during frame transmission.	R/W
b11	CND	Carrier Not Detect Flag	0: A carrier has been detected when transmission starts. 1: A carrier has not been detected during preamble transmission.	R/W
b15 to b12	—	Reserved	The read value is 0. The write value should be 0.	R/W
b16	RFOF	Receive FIFO Overflow Flag	0: Overflow has not occurred. 1: Overflow has occurred.	R/W
b17	RDE	Receive Descriptor Empty Flag	0: The EDMAC detects that the receive descriptor valid bit (RD0.RACT) is 1. 1: The EDMAC detects that the receive descriptor valid bit (RD0.RACT) is 0.	R/W
b18	FR	Frame Receive Flag	0: Frame has not been received. 1: Frame has been received. Update of the receive descriptor is complete.	R/W
b19	TFUF	Transmit FIFO Underflow Flag	0: Underflow has not occurred. 1: Underflow has occurred.	R/W
b20	TDE	Transmit Descriptor Empty Flag	0: The EDMAC detects that the transmit descriptor valid bit (TD0.TACT) is 1. 1: The EDMAC detects that the transmit descriptor valid bit (TD0.TACT) is 0.	R/W

Bit	Symbol	Bit Name	Description	R/W
b21	TC	Frame Transfer Complete Flag	0: Transfer have not been completed, or no transfer has been requested. 1: All frames indicated by the transmit descriptor have been completely transferred to the transmit FIFO.	R/W
b22	ECI	ETHERC Status Register Source Flag	0: ETHERC status interrupt source has not been detected. 1: ETHERC status interrupt source has been detected.	R *1
b23	—	Reserved	The read value is 0. The write value should be 0.	R/W
b24	RFCOF	Receive Frame Counter Overflow Flag	0: Receive frame counter has not overflowed. 1: Receive frame counter has overflowed.	R/W
b25	RABT	Receive Abort Detect Flag	0: Frame reception has not been aborted or no reception has been requested. 1: Frame reception has been aborted.	R/W
b26	TABT	Transmit Abort Detect Flag	0: Frame transmission has not been aborted or no transmission has been requested. 1: Frame transmission has been aborted.	R/W
b29 to b27	—	Reserved	The read value is 0. The write value should be 0.	R/W
b30	TWB	Write-Back Complete Flag	0: Write-back has not been completed, or no transmission has been requested. 1: Write-back to the transmit descriptor has been completed.	R/W
b31	—	Reserved	The read value is 0. The write value should be 0.	R/W

Note 1. The ECI flag is read-only. When the source in the ETHERCn.ECSR register is cleared, the ECI flag is also cleared.

The EDMACn.EESR register indicates the ETHERC and EDMAC communication status.
Each flag in the EESR register can be output as an interrupt request signal (EINTn) from the EDMAC. Each flag, excluding the ECI flag, becomes 0 by writing 1. The value of each flag is not changed by writing 0. Each interrupt source can be enabled by the corresponding bit in the EDMACn.EESIPR register.

CERF Flag (CRC Error Flag)

The CERF flag becomes 1 when an error is detected in checking the frame check sequence (FCS) field of the receive frame.

PRE Flag (PHY-LSI Receive Error Flag)

The PRE flag indicates the RX_ER signal output from the PHY-LSI is high.

RTSF Flag (Frame-Too-Short Error Flag)

The RTSF flag indicates that a received frame was less than 64 bytes.

RTLF Flag (Frame-Too-Long Error Flag)

The RTLF flag indicates that a received frame is greater than the upper limit of the receive frame length set in the ETHERCn.RFLR register. The excess data is discarded.

RRF Flag (Alignment Error Flag)

The RRF flag indicates that a frame is not an integral number of octets. The last word that is not an integral number of octets is not transferred.
An error frame shorter than 16 bytes is discarded and the RRF flag does not become 1.

RMAF Flag (Multicast Address Frame Receive Flag)

The RMAF flag indicates that a multicast frame has been received.

TRO Flag (Transmit Retry Over Flag)

This flag indicates that a collision occurred again during the 15th retry of frame transmission.

CD Flag (Late Collision Detect Flag)

The CD flag indicates that a late collision has been detected during frame transmission.

DLC Flag (Loss of Carrier Detect Flag)

The DLC flag indicates that a loss of carrier has been detected during frame transmission.

CND Flag (Carrier Not Detect Flag)

The CND flag becomes 1 when a carrier has not been detected during preamble transmission.

RFOF Flag (Receive FIFO Overflow Flag)

The RFOF flag indicates that the receive FIFO has overflowed during frame reception.

RDE Flag (Receive Descriptor Empty Flag)

The RDE flag indicates that the read receive descriptor is invalid.
When this flag becomes 1, set the RD0.RACT bit in the receive descriptor to 1 and set the EDRRR.RR bit to 1 to resume reception.

FR Flag (Frame Receive Flag)

The FR flag indicates that a frame has been received and the receive descriptor has been updated. The FR flag becomes 1 every time a frame is received.

TFUF Flag (Transmit FIFO Underflow Flag)

The TFUF flag indicates that no data remains in the transmit FIFO during frame transmission. Incomplete data is sent on the line.

TDE Flag (Transmit Descriptor Empty Flag)

The TDE flag indicates that the TD0.TACT bit of the transmit descriptor is 0 while the previous transmit descriptor indicates that the frame is not complete (TD0.TFP[1:0] bits are 10b or 00b) in multi-buffer frame transmission. As a result, an incomplete frame may be sent.
When this flag becomes 1, perform a software reset and then set the EDTRR.TR bit to 1 to resume transmission. Transmission starts from the address stored in the TDLAR register.

TC Flag (Frame Transfer Complete Flag)

The TC flag indicates that all the data specified by the transmit descriptor has been transmitted from the ETHERC. This flag becomes 1 when one frame has been transmitted in single-buffer frame transmission or when the last data of a frame is transmitted in multi-buffer frame transmission and the TD0.TACT bit in the next transmit descriptor is 0. After frame transmission is completed, the EDMAC writes the transfer status back to the descriptor.

ECI Flag (ETHERC Status Register Source Flag)

The ECI flag becomes 1 when an interrupt request is generated by the ETHERCn.ECSR register.

RFCOF Flag (Receive Frame Counter Overflow Flag)

The RFCOF flag indicates that the next frame reception starts while the number of frames stored in the receive FIFO reaches the maximum number of frames (16 frames). Note that the received frame is discarded while the RFCOF flag is 1.

RABT Flag (Receive Abort Detect Flag)

The RABT flag indicates that the ETHERC has aborted frame reception due to a CRC error, PHY-LSI receive error, frame-too-short error, frame-too-long error, or other error.
An error frame shorter than 16 bytes is discarded and the RABT flag does not become 1.

TABT Flag (Transmit Abort Detect Flag)

The TABT flag indicates that the ETHERC has aborted frame transmission due to transmit retry over, loss of carrier, no carrier detection, or other error.

TWB Flag (Write-Back Complete Flag)

The TWB flag indicates the EDMAC has completed writing back to the descriptor after frame transmission. Note that this flag becomes 1 after each frame transmission when the TRIMD.TIM bit is 0. This flag becomes 1 only when the TRIMD.TIS bit is 1.

37.2.7 PTP/EDMAC Status Register (PTPEDMAC.EESR)

Address(es): PTPEDMAC.EESR 000C 0428h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b26	TABT	Transmit Abort Detect Flag	0: Frame transmission has not been aborted or transmission has not been requested. 1: Frame transmission has been aborted.	R/W
b29 to b27	—	Reserved	The read value is 0. The write value should be 0.	R/W
b30	TWB	Write-Back Complete Flag	0: Write-back has not been completed, or transmission has not been requested. 1: Write-back to the transmit descriptor has been completed.	R/W
b31	—	Reserved	The read value is 0. The write value should be 0.	R/W

The PTPEDMAC.EESR register indicates the PTPEDMAC communication status.
Each flag in the EESR register can be output as an interrupt request signal (PINT) from the PTPEDMAC. Each flag becomes 0 by writing 1. The value of each flag is not changed by writing 0. Each interrupt source, excluding the TYPE[3:0] flag, can be enabled by setting the corresponding bit in the PTPEDMAC.EESIPR register.

TYPE[3:0] Flags (PTP v2 Message Type Flag)

The TYPE[3:0] flags indicate the type of received PTP message.

PVER Flag (PTP v2 Packet Flag)

The PVER flag indicates whether the received packet is a PTP v2 packet.

RPORT Flag (Receive Port Flag)

The RPORT flag indicates which Ethernet port has been used for receiving PTP messages.

MACE Flag (MAC Address Mismatch Flag)

The MACE flag indicates the source MAC address is different from the set value.

RFOF Flag (Receive FIFO Overflow Flag)

The RFOF flag indicates that the receive FIFO has overflowed during frame reception.

RDE Flag (Receive Descriptor Empty Flag)

The RDE flag indicates that the read receive descriptor is invalid.
When this flag becomes 1, set the RD0.RACT bit in the receive descriptor to 1 and set the EDRRR.RR bit to 1 to resume reception.

FR Flag (Frame Receive Flag)

The FR flag indicates that a frame has been received and the receive descriptor has been updated. The FR flag becomes 1 every time a frame is received.

TFUF Flag (Transmit FIFO Underflow Flag)

The TFUF flag indicates that no data remains in the transmit FIFO during frame transmission. Incomplete data is sent on the line.

TDE Flag (Transmit Descriptor Empty Flag)

The TDE flag indicates that the TD0.TACT bit of the transmit descriptor is 0 while the previous transmit descriptor indicates that the frame is not complete (TD0.TFP[1:0] bits are 10b or 00b) in multi-buffer frame transmission. As a result, an incomplete frame may be sent.
When this flag becomes 1, perform a software reset and then set the EDTRR.TR bit to 1 to resume transmission.

Transmission starts from the address stored in the TDLAR register.

TC Flag (Frame Transfer Complete Flag)

The TC flag indicates that all the data specified by the transmit descriptor has been transmitted from the ETHERC. This flag becomes 1 when one frame has been transmitted in single-buffer frame transmission or when the last data of a frame is transmitted in multi-buffer frame transmission and the TD0.TACT bit in the next transmit descriptor is 0. After frame transmission is completed, the PTPEDMAC writes the transfer status back to the descriptor.

RFCOF Flag (Receive Frame Counter Overflow Flag)

The RFCOF flag indicates that the next frame reception starts while the number of frames stored in the receive FIFO reaches the maximum number of frames (16 frames). Note that the received frame is discarded while the RFCOF flag is 1.

TABT Flag (Transmit Abort Detect Flag)

The TABT flag indicates that the ETHERC has aborted frame transmission due to transmit retry over, loss of carrier, no carrier detection, or other error.

TWB Flag (Write-Back Complete Flag)

The TWB flag indicates the PTPEDMAC has completed writing back to the descriptor after frame transmission. Note that this flag becomes 1 after each frame transmission when the TRIMD.TIM bit is 0. This flag becomes 1 only when the TRIMD.TIS bit is 1.

37.2.8 ETHERC/EDMAC Status Interrupt Enable Register (EDMACn.EESIPR)

Address(es): EDMAC0.EESIPR 000C 0030h, EDMAC1.EESIPR 000C 0230h

b15 to b9	—	Reserved	The read value is 0. The write value should be 0.	R/W
b16	RFOFIP	Receive FIFO Overflow Interrupt Request Enable	0: Overflow interrupt request is disabled. 1: Overflow interrupt request is enabled.	R/W
b17	RDEIP	Receive Descriptor Empty Interrupt Request Enable	0: Receive descriptor empty interrupt request is disabled. 1: Receive descriptor empty interrupt request is enabled.	R/W
b18	FRIP	Frame Receive Interrupt Request Enable	0: Frame receive interrupt request is disabled. 1: Frame receive interrupt request is enabled.	R/W
b19	TFUFIP	Transmit FIFO Underflow Interrupt Request Enable	0: Underflow interrupt request is disabled. 1: Underflow interrupt request is enabled.	R/W
b20	TDEIP	Transmit Descriptor Empty Interrupt Request Enable	0: Transmit descriptor empty interrupt request is disabled. 1: Transmit descriptor empty interrupt request is enabled.	R/W
b21	TCIP	Frame Transfer Complete Interrupt Request Enable	0: Frame transmission complete interrupt request is disabled. 1: Frame transmission complete interrupt request is enabled.	R/W
b23, b22	—	Reserved	The read value is 0. The write value should be 0.	R/W
b24	RFCOFIP	Receive Frame Counter Overflow Interrupt Request Enable	0: Receive frame counter overflow interrupt request is disabled. 1: Receive frame counter overflow interrupt request is enabled.	R/W
b25	—	Reserved	The read value is 0. The write value should be 0.	R/W
b26	TABTIP	Transmit Abort Detect Interrupt Request Enable	0: Transmit abort detect interrupt request is disabled. 1: Transmit abort detect interrupt request is enabled.	R/W
b29 to b27	—	Reserved	The read value is 0. The write value should be 0.	R/W

Bit	Symbol	Bit Name	Description	R/W
b30	TWBIP	Write-Back Complete Interrupt Request Enable	0: Write-back complete interrupt request is disabled. 1: Write-back complete interrupt request is enabled.	R/W
b31	—	Reserved	The read value is 0. The write value should be 0.	R/W

The PTPEDMAC.EESIPR register enables interrupt requests corresponding to bits in the PTPEDMAC.EESR register. When a bit in this register is 1, the corresponding interrupt request is enabled.

37.2.10 ETHERC/EDMAC Transmit/Receive Status Copy Enable Register (EDMACn.TRSCER)

Address(es): EDMAC0.TRSCER 000C 0038h, EDMAC1.TRSCER 000C 0238h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	RMAFCE	—	—	RRFCE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	The read value is 0. The write value should be 0.	R/W
b4	RRFCE	RRF Flag Copy Enable	0: The EESR.RRF flag status is reflected in the RD0.RFE bit of the receive descriptor. 1: The EESR.RRF flag status is not reflected in the RD0.RFE bit of the receive descriptor.	R/W
b6, b5	—	Reserved	The read value is 0. The write value should be 0.	R/W
b7	RMAFCE	RMAF Flag Copy Enable	0: The EESR.RMAF flag status is reflected in the RD0.RFE bit of the receive descriptor. 1: The EESR.RMAF flag status is not reflected in the RD0.RFE bit of the receive descriptor.	R/W
b31 to b8	—	Reserved	The read value is 0. The write value should be 0.	R/W

The EDMACn.TRSCER register selects whether the receive status indicated by flags EDMACn.EESR.RMAF and RRF is reflected in the RFE bit of the receive descriptor as a summary. The bits in the TRSCER register correspond to bits in the EESR register that have the same number. When setting the RMAFCE or RRFCE bit to 0, the corresponding receive status (EESR.RMAF or RRF flag) is reflected in the RFE bit of the receive descriptor. When setting the RMAFCE or RRFCE bit to 1, the corresponding receive status is not reflected in the RFE bit.

37.2.11 Missed-Frame Counter Register (RMFCR)

Address(es): EDMAC0.RMFCR 000C 0040h, EDMAC1.RMFCR 000C 0240h, PTPEDMAC.RMFCR 000C 0440h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MFC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	MFC[15:0]	Missed-Frame Counter	These bits indicate the number of frames that are discarded and not transferred to the receive buffer during reception.	R/W
b31 to b16	—	Reserved	The read value is 0. The write value should be 0.	R/W

The RMFCR register indicates that the number of frames that could not be stored in the receive FIFO and were therefore discarded during reception. When the receive FIFO overflows, it stops receiving data, and the remaining frames are discarded. At the same time, the RMFCR register value is incremented. When the RMFCR register value reaches FFFFh, incrementing is halted. When any value is written to the RMFCR register, the counter value becomes 0.
For the frame that has not been completely received, after data in the receive FIFO is transferred to the receive buffer, the RACT bit in the receive descriptor 0 (RD0) becomes 0 (descriptor disabled), the RFS9 bit becomes 1 (receive FIFO overflow), and the EDMACn.EESR.RFOF or PTPEDMAC.EESR.RFOF flag becomes 1 (overflow has occurred).

37.2.12 Transmit FIFO Threshold Register (TFTR)

Address(es): EDMAC0.TFTR 000C 0048h, EDMAC1.TFTR 000C 0248h, PTPEDMAC.TFTR 000C 0448h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	TFT[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b10 to b0	TFT[10:0]	Transmit FIFO Threshold	000h: Store and forward mode 001h to 00Ch: Setting prohibited 00Dh to 200h: The threshold is the set value multiplied by 4. Example: 00Dh: 52 bytes 040h: 256 bytes 100h: 1024 bytes 200h: 2048 bytes 201h to 7FFh: Setting prohibited	R/W
b31 to b11	—	Reserved	The read value is 0. The write value should be 0.	R/W

Note 1. When starting transmission before one frame data has been completely written, take care to prevent an underflow.
Note 2. To prevent a transmit underflow, using the initial value (store and forward mode) is recommended.

The TFTR register sets the transmit FIFO threshold at which the first transmission starts. The actual threshold is the set value multiplied by 4.

The ETHERC starts transmission when the amount of data in the transmit FIFO exceeds the number of bytes set in the TFTR register, when the transmit FIFO is full, or when one frame data has been completely written. Set the TFTR register while the EDTRR.TR bit is 0.

37.2.13 FIFO Depth Register (FDR)

Address(es): EDMAC0.FDR 000C 0050h, EDMAC1.FDR 000C 0250h, PTPEDMAC.FDR 000C 0450h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	TFD[4:0]					—	—	—	RFD[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	RFD[4:0]	Receive FIFO Depth	b4 b0 01111: 4096 bytes Settings other than above are prohibited.	R/W
b7 to b5	—	Reserved	The read value is 0. The write value should be 0.	R/W
b12 to b8	TFD[4:0]	Transmit FIFO Depth	b12 b8 00111: 2048 bytes Settings other than above are prohibited.	R/W
b31 to b13	—	Reserved	The read value is 0. The write value should be 0.	R/W

The FDR register sets the transmit and receive FIFO depths.
Set this register to 0000 070Fh before starting transmission and reception.

37.2.14 Receive Method Control Register (RMCR)

Address(es): EDMAC0.RMCR 000C 0058h, EDMAC1.RMCR 000C 0258h, PTPEDMAC.RMCR 000C 0458h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RNR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RNR	Receive Request Reset	0: EDRRR.RR bit (receive request bit) is set to 0 when one frame has been received. 1: EDRRR.RR bit (receive request bit) is not set to 0 when one frame has been received.	R/W
b31 to b1	—	Reserved	The read value is 0. The write value should be 0.	R/W

The RMCR register sets how to control the EDRRR.RR bit when receiving a frame.
Since the EDRRR.RR bit becomes 0 when one frame has been received while the RNR bit is 0, the RR bit needs to be set to 1 by software to receive the subsequent frame.
Since the EDRRR.RR bit does not become 0 when one frame has been received while the RNR bit is 1, the EDMAC reads the next receive descriptor and continues receiving frames. However, the EDRRR.RR bit becomes 0 when the RD0.RACT bit in the receive descriptor is 0. It is recommended to set the RNR bit to 1 when receiving data continuously.
Set the RMCR register while the EDRRR.RR bit is 0.

37.2.15 Transmit FIFO Underflow Counter (TFUCR)

Address(es): EDMAC0.TFUCR 000C 0064h, EDMAC1.TFUCR 000C 0264h, PTPEDMAC.TFUCR 000C 0464h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	UNDER[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	UNDER[15:0]	Transmit FIFO Underflow Count	These bits indicate how many times the transmit FIFO has underflowed. The counter stops when the counter value reaches FFFFh.	R/W
b31 to b16	—	Reserved	The read value is 0. The write value should be 0.	R/W

The TFUCR register indicates how many times the transmit FIFO has underflowed.
When writing any value to the TFUCR register, the counter value becomes 0.

37.2.16 Receive FIFO Overflow Counter (RFOCR)

Address(es): EDMAC0.RFOCR 000C 0068h, EDMAC1.RFOCR 000C 0268h, PTPEDMAC.RFOCR 000C 0468h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVER[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	OVER[15:0]	Receive FIFO Overflow Count	These bits indicate how many times the receive FIFO has overflowed. The counter stops when the counter value reaches FFFFh.	R/W
b31 to b16	—	Reserved	The read value is 0. The write value should be 0.	R/W

The RFOCR register indicates how many times the receive FIFO has overflowed.
When writing any value to the RFOCR register, the counter value becomes 0.

37.2.17 Independent Output Signal Setting Register (IOSR)

Address(es): EDMAC0.IOSR 000C 006Ch, EDMAC1.IOSR 000C 026Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ELB
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ELB	External Loopback Mode	0: The ETn_EXOUT pin outputs low. 1: The ETn_EXOUT pin outputs high.	R/W
b31 to b1	—	Reserved	The read value is 0. The write value should be 0.	R/W

The IOSR register selects the output level of the ETHERC external output pin (ETn_EXOUT) in external loopback mode.

The ELB bit value is output to the ETn_EXOUT pin of the MCU as is, which can be used to set loopback mode for the PHY-LSI. To use the loopback function of the PHY-LSI through this register, the PHY-LSI needs to be provided with the pin to be connected to the ETn_EXOUT pin.

37.2.18 Flow Control Start FIFO Threshold Setting Register (FCFTR)

Address(es): EDMAC0.FCFTR 000C 0070h, EDMAC1.FCFTR 000C 0270h, PTPEDMAC.FCFTR 000C 0470h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	RFFO[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	RFDO[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	RFDO[2:0]	Receive FIFO Data PAUSE Output Threshold	b2 b1 b0 0 0 0: When 224 (256 - 32) bytes of data is stored in the receive FIFO. 0 0 1: When 480 (512 - 32) bytes of data is stored in the receive FIFO. : 1 1 0: When 1760 (1792 - 32) bytes of data is stored in the receive FIFO. 1 1 1: When 2016 (2048 - 32) bytes of data is stored in the receive FIFO.	R/W
b15 to b3	—	Reserved	The read value is 0. The write value should be 0.	R/W
b18 to b16	RFFO[2:0]	Receive FIFO Frame PAUSE Output Threshold	b18 b17 b16 0 0 0: When 2 receive frames have been stored in the receive FIFO. 0 0 1: When 4 receive frames have been stored in the receive FIFO. 0 1 0: When 6 receive frames have been stored in the receive FIFO. : 1 1 0: When 14 receive frames have been stored in the receive FIFO. 1 1 1: When 16 receive frames have been stored in the receive FIFO.	R/W
b31 to b19	—	Reserved	The read value is 0. The write value should be 0.	R/W

The FCFTR register sets the ETHERC flow control (sets the threshold for automatically transmitting a PAUSE frame). The threshold can be set using the data size (RFDO[2:0] bits) and the number of frames (RFFO[2:0] bits) stored in the receive FIFO. The flow control starts when the stored data size or number of stored frames reaches its threshold.

37.2.19 Receive Data Padding Insert Register (RPADIR)

Address(es): EDMAC0.RPADIR 000C 0078h, EDMAC1.RPADIR 000C 0278h, PTPEDMAC.RPADIR 000C 0478h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PADS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	PADR[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	PADR[5:0]	Padding Slot	00h: Padding is inserted at the head of received data. 01h: Padding is inserted between the 1st byte and 2nd byte of received data. : 3Eh: Padding is inserted between the 62nd byte and 63rd byte of received data. 3Fh: Padding is inserted between the 63rd byte and 64th byte of received data	R/W
b15 to b6	—	Reserved	The read value is 0. The write value should be 0.	R/W
b17, b16	PADS[1:0]	Padding Size	b17 b16 0 0: No padding is inserted. 0 1: 1 byte is inserted. 1 0: 2 bytes are inserted. 1 1: 3 bytes are inserted.	R/W
b31 to b18	—	Reserved	The read value is 0. The write value should be 0.	R/W

The RPADIR register sets insertion of padding for received data. The padding value is 00h.
Set the EDMR.SWR bit to 1 to reset before rewriting the RPADIR register.

37.2.20 Transmit Interrupt Setting Register (TRIMD)

Address(es): EDMAC0.TRIMD 000C 007Ch, EDMAC1.TRIMD 000C 027Ch, PTPEDMAC.TRIMD 000C 047Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	TIM	—	—	—	TIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TIS	Transmit Interrupt Enable	0: Transmit Interrupt is disabled. 1: Transmit Interrupt is enabled. Set the EESR.TWB flag to 1 in the mode selected by the TIM bit to notify an interrupt.	R/W
b3 to b1	—	Reserved	The read value is 0. The write value should be 0.	R/W
b4	TIM	Transmit Interrupt Mode	0: Transmission complete interrupt mode An interrupt occurs when a frame has been transmitted. 1: Write-back complete interrupt mode An interrupt occurs when write-back to the transmit descriptor has been completed while the TWBI bit is 1.	R/W
b31 to b5	—	Reserved	The read value is 0. The write value should be 0.	R/W

The TRIMD register sets transmit interrupt mode and enables/disables the transmit interrupt.
When the condition set in this register is satisfied, the EESR.TWB flag becomes 1, and an interrupt request is output when the EESIPR.TWBIP bit is 1.

37.2.21 Receive Buffer Write Address Register (RBWAR)

Address(es): EDMAC0.RBWAR 000C 00C8h, EDMAC1.RBWAR 000C 02C8h, PTPEDMAC.RBWAR 000C 04C8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The RBWAR register indicates the last address that the EDMAC has written data to when writing to the receive buffer. Refer to the address indicated by the RBWAR register to recognize which address in the receive buffer the EDMAC is writing data to. Note that the address that the EDMAC is outputting to the receive buffer may not match the read value of the RBWAR register during data reception.
The RBWAR register is read only. Do not write to this register.

37.2.22 Receive Descriptor Fetch Address Register (RDFAR)

Address(es): EDMAC0.RDFAR 000C 00CCh, EDMAC1.RDFAR 000C 02CCh, PTPEDMAC.RDFAR 000C 04CCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The RDFAR register indicates the start address of the last fetched receive descriptor when the EDMAC fetches descriptor information from the receive descriptor.
Refer to the address indicated by the RDFAR register to recognize which receive descriptor information the EDMAC is using for the current processing. Note that the address of the receive descriptor that the EDMAC fetches may not match the read value of the RDFAR register during data reception.
The RDFAR is read only. Do not write to this register.

37.2.23 Transmit Buffer Read Address Register (TBRAR)

Address(es): EDMAC0.TBRAR 000C 00D4h, EDMAC1.TBRAR 000C 02D4h, PTPEDMAC.TBRAR 000C 04D4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The TBRAR register indicates the last address that the EDMAC has read data from when reading data from the transmit buffer.
Refer to the address indicated by the TBRAR register to recognize which address in the transmit buffer the EDMAC is reading from. Note that the address that the EDMAC is outputting to the transmit buffer may not match the read value of the TBRAR register.
The TBRAR register is read only. Do not write to this register.

37.2.24 Transmit Descriptor Fetch Address Register (TDFAR)

Address(es): EDMAC0.TDFAR 000C 00D8h, EDMAC1.TDFAR 000C 02D8h, PTPEDMAC.TDFAR 000C 04D8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The TDFAR register indicates the start address of the last fetched transmit descriptor when the EDMAC fetches descriptor information from the transmit descriptor.

Refer to the address indicated by the TDFAR register to recognize which transmit descriptor information the EDMAC is using for the current processing. Note that the address of the transmit descriptor that the EDMAC fetches may not match the read value of the TDFAR register.

The TDFAR is read only. Do not write to this register.

37.3 Operation

The EDMAC transfers data according to the information written in the descriptor. Two types of descriptors are provided: transmit descriptor and receive descriptor. A descriptor includes the buffer size, address, and transmit/receive status. The EDMAC transmits or receives data continuously using sequentially arranged descriptors (descriptor list).

37.3.1 Descriptor Lists and Data Buffers

To transfer data using the EDMAC, create the transmit and receive descriptor lists on the memory, set the start address of the transmit descriptor list to the TDLAR register, and set the start address of the receive descriptor list to the RDLAR register. Also, transmit and receive buffers corresponding to the each descriptor are required.
Align the descriptor list on the appropriate address boundary according to the descriptor length set by the EDMR.DL[1:0] bits. The transmit buffer can be aligned on a long word boundary, word boundary, or byte boundary. When the valid transmit buffer size is 16 bytes or less, align it on a 32-byte boundary. Align the receive buffer on a 32-byte boundary. Set different addresses for the transmit and receive descriptors and buffers for EDMAC0, EDMAC1, and the PTPEDMAC.

37.3.1.1 Transmit Descriptor

Figure 37.3 shows the relation between a transmit descriptor and transmit buffer. A transmit descriptor consists of TD0 to TD2. The transmit frame and transmit buffer configuration can be selected from one buffer per frame (single-buffer frame transmission) or multiple buffers per frame (multi-buffer frame transmission) by setting the transmit descriptor.

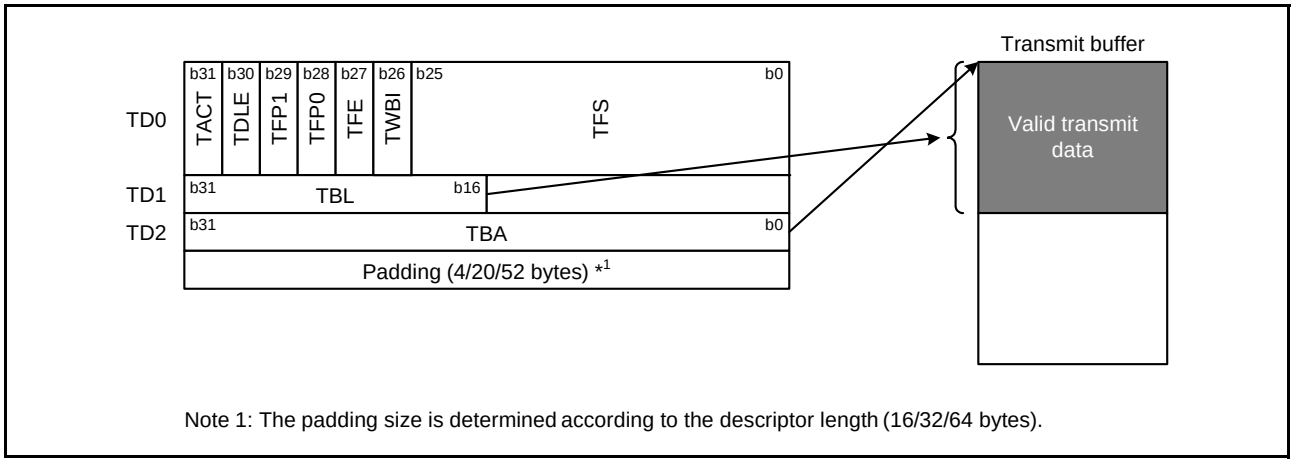

Figure 37.3 Relation between a Transmit Descriptor and Transmit Buffer

(1) Transmit Descriptor 0 (TD0)

Bit	Symbol	Bit Name	Description	R/W
b25 to b0	TFS	Transmit Frame Status	Set all bits to 0 when creating a descriptor. After write-back, the bits indicate the following: [for EDMACn] TFS25 to TFS9: Reserved TFS8: Transmit abort is detected (the value is equivalent to the EESR.TABT flag). TFS7 to TFS4: Reserved TFS3: No carrier is detected (the value is equivalent to the EESR.CND flag). TFS2: Loss of carrier is detected (the value is equivalent to the EESR.DLC flag). TFS1: Late collision during transmission is detected (the value is equivalent to the EESR.CD flag). TFS0: Transmit retry over (the value is equivalent to the EESR.TRO flag) When each bit becomes 1, it indicates that the corresponding error has occurred during frame transmission. When any of the TFS bits becomes 1, the TFE bit also becomes 1. When any bit from TFS3 to TFS0 becomes 1, the TFS8 bit also becomes 1. [for the PTPEDMAC] TFS25 to TFS9: Reserved TFS8: Transmit abort is detected (the value is equivalent to the EESR.TABT flag). TFS7 to TFS1: Reserved TFS0: The transmission source MAC address of the transmit frame data does not match the set value (the value is equivalent to the EESR.MACE flag). When each bit becomes 1, it indicates that the corresponding error has occurred during frame transmission. When any of the TFS bits becomes 1, the TFE bit also becomes 1. When TFS0 becomes 1, TFS8 also becomes 1.	R/W
b26	TWBI	Write-Back Complete Interrupt Enable	0: Interrupt does not occur when write-back to this descriptor has been completed. 1: Interrupt occurs when write-back to this descriptor has been completed.	R/W
b27	TFE	Transmit Frame Error	0: Frame transmission is successfully completed. 1: An error occurs during frame transmission (transmission aborted).	R/W
b29, b28	TFP[1:0]	Transmit Frame Position	b29 b28 0 0: Transmit buffer indicated by this descriptor is the middle of a transmit frame (frame information is incomplete). 0 1: Transmit buffer indicated by this descriptor is the end of a transmit frame (frame information is complete). 1 0: Transmit buffer indicated by this descriptor is the head of a transmit frame (frame information is incomplete.) 1 1: Transmit buffer indicated by this descriptor is all of a transmit frame (one buffer per frame).	R/W
b30	TDLE	Transmit Descriptor List End	When this bit is 1, it indicates that this descriptor is the last descriptor of the descriptor list.	R/W
b31	TACT	Transmit Descriptor Valid	This bit indicates that this descriptor is valid.	R/W

Note: Bits for write-back are underlined.

TD0 indicates the transmit frame settings, and the status after transmission.

TWBI Bit (Write-Back Complete Interrupt Enable)

This bit value is valid when the TRIMD.TIM bit is 1. Set the TRIMD.TIS bit and EESIPR.TWBIP bit to 1 to generate an interrupt request.

TFE Bit (Transmit Frame Error)

When the TFE bit is 1, it indicates that one or more of the TFS bits is 1.

TFP[1:0] Bits (Transmit Frame Position)

The TFP[1:0] bits indicate which part of a transmit frame corresponds to the transmit buffer indicated by this descriptor. The TFP[1:0] and TD1.TBL bit settings must be logically consistent in the previous and next descriptors.

TACT Bit (Transmit Descriptor Valid)

The TACT bit indicates that this descriptor is valid. The TACT bit is set to 1 by software. This bit becomes 0 when the transmit frame has been transferred or when the transmission is aborted.

(2) Transmit Descriptor 1 (TD1)

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	The read value is 0. The write value should be 0.	R/W
b31 to b16	TBL	Transmit Buffer Length	Set a valid byte length of the corresponding transmit buffer. Set a value equal to or greater than 1.	R/W

TD1 is used to set a valid byte length of the transmit buffer.

(3) Transmit Descriptor 2 (TD2)

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	TBA	Transmit Buffer Address	Set the start address of the transmit buffer. When the TD1.TBL bit value is 1 to 16 bytes, align it on a 32-byte boundary.	R/W

TD2 is used to set the start address of the transmit buffer.

37.3.1.2 Receive Descriptor

Figure 37.4 shows the relation between a receive descriptor and receive buffer. The receive frame and receive buffer configuration can be selected from one buffer per frame (single-buffer frame transmission) or multiple buffers per frame (multi-buffer frame transmission) by setting the receive descriptor. If the receive buffer length (RBL) is set to 0, operation indicated by the descriptor is not guaranteed.

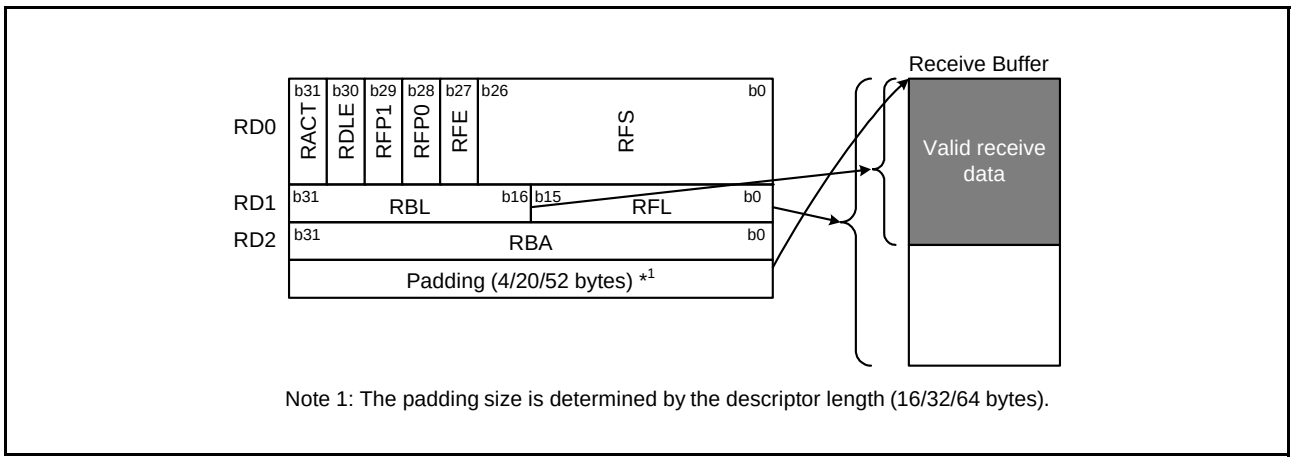

Figure 37.4 Relation between Receive Descriptor and Receive Buffer

(1) Receive Descriptor 0 (RD0)

Bit	Symbol	Bit Name	Description	R/W
b26 to b0	RFS	Receive Frame Status	Set all bits to 0 when creating a descriptor. After write-back, the bits indicate the following: [for EDMACn] RFS26 to RFS10: Reserved RFS9: Receive FIFO overflow (the value is equivalent to the EESR.RFOF flag) RFS8: Receive abort is detected (the value is equivalent to the EESR.RABT flag). RFS7: Multicast address frame is received (the value is equivalent to the EESR.RMAF flag). RFS6 and RFS5: Reserved RFS4: Alignment error is detected (the value is equivalent to the EESR.RRF flag). RFS3: Frame-too-long error (the value is equivalent to the EESR.RTLF flag) RFS2: Frame-too-short error (the value is equivalent to the EESR.RTSF flag) RFS1: PHY-LSI receive error (the value is equivalent to the EESR.PRE flag) RFS0: CRC error (the value is equivalent to the EESR.CERF flag) When each bit becomes 1, it indicates that the corresponding error has occurred during frame reception. When any of the RFS bits becomes 1, the RFE bit also becomes 1 (set the TRSCER register to select whether bits RFS7 and RFS4 are reflected in the RFE bit). When any bit from RFS3 to RFS0 becomes 1, the RFS8 bit also becomes 1. [for the PTPEDMAC] RFS26 to RFS10: Reserved RFS9: Receive FIFO overflow (the value is equivalent to the EESR.RFOF flag) RFS8: Reserved RFS7: Receive port (the value is equivalent to the EESR.RPORT flag) RFS4: PTPV2 packet is received (the value is equivalent to the EESR.PVER flag). The PTPEDMAC can receive only PTP packets. If a non-PTP packet is received, the packet is not transferred to the PTPEDMAC, and it is discarded. RFS3 to RFS0: Type of the received PTP message (the value is equivalent to the EESR.TYPE[3:0] flags) Each bit indicates the status of the received frame.	R/W
b27	RFE	Receive Frame Error	[for EDMACn] 0: No error has occurred in the received frame. 1: An error has occurred in the received frame. [for the PTPEDMAC] Reserved	R/W
b29, b28	RFP[1:0]	Receive Frame Position	b29 b28 0 0: Receive buffer indicated by this descriptor is the middle of a receive frame (frame information is incomplete). 0 1: Receive buffer indicated by this descriptor is the end of a receive frame (frame information is complete). 1 0: Receive buffer indicated by this descriptor is the head of a receive frame (frame information is incomplete). 1 1: Receive buffer indicated by this descriptor is all of a receive frame (one buffer per frame).	R/W
b30	RDLE	Receive Descriptor List End	When this bit is 1, it indicates that this descriptor is the last one of the descriptor list.	R/W
b31	RACT	Receive Descriptor Valid	Indicates that this descriptor is valid.	R/W

Note: Bits for write-back are underlined.

RD0 indicates the receive frame status.

RFE Bit (Receive Frame Error)

When the RFE bit is 1, it indicates that one or more of the RFS bits is 1 (set the TRSCER register to select whether bits RFS7 and RFS4 of EDMACn are reflected in the RFE bit).

RFP[1:0] Bits (Receive Frame Position)

The RFP[1:0] bits indicate which part of a receive frame corresponds to the receive buffer indicated by this descriptor.

RACT Bit (Receive Descriptor Valid)

The RACT bit indicates that this descriptor is valid. The RACT bit is set to 1 by software. This bit becomes 0 when all data has been transferred to the receive buffer indicated by RD2 or when the receive buffer becomes full.

(2) Receive Descriptor 1 (RD1)

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	RFL	Receive Frame Length	These bits indicate the length (number of bytes) of the receive frame stored in the buffer. The number of bytes for padding set by the RPADIR register is not included. These bits are written back to the descriptor corresponding to the end of a frame.	R/W
b31 to b16	RBL	Receive Buffer Length	These bits indicate the byte length of the corresponding receive buffer. Set an integral multiple of 32 as the buffer length.	R/W

Note: Bits for write-back are underlined.

RD1 indicates the receive buffer length. When reception is completed, the receive frame length is written back.

(3) Receive Descriptor 2 (RD2)

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	RBA	Receive Buffer Address	These bits indicate the start address of the receive buffer. Align the buffer address on a 32-byte boundary.	R/W

RD2 indicates the start address of the receive buffer.

37.3.2 Transmission

When setting the EDTRR.TR bit to 1 while the ETHERCn.ECMR.TE bit is 1, the EDMAC reads the descriptor following the previously used descriptor in the transmit descriptor list (or the descriptor indicated by the TDLAR register after a reset). When the TACT bit is 1 in the transmit descriptor (TD0), the EDMAC sequentially reads transmit data from the start address of the transmit buffer indicated by transmit descriptor 2 (TD2) and transfers them to the ETHERC via the transmit FIFO. The ETHERC creates a transmit frame and starts transmission to the MII/RMII. When all data indicated by the TD1.TBL bit is transferred, write-back is performed according to the TD0.TFP[1:0] bits as follows:

- When the TD0.TFP[1:0] bits are 00b or 10b (frame information is incomplete), the TD0.TACT bit is written back.
- When the TD0.TFP[1:0] bits are 01b or 11b (frame information is complete), bits TD0.TACT, TD0.TFS, and TD0.TFE are written back.

When the TD0.TACT bit in the read descriptor is 1, the EDMAC continues reading descriptors and transmit frames. When the TD0.TACT bit in the read descriptor is 0, the EDMAC sets the EDTRR.TR bit to 0 and stops transmission.

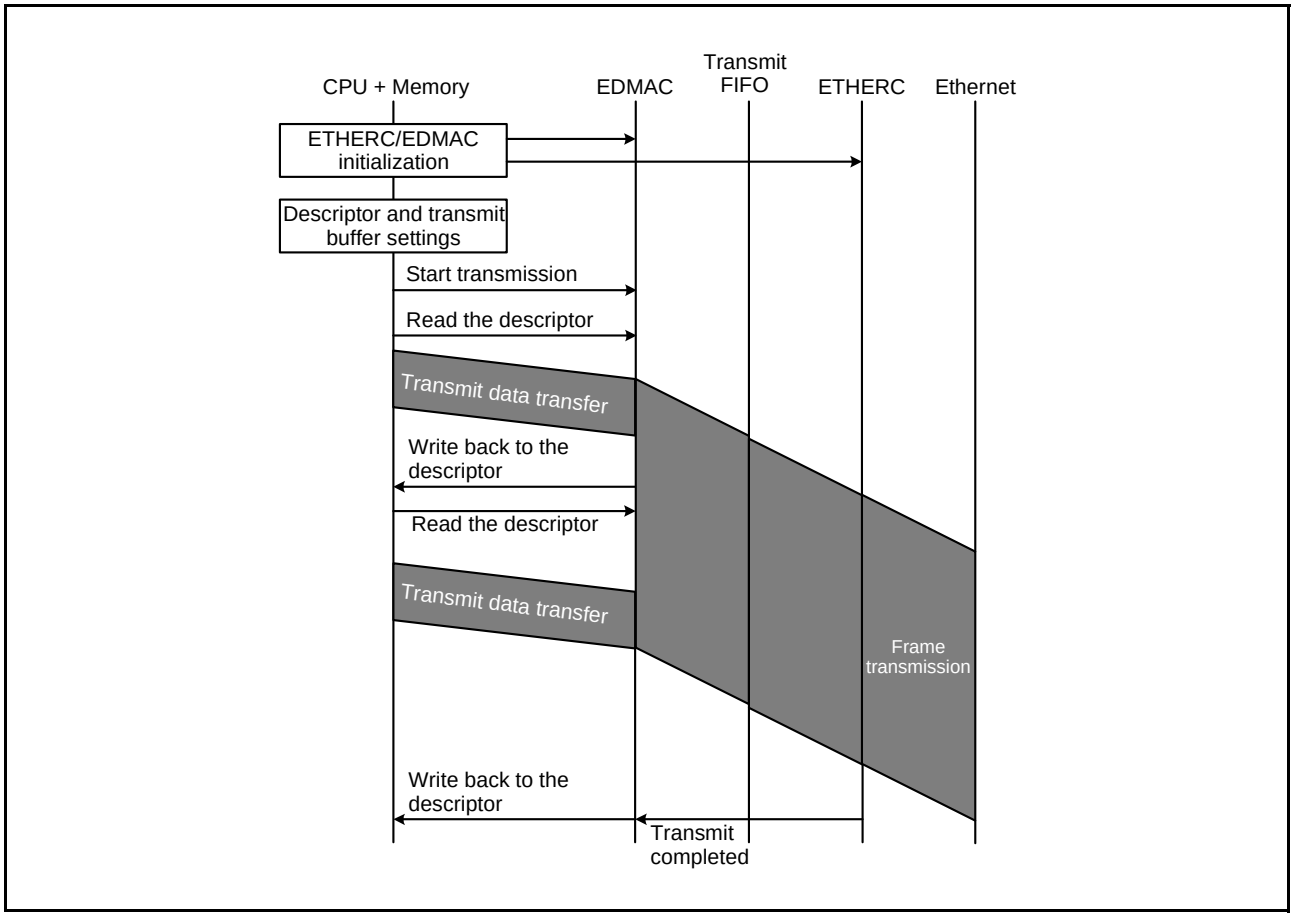

Figure 37.5 Example of Transmission Flow

37.3.3 Reception

When setting the EDRRR.RR bit to 1 while the ETHERCn.ECMR.RE bit is 1, the EDMAC reads the receive descriptor following the previously used descriptor (or descriptor indicated by the RDLAR register after a reset) and then waits for reception. While the RD0.RACT bit is 1, if the data stored to the receive FIFO is 32 bytes or more, or if the end byte of the frame is stored in the receive buffer, the EDMAC transfers data from the receive FIFO to the receive buffer indicated by receive descriptor 2 (RD2). If the data length of the received frame is longer than the buffer length set by the RBL bit in receive descriptor 1 (RD1), the EDMAC writes back 10b or 00b to the RD0.RFP[1:0] bits and 0 to the RD0.RACT bit when the receive buffer becomes full, and then the EDMAC reads the next data. After that, the EDMAC transfers data to another receive buffer. When the frame reception is completed or when the frame reception is aborted by an error, the EDMAC writes back 11b or 01b to the RD0.RFP[1:0] bits, 0 to the RD0.RACT bit, and the receive frame length to the RD1.RFL bit*1. When the RMCR.RNR bit is 1, the EDMAC reads the next descriptor and waits for reception. When the RNR bit is 0, the EDMAC sets the EDRRR.RR bit to 0 and stops reception.

Note 1. When the frame reception is aborted if the data stored in the receive FIFO is less than 16 bytes, the data is not transferred, but discarded. In this case, the corresponding error flag does not become 1.

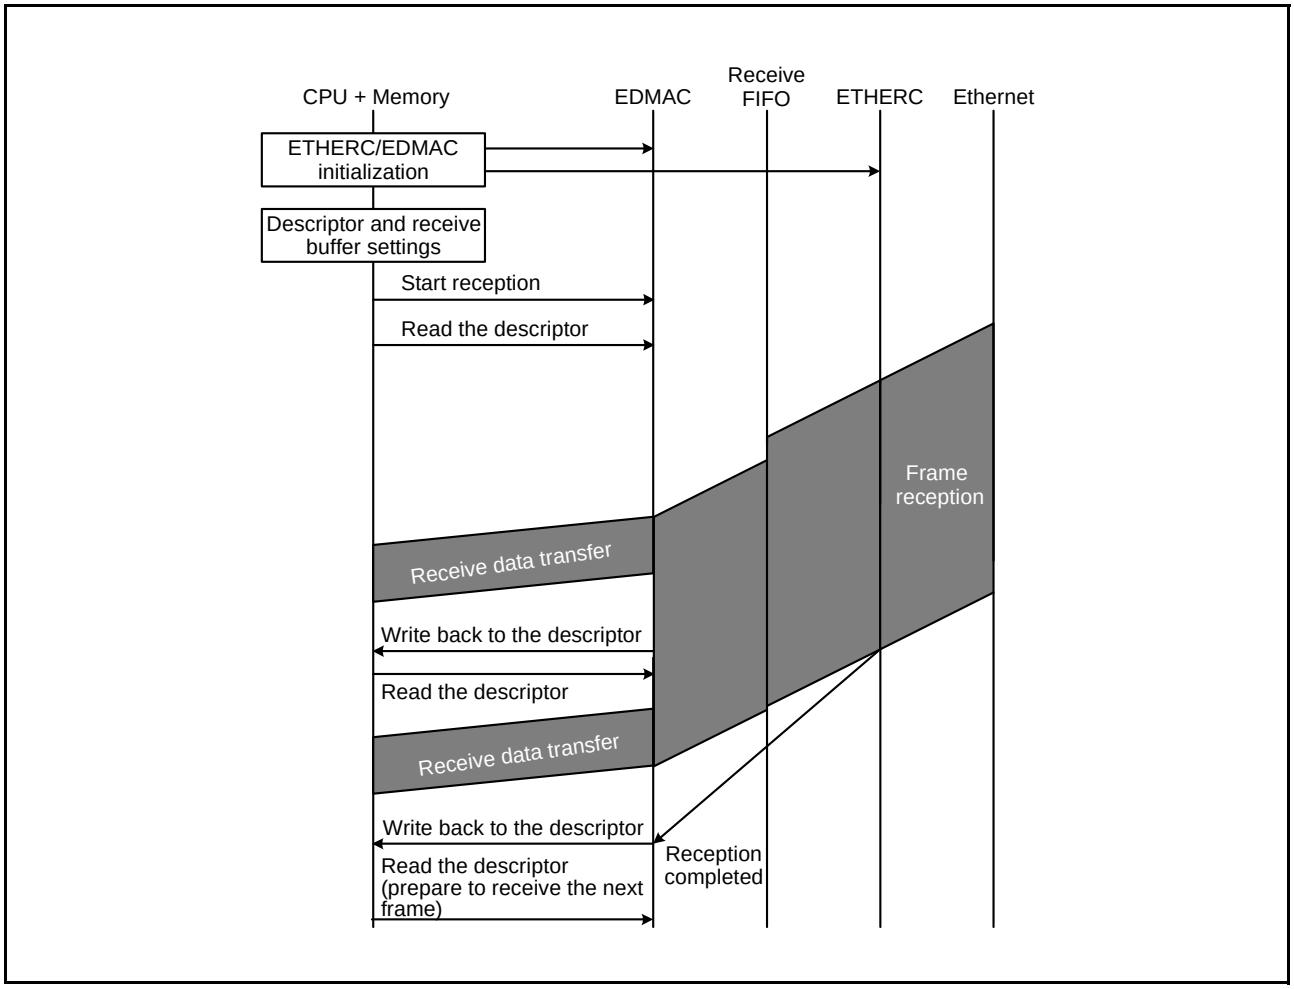

Figure 37.6 Example of Reception Flow

37.3.4 Multi-Buffer Frame Transmission

37.3.4.1 Error Processing While Transmitting a Multi-Buffer Frame

If an error occurs during multi-buffer frame transmission, the EDMAC performs the processing shown in Figure 37.7. In the figure, when the TACT bit of transmit descriptor 0 (TD0) is 0, the descriptor indicates that all data in the buffer has been successfully transmitted. When the TACT bit is 1, the descriptor indicates that data in the buffer has not yet been transmitted. If a frame transmit error *1 occurs in the head or middle of the frame while the TD0.TACT bit is 1, the EDMAC stops data transmission from the transmit FIFO and EDMAC data transfer, and sets the TD0.TACT bit to 0. After that, the EDMAC reads the next descriptor to see if the descriptor indicates the middle of the fame (TD0.TFP[1:0] bits are 00b) or the end of the frame (TD0.TFP[1:0] bits are 01b). When the descriptor indicates the middle of the frame, the EDMAC sets the TD0.TACT bit to 0 and reads the next descriptor. When the descriptor indicates the end of the frame, the EDMAC not only sets the TD0.TACT bit to 0, but also writes back to bits TD0.TFE and TD0.TFS. After an error occurs, data in the buffer is not transmitted until write-back to the descriptor for the end of the frame. When the corresponding transmit error interrupt is enabled in the EESIPR register, an interrupt request is generated immediately after write-back to the descriptor for the end of the frame.

Note 1. For EDMACn, a transmit retry-over condition, late collision, or loss of carrier is detected, or a carrier is not detected. For the PTPEDMAC, the MAC address does not match the set value.

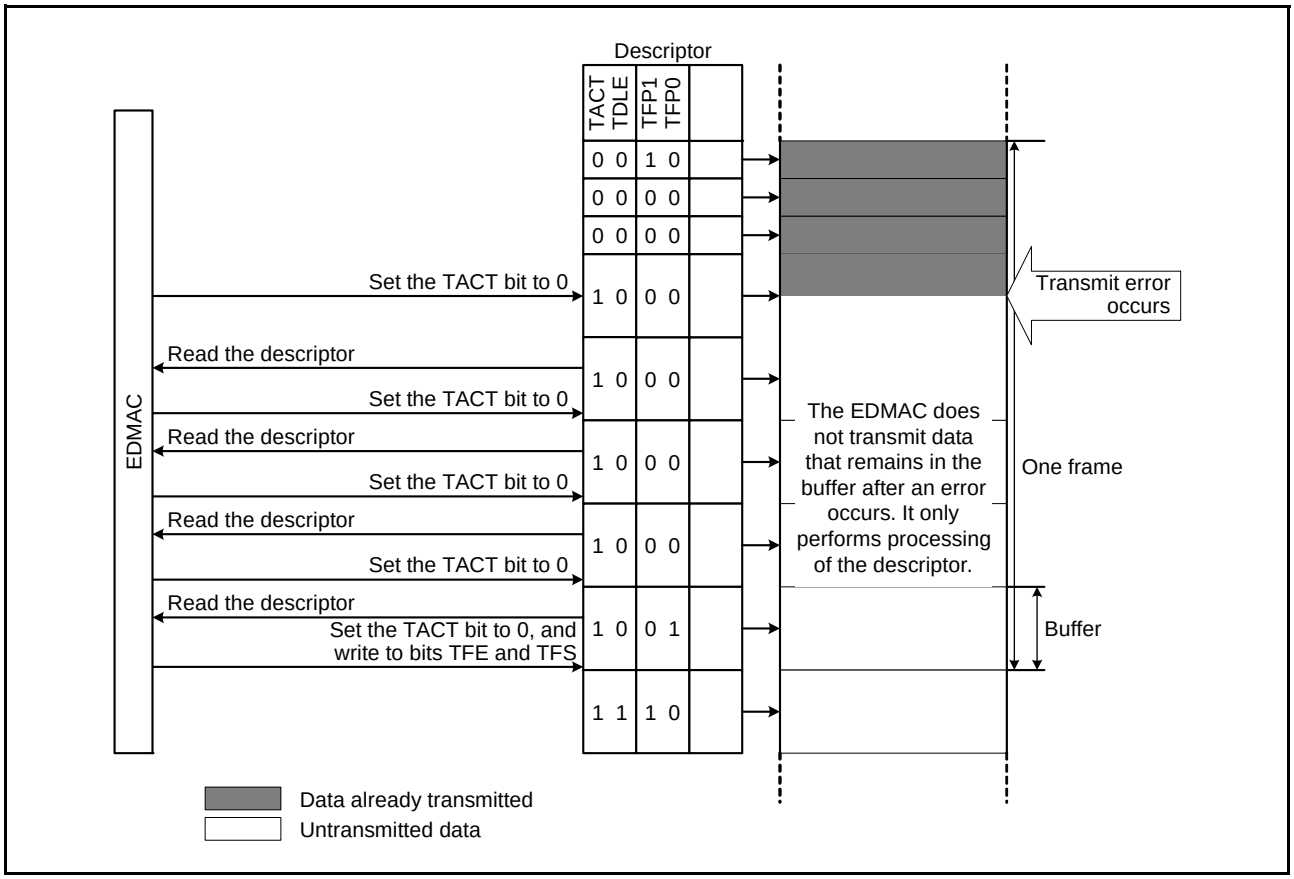

Figure 37.7 EDMAC Operation After a Transmit Error Occurs

37.3.4.2 Error Processing While Receiving a Multi-Buffer Frame

If an error occurs during multi-buffer frame reception, the EDMAC performs the processing shown in Figure 37.8. In the figure, when the RACT bit of receive descriptor 0 (RD0) is 0, the descriptor indicates that data has been successfully received in the buffer. When the RACT bit is 1, the descriptor indicates that data has not yet been received in the buffer. If a frame receive error *1 occurs, the EDMAC stops receiving data of the frame, but it transfers data that has already been stored in the receive FIFO to the receive buffer.

When the receive buffer becomes full during transfer, the EDMAC sets the RACT bit to 0 and the RFP[1:0] bits to 10b or 00b and reads the next descriptor. After all data in the receive FIFO has been transferred, the EDMAC writes back the status to the descriptor.

When the corresponding receive error interrupt is enabled in the EESIPR register, an interrupt request is generated immediately after write-back to the descriptor. When there is a request to receive a new frame, the EDMAC continues reception using the descriptor following the descriptor where the error occurred.

Note 1. For EDMACn, a CRC error, PHY-LSI receive error, frame-too-short error, frame-too-long error, or alignment error is detected. For the PTPEDMAC, a parity error is detected.

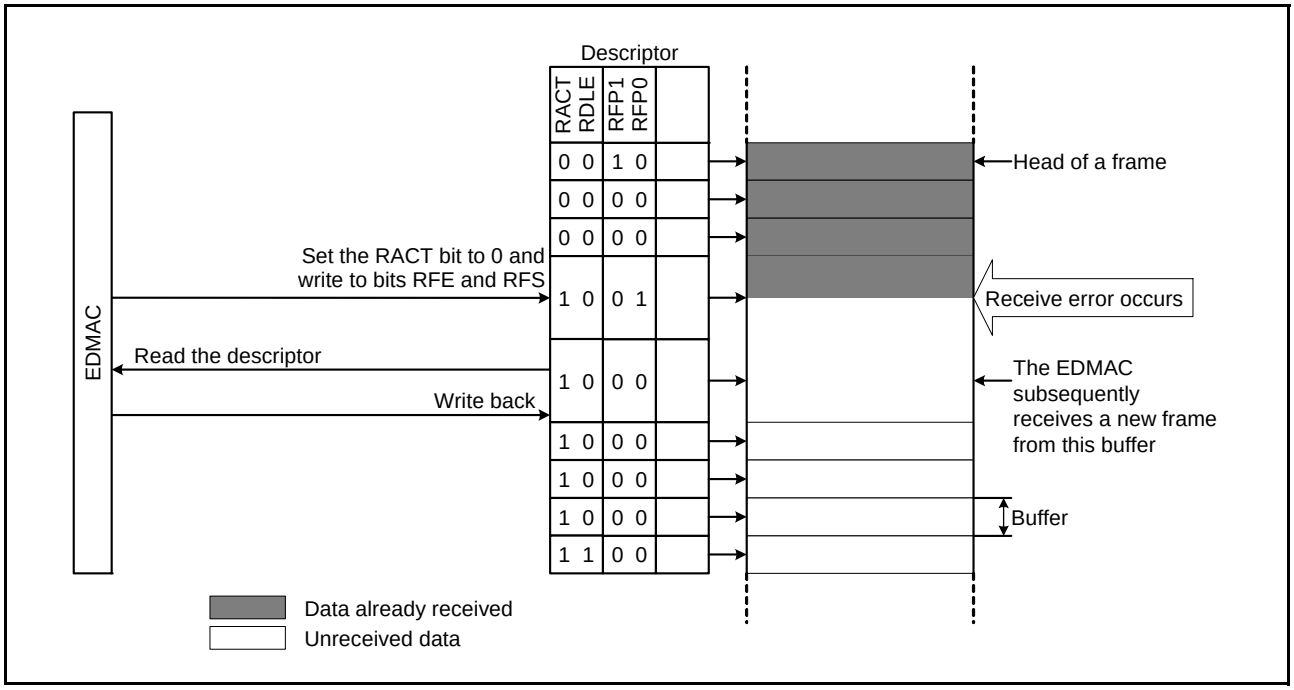

Figure 37.8 EDMAC Operation After a Receive Error Occurs

37.3.5 EDMAC Channel Priority

Priority of the three EDMAC channels (EDMAC0, EDMAC1, PTPEDMAC) is determined in a round-robin fashion. Each time transfer of one channel is completed, the channel becomes the lowest priority. This operation is shown in Figure 37.9. After a reset, the priority is EDMAC0 > EDMAC1 > PTPEDMAC.

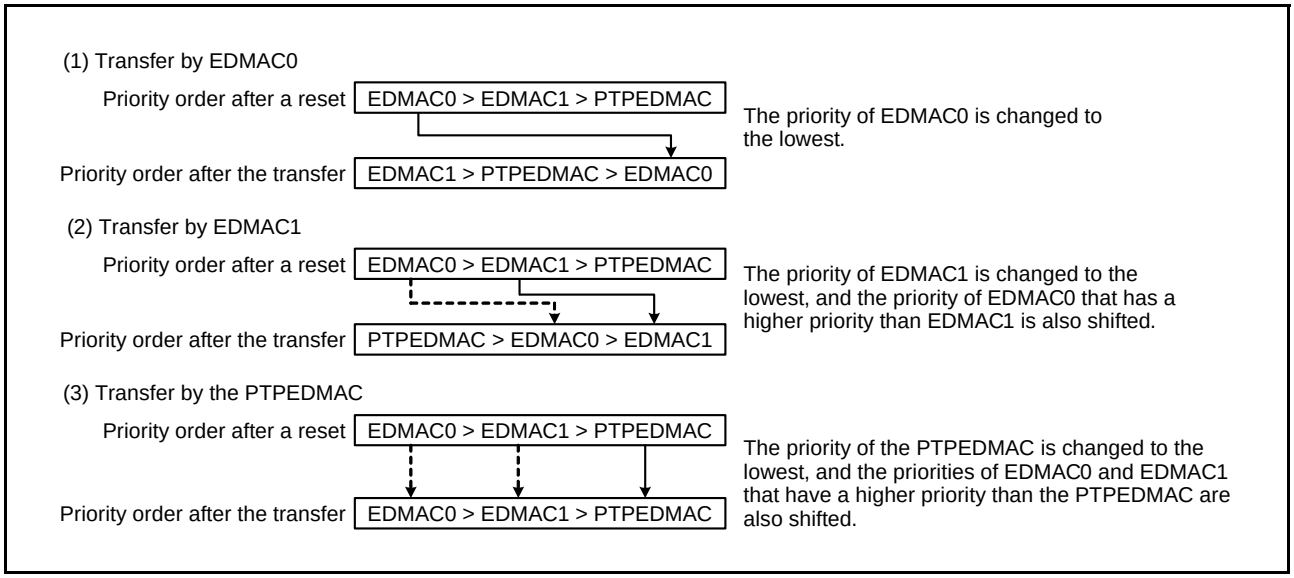

Figure 37.9 Operation in Round-Robin Fashion

Figure 37.10 shows change of the channel priority order when transfer requests are concurrently generated to EDMAC0 and the PTPEDMAC and a transfer request to the EDMAC1 while EDMAC0 is transferring data.

1. Transfer requests are concurrently generated to EDMAC0 and the PTPEDMAC.
2. Since EDMAC0 has a higher priority than the PTPEDMAC, EDMAC0 starts a transfer (PTPEDMAC waits to transfer).
3. A transfer request is generated to EDMAC1 during the transfer by EDMAC0 (EDMAC1 and the PTPEDMAC wait to transfer).
4. After EDMAC0 ends the transfer, the priority of EDMAC0 is changed to the lowest.
5. Since EDMAC1 has higher priority than the PTPEDMAC at this time, EDMAC1 starts a transfer (PTPEDMAC waits to transfer).
6. After EDMAC1 ends the transfer, the priority of EDMAC1 is changed to the lowest.
7. The PTPEDMAC starts a transfer.
8. After the PTPEDMAC ends the transfer, the priority of PTPEDMAC is changed to the lowest.

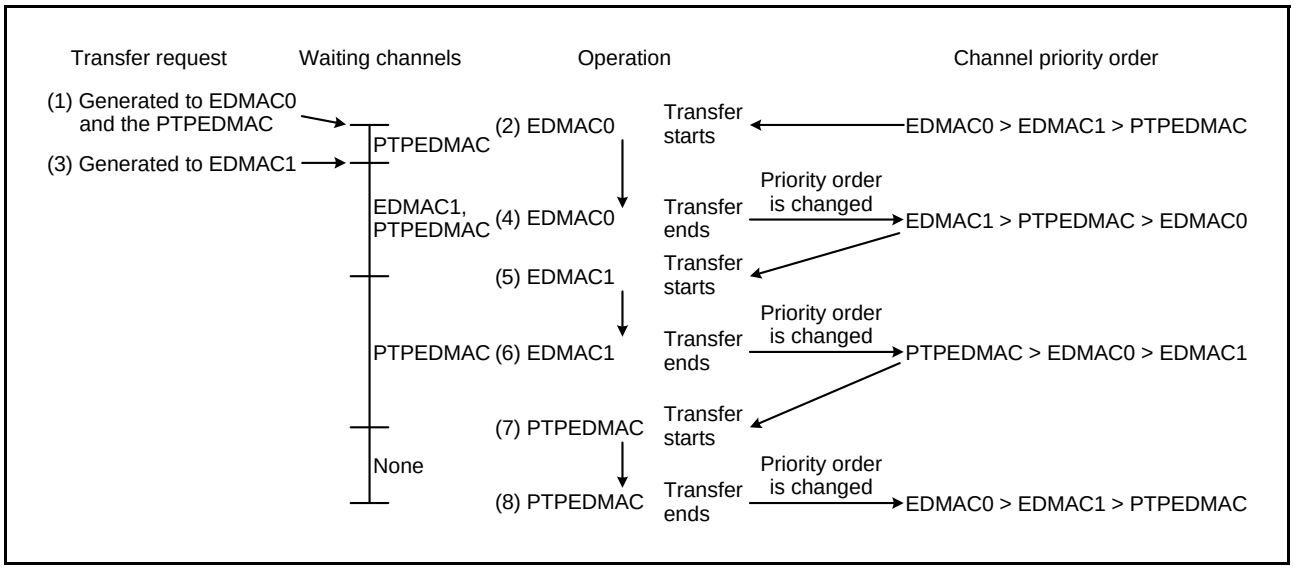

Figure 37.10 Channel Priority in Round-Robin Fashion

37.4 Interrupts

When any of the status flags in the EESR register becomes 1 while the corresponding interrupt request enable bit in the EESIPR register is 1, EDMACn outputs an EINTn interrupt request or the PTPEDMAC outputs a PINT interrupt request to the CPU.

37.5 Usage Notes

37.5.1 Setting the Module-Stop Function

Module stop control register B (MSTPCRB) is used to enable/disable the EDMAC operation. After a reset, the EDMAC is stopped. After exiting the module-stop state, registers can be accessed. Refer to section 11, Low Power Consumption for details.

37.5.2 Stopping the EDMAC during Operations

When stopping EDMAC operation by using a WAIT instruction or module-stop function while the EDMAC is running, confirm that bits EDTRR.TR and EDRRR.RR are 0. If the EDMAC is stopped while the EDTRR.TR or EDRRR.RR bit 1, the data for the frame that is being transmitted or received may not be complete, and EDMAC operation after exiting the sleep mode or module-stop state is not guaranteed.

37.5.3 Illegal Address Access Detection

When the illegal address access detection on the EDMAC operation is to be used, set the BSC.BEREN.IGAEN bit and ICU.IER02.IEN0 bit to 1.

If the BSC.BERSR1.MST[2:0] bits are 110b when a bus error interrupt occurs, set the EDMR.SWR bit to 1 (EDMAC and ETHERC are reset) and then configure the EDMAC and ETHERC again.

38. USB 2.0 FS Host/Function Module (USBb)

38.1 Overview

This MCU incorporates a USB 2.0 FS host/function module.
The USB module is a USB controller that is equipped to operate as a host controller or function controller. The module supports full-speed and low-speed (only for the host controller) transfer as defined in Universal Serial Bus (USB) Specification 2.0. The module has an internal USB transceiver and supports all of the transfer types defined in USB Specification 2.0.
The USB has buffer memory for data transfer, providing a maximum of 10 pipes. PIPE1 to PIPE9 can be assigned any endpoint number based on peripheral devices used for communication or based on the user system.
Table 38.1 shows the specifications of the USB.

Table 38.1 USB Specifications

Item	Specifications
Features	• USB Device Controller (UDC) and transceiver for USB 2.0 are incorporated. Host controller, function controller, and On-The-Go (OTG) are supported (one channel) • The host controller and the function controller can be switched by software. • Self-power mode or bus power mode can be selected.
	When the host controller is selected: • Full-speed transfer (12 Mbps) and low-speed transfer (1.5 Mbps) are supported • Automatic scheduling for SOF and packet transmissions • Programmable intervals for isochronous and interrupt transfers • Multiple peripheral devices can be connected for communication via a one-stage hub.
	When the function controller is selected: • Full-speed transfer (12 Mbps)*1 is supported • Control transfer stage control function • Device state control function • Auto response function for SET_ADDRESS request • SOF interpolation function
Communication data transfer type	• Control transfer • Bulk transfer • Interrupt transfer • Isochronous transfer
Pipe configuration	• Buffer memory for USB communication is provided. • Up to 10 pipes can be selected (including the default control pipe). • PIPE1 to PIPE9 can be assigned any endpoint number.
	Transfer conditions that can be set for each pipe: • PIPE0: Control transfer, 64-byte single buffer • PIPE1 and PIPE2: 64-byte double buffer can be specified for bulk transfer 256-byte double buffer for isochronous transfer • PIPE3 to PIPE5: Bulk transfer, 64-byte double buffer • PIPE6 to PIPE9: Interrupt transfer, 64-byte single buffer
Others	• Reception ending function using transaction count • Function that changes the BRDY interrupt event notification timing (BFRE) • Function that automatically clears the buffer memory after the data for the pipe specified at the DnFIFO (n = 0, 1) port has been read (DCLRM) • NAK setting function for response PID generated by end of transfer (SHTNAK) • On-chip pull-up and pull-down resistors of D+/D–
Low power consumption function	Module stop state can be set.

Note 1. When the function controller is selected, low-speed transfer (1.5 Mbps) is not supported.

Figure 38.1 shows a block diagram of the USB.

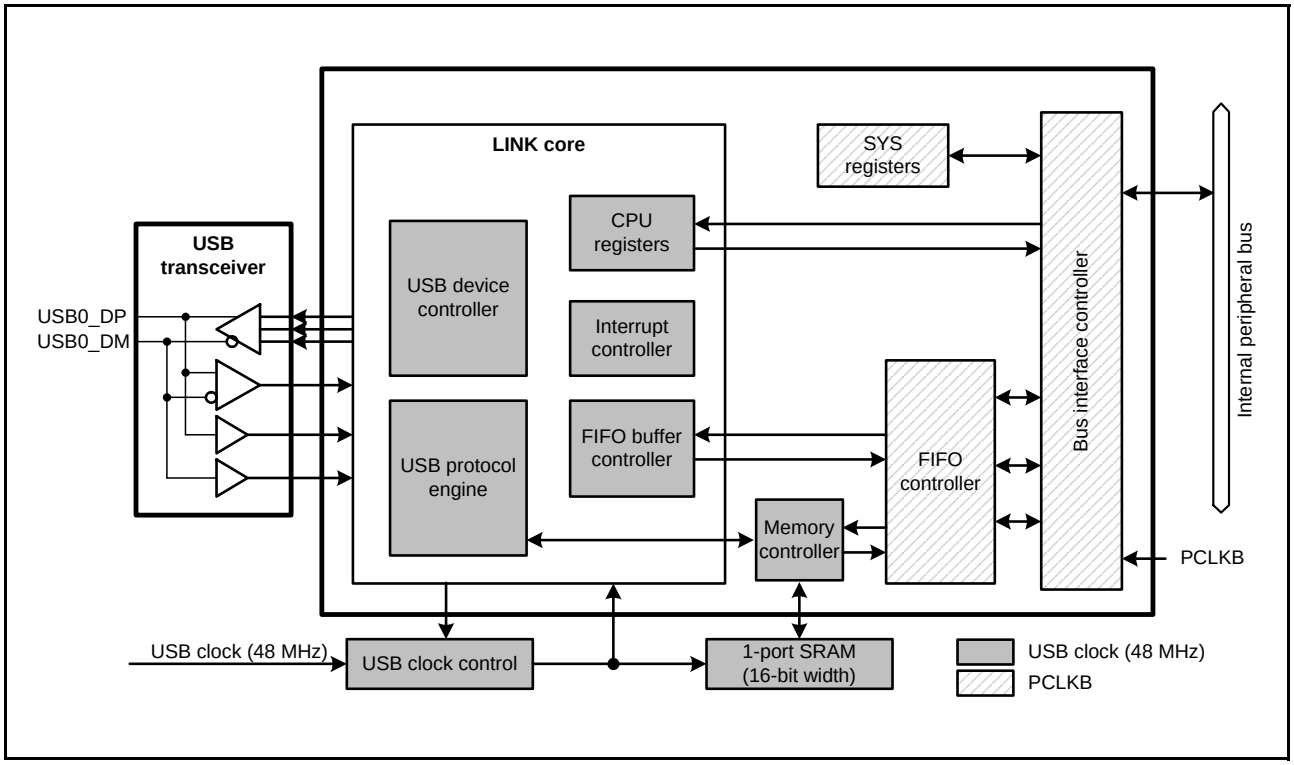

Figure 38.1 USB Block Diagram

Table 38.2 lists the I/O pins of the USB.

Table 38.2 USB Pin Configuration

Port	Pin Name	I/O	Function
USB	USB0_DP	I/O	D+ I/O pin of the USB on-chip transceiver This pin should be connected to the D+ pin of the USB bus.
	USB0_DM	I/O	D– I/O pin of the USB on-chip transceiver This pin should be connected to the D– pin of the USB bus.
	USB0_VBUS	Input	USB cable connection monitor pin This pin should be connected to VBUS of the USB bus. The VBUS pin status (connected or disconnected) can be detected when the USB module is operating as a function controller.
	USB0_EXICEN	Output	Low-power control signal for external power supply (OTG) chip
	USB0_VBUSEN	Output	VBUS (5 V) supply enable signal for external power supply chip
	USB0_OVRCURA USB0_OVRCURB	Input	External overcurrent detection signals should be connected to these pins. VBUS comparator signals should be connected to these pins when the OTG power supply chip is connected.
	USB0_ID	Input	MicroAB connector ID input signal should be connected to this pin during operation in OTG mode.
Common	VCC_USB	Input	USB power supply pin
	VSS_USB	Input	USB ground pin

38.2 Register Descriptions

38.2.1 System Configuration Control Register (SYSCFG)

Address(es): 000A 0000h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SCKE	—	—	—	DCFM	DRPD	DPRPU	—	—	—	USBE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	USBE	USB Operation Enable	0: USB operation is disabled. 1: USB operation is enabled.	R/W
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	DPRPU	D+ Line Resistor Control	0: Pulling up the line is disabled. 1: Pulling up the line is enabled.	R/W
b5	DRPD	D+/D– Line Resistor Control	0: Pulling down the lines is disabled. 1: Pulling down the lines is enabled.	R/W
b6	DCFM	Controller Function Select	0: Function controller is selected. 1: Host controller is selected.	R/W
b9 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b10	SCKE	USB Clock Enable*1	0: Stops supplying the clock signal to the USB. 1: Enables supplying the clock signal to the USB.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. After writing 1 to the SCKE bit, read it and confirm it is set to 1.

USBE Bit (USB Operation Enable)

The USBE bit enables or disables operation of the USB.

Modifying the USBE bit from 1 to 0 initializes the register bits listed in Table 38.3.

This bit should be modified while the SCKE bit is 1.

When the host controller is selected, this bit should be set to 1 after setting the DRPD bit to 1, eliminating SYSSTS0.LNST[1:0] flag chattering, and confirming that the USB bus state is stabilized.

Table 38.3 Registers Initialized by Writing 0 to the SYSCFG.USBE Bit

Selected Function	Register	Bit	Remarks
Function controller	SYSSTS0	LNST[1:0]	The value is retained when the host controller is selected.
	DVSTCTR0	RHST[2:0]	
	INTSTS0	DVSQ[2:0]	The value is retained when the host controller is selected.
	USBADDR	USBADDR[6:0]	The value is retained when the host controller is selected.
	USBREQ	BREQUEST[7:0], BMREQUESTTYPE[7:0]	The value is retained when the host controller is selected.
	USBVAL	WVALUE[15:0]	The value is retained when the host controller is selected.
	USBINDX	WINDEX[15:0]	The value is retained when the host controller is selected.
	USBLENG	WLENGTH[15:0]	The value is retained when the host controller is selected.
Host controller	DVSTCTR0	RHST[2:0]	
	FRMNUM	FRNM[10:0]	The value is retained when the function controller is selected.

DPRPU Bit (D+ Line Resistor Control)

The DPRPU bit enables or disables pulling up the D+ line when the function controller is selected.
When the DPRPU bit is set to 1 while the function controller is selected, the bit forces a pull-up of the D+ line to notify the USB host of connection. Modifying the DPRPU bit from 1 to 0 allows the USB to release the D+ line, thus notifying the USB host of disconnection.
This bit should be set to 1 if the function controller is selected, and should be set to 0 if the host controller is selected.

DRPD Bit (D+/D– Line Resistor Control)

The DRPD bit enables or disables pulling down D+ and D– lines when the host controller is selected.
This bit should be set to 1 if the host controller is selected, and should be set to 0 if the function controller is selected.

DCFM Bit (Controller Function Select)

The DCFM bit selects the function of the USB.
This bit should be modified when the DPRPU and DRPD bits are all 0.

SCKE Bit (USB Clock Enable)

The SCKE bit stops or enables supplying 48-MHz clock signals to the USB.
When this bit is 0, only SYSCFG can be read from and written to; the other registers related to the USB cannot be read from or written to.

38.2.2 System Configuration Status Register 0 (SYSSTS0)

Address(es): 000A 0004h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVCMON[1:0]		—	—	—	—	—	—	—	HTACT	SOFEA	—	—	IDMON	LNST[1:0]	
Value after reset:	0*1	0*1	0	0	0	0	0	0	0	0	0	0	0	0*1	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	LNST[1:0]	USB Data Line Status Monitor Flag	Refer to Table 38.4.	R
b2	IDMON	External ID0 Input Pin Monitor Flag	0: USB0_ID pin is low 1: USB0_ID pin is high	R
b4, b3	—	Reserved	These bits are read as 0 and cannot be modified.	R
b5	SOFEA	SOF Active Monitor Flag When the Host Controller is Selected	Indicates the SOF output status. 0: SOF output is stopped. 1: SOF output is operating.	R
b6	HTACT	USB Host Sequencer Status Monitor Flag	0: Host sequencer of the USB is completely stopped. 1: Host sequencer of the USB is not completely stopped.	R
b13 to b7	—	Reserved	These bits are read as 0 and cannot be modified.	R
b15, b14	OVCMON[1:0]	External USB0_OVRCURA/ USB0_OVRCURB Input Pin Monitor Flag	The OVCMON[1] flag indicates the status of the USB0_OVRCURA pin. The OVCMON[0] flag indicates the status of the USB0_OVRCURB pin.	R

Note 1. Depends on the status of the USB0_OVRCURA/USB0_OVRCURB and USB0_ID pins.

LNST[1:0] Flags (USB Data Line Status Monitor Flag)

The LNST[1:0] flags indicate the state of the USB data lines (D+ and D– lines). Refer to Table 38.4.

The LNST[1:0] flags should be read after the connection processing (SYSCFG.DPRPU bit = 1) when the function controller is selected; whereas after enabling pull-down of the lines (SYSCFG.DRPD bit = 1) when the host controller is selected.

SOFEA Flag (SOF Active Monitor Flag When the Host Controller is Selected)

When the USB module is suspended while host mode is used, this bit can be used to confirm whether the last SOF has been output after DVSTCTR0.UACT is set to 0.

Confirm that both the HTACT and SOFEA flags are 0 before stopping the USB module while SYSCFG.USBE is 0 and setting the SYSCFG.SCKE bit to 0 to stop the clock during host mode communication.

HTACT Flag (USB Host Sequencer Status Monitor Flag)

The HTACT flag is 0 when the host sequencer of the USB is completely stopped.

Confirm that the HTACT flag is 0 before setting this controller to the USB suspended state while DVSTCTR0.UACT bit is 0 and setting the SCKE bit to 0 to stop the clock during host mode communication.

OVCMON[1:0] Flags (External USB0_OVRCURA/ USB0_OVRCURB Input Pin Monitor Flag)

The OVCMON[1:0] flags indicate the status of overcurrent from an external power supply chip.

Table 38.4 Status of USB Data Bus Lines (D+ Line, D– Line)

LNST[1:0] Flags	During Low-Speed Operation (Only in Host Controller Operation)	During Full-Speed Operation
00b	SE0	SE0
01b	K-State	J-State
10b	J-State	K-State
11b	SE1	SE1

38.2.3 Device State Control Register 0 (DVSTCTR0)

Address(es): 000A 0008h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b11	HNPBTOA	Host Negotiation Protocol (HNP) Control	This bit is used when switching from device B to device A while in OTG mode. If the HNPBTOA bit is 1, the internal function control keeps the suspended state until the HNP processing ends even though SYSCFG.DPRPU = 0 or SYSCFG.DCFM = 1.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

x: Don't care

RHST[2:0] Flags (USB Bus Reset Status Flag)

The RHST[2:0] flags indicate the status of the USB bus reset.
When the host controller is selected, the RHST[2:0] flags indicate 100b after the USBRST bit has been set to 1 by software.
The USB fixes the value of the RHST[2:0] flags when 0 is written to the USBRST bit by software and the USB completes SE0 driving.
When the function controller is selected, the RHST[2:0] flags indicate 010b (connection while DPRPU = 1) when the USB detects the USB bus reset, and a DVST interrupt is generated.

UACT Bit (USB Bus Enable)

The UACT bit enables operation of the USB bus (controls the SOF packet transmission to the USB bus) when the host controller is selected.
With this bit set to 1, the USB puts the USB port to the USB-bus enabled state and performs SOF output and data transmission and reception.
This module starts outputting SOF packets within one frame after 1 has been written to the UACT bit by software.
With this bit set to 0, the USB enters the idle state after outputting SOF packets.
The USB sets the UACT bit to 0 on any of the following conditions.

- A DTCH interrupt is detected during communication (while UACT = 1).
- An EOFERR interrupt is detected during communication (while UACT = 1).

Writing 1 to this bit should be done at the end of the USB reset processing (writing 0 to the USBRST bit) or at the end of the resume processing from the suspended state (writing 0 to the RESUME bit).
This bit should be set to 0 if the function controller is selected.

RESUME Bit (Resume Output)

The RESUME bit controls the resume signal output when the host controller is selected.
Setting the RESUME bit to 1 allows the USB to drive the port to the K-state and output the resume signal.
The USB sets the RESUME bit to 1 on detecting the remote wakeup signal while RWUPE is 1 in the USB suspended state.
The USB continues outputting K-state while the RESUME bit = 1 (until the RESUME bit is set to 0 by software). The RESUME bit should be 1 (= resume period) for the time defined by USB Specification 2.0.
This bit should be set to 1 in the suspended state.
Write 1 to the UACT bit simultaneously with the end of the resume processing (writing 0 to the RESUME bit).
This bit should be set to 0 if the function controller is selected.

USBRST Bit (USB Bus Reset Output)

The USBRST bit controls the USB bus reset signal output when the host controller is selected.
When the host controller is selected, setting this bit to 1 allows the USB to drive SE0 of the USB port to reset the USB bus.
The USB continues outputting SE0 while USBRST = 1 (until the USBRST bit is set to 1 by software). The USBRST bit should be 1 (= USB bus reset period) for the time defined by USB Specification 2.0.
Writing 1 to this bit during communication (the UACT bit = 1) or during the resume processing (the RESUME bit = 1) prevents the USB from starting the USB bus reset processing until both the UACT and RESUME bits become 0.
Write 1 to the UACT bit simultaneously with the end of the USB bus reset processing (writing 0 to the USBRST bit).
This bit should be set to 0 if the function controller is selected.

RWUPE Bit (Wakeup Detection Enable)

The RWUPE bit enables or disables the downstream port peripheral device to use the remote wakeup function (resume signal output) when the host controller is selected.

With this bit set to 1, on detecting the remote wakeup signal, the USB detects the resume signal (K-state for 2.5 μs) from the downstream port device and performs the resume processing (drives the port to the K-state).

With this bit set to 0, the USB ignores the detected remote wakeup signal (K-state) from the peripheral device connected to the USB port.

While the RWUPE bit is 1, the internal clock should not be stopped even in the suspended state (SYSCFG.SCKE bit should be set to 1).

This bit should be set to 0 if the function controller is selected.

WKUP Bit (Wakeup Output)

The WKUP bit enables or disables outputting the remote wakeup signal (resume signal) to the USB bus when the function controller is selected.

The USB controls the output time of a remote wakeup signal. When this bit is set to 1, the USB sets this bit to 0 after outputting the 10-ms K-state.

According to USB Specification 2.0, the USB bus idle state must be kept for 5 ms or longer before a remote wakeup signal is sent. If the USB writes 1 to this bit right after detection of the suspended state, the K-state will be output after 2 ms.

Do not write 1 to this bit, unless the device state is in the suspended state (INTSTS0.DVSQ[2:0] flags = 1xxb) and the USB host enables the remote wakeup signal. When this bit is set to 1, the internal clock must not be stopped even in the suspended state (write 1 to this bit while the SYSCFG.SCKE bit = 1).

This bit should be set to 0 if the host controller is selected.

HNPBTOA Bit (Host Negotiation Protocol (HNP) Control)

The HNPBTOA bit is used when switching from device B to device A while in OTG mode. If the HNPBTOA bit is 1, the internal function control keeps the suspended state until the HNP processing ends even though the SYSCFG.DPRPU bit = 0 or SYSCFG.DCFM = 1 is set. Even if the falling edge of the D+ signal is detected at this time, no resume (RESM) interrupt is generated.

After this bit is set to 1, write 0 to this bit by software to terminate the HNP processing when connection to the host (pull-up on the target side) or timeout of the HNP processing is detected.

38.2.4 CFIFO Port Register (CFIFO)
D0FIFO Port Register (D0FIFO)
D1FIFO Port Register (D1FIFO)

(1) When the MBW bit is 1

Address(es): CFIFO 000A 0014h, D0FIFO 000A 0018h, D1FIFO 000A 001Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	FIFO Port	This port is used for reading receive data from the FIFO buffer and writing transmit data to the FIFO buffer.	R/W

(2) When the MBW bit is 0

Address(es): CFIFO 000A 0014h, D0FIFO 000A 0018h, D1FIFO 000A 001Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	L[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	L[7:0]	FIFO Port	This port is used for reading receive data from the FIFO buffer and writing transmit data to the FIFO buffer.	R/W

There are three FIFO ports: CFIFO, D0FIFO, and D1FIFO. Each FIFO port is configured of a port register (CFIFO, D0FIFO, or D1FIFO) that handles reading of data from the FIFO buffer memory and writing of data to the FIFO buffer memory, a port select register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL) that is used to select the pipe assigned to the FIFO port, and a port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR).
Each FIFO port has the following precautions.

- The FIFO buffer for DCP (control transfer) should be accessed through the CFIFO port.
- Accessing a FIFO buffer using DMA/DTC transfer should be performed through the D0FIFO or D1FIFO port.
- The D0FIFO and D1FIFO ports can also be accessed by the CPU.
- When using functions specific to a FIFO port, the pipe number (selected pipe) specified by the CURPIPE[3:0] bits in the port select register cannot be changed (when the DMA/DTC transfer function is used, etc.).
- The same pipe should not be assigned to two or more FIFO ports.
- There are two FIFO buffer states: the access right for a FIFO buffer can be on the CPU side or on the Serial Interface Engine (SIE) side. When the access right for a FIFO buffer is on the SIE side, the FIFO buffer cannot be accessed from the CPU.

FIFO Port Bit

Accessing the FIFO port bits allows reading the received data from the FIFO buffer or writing the transmit data to the FIFO buffer.

Each FIFO port register can be accessed only while the FRDY flag in each FIFO port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR) is 1.

The valid bits in a FIFO port register depend on the settings of the corresponding MBW bit of the FIFO port select register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL).

When the MBW bit is 1 (16-bit width), the data arrangement may differ from the data arrangement on the RAM depending on the value of the MDE.MDE[2:0] bits and the setting of the BIGEND bit (CFIFOSEL.BIGEND, D0FIFOSEL.BIGEND, or D1FIFOSEL.BIGEND). Table 38.5 lists the endian operation in 16-bit access. Note that if the total number of transmit data bytes is odd, access the L[7:0] bits in bytes when writing the last data.

When the MBW bit is 0 (8-bit width), access the L[7:0] bits in bytes.

Table 38.5 Endian Operation in 16-Bit Access

MDE.MDE[2:0] bits	CFIFOSEL.BIGEND Bit D0FIFOSEL.BIGEND Bit D1FIFOSEL.BIGEND Bit	Bits 15 to 8	Bits 7 to 0	Remarks
000b (big endian)	0 (little endian)	Data in address N + 1	Data in address N	Bytes reversed
	1 (big endian)	Data in address N	Data in address N + 1	
111b (little endian)	0 (little endian)	Data in address N + 1	Data in address N	
	1 (big endian)	Data in address N	Data in address N + 1	Bytes reversed

38.2.5 CFIFO Port Select Register (CFIFOSEL)
D0FIFO Port Select Register (D0FIFOSEL)
D1FIFO Port Select Register (D1FIFOSEL)

- CFIFOSEL

Address(es): 000A 0020h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	ISEL	CFIFO Port Access Direction When DCP is Selected	0: Reading from the buffer memory is selected. 1: Writing to the buffer memory is selected.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	BIGEND	CFIFO Port Endian Control	0: Little endian 1: Big endian	R/W
b9	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b10	MBW	CFIFO Port Access Bit Width	0: 8-bit width 1: 16-bit width	R/W
b13 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	REW	Buffer Pointer Rewind	0: The buffer pointer is not rewound. 1: The buffer pointer is rewound.	R/W*1
b15	RCNT	Read Count Mode	0: The DTLN[8:0] flags (CFIFOCTR.DTLN[8:0], D0FIFOCTR.DTLN[8:0], D1FIFOCTR.DTLN[8:0]) are cleared when all of the receive data has been read from the CFIFO. (In double buffer mode, the DTLN[8:0] bit value is cleared when all the data has been read from only a single plane.) 1: The DTLN[8:0] flags are decremented each time the receive data is read from the CFIFO.	R/W

Note 1. Only 0 can be read.

The same pipe should not be specified by the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. When the CURPIPE[3:0] bits in the D0FIFOSEL and D1FIFOSEL registers are set to 0000b, no pipe is selected.

The pipe number should not be changed while the DMA/DTC transfer is enabled.

CURPIPE[3:0] Bits (CFIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number using which data is read or written through the CFIFO port.
After writing to these bits, read these bits to check that the written value agrees with the read value before proceeding to the next process.
Do not set the same pipe number to the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers.
Even if an attempt is made to modify the setting of these bits during access to the FIFO buffer, the current access setting is retained until the access is completed. Then, the modification becomes effective, thus enabling continuous access.

ISEL Bit (CFIFO Port Access Direction When DCP is Selected)

After writing to the ISEL bit with the DCP being a selected pipe, read this bit to check that the written value agrees with the read value before proceeding to the next process.
Set this bit and the CURPIPE[3:0] bits simultaneously.

MBW Bit (CFIFO Port Access Bit Width)

The MBW bit specifies the bit width for accessing the CFIFO port.
When the selected pipe is in the receiving direction, once reading data is started after setting this bit, this bit should not be modified until all the data has been read.
When the selected pipe is in the receiving direction, set the CURPIPE[3:0] bits to a different value once, and then set these bits and the MBW bit simultaneously. For the procedure for modifying the CURPIPE[3:0] bits, follow the description of these bits.
When the selected pipe is in the transmitting direction, the bit width cannot be changed from 8-bit width to 16-bit width while data is being written to the buffer memory.
An odd number of bytes can also be written through byte-access control even when 16-bit width is selected.

REW Bit (Buffer Pointer Rewind)

The REW bit specifies whether or not to rewind the buffer pointer.
When the selected pipe is in the receiving direction, setting the REW bit to 1 while the FIFO buffer is being read allows re-reading the FIFO buffer from the first data (in double buffer mode, re-reading the currently-read FIFO buffer plane from the first data is allowed).
Do not set the REW bit to 1 simultaneously with modifying the CURPIPE[3:0] bits. Before setting the REW bit to 1, be sure to check that the FRDY flag is 1.
To re-write to the FIFO buffer again from the first data for the pipe in the transmitting direction, use the BCLR bit.

- D0FIFOSEL, D1FIFOSEL

Address(es): D0FIFOSEL 000A 0028h, D1FIFOSEL 000A 002Ch

b11	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b12	DREQE	DMA/DTC Transfer Request Enable	0: DMA/DTC transfer request is disabled. 1: DMA/DTC transfer request is enabled.	R/W
b13	DCLRM	Auto Buffer Memory Clear Mode Accessed after Specified Pipe Data is Read	0: Auto buffer clear mode is disabled. 1: Auto buffer clear mode is enabled.	R/W
b14	REW	Buffer Pointer Rewind	0: The buffer pointer is not rewound. 1: The buffer pointer is rewound.	R/W*1
b15	RCNT	Read Count Mode	0: The DTLN[8:0] flags (CFIFOCTR.DTLN[8:0], D0FIFOCTR.DTLN[8:0], D1FIFOCTR.DTLN[8:0]) are cleared when all of the receive data has been read from the DnFIFO. (In double buffer mode, the DTLN bit Value is cleared when all the data has been read from only a single plane.) 1: The DTLN[8:0] flags are decremented each time the receive data is read from the DnFIFO. (n = 0, 1)	R/W

Note 1. Only 0 can be read.

The same pipe should not be specified by the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. When the CURPIPE[3:0] bits in the D0FIFOSEL and D1FIFOSEL registers are set to 0000b, no pipe is selected.

The pipe number should not be changed while the DMA/DTC transfer is enabled.

CURPIPE[3:0] Bits (FIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number using which data is read or written through the D0FIFO port or D1FIFO port.
After writing to these bits, read these bits to check that the written value agrees with the read value before proceeding to the next process.
Do not set the same pipe number to the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers.
Even if an attempt is made to modify the setting of these bits during access to the FIFO buffer, the current access setting is retained until the access is completed. Then, the modification becomes effective, thus enabling continuous access.

MBW Bit (FIFO Port Access Bit Width)

The MBW bit specifies the bit width for accessing the D0FIFO port or D1FIFO port.
When the selected pipe is in the receiving direction, once reading data is started after setting this bit, this bit should not be modified until all the data has been read.
When the selected pipe is in the receiving direction, set the CURPIPE[3:0] bits to a different value once, and then set these bits and the MBW bit simultaneously. For the procedure for modifying the CURPIPE[3:0] bits, follow the description of these bits.
When the selected pipe is in the transmitting direction, the bit width cannot be changed from 8-bit width to 16-bit width while data is being written to the buffer memory.
An odd number of bytes can also be written through byte-access control even when 16-bit width is selected.

DREQE Bit (DMA/DTC Transfer Request Enable)

The DREQE bit enables or disables the DMA/DTC transfer request to be issued.
Before setting the DREQE bit to 1 to enable the DMA/DTC transfer request to be issued, set the CURPIPE[3:0] bits.
When modifying the setting of the CURPIPE[3:0] bits, set this bit to 0 first.

DCLRM Bit (Auto Buffer Memory Clear Mode Accessed after Specified Pipe Data is Read)

The DCLRM bit enables or disables the buffer memory to be cleared automatically after data has been read using the selected pipe.
With this bit set to 1, the USB sets the BCLR bit to 1 for the FIFO buffer of the selected pipe on receiving a zero-length packet while the FIFO buffer assigned to the selected pipe is empty, or on receiving a short packet and reading the data while the PIPECFG.BFRE bit is 1.
When using the USB with the SOFCFG.BRDYM bit set to 1, set this bit to 0.

REW Bit (Buffer Pointer Rewind)

The REW bit specifies whether or not to rewind the buffer pointer.
When the selected pipe is in the receiving direction, setting the REW bit to 1 while the FIFO buffer is being read allows re-reading the FIFO buffer from the first data (in double buffer mode, re-reading the currently-read FIFO buffer plane from the first data is allowed).
Do not set the REW bit to 1 simultaneously with modifying the CURPIPE[3:0] bits. Before setting the REW bit to 1, be sure to check that the FRDY flag is 1.
To re-write to the FIFO buffer again from the first data for the pipe in the transmitting direction, use the BCLR bit.

RCNT Bit (Read Count Mode)

The RCNT bit specifies the read mode for the value in the CFIFOCTR.DTLN bit.
When accessing DnFIFO with the PIPECFG.BFRE bit set to 1, set the RCNT bit to 0.

38.2.6 CFIFO Port Control Register (CFIFOCTR)
D0FIFO Port Control Register (D0FIFOCTR)
D1FIFO Port Control Register (D1FIFOCTR)

Address(es): CFIFOCTR 000A 0022h, D0FIFOCTR 000A 002Ah, D1FIFOCTR 000A 002Eh

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b8 to b0	DTLN[8:0]	Receive Data Length Flag	Indicate the length of the receive data. These bits indicate different values depending on the setting of the RCNT bit in the port select register. For details, refer to the description on the DTLN[8:0] flags shown below.	R
b12 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13	FRDY	FIFO Port Ready Flag	0: FIFO port access is disabled. 1: FIFO port access is enabled.	R
b14	BCLR	CPU Buffer Clear	0: Does not operate. 1: Clears the buffer memory on the CPU side.	R/W*1
b15	BVAL	Buffer Memory Valid	0: Invalid 1: Writing ended	R/W

Note 1. Only 0 can be read.

Registers CFIFOCTR, D0FIFOCTR, and D1FIFOCTR correspond to CFIFO, D0FIFO, and D1FIFO, respectively.

DTLN[8:0] Flags (Receive Data Length Flag)

The DTLN[8:0] flags indicate the length of the receive data.
While the FIFO buffer is being read, the DTLN[8:0] flags indicate different values depending on the DnFIFOSEL.RCNT bit (n = 0, 1) value as described below.

- RCNT = 0
  The USB sets the DTLN[8:0] flags to indicate the length of the receive data until the CPU or DMAC/DTC has read all the received data from a single FIFO buffer plane.
  While the PIPECFG.BFRE bit = 1, these bits retain the length of the receive data until the BCLR bit is set to 1 even after all the data has been read.
- RCNT = 1
  The USB decrements the value indicated by the DTLN[8:0] flags each time data is read from the FIFO buffer. (The value is decremented by one when the MBW bit is 0, and by two when the MBW bit is 1.)
  The USB sets these bits to 0 when all the data has been read from one FIFO buffer plane. However, in double buffer mode, if data has been received in one FIFO buffer plane before all the data has been read from the other plane, the USB sets these bits to indicate the length of the receive data in the former plane when all the data has been read from the latter plane.

FRDY Flag (FIFO Port Ready Flag)

The FRDY flag indicates whether the FIFO port can be accessed by the CPU or DMAC/DTC.
In the following cases, the USB sets the FRDY flag to 1 but data cannot be read via the FIFO port because there is no data to be read. In these cases, set the BCLR bit to 1 to clear the FIFO buffer, and enable transmission and reception of the next data.

- A zero-length packet is received when the FIFO buffer assigned to the selected pipe is empty.
- A short packet is received and the data is completely read while the PIPECFG.BFRE bit = 1.

BCLR Bit (CPU Buffer Clear)

The BCLR bit should be set to 1 to clear the FIFO buffer on the CPU side for the selected pipe.
When double buffer mode is set for the FIFO buffer assigned to the selected pipe, the USB clears only one plane of the FIFO buffer even when both planes are read-enabled.
When the selected pipe is the DCP, setting the BCLR bit to 1 allows the USB to clear the FIFO buffer regardless of whether the FIFO buffer is on the CPU side or SIE side. To clear the buffer on the SIE side, set the DCPCTR.PID[1:0] bits for the DCP to 00b (NAK) before setting the BCLR bit to 1.
When the selected pipe is in the transmitting direction, if 1 is written to the BVAL bit and the BCLR bit simultaneously, the USB clears the data that has been written before it, enabling transmission of a zero-length packet.
When the selected pipe is not the DCP, writing 1 to the BCLR bit should be done while the FRDY flag in the FIFO port control register is 1 (set by the USB).

BVAL Bit (Buffer Memory Valid)

The BVAL bit should be set to 1 when data has been completely written to the FIFO buffer on the CPU side for the pipe selected using the CURPIPE[3:0] bits (selected pipe).
When the selected pipe is in the transmitting direction, set the BVAL bit to 1 in the following cases. Then, the USB switches the FIFO buffer from the CPU side to the SIE side, thus enabling transmission.

- To transmit a short packet, set the BVAL bit to 1 after data has been written.
- To transmit a zero-length packet, set the BVAL bit to 1 before data is written to the FIFO buffer.

When data of the maximum packet size has been written for the pipe in continuous transfer mode, the USB sets the BVAL bit to 1 and switches the FIFO buffer from the CPU side to the SIE side, thus enabling transmission.
Writing 1 to the BVAL bit should be done while the FRDY flag is 1 (set by the USB).
When the selected pipe is in the receiving direction, do not set the BVAL bit to 1.

38.2.7 Interrupt Enable Register 0 (INTENB0)

Address(es): 000A 0030h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b12	DVSE	Device State Transition Interrupt Enable*1	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b13	SOFE	Frame Number Update Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b14	RSME	Resume Interrupt Enable*1	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b15	VBSE	VBUS Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W

Note 1. The RSME, DVSE, and CTRE bits can be set to 1 only when the function controller is selected; do not set these bits to 1 to enable the corresponding interrupt output when the host controller is selected.

On detecting the interrupt corresponding to the bit in the INTENB0 register to which 1 has been set by software, the USB generates the USB interrupt request.

The USB sets 1 to each status bit in the INTSTS0 register when a detection condition of the corresponding interrupt source has been satisfied regardless of the setting in the INTENB0 register (regardless of whether the interrupt output is enabled or disabled).

While the status bit in the INTSTS0 register corresponding to the interrupt source indicates 1, the USB generates the USB interrupt request when the corresponding interrupt enable bit in the INTENB0 register is modified from 0 to 1 by software.

38.2.8 Interrupt Enable Register 1 (INTENB1)

Address(es): 000A 0032h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVRCRE	BCHGE	—	DTCHE	ATTCHE	—	—	—	—	EOFERRE	SIGNE	SACKE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	SACKE	Setup Transaction Normal Response Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b5	SIGNE	Setup Transaction Error Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b6	EOFERRE	EOF Error Detection Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b10 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11	ATTCHE	Connection Detection Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b12	DTCHE	Disconnection Detection Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b13	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b14	BCHGE	USB Bus Change Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b15	OVRCRE	Overcurrent Input Change Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W

Note: The bits in the INTENB1 register can be set to 1 only when the host controller is selected; do not set these bits to 1 to enable the corresponding interrupt output when the function controller is selected.

The INTENB1 register specifies the interrupt masks when the host controller is selected, and for the setup transaction. On detecting the interrupt corresponding to the bit in the INTENB1 register to which 1 has been set by software, the USB generates the USB interrupt request.

The USB sets 1 to each status bit in the INTSTS1 register when a detection condition of the corresponding interrupt source has been satisfied regardless of the setting in the INTENB1 register (regardless of whether the interrupt output is enabled or disabled).

While the status bit in the INTSTS1 register corresponding to the interrupt source indicates 1, the USB generates the USB interrupt request when the corresponding interrupt enable bit in the INTENB1 register is modified from 0 to 1 by software.

When the function controller is selected, the interrupts should not be enabled.

38.2.9 BRDY Interrupt Enable Register (BRDYENB)

Address(es): 000A 0036h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPE9BRDYE	PIPE8BRDYE	PIPE7BRDYE	PIPE6BRDYE	PIPE5BRDYE	PIPE4BRDYE	PIPE3BRDYE	PIPE2BRDYE	PIPE1BRDYE	PIPE0BRDYE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PIPE0BRDYE	BRDY Interrupt Enable for PIPE0	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b1	PIPE1BRDYE	BRDY Interrupt Enable for PIPE1	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b2	PIPE2BRDYE	BRDY Interrupt Enable for PIPE2	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b3	PIPE3BRDYE	BRDY Interrupt Enable for PIPE3	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b4	PIPE4BRDYE	BRDY Interrupt Enable for PIPE4	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b5	PIPE5BRDYE	BRDY Interrupt Enable for PIPE5	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b6	PIPE6BRDYE	BRDY Interrupt Enable for PIPE6	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b7	PIPE7BRDYE	BRDY Interrupt Enable for PIPE7	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b8	PIPE8BRDYE	BRDY Interrupt Enable for PIPE8	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b9	PIPE9BRDYE	BRDY Interrupt Enable for PIPE9	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The BRDYENB register enables or disables the INTSTS0.BRDY flag to be set to 1 when the BRDY interrupt is detected for each pipe.

On detecting the BRDY interrupt for the pipe corresponding to the bit in the BRDYENB register to which 1 has been set by software, the USB sets 1 to the corresponding BRDYSTS.PIPEnBRDY flag (n = 0 to 9) and the INTSTS0.BRDY flag. If INTENB0.BRDYE = 1 at this time, the USB generates the BRDY interrupt request.

While at least one PIPEnBRDY flag indicates 1, the USB generates the BRDY interrupt request when the corresponding interrupt enable bit in the BRDYENB register is modified from 0 to 1 by software.

38.2.10 NRDY Interrupt Enable Register (NRDYENB)

Address(es): 000A 0038h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPE9NRDYE	PIPE8NRDYE	PIPE7NRDYE	PIPE6NRDYE	PIPE5NRDYE	PIPE4NRDYE	PIPE3NRDYE	PIPE2NRDYE	PIPE1NRDYE	PIPE0NRDYE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PIPE0NRDYE	NRDY Interrupt Enable for PIPE0	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b1	PIPE1NRDYE	NRDY Interrupt Enable for PIPE1	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b2	PIPE2NRDYE	NRDY Interrupt Enable for PIPE2	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b3	PIPE3NRDYE	NRDY Interrupt Enable for PIPE3	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b4	PIPE4NRDYE	NRDY Interrupt Enable for PIPE4	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b5	PIPE5NRDYE	NRDY Interrupt Enable for PIPE5	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b6	PIPE6NRDYE	NRDY Interrupt Enable for PIPE6	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b7	PIPE7NRDYE	NRDY Interrupt Enable for PIPE7	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b8	PIPE8NRDYE	NRDY Interrupt Enable for PIPE8	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b9	PIPE9NRDYE	NRDY Interrupt Enable for PIPE9	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The NRDYENB register enables or disables the INTSTS0.NRDY flag to be set to 1 when the NRDY interrupt is detected for each pipe.

On detecting the NRDY interrupt for the pipe corresponding to the bit in the NRDYENB register to which 1 has been set by software, the USB sets 1 to the corresponding NRDYSTS.PIPEnNRDY flag (n = 0 to 9) and the INTSTS0.NRDY flag. If INTENB0.NRDYE = 1 at this time, the USB generates the NRDY interrupt request.

While at least one PIPEnNRDY flag indicates 1, the USB generates the NRDY interrupt request when the corresponding interrupt enable bit in the NRDYENB register is modified from 0 to 1 by software.

38.2.11 BEMP Interrupt Enable Register (BEMPENB)

Address(es): 000A 003Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPE9BEMPE	PIPE8BEMPE	PIPE7BEMPE	PIPE6BEMPE	PIPE5BEMPE	PIPE4BEMPE	PIPE3BEMPE	PIPE2BEMPE	PIPE1BEMPE	PIPE0BEMPE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PIPE0BEMPE	BEMP Interrupt Enable for PIPE0	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b1	PIPE1BEMPE	BEMP Interrupt Enable for PIPE1	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b2	PIPE2BEMPE	BEMP Interrupt Enable for PIPE2	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b3	PIPE3BEMPE	BEMP Interrupt Enable for PIPE3	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b4	PIPE4BEMPE	BEMP Interrupt Enable for PIPE4	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b5	PIPE5BEMPE	BEMP Interrupt Enable for PIPE5	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b6	PIPE6BEMPE	BEMP Interrupt Enable for PIPE6	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b7	PIPE7BEMPE	BEMP Interrupt Enable for PIPE7	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b8	PIPE8BEMPE	BEMP Interrupt Enable for PIPE8	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b9	PIPE9BEMPE	BEMP Interrupt Enable for PIPE9	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The BEMPENB register enables or disables the INTSTS0.BEMP flag to be set to 1 when the BEMP interrupt is detected for each pipe.

On detecting the BEMP interrupt for the pipe corresponding to the bit in the BEMPENB register to which 1 has been set by software, the USB sets 1 to the corresponding BEMPSTS.PIPEnBEMP flag (n = 0 to 9) and the INTSTS0.BEMP flag. If INTENB0.BEMPE = 1 at this time, the USB generates the BEMP interrupt request.

While at least one PIPEnBEMP flag in the BEMPSTS register indicates 1, the USB generates the BEMP interrupt request when the corresponding interrupt enable bit in the BEMPENB register is modified from 0 to 1 by software.

38.2.12 SOF Output Configuration Register (SOFCFG)

Address(es): 000A 003Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	TRNENSEL	—	BRDYM	—	EDGESTS	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	EDGESTS	Edge Interrupt Output Status Monitor Flag*1	Indicates 1 when the edge interrupt output signal is in the middle of the edge processing.	R
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	BRDYM	BRDY Interrupt Status Clear Timing	0: Software clears the status. 1: The USB clears the status when data has been read from the FIFO buffer or data has been written to the FIFO buffer.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b8	TRNENSEL	Transaction-Enabled Time Select*1	0: For non-low-speed communication 1: For low-speed communication	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Confirm that this bit is 0 before stopping the clock supply to the USB module.

EDGESTS Flag (Edge Interrupt Output Status Monitor Flag)

The EDGESTS flag indicates 1 when the edge interrupt output signal is in the middle of the edge processing.
Confirm that this flag is 0 before stopping the clock supply to the USB.

BRDYM Bit (BRDY Interrupt Status Clear Timing)

The BRDYM bit specifies the timing for clearing the BRDY interrupt status for each pipe.

TRNENSEL Bit (Transaction-Enabled Time Select)

The TRNENSEL bit selects, for full-speed or low-speed communication, the transaction-enabled time in which the USB issues tokens in a frame via the port.
Set the TRNENSEL bit to 1 when a low-speed device is connected.
The TRNENSEL bit is valid only when the host controller is selected.
This bit should be set to 0 if the function controller is selected.

38.2.13 Interrupt Status Register 0 (INTSTS0)

Address(es): 000A 0040h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b2 to b0	CTSQ[2:0]	Control Transfer Stage Flag	b2 b0 0 0 0: Idle or setup stage 0 0 1: Control read data stage 0 1 0: Control read status stage 0 1 1: Control write data stage 1 0 0: Control write status stage 1 0 1: Control write (no data) status stage 1 1 0: Control transfer sequence error	R
b3	VALID	USB Request Reception Flag	0: Setup packet is not received. 1: Setup packet is received.	R/W
b6 to b4	DVSQ[2:0]	Device State Flag	b6 b4 0 0 0: Powered state 0 0 1: Default state 0 1 0: Address state 0 1 1: Configured state 1 x x: Suspended state	R
b7	VBSTS	VBUS Input Status Flag	0: USB0_VBUS pin is low. 1: USB0_VBUS pin is high.	R
b8	BRDY	Buffer Ready Interrupt Status Flag	0: BRDY interrupts are not generated. 1: BRDY interrupts are generated.	R
b9	NRDY	Buffer Not Ready Interrupt Status Flag	0: NRDY interrupts are not generated. 1: NRDY interrupts are generated.	R
b10	BEMP	Buffer Empty Interrupt Status Flag	0: BEMP interrupts are not generated. 1: BEMP interrupts are generated.	R
b11	CTRT	Control Transfer Stage Transition Interrupt Status Flag*5	0: Control transfer stage transition interrupts are not generated. 1: Control transfer stage transition interrupts are generated.	R/W*4
b12	DVST	Device State Transition Interrupt Status Flag*5	0: Device state transition interrupts are not generated. 1: Device state transition interrupts are generated.	R/W*4
b13	SOFR	Frame Number Refresh Interrupt Status Flag	0: SOF interrupts are not generated. 1: SOF interrupts are generated.	R/W*4
b14	RESM	Resume Interrupt Status Flag *5,*6	0: Resume interrupts are not generated. 1: Resume interrupts are generated.	R/W*4
b15	VBINT	VBUS Interrupt Status Flag*6	0: VBUS interrupts are not generated. 1: VBUS interrupts are generated.	R/W*4

x: Don't care

Note 1. The value is 0 when the MCU is reset and 1 after a USB bus reset.
Note 2. The value is 1 when the USB0_VBUS pin is high and 0 when the USB0_VBUS pin is low.
Note 3. The value is 000b when the MCU is reset and 001b after a USB bus reset.
Note 4. To clear the VBINT, RESM, SOFR, DVST, CTRT, or VALID flag, write 0 only to the flags to be cleared; write 1 to the other flags. Do not write 0 to the status flags indicating 0.
Note 5. The status of the RESM, DVST, and CTRT flags are changed only when the function controller is selected. Set the corresponding interrupt enable bits to 0 (disabled) when the host controller is selected.
Note 6. A change in the status indicated by the VBINT and RESM flags can be detected even while the clock supply is stopped (the SCKE bit = 0), and the interrupts are output when the corresponding interrupt enable bits are enabled. Clearing the status through software should be done after enabling the clock supply.

CTSQ[2:0] Flags (Control Transfer Stage Flag)

When the host controller is selected, the read value is invalid.

VALID Flag (USB Request Reception Flag)

When the host controller is selected, the read value is invalid.

DVSQ[2:0] Flags (Device State Flag)

The DVSQ[2:0] flags are initialized by a USB bus reset.
When the host controller is selected, the read value is invalid.

BRDY Flag (Buffer Ready Interrupt Status Flag)

Indicates the BRDY interrupt status.
The USB sets the BRDY flag to 1 when at least one PIPEnBRDY flag (n = 0 to 9) is set to 1 among the PIPEnBRDY flags. These bits correspond to the BRDYENB.PIPEnBRDYE bits (n = 0 to 9) to which 1 has been set, when the USB detects the BRDY interrupt status in at least one pipe among the pipes for which the BRDY interrupt output is enabled by software.
For the conditions for PIPEnBRDY status assertion, refer to section 38.3.3.1, BRDY Interrupt.
The USB sets the BRDY flag to 0 when 0 is written by software to all the PIPEnBRDY flags corresponding to the PIPEnBRDYE bits that have been set to 1.
The BRDY flag cannot be set to 0 even if 0 is written to this bit by software.

NRDY Flag (Buffer Not Ready Interrupt Status Flag)

The USB sets the NRDY flag to 1 when at least one PIPEnNRDY flag (n = 0 to 9) is set to 1 among the PIPEnNRDY flags corresponding to the PIPEnNRDYE bits (n = 0 to 9) to which 1 has been set (when the USB detects the NRDY interrupt status in at least one pipe among the pipes for which software enables the NRDY interrupt output).
For the conditions for PIPEnNRDY status assertion, refer to section 38.3.3.2, NRDY Interrupt.
The USB sets the NRDY flag to 0 when 0 is written by software to all the PIPEnNRDY flags corresponding to the PIPEnNRDYE bits that have been set to 1.
The NRDY flag cannot be set to 0 even if 0 is written to this bit by software.

BEMP Flag (Buffer Empty Interrupt Status Flag)

The USB sets the BEMP flag to 1 when at least one PIPEnBEMP flag (n = 0 to 9) is set to 1 among the PIPEnBEMP flags corresponding to the PIPEnBEMPE bits (n = 0 to 9) to which 1 has been set (when the USB detects the BEMP interrupt status in at least one pipe among the pipes for which the BEMP interrupt output is enabled by software).
For the conditions for PIPEnBEMP status assertion, refer to section 38.3.3.3, BEMP Interrupt.
The USB sets the BEMP flag to 0 when 0 is written by software to all the PIPEnBEMP flags corresponding to the PIPEnBEMPE bits that have been set to 1.
The BEMP flag cannot be set to 0 even if 0 is written to this bit by software.

CTRT Flag (Control Transfer Stage Transition Interrupt Status Flag)

When the function controller is selected, the USB updates the value of the CTSQ[2:0] flags and sets the CTRT flag to 1 on detecting a change in the control transfer stage.
When a control transfer stage transition interrupt is generated, clear the status before the USB detects the next control transfer stage transition.
When the host controller is selected, the read value is invalid.

DVST Flag (Device State Transition Interrupt Status Flag)

When the function controller is selected, the USB updates the DVSQ[2:0] value and sets the DVST flag to 1 on detecting a change in the device state.
When a device state transition interrupt is generated, clear the status before the USB detects the next device state transition.
When the host controller is selected, the read value is invalid.

SOFR Flag (Frame Number Refresh Interrupt Status Flag)

(1) When the host controller is selected
The USB sets the SOFR flag to 1 on updating the frame number when the DVSTCTR0.UACT bit has been set to 1 by software. (A frame number refresh interrupt is detected every 1 ms.)
(2) When the function controller is selected
The USB sets the SOFR flag to 1 on updating the frame number. (A frame number refresh interrupt is detected every 1 ms.)
The USB can detect an SOFR interrupt through the internal interpolation function even when a damaged SOF packet is received from the USB host.

RESM Flag (Resume Interrupt Status Flag)

When the function controller is selected, the USB sets the RESM flag to 1 on detecting the falling edge of the signal on the USB0_DP pin in the suspended state (DVSQ[2:0] = 1xxb).
When the host controller is selected, the read value is invalid.

VBINT Flag (VBUS Interrupt Status Flag)

The USB sets the VBINT flag to 1 on detecting a level change (high to low or low to high) in the USB0_VBUS pin input value. The USB sets the VBSTS flag to indicate the USB0_VBUS pin input value. When the VBUS interrupt is generated, use software to repeat reading the VBSTS flag until the same value is read three or more times, and eliminate chattering.

38.2.14 Interrupt Status Register 1 (INTSTS1)

Address(es): 000A 0042h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	SACK	Setup Transaction Normal Response Interrupt Status Flag	0: SACK interrupts are not generated. 1: SACK interrupts are generated.	R/W *1
b5	SIGN	Setup Transaction Error Interrupt Status Flag	0: SIGN interrupts are not generated. 1: SIGN interrupts are generated.	R/W *1
b6	EOFERR	EOF Error Detection Interrupt Status Flag	0: EOFERR interrupts are not generated. 1: EOFERR interrupts are generated.	R/W *1
b10 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11	ATTCH	ATTCH Interrupt Status Flag	0: ATTCH interrupts are not generated. 1: ATTCH interrupts are generated.	R/W *1
b12	DTCH	USB Disconnection Detection Interrupt Status Flag	0: DTCH interrupts are not generated. 1: DTCH interrupts are generated.	R/W *1
b13	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b14	BCHG	USB Bus Change Interrupt Status Flag *2	0: BCHG interrupts are not generated. 1: BCHG interrupts are generated.	R/W *1
b15	OVRCR	Overcurrent Input Change Interrupt Status Flag*2	0: OVRCR interrupts are not generated. 1: OVRCR interrupts are generated.	R/W *1

Note 1. To clear the status indicated by the flags in the INTSTS1 register, write 0 only to the flags to be cleared; write 1 to the other flags.

Note 2. A change in the status indicated by the OVRCR or BCHG flag can be detected even while the clock supply is stopped (while the SYSCFG.SCKE bit = 0), and the interrupt is output when the corresponding interrupt enable bit is enabled. Clearing the status through software should be done after setting the SYSCFG.SCKE bit to 1.
No interrupts other than those indicated by the BCHG and OVRCR flags can be detected while the clock supply is stopped (while the SYSCFG.SCKE bit = 0).

The INTSTS1 register is used to confirm the status of each interrupt when the host controller is selected.
The various status change interrupts indicated by the flags in the INTSTS1 register should be enabled only when the host controller is selected.

SACK Flag (Setup Transaction Normal Response Interrupt Status Flag)

Indicates the status of the setup transaction normal response interrupt when the host controller is selected.
The USB detects the SACK interrupt when ACK response is returned from the peripheral device during the setup transactions issued by the USB, and sets the SACK flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the SACK interrupt.
When the function controller is selected, the read value is invalid.

SIGN Flag (Setup Transaction Error Interrupt Status Flag)

Indicates the status of the setup transaction error interrupt when the host controller is selected.
The USB detects the SIGN interrupt when ACK response is not returned from the peripheral device three consecutive times during the setup transactions issued by this module, and sets the SIGN flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the SIGN interrupt.
Specifically, the USB detects the SIGN interrupt when any of the following response conditions occur for three consecutive setup transactions.

- Timeout is detected by the USB when the peripheral device has returned no response.
- A damaged ACK packet is received.
- A handshake other than ACK (NAK, NYET, or STALL) is received.

When the function controller is selected, the read value is invalid.

EOFERR Flag (EOF Error Detection Interrupt Status Flag)

Indicates the status of the EOFERR interrupt when the host controller is selected.
The USB detects the EOFERR interrupt on detecting that communication is not completed at the EOF2 timing prescribed by USB Specification 2.0, and sets the EOFERR flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the EOFERR interrupt.
After detecting the EOFERR interrupt, the USB controls hardware as described below (irrespective of the setting of the corresponding interrupt enable bit). All pipes in which communications are currently carried out for the USB port should be terminated by software and perform re-enumeration of the USB port.

- Modifies the DVSTCTR0.UACT bit for the port in which an EOFERR interrupt has been detected to 0.
- Puts the port in which an EOFERR interrupt has been generated into the idle state.

When the function controller is selected, the read value is invalid.

ATTCH Flag (ATTCH Interrupt Status Flag)

Indicates the status of the ATTCH interrupt when the host controller is selected.
The USB detects the ATTCH interrupt on detecting J-state or K-state of the full-speed or low-speed signal level for 2.5 µs, and sets the ATTCH flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the interrupt.
Specifically, the USB detects the ATTCH interrupt on any of the following conditions.

- K-state, SE0, or SE1 changes to J-state, and J-state continues for 2.5 µs.
- J-state, SE0, or SE1 changes to K-state, and K-state continues for 2.5 µs.

When the function controller is selected, the read value is invalid.

DTCH Flag (USB Disconnection Detection Interrupt Status Flag)

Indicates the status of the USB disconnection detection interrupt when the host controller is selected.
The USB detects the DTCH interrupt on detecting USB bus disconnection, and sets the DTCH flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the interrupt.
The USB detects bus disconnection based on USB Specification 2.0.
After detecting the DTCH interrupt, the USB controls hardware as described below (irrespective of the setting of the corresponding interrupt enable bit). All the pipes in which communications are currently carried out for the USB port should be terminated by software and make a transition to the wait state for bus connection to the USB port (wait state for ATTCH interrupt generation).

- Modifies the DVSTCTR0.UACT bit for the port in which a DTCH interrupt has been detected to 0.
- Puts the port in which a DTCH interrupt has been generated into the idle state.

When the function controller is selected, the read value is invalid.

BCHG Flag (USB Bus Change Interrupt Status Flag)

Indicates the status of the USB bus change interrupt.
The USB detects the BCHG interrupt when a change in the full-speed or low-speed signal level occurs on the USB port (a change from J-state, K-state, or SE0 to J-state, K-state, or SE0), and sets the BCHG flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the interrupt.
The USB sets the LNST[1:0] flags to indicate the current input state of the USB port. When the BCHG interrupt is generated, use software to repeat reading the LNST[1:0] flags until the same value is read three or more times, and eliminate chattering.
A change in the USB bus state can be detected even while the internal clock supply is stopped.
When the function controller is selected, the read value is invalid.

OVRCR Flag (Overcurrent Input Change Interrupt Status Flag)

Indicates the status of the USB0_OVRCURA and USB0_OVRCURB input pin change interrupt.
The USB detects the OVRCR interrupt when a change (high to low or low to high) occurs in at least one of the input values to the USB0_OVRCURA and USB0_OVRCURB pins, and sets the OVRCR flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the interrupt.

38.2.15 BRDY Interrupt Status Register (BRDYSTS)

Address(es): 000A 0046h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPE9BRDY	PIPE8BRDY	PIPE7BRDY	PIPE6BRDY	PIPE5BRDY	PIPE4BRDY	PIPE3BRDY	PIPE2BRDY	PIPE1BRDY	PIPE0BRDY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PIPE0BRDY	BRDY Interrupt Status Flag for PIPE0*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b1	PIPE1BRDY	BRDY Interrupt Status Flag for PIPE1*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b2	PIPE2BRDY	BRDY Interrupt Status Flag for PIPE2*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b3	PIPE3BRDY	BRDY Interrupt Status Flag for PIPE3*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b4	PIPE4BRDY	BRDY Interrupt Status Flag for PIPE4*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b5	PIPE5BRDY	BRDY Interrupt Status Flag for PIPE5*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b6	PIPE6BRDY	BRDY Interrupt Status Flag for PIPE6*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b7	PIPE7BRDY	BRDY Interrupt Status Flag for PIPE7*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b8	PIPE8BRDY	BRDY Interrupt Status Flag for PIPE8*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b9	PIPE9BRDY	BRDY Interrupt Status Flag for PIPE9*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. When the SOFCFG.BRDYM bit is set to 0, to clear the status indicated by the flags in the BRDYSTS register, write 0 only to the flags to be cleared; write 1 to the other flags.

Note 2. When the SOFCFG.BRDYM bit is set to 0, clearing BRDY Interrupts should be done before accessing the FIFO.

38.2.16 NRDY Interrupt Status Register (NRDYSTS)

Address(es): 000A 0048h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPE9NRDY	PIPE8NRDY	PIPE7NRDY	PIPE6NRDY	PIPE5NRDY	PIPE4NRDY	PIPE3NRDY	PIPE2NRDY	PIPE1NRDY	PIPE0NRDY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PIPE0NRDY	NRDY Interrupt Status Flag for PIPE0	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b1	PIPE1NRDY	NRDY Interrupt Status Flag for PIPE1	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b2	PIPE2NRDY	NRDY Interrupt Status Flag for PIPE2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b3	PIPE3NRDY	NRDY Interrupt Status Flag for PIPE3	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b4	PIPE4NRDY	NRDY Interrupt Status Flag for PIPE4	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b5	PIPE5NRDY	NRDY Interrupt Status Flag for PIPE5	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b6	PIPE6NRDY	NRDY Interrupt Status Flag for PIPE6	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b7	PIPE7NRDY	NRDY Interrupt Status Flag for PIPE7	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b8	PIPE8NRDY	NRDY Interrupt Status Flag for PIPE8	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b9	PIPE9NRDY	NRDY Interrupt Status Flag for PIPE9	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. To clear the status indicated by the flags in the NRDYSTS register, write 0 only to the flags to be cleared; write 1 to the other flags.

38.2.17 BEMP Interrupt Status Register (BEMPSTS)

Address(es): 000A 004Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPE9BEMP	PIPE8BEMP	PIPE7BEMP	PIPE6BEMP	PIPE5BEMP	PIPE4BEMP	PIPE3BEMP	PIPE2BEMP	PIPE1BEMP	PIPE0BEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PIPE0BEMP	BEMP Interrupt Status Flag for PIPE0	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b1	PIPE1BEMP	BEMP Interrupt Status Flag for PIPE1	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b2	PIPE2BEMP	BEMP Interrupt Status Flag for PIPE2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b3	PIPE3BEMP	BEMP Interrupt Status Flag for PIPE3	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b4	PIPE4BEMP	BEMP Interrupt Status Flag for PIPE4	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b5	PIPE5BEMP	BEMP Interrupt Status Flag for PIPE5	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b6	PIPE6BEMP	BEMP Interrupt Status Flag for PIPE6	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b7	PIPE7BEMP	BEMP Interrupt Status Flag for PIPE7	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b8	PIPE8BEMP	BEMP Interrupt Status Flag for PIPE8	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b9	PIPE9BEMP	BEMP Interrupt Status Flag for PIPE9	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. To clear the status indicated by the flags in the BEMPSTS register, write 0 only to the flags to be cleared; write 1 to the other flags.

38.2.18 Frame Number Register (FRMNUM)

Address(es): 000A 004Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVRN	CRCE	—	—	—	FRNM[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b10 to b0	FRNM[10:0]	Frame Number Flag	Latest frame number	R
b13 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	CRCE	Receive Data Error Flag	0: No error 1: An error occurred	R/W*1
b15	OVRN	Overrun/Underrun Detection Status Flag	0: No error 1: An error occurred	R/W*1

Note 1. To clear the status, write 0 only to the bits to be cleared; write 1 to the other bits.

FRNM[10:0] Flags (Frame Number Flag)

These bits indicate the latest frame number for the USB after the issuing of an SOF packet every 1 ms or writing to the FRNM[10:0] flags at the SOF packet reception.

CRCE Flag (Receive Data Error Flag)

Indicates whether a CRC error or bit stuffing error has been detected in the pipe during isochronous transfer.
The CRCE flag can be set to 0 by writing 0 to the CRCE flag by software. Here, 1 should be written to the other bits in FRMNUM.
On detecting a CRC error, the USB generates the internal NRDY interrupt request.

OVRN Flag (Overrun/Underrun Detection Status Flag)

Indicates whether an overrun/underrun error has been detected in the pipe during isochronous transfer.
The OVRN flag can be set to 0 by writing 0 to the OVRN flag by software. Here, 1 should be written to the other bits in FRMNUM.

(1) When the host controller is selected

The USB sets the OVRN flag to 1 on any of the following conditions.

- For the isochronous transfer pipe in the transmitting direction, the time to issue an OUT token comes before all the transmit data has been written to the FIFO buffer.
- For the isochronous transfer pipe in the receiving direction, the time to issue an IN token comes when no FIFO buffer planes are empty.

(2) When the function controller is selected

The USB sets the OVRN flag to 1 on any of the following conditions.

- For the isochronous transfer pipe in the transmitting direction, the IN token is received before all the transmit data has been written to the FIFO buffer.
- For the isochronous transfer pipe in the receiving direction, the OUT token is received when no FIFO buffer planes are empty.

38.2.19 Device State Change Register (DVCHGR)

Address(es): 000A 004Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DVCHG	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b14 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	DVCHG	Device State Change	0: Disables the writing to the USBADDR.STSRECOV[3:0] bits and USBADDR.USBADDR[6:0] bits. 1: Enables the writing to the USBADDR.STSRECOV[3:0] bits and USBADDR.USBADDR[6:0] bits.	R/W

For details, refer to section 38.3.1.5, Release from Deep Software Standby Mode Due to USB Suspend/ Resume Interrupts.

38.2.20 USB Address Register (USBADDR)

Address(es): 000A 0050h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	STSRECOV[3:0]				—	USBADDR[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	USBADDR[6:0]	USB Address	When the function controller is selected, these bits indicate the USB address assigned by the host when the SET_ADDRESS request is successfully processed.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b11 to b8	STSRECOV[3:0]	Status Recovery	• Recovery when the function controller is selected b11 b8 1 0 0 1: Return to the full-speed state (bits DVSTCTR0.RHST[2:0] = 010b), bits INTSTS0.DVSQ[2:0] = 001b (Default state) 1 0 1 0: Return to the full-speed state (bits DVSTCTR0.RHST[2:0] = 010b), bits INTSTS0.DVSQ[2:0] = 010b (Address state) 1 0 1 1: Return to the full-speed state (bits DVSTCTR0.RHST[2:0] = 010b), bits INTSTS0.DVSQ[2:0] = 011b (Configured state) Settings other than above are prohibited. • Recovery when the host controller is selected b11 b8 1 0 0 0: Return to the full-speed state (bits DVSTCTR0.RHST[2:0] = 010b) Settings other than above are prohibited.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

USBADDR[6:0] Bits (USB Address)

On detecting the USB bus reset, the USB sets the USBADDR[6:0] bits to 00h.

The writing to these bits is enabled while the DVCHGR.DVCHG bits are set to 1. On returning from the USB power shut-off, the operation can resume to the USB address before the shut-off by the software.

When the host controller is selected, the USBADDR[6:0] bits are invalid.

The USBADDR[6:0] bits are initialized when a USB bus reset is detected.

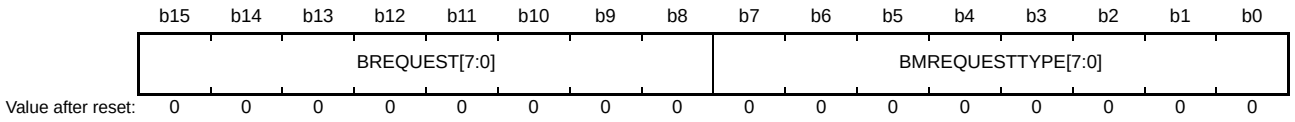
STSRECOV[3:0] Bits (Status Recovery)

These bits are used to resume the state of the internal sequencer on returning from the USB power shut-off. For details, refer to section 38.3.1.5, Release from Deep Software Standby Mode Due to USB Suspend/Resume Interrupts.

The writing to the STSRECOV[3:0] bits is enabled while the DVCHGR.DVCHG bit is set to 1.

38.2.21 USB Request Type Register (USBREQ)

Address(es): 000A 0054h



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	BMREQUESTTYPE[7:0]	Request Type	These bits store the USB request bmRequestType value.	R/W *1
b15 to b8	BREQUEST[7:0]	Request	These bits store the USB request bRequest value.	R/W *1

Note 1. When the function controller is selected, these bits can only be read from, and writing to these bits is invalid. When the host controller is selected, these bits can be read from and written to.

The USBREQ register stores setup requests for control transfers.
When the function controller is selected, the values of bRequest and bmRequestType that have been received are stored.
When the host controller is selected, the values of bRequest and bmRequestType to be transmitted are set.
The USBREQ register is initialized by a USB bus reset.

BMREQUESTTYPE[7:0] Bits (Request Type)

These bits hold the value of the bmRequestType field of a USB request.

- When the host controller is selected:
  Set these bits to the value of the USB request data in setup transactions for transmission. Do not overwrite the value of the BMREQUESTTYPE[7:0] bits while the DCPCTR.SUREQ bit = 1.
- When the function controller is selected:
  These bits indicate the value of the USB request data in setup transactions for reception. Writing to the bits has no effect.

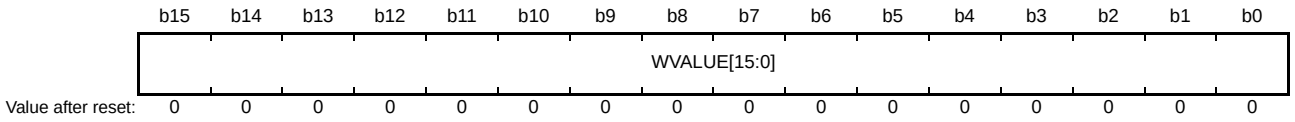
BREQUEST[7:0] Bits (Request)

These bits store bRequest value of the USB request.

- When the host controller is selected:
  Set these bits to the value of the USB request data in setup transactions for transmission. Do not overwrite the value of the BREQUEST[7:0] bits while the DCPCTR.SUREQ bit = 1.
- When the function controller is selected:
  These bits indicate the value of the USB request data in setup transactions for reception. Writing to the bits has no effect.

38.2.22 USB Request Value Register (USBVAL)

Address(es): 000A 0056h



Bit	Symbol	Bit Name	Description	R/W
b15 to b0	WVALUE[15:0]	Value	These bits store the USB request wValue value.	R/W *1

Note 1. When the function controller is selected, these bits can only be read from, and writing to these bits is invalid. When the host controller is selected, these bits can be read from and written to.

When the function controller is selected, the value of wValue that has been received is stored in the USBVAL register.
When the host controller is selected, the value of wValue to be transmitted is set.
The USBVAL register is initialized by a USB bus reset.

WVALUE[15:0] Bits (Value)

These bits store wRequest value of the USB request.

- When the host controller is selected:
  Set these bits to the value of the wValue field in USB requests of setup transactions for transmission. Do not overwrite the value of the WVALUE[15:0] bits while the DCPCTR.SUREQ bit = 1.
- When the function controller is selected:
  These bits indicate the value of the wValue field in USB requests received in setup transactions for reception. Writing to the WVALUE[15:0] bits has no effect.

38.2.23 USB Request Index Register (USBINDX)

Address(es): 000A 0058h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WINDEX[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	WINDEX[15:0]	Index	These bits store the USB request wIndex value.	R/W *1

Note 1. When the function controller is selected, these bits can only be read from, and writing to these bits is invalid. When the host controller is selected, these bits can be read from and written to.

The USBINDX register stores setup requests for control transfers.
When the function controller is selected, the value of wIndex that has been received is stored. When the host controller is selected, the value of wIndex to be transmitted is set.
The USBINDX register is initialized by a USB bus reset.

WINDEX[15:0] Bits (Index)

These bits hold the value of the wIndex field of a USB request.

- When the host controller is selected:
  Set these bits to the value of the wIndex field in USB requests of setup transactions for transmission. Do not overwrite the value of the WINDEX[15:0] bits while the DCPCTR.SUREQ bit = 1.
- When the function controller is selected:
  These bits indicate the value of the wIndex field in USB requests received in setup transactions for reception. Writing to the WINDEX[15:0] bits has no effect.

38.2.24 USB Request Length Register (USBLENG)

Address(es): 000A 005Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WLENGTH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	WLENGTH[15:0]	Length	These bits store the USB request wLength value.	R/W *1

Note 1. When the function controller is selected, these bits can only be read from, and writing to these bits is invalid. When the host controller is selected, these bits can be read from and written to.

The USBLENG register stores setup requests for control transfers.
When the function controller is selected, the value of wLength that has been received is stored. When the host controller is selected, the value of wLength to be transmitted is set.
The USBLENG register is initialized by a USB bus reset.

WLENGTH[15:0] Bits (Length)

These bits hold the value of the wLength field of a USB request.

- When the host controller is selected:
  Set these bits to the value of the wLength field in USB requests of setup transactions for transmission. Do not overwrite the value of the WLENGTH[15:0] bits while the DCPCTR.SUREQ bit = 1.
- When the function controller is selected:
  These bits indicate the value of the wLength field in USB requests received in setup transactions for reception. Writing to the WLENGTH[15:0] bits has no effect.

38.2.25 DCP Configuration Register (DCPCFG)

Address(es): 000A 005Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	SHTNAK	—	—	DIR	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	DIR	Transfer Direction*1	0: Data receiving direction 1: Data transmitting direction	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	SHTNAK	Pipe Disabled at End of Transfer*1	0: Pipe continued at the end of transfer 1: Pipe disabled at the end of transfer	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Modify this bit while DCPCTR.PID[1:0] bits are 00b (NAK). Before modifying this bit after modifying the DCPCTR.PID[1:0] bits for the DCP from 01b (BUF) to 00b (NAK), check that the DCPCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

DIR Bit (Transfer Direction)

When the host controller is selected, the DIR bit sets the transfer direction of the data stage and status stage.
When the function controller is selected, the DIR bit should be set to 0.

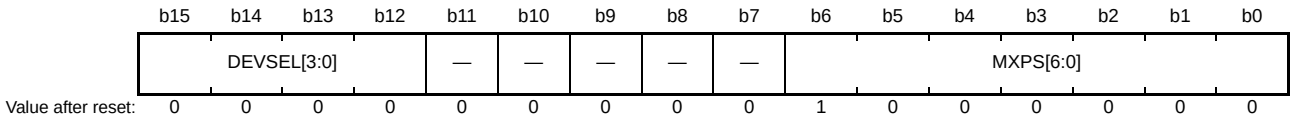
SHTNAK Bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to modify PID[1:0] bits to 00b (NAK) upon the end of transfer when the selected pipe is in the receiving direction.
The SHTNAK bit is valid when the selected pipe in the receiving direction.
When the SHTNAK bit is set to 1, the USB modifies the DCPCTR.PID[1:0] bits for the DCP to 00b (NAK) on determining the end of the transfer. The USB determines that the transfer has ended on the following condition.

- A short packet (including a zero-length packet) is successfully received.

38.2.26 DCP Maximum Packet Size Register (DCPMAXP)

Address(es): 000A 005Eh



Bit	Symbol	Bit Name	Description	R/W
b6 to b0	MXPS[6:0]	Maximum Packet Size*1	These bits set the maximum amount of data (maximum packet size) in payloads for the DCP.	R/W
b11 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b12	DEVSEL[3:0]	Device Select*2	b15 b12 0 0 0 0: Address 0000 0 0 0 1: Address 0001 0 0 1 0: Address 0010 0 0 1 1: Address 0011 0 1 0 0: Address 0100 0 1 0 1: Address 0101 Settings other than above are prohibited.	R/W

Note 1. Modify the MXPS[6:0] bits while PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the DCPCTR.PID[1:0] bits for the DCP from 01b (BUF) to 00b (NAK), check that the DCPCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software. After modifying the MXPS[6:0] bits and the DCP has been set to the CURPIPE[3:0] bits in a port select register, clear the buffer by setting the BCLR bit the port control register to 1.

Note 2. Modify the DEVSEL[3:0] bits while PID[1:0] bits are 00b (NAK) and the DCPCTR.SUREQ bit is 0. To modify these bits after modifying the DCPCTR.PID[1:0] bits for the DCP from 01b (BUF) to 00b (NAK), check that the DCPCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

MXPS[6:0] Bits (Maximum Packet Size)

The MXPS[6:0] bits specify the maximum amount of data (maximum packet size) in payloads for the DCP. The initial value of the bits is 40h (64 bytes).

Ensure that the setting of the MXPS[6:0] bits is in compliance with USB Specification 2.0.

Do not write to the FIFO buffer or set PID[1:0] = 01b (BUF) while the setting of the MXPS[6:0] bits is 0.

DEVSEL[3:0] Bits (Device Select)

When the host controller is selected, these bits specify the address of the peripheral device which is the communication target during control transfer.

The DEVSEL[3:0] bits should be set after setting the address to the DEVADDn (n = 0 to 5) register corresponding to the value to be set in the DEVSEL[3:0] bits. For example, before setting the DEVSEL[3:0] bits to 0010b, the address should be set to DEVADD2.

When the function controller is selected, the DEVSEL[3:0] bits should be set to 0000b.

38.2.27 DCP Control Register (DCPCTR)

Address(es): 000A 0060h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BSTS	SUREQ	—	—	SUREQ CLR	—	—	SQCLR	SQSET	SQMON	PBUSY	—	—	CCPL	PID[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	PID[1:0]	Response PID	b1 b0 0 0: NAK response 0 1: BUF response (depending on the buffer state) 1 0: STALL response 1 1: STALL response	R/W
b2	CCPL	Control Transfer End Enable	0: Invalid 1: Completion of control transfer is enabled.	R/W
b4, b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	PBUSY	Pipe Busy Flag	0: DCP is not used for the transaction. 1: DCP is used for the transaction.	R
b6	SQMON	Sequence Toggle Bit Monitor Flag	0: DATA0 1: DATA1	R
b7	SQSET	Sequence Toggle Bit Set*2	0: Invalid 1: Specifies DATA1.	R/W*1
b8	SQCLR	Sequence Toggle Bit Clear*2	0: Invalid 1: Specifies DATA0.	R/W*1
b10, b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11	SUREQCLR	SUREQ Bit Clear	0: Invalid 1: Clears the SUREQ bit to 0.	R/W
b13, b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	SUREQ	Setup Token Transmission	0: Invalid 1: Transmits the setup packet.	R/W
b15	BSTS	Buffer Status Flag	0: Buffer access is disabled. 1: Buffer access is enabled.	R

Note 1. Only 0 can be read.
Note 2. Write 1 to the SQSET and SQCLR bits while PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the PID[1:0] bits for the DCP from 01b (BUF) to 00b (NAK), check that the PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

PID[1:0] Bits (Response PID)

The PID[1:0] bits control the response type of the USB during control transfer.

(1) When the host controller is selected

Modify the setting of the PID[1:0] bits from 00b (NAK) to 01b (BUF) using the following procedure.

- When the transmitting direction is set
  Write all the transmit data to the FIFO buffer while the DVSTCTR0.UACT bit is 1 and PID[1:0] bits are 00b (NAK), and then write 01b (BUF response). After PID[1:0] have been set to 01b (BUF), the USB executes the OUT transaction.
- When the receiving direction is set
  Check that the FIFO buffer is empty (or empty the buffer) while the DVSTCTR0.UACT bit is 1 and PID[1:0] bits are 00b (NAK), and then set PID[1:0] bits to 01b (BUF). After PID[1:0] bits have been set to 01b (BUF), the USB executes the IN transaction.

The USB modifies the setting of the PID[1:0] bits as follows.

- The USB sets PID[1:0] bits to 11b (STALL) on receiving the data of a size exceeding the maximum packet size when the PID[1:0] bits has been set to 01b (BUF) by software.
- The USB sets PID[1:0] bits to 00b (NAK) on detecting a receive error, such as a CRC error, three consecutive times.
- The USB also sets PID[1:0] bits to 11b (STALL) on receiving the STALL handshake.

(2) When the function controller is selected

The USB modifies the setting of the PID[1:0] bits as follows.

- The USB modifies the PID[1:0] bits to 00b (NAK) on receiving the setup packet. Here, the USB sets the INTSTS0.VALID flag to 1. The setting of the PID[1:0] bits cannot be modified until the VALID flag is set to 0 by software.
- The USB sets PID[1:0] bits to 11b (STALL) on receiving the data of a size exceeding the maximum packet size when the PID[1:0] bits have been set to 01b (BUF) by software.
- The USB sets PID[1:0] bits to 1xb (STALL) on detecting the control transfer sequence error.
- The USB sets PID[1:0] bits to 00b (NAK) on detecting the USB bus reset.

The USB does not check the setting of the PID[1:0] bits while the SET_ADDRESS request is processed.
The PID[1:0] bits are initialized by a USB bus reset.

CCPL Bit (Control Transfer End Enable)

When the function controller is selected, setting the CCPL bit to 1 enables the status stage of the control transfer to be completed.
When the CCPL bit is set to 1 by software while the corresponding PID[1:0] bits are set to 01b (BUF), the USB completes the control transfer status stage.
During control read transfer, the USB transmits the ACK handshake in response to the OUT transaction from the USB host, and transmits the zero-length packet in response to the IN transaction from the USB host during control write or no-data control transfer. However, on detecting the SET_ADDRESS request, the USB operates in auto response mode from the setup stage up to the status stage completion irrespective of the setting of the CCPL bit.
The USB modifies the CCPL bit from 1 to 0 on receiving a new setup packet.
1 cannot be written to the CCPL bit by software while the INTSTS0.VALID flag is 1.
The CCPL bit is initialized by a USB bus reset.
When the host controller is selected, be sure to write 0 to the CCPL bit.

PBUSY Flag (Pipe Busy Flag)

The PBUSY flag indicates whether DCP is used or not for the transaction when USB changes the PID[1:0] bits from 01b (BUF) to 00b (NAK).
The USB modifies the PBUSY flag from 0 to 1 upon start of the USB transaction for the relevant pipe, and modifies the PBUSY flag from 1 to 0 upon completion of one transaction.
Reading the PBUSY flag after the PID[1:0] bits have been set to 00b (NAK) by software allows checking whether modification of the pipe settings is possible.
For details, refer to section 38.3.4.1, Pipe Control Register Switching Procedures.

SQMON Flag (Sequence Toggle Bit Monitor Flag)

The SQMON flag indicates the expected value of the sequence toggle bit for the next transaction during the DCP transfer.
The USB allows the SQMON flag to toggle upon normal completion of the transaction. However, the SQMON flag is not allowed to toggle when a data PID mismatch occurs during the transfer in the receiving direction.
When the function controller is selected, the USB sets the SQMON flag to 1 (specifies DATA1 as the expected value) upon successful reception of the setup packet.
When the function controller is selected, the USB does not reference the SQMON flag during the IN/OUT transaction of the status stage, and does not allow the SQMON flag to toggle upon normal completion.

SQSET Bit (Sequence Toggle Bit Set)

The SQSET bit specifies DATA1 as the expected value of the sequence toggle bit for the next transaction during the DCP transfer.
Do not set the SQCLR and SQSET bits to 1 simultaneously.

SQCLR Bit (Sequence Toggle Bit Clear)

The SQCLR bit specifies DATA0 as the expected value of the sequence toggle bit for the next transaction during the DCP transfer. The SQCLR bit indicates 0.
Do not set the SQCLR and SQSET bits to 1 simultaneously.

SUREQCLR Bit (SUREQ Bit Clear)

When the host controller is selected, setting the SUREQCLR bit to 1 clears the SUREQ bit to 0. The SUREQCLR bit indicates 0.
Set the SUREQCLR bit to 1 through software when communication has stopped with the SUREQ bit being 1 during the setup transaction. However, for normal setup transactions, the USB automatically clears the SUREQ bit to 0 upon completion of the transaction; therefore, clearing the SUREQ bit through software is not necessary.
Controlling the SUREQ bit through the SUREQCLR bit must be done while the DVSTCTR0.UACT bit is 0 and thus communication is halted or while no transfer is being performed with bus disconnection detected.
When the function controller is selected, be sure to write 0 to the SUREQCLR bit.

SUREQ Bit (Setup Token Transmission)

The USB transmits the setup packet by setting the SUREQ bit to 1 when the host controller is selected.
After completing the setup transaction process, the USB generates either the SACK or SIGN interrupt and sets the SUREQ bit to 0.
The USB also sets the SUREQ bit to 0 when software sets the SUREQCLR bit to 1.
Before setting the SUREQ bit to 1, set the DCPMAXP.DEVSEL[3:0] bits, registers USBREQ, USBVAL, USBINDX, and USBLENG appropriately to transmit the desired USB request in the setup transaction. Before setting this bit to 1, check that the PID[1:0] bits for the DCP are set to 00b (NAK). After setting the SUREQ bit to 1, do not modify the DCPMAXP.DEVSEL[3:0] bits, registers USBREQ, USBVAL, USBINDX, or USBLENG until the setup transaction is completed (the SUREQ bit = 1).
Write 1 to the SUREQ bit only when transmitting the setup token; for other purposes, write 0.
When the function controller is selected, be sure to write 0 to the SUREQ bit.

BSTS Flag (Buffer Status Flag)

Indicates whether DCP FIFO buffer access is enabled or disabled.
The meaning of the BSTS flag depends on the setting of ISEL bit in the port select register as shown below.

- When the ISEL bit = 0, the BSTS flag indicates whether the received data can be read from the buffer.
- When the ISEL bit = 1, the BSTS flag indicates whether the data to be transmitted can be written to the buffer.

38.2.28 Pipe Window Select Register (PIPESEL)

Address(es): 000A 0064h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	PIPESEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	PIPESEL[3:0]	Pipe Window Select	b3 b0 0 0 0 0: No pipe selected 0 0 0 1: PIPE1 0 0 1 0: PIPE2 0 0 1 1: PIPE3 0 1 0 0: PIPE4 0 1 0 1: PIPE5 0 1 1 0: PIPE6 0 1 1 1: PIPE7 1 0 0 0: PIPE8 1 0 0 1: PIPE9 Settings other than above are prohibited.	R/W
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

PIPE1 to PIPE 9 should be set using registers PIPESEL, PIPECFG, PIPEMAXP, PIPEPERI, PIPEnCTR, PIPEnTRE, and PIPEnTRN.

After selecting the pipe using the PIPESEL register, functions of the pipe should be set using registers PIPECFG, PIPEMAXP, and PIPEPERI. PIPEnCTR, PIPEnTRE, and PIPEnTRN can be set regardless of the pipe selection in the PIPESEL register.

PIPESEL[3:0] Bits (Pipe Window Select)

The PIPESEL[3:0] bits select the pipe number corresponding to registers PIPECFG, PIPEMAXP, and PIPEPERI which data are written to or read from.

Selecting a pipe number through the PIPESEL[3:0] bits allows writing to and reading from registers PIPECFG, PIPEMAXP, and PIPEPERI which correspond to the selected pipe number.

When PIPESEL[3:0] = 0000b, 0 is read from all of the bits in registers PIPECFG, PIPEMAXP, and PIPEPERI. Writing to these bits is invalid.

38.2.29 Pipe Configuration Register (PIPECFG)

Address(es): 000A 0068h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Note 1. Modify the TYPE[1:0], SHTNAK, and EPNUM[3:0] bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

Note 2. Modify the BFRE, DBLB, and DIR bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK) and before the pipe is selected by the CURPIPE[3:0] bits in the port select register. Before modifying these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), checking the PIPEnCTR.PBUSY flag through software is not necessary.

Note 3. To modify the BFRE, DBLB, and DIR bits after completing USB communication using the selected pipe, write 1 and then 0 to the PIPEnCTR.ACLRM bit continuously through software to clear the FIFO buffer assigned to the selected pipe while the PID[1:0] bits and CURPIPE[3:0] bits are in the state described in the above note 2.

The PIPECFG register specifies the transfer type, buffer memory access direction, and endpoint numbers for PIPE1 to PIPE9. It also selects single or double buffer mode, and whether to continue or disable pipe operation at the end of transfer.

EPNUM[3:0] Bits (Endpoint Number)

The EPNUM[3:0] bits specify the endpoint number for the selected pipe.
Setting 0000b means an unused pipe.
Do not make the settings such that the combination of the settings of the DIR and EPNUM[3:0] bits should be the same for two or more pipes (EPNUM[3:0] bits = 0000b can be set for all of the pipes).

DIR Bit (Transfer Direction)

The DIR bit specifies the transfer direction for the selected pipe.
When the DIR bit has been set to 0 by software, the USB uses the selected pipe in the receiving direction, and when software has set the DIR bit to 1, the USB uses the selected pipe in the transmitting direction.

SHTNAK Bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to modify the PID[1:0] bits to 00b (NAK) upon the end of transfer when the selected pipe is in the receiving direction.
The SHTNAK bit is valid when the selected pipe is PIPE1 to PIPE5 in the receiving direction.
When the SHTNAK bit has been set to 1 by software for the selected pipe in the receiving direction, the USB modifies the PIPEnCTR.PID[1:0] bits corresponding to the selected pipe to 00b (NAK) on determining the end of the transfer. The USB determines that the transfer has ended on any of the following conditions.

- A short packet (including a zero-length packet) is successfully received.
- The transaction counter is used and the number of packets specified by the counter are successfully received.

DBLB Bit (Double Buffer Mode)

The DBLB bit selects either single or double buffer mode for the FIFO buffer used by the selected pipe.
The DBLB bit is valid when PIPE1 to PIPE5 are selected.

BFRE Bit (BRDY Interrupt Operation Specification)

The BFRE bit specifies the BRDY interrupt generation timing from the USB to the CPU with respect to the selected pipe.
When the BFRE bit has been set to 1 by software and the selected pipe is in the receiving direction, the USB detects the transfer completion and generates the BRDY interrupt on having read the relevant packet.
When the BRDY interrupt is generated with the above conditions, 1 should be written to the BCLR bit in the port control register by software. The FIFO buffer assigned to the selected pipe is not enabled for reception until 1 is written to the BCLR bit.
When the BFRE bit has been set to 1 by software and the selected pipe is in the transmitting direction, the USB does not generate the BRDY interrupt.
For details, refer to section 38.3.3.1, BRDY Interrupt.

TYPE[1:0] Bits (Transfer Type)

The TYPE[1:0] bits select the transfer type for the pipe selected by the PIPESEL.PIPESEL[3:0] bits (selected pipe).
Before setting the PID[1:0] bits to 01b (BUF) for the selected pipe (before starting USB communication using the selected pipe), set the TYPE[1:0] bits to a value other than 00b.

38.2.30 Pipe Maximum Packet Size Register (PIPEMAXP)

Address(es): 000A 006Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DEVSEL[3:0]				—	—	—	MXPS[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0/1 *1	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b8 to b0	MXPS[8:0]	Maximum Packet Size*2	• PIPE1 and PIPE2: 1 byte (001h) to 256 bytes (100h) • PIPE3 to PIPE5: 8 bytes (008h), 16 bytes (010h), 32 bytes (020h), 64 bytes (040h) (Bits [8:7] and [2:0] are not provided.) • PIPE6 to PIPE9: 1 byte (001h) to 64 bytes (040h) (Bits [8:7] are not provided.)	R/W
b11 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b12	DEVSEL[3:0]	Device Select*3	b3 b0 0 0 0 0: Address 0000 0 0 0 1: Address 0001 0 0 1 0: Address 0010 0 0 1 1: Address 0011 0 1 0 0: Address 0100 0 1 0 1: Address 0101 Settings other than above are prohibited.	R/W

Note 1. The value of these bits is 0000h when no pipe is selected with the PIPESEL.PIPESEL[3:0] bits and 0040h when a pipe is selected.

Note 2. Modify the MXPS[8:0] bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK) and before the pipe is selected by the CURPIPE[3:0] bits in the port select register. Before modifying these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

Note 3. Modify the DEVSEL[3:0] bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK). To modify these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

The PIPEMAXP register specifies the maximum packet size for PIPE1 to PIPE9.

MXPS[8:0] Bits (Maximum Packet Size)

The MXPS[8:0] bits specify the maximum data payload (maximum packet size) for the selected pipe.

These bits should be set to the appropriate value for each transfer type based on USB Specification 2.0. Note that the maximum value of PIPE1 and PIPE2 is 256. While MXPS[8:0] = 000h, do not write to the FIFO buffer or do not set the PID[1:0] bits to 01b (BUF).

DEVSEL[3:0] Bits (Device Select)

When the host controller is selected, these bits specify the USB device address of the peripheral device which is the communication target.

The DEVSEL[3:0] bits should be set after setting the address to the DEVADDn (n = 0 to 5) register corresponding to the value to be set in the DEVSEL[3:0] bits. For example, before setting the DEVSEL[3:0] bits to 0010b, the address should be set to DEVADD2.

When the function controller is selected, the DEVSEL[3:0] bits should be set to 0000b.

38.2.31 Pipe Cycle Control Register (PIPEPERI)

Address(es): 000A 006Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	IFIS	—	—	—	—	—	—	—	—	—	IITV[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	IITV[2:0]	Interval Error Detection Interval *1	Specify the interval error detection timing for the selected pipe in terms of frames, which is expressed as nth power of 2.	R/W
b11 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	IFIS	Isochronous IN Buffer Flush	0: The buffer is not flushed. 1: The buffer is flushed.	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Modify the IITV[2:0] bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK). To modify these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

The PIPEPERI register selects whether the buffer is flushed or not when an interval error occurred during isochronous IN transfer, and sets the interval error detection interval for PIPE1 to PIPE9.

IITV[2:0] Bits (Interval Error Detection Interval)

Before modifying the IITV[2:0] bits after USB communication has been completed with the IITV[2:0] bits set to a certain value, set the PID[1:0] bits to 00b (NAK) and then set the PIPEnCTR.ACLRM bit to 1 to initialize the interval timer.

The IITV[2:0] bits are invalid for PIPE3 to PIPE5; set the IITV[2:0] bits to 000b for PIPE3 to PIPE5.

IFIS Bit (Isochronous IN Buffer Flush)

Specifies whether to flush the buffer when the pipe selected by the PIPESEL.PIPESEL[3:0] bits (selected pipe) is used for isochronous IN transfers.

When the function controller is selected and the selected pipe is for isochronous IN transfers, the USB automatically clears the FIFO buffer when the USB fails to receive the IN token from the USB host within the interval set by the IITV[2:0] bits in terms of frames.

In double buffer mode (the PIPECFG.DBLB bit = 1), the USB only clears the data in the plane used earlier.

The USB clears the FIFO buffer on receiving the SOF packet immediately after the frame in which the USB has expected to receive the IN token. Even if the SOF packet is damaged, the USB also clears the FIFO buffer at the right timing to receive the SOF packet by using the internal interpolation function.

When the host controller is selected, set the IITV[2:0] bits to 000b.

When the selected pipe is not for isochronous transfer, set the IITV[2:0] bits to 000b.

38.2.32 PIPEn Control Registers (PIPEnCTR) (n = 1 to 9)

- PIPEnCTR (n = 1 to 5)

Address(es): PIPE1CTR 000A 0070h, PIPE2CTR 000A 0072h, PIPE3CTR 000A 0074h, PIPE4CTR 000A 0076h, PIPE5CTR 000A 0078h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	PID[1:0]	Response PID	b1 b0 0 0: NAK response 0 1: BUF response (depending on the buffer state) 1 0: STALL response 1 1: STALL response	R/W
b4 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	PBUSY	Pipe Busy Flag	0: The relevant pipe is not used for the transaction. 1: The relevant pipe is used for the transaction.	R
b6	SQMON	Sequence Toggle Bit Confirmation	0: DATA0 1: DATA1	R
b7	SQSET	Sequence Toggle Bit Set*2	0: Write disabled 1: Specifies DATA1.	R/W*1
b8	SQCLR	Sequence Toggle Bit Clear *2	0: Write disabled 1: Specifies DATA0.	R/W*1
b9	ACLRM	Auto Buffer Clear Mode*3	0: Disabled 1: Enabled (all buffers are initialized)	R/W
b10	ATREPM	Auto Response Mode*2	0: Auto response is disabled. 1: Auto response is enabled.	R/W
b13 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	INBUFM	Transmit Buffer Monitor Flag	0: There is no data to be transmitted in the buffer memory. 1: There is data to be transmitted in the buffer memory.	R
b15	BSTS	Buffer Status Flag	0: Buffer access by the CPU is disabled. 1: Buffer access by the CPU is enabled.	R

Note 1. Only 0 can be read.
Note 2. Modify the ATREPM bit or write 1 to the SQCLR or SQSET bit while the PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.
Note 3. Modify the ACLRM bit while PID[1:0] bits are 00b (NAK) and before the pipe is selected by the CURPIPE[3:0] bits in the port select register. Before modifying this bit after modifying the PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

The PIPEnCTR register can be set regardless of the pipe selection in the PIPESEL register.

PID[1:0] Bits (Response PID)

The PID[1:0] bits specify the response type for the next transaction of the relevant pipe.
The default setting of the PID[1:0] bits are 00b (NAK). Modify the setting of the PID[1:0] bits to 01b (BUF) to use the relevant pipe for USB transfer. Table 38.6 and Table 38.7 show the basic operation (operation when there are no errors in the transmitted and received packets) of the USB depending on the PID[1:0] bit setting.
After modifying the setting of the PID[1:0] bits through software from 01b (BUF) to 00b (NAK) during USB communication using the relevant pipe, check that the PBUSY flag is 1 to see if USB transfer using the relevant pipe has actually entered the NAK state. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.
The USB modifies the setting of the PID[1:0] bits in the following cases.

- The USB sets the PID[1:0] bits to 00b (NAK) on recognizing the completion of the transfer when the relevant pipe is in the receiving direction and the PIPECFG.SHTNAK bit for the selected pipe has been set to 1 by software.
- The USB sets the PID[1:0] bits to 11b (STALL) on receiving a data packet with a payload exceeding the maximum packet size of the relevant pipe.
- The USB sets the PID[1:0] bits to 00b (NAK) on detecting a USB bus reset when the function controller is selected.
- The USB sets the PID[1:0] bits to 00b (NAK) on detecting a receive error, such as a CRC error, three consecutive times when the host controller is selected.
- The USB sets the PID[1:0] bits to 11b (STALL) on receiving the STALL handshake when the host controller is selected.

To specify each response type, set the PID[1:0] bits as follows.

- To make a transition from NAK (00b) to STALL, set 10b.
- To make a transition from BUF (01b) to STALL, set 11b.
- To make a transition from STALL (11b) to NAK, set 10b and then 00b.
- To make a transition from STALL (11b) to BUF, set 10b, 00b, and then 01b.
- To make a transition from STALL (10b) to BUF, set 00b and then 01b.

PBUSY Flag (Pipe Busy Flag)

The PBUSY flag indicates whether the relevant pipe is being currently used or not for the transaction.
The USB modifies the PBUSY flag from 0 to 1 upon start of the USB transaction for the relevant pipe, and modifies the PBUSY flag from 1 to 0 upon completion of one transaction.
Reading the PBUSY flag after the PID[1:0] bits have been set to 00b (NAK) by software allows checking whether modification of the pipe settings is possible.
For details, refer to section 38.3.4.1, Pipe Control Register Switching Procedures.

SQMON Bit (Sequence Toggle Bit Confirmation)

The SQMON flag indicates the expected value of the sequence toggle bit for the next transaction of the relevant pipe.
When the relevant pipe is not for the isochronous transfer, the USB allows the SQMON flag to toggle upon normal completion of the transaction. However, the SQMON flag is not allowed to toggle when a data PID mismatch occurs during the transfer in the receiving direction.

SQSET Bit (Sequence Toggle Bit Set)

The SQSET bit should be set to 1 to set DATA1 as the expected value of the sequence toggle bit for the next transaction of the relevant pipe.
Setting the SQSET bit to 1 through software allows the USB to set DATA1 as the expected value of the sequence toggle bit of the relevant pipe. The USB sets the SQSET bit to 0.

SQCLR Bit (Sequence Toggle Bit Clear)

The SQCLR bit should be set to 1 to clear the expected value (to set DATA0 as the expected value) of the sequence toggle bit for the next transaction of the relevant pipe.
Setting the SQCLR bit to 1 through software allows the USB to set DATA0 as the expected value of the sequence toggle bit of the relevant pipe. The USB sets the SQCLR bit to 0.

ACLRM Bit (Auto Buffer Clear Mode)

Enables or disables auto buffer clear mode for the relevant pipe.
To delete the information in the FIFO buffer assigned to the relevant pipe completely, write 1 and then 0 to the ACLRM bit continuously.
Table 38.8 shows the information cleared by writing 1 and 0 to the ACLRM bit continuously and the cases in which clearing the information is necessary.

ATREPM Bit (Auto Response Mode)

Enables or disables auto response mode for the relevant pipe.
When the function controller is selected and the relevant pipe is for bulk transfer, the ATREPM bit can be set to 1.
When the ATREPM bit is set to 1, the USB responds to the token from the USB host as described below.
(1) When the relevant pipe is for bulk IN transfer (the PIPECFG.TYPE[1:0] bits = 01b and the PIPECFG.DIR bit = 1)
When the ATREPM bit = 1 and PID[1:0] = 01b (BUF), the USB transmits a zero-length packet in response to the IN token.
The USB updates (allows toggling of) the sequence toggle bit (data PID) each time the USB receives ACK from the USB host (in a single transaction, IN token is received, zero-length packet is transmitted, and then ACK is received.).
In this case, the USB does not generate the BRDY or BEMP interrupt.
(2) When the relevant pipe is for bulk OUT transfer (the PIPECFG.TYPE[1:0] bits = 01b and the PIPECFG.DIR bit = 0)
When the ATREPM bit = 1 and PID[1:0] = 01b (BUF), the USB returns NAK in response to the OUT token and generates the NRDY interrupt.
For USB communication in auto response mode, set the ATREPM bit to 1 while the FIFO buffer is empty. Do not write to the FIFO buffer during USB communication in auto response mode.
When the relevant pipe is for isochronous transfer, be sure to set the ATREPM bit to 0.
When the host controller is selected, be sure to set the ATREPM bit to 0.

INBUFM Flag (Transmit Buffer Monitor Flag)

Indicates the relevant FIFO buffer status when the relevant pipe is in the transmitting direction.
When the relevant pipe is in the transmitting direction (the PIPECFG.DIR bit = 1), the USB sets the INBUFM flag to 1 when the CPU or DMAC/DTC completes writing data to at least one FIFO buffer plane.
The USB sets the INBUFM flag to 0 when the USB completes transmitting the data from the FIFO buffer plane to which all the data has been written. In double buffer mode (the PIPECFG.DBLB bit = 1), the USB sets the INBUFM flag to 0 when the USB completes transmitting the data from the two FIFO buffer planes before the CPU or DMAC/DTC completes writing data to one FIFO buffer plane.
The INBUFM flag indicates the same value as the BSTS flag when the relevant pipe is in the receiving direction (the PIPECFG.DIR bit = 0).

BSTS Flag (Buffer Status Flag)

Indicates the FIFO buffer status for the relevant pipe.

The meaning of the BSTS flag depends on the settings of the PIPECFG.DIR bit, PIPECFG.BFRE bit, and DnFIFOSEL.DCLRM bits as shown in Table 38.9.

Table 38.6 Operation of USB depending on PID[1:0] Bits Setting (When Host Controller is Selected)

PID[1:0] Bits	Transfer Type	Transfer Direction (DIR Bit)	Operation of USB
00b (NAK)	Operation does not depend on the setting.	Operation does not depend on the setting.	Does not issue tokens.
01b (BUF)	Bulk or interrupt	Operation does not depend on the setting.	Issues tokens while the DVSTCTR0.UACT bit is 1 and the FIFO buffer corresponding to the relevant pipe is ready for transmission and reception. Does not issue tokens while the DVSTCTR0.UACT bit is 0 or the FIFO buffer corresponding to the relevant pipe is not ready for transmission or reception.
	Isochronous	Operation does not depend on the setting.	Issues tokens irrespective of the status of the FIFO buffer corresponding to the relevant pipe.
10b (STALL) or 11b (STALL)	Operation does not depend on the setting.	Operation does not depend on the setting.	Does not issue tokens.

Table 38.7 Operation of USB depending on PID[1:0] Bits Setting (When Function Controller is Selected)

PID[1:0] Bits	Transfer Type	Transfer Direction (DIR Bit)	Operation of USB
00b (NAK)	Bulk or interrupt	Operation does not depend on the setting.	Returns NAK in response to the token from the USB host.
	Isochronous	Operation does not depend on the setting.	Returns nothing in response to the token from the USB host.
01b (BUF)	Bulk	Receiving direction (DIR bit = 0)	Receives data and returns ACK in response to the OUT token from the USB host if the FIFO buffer corresponding to the relevant pipe is ready for reception.
	Interrupt	Receiving direction (DIR bit = 0)	Receives data and returns ACK in response to the OUT token from the USB host if the FIFO buffer corresponding to the relevant pipe is ready for reception.
	Bulk or interrupt	Transmitting direction (DIR bit = 1)	Transmits data in response to the token from the USB host if the corresponding FIFO buffer is ready for transmission. Returns NAK if not ready.
	Isochronous	Receiving direction (DIR bit = 0)	Receives data in response to the OUT token from the USB host if the FIFO buffer corresponding to the relevant pipe is ready for reception. Discards data if not ready.
	Isochronous	Transmitting direction (DIR bit = 1)	Transmits data in response to the token from the USB host if the corresponding FIFO buffer is ready for transmission. Transmits the zero-length packet if not ready.
10b (STALL) or 11b (STALL)	Bulk or interrupt	Operation does not depend on the setting.	Returns STALL in response to the token from the USB host.
	Isochronous	Operation does not depend on the setting.	Returns nothing in response to the token from the USB host.

Table 38.8 Information Cleared by USB by Setting ACLRM = 1

No.	Information Cleared by ACLRM Bit Manipulation	Cases in which Clearing Information is Necessary
1	All the information in the FIFO buffer assigned to the relevant pipe (both FIFO buffer planes are cleared when double buffer mode is selected)	When the pipe is to be initialized
2	The interval count value when the relevant pipe is for isochronous transfer	When the interval count value is to be reset
3	Internal flags concerning the PIPECFG.BFRE bit	When the PIPECFG.BFRE setting is modified
4	FIFO buffer toggle control	When the PIPECFG.DBLB setting is modified
5	Internal flags concerning the transaction count	When the transaction count function is forcibly terminated

Table 38.9 Operation of BSTS Flag

DIR Bit	BFRE Bit	DCLRM Bit	BSTS Flag Function
0	0	0	The received data can be read from the FIFO buffer. The received data has been completely read from the FIFO buffer.
		1	Setting prohibited
	1	0	The received data can be read from the FIFO buffer. The BCLR bit in the port control register has been set to 1 by software after the received data has been completely read from the FIFO buffer.
		1	The received data can be read from the FIFO buffer. The received data has been completely read from the FIFO buffer.
1	0	0	The transmit data can be written to the FIFO buffer. The transmit data has been completely written to the FIFO buffer.
		1	Setting prohibited
	1	0	Setting prohibited
		1	Setting prohibited

- PIPEnCTR (n = 6 to 9)

Address(es): PIPE6CTR 000A 007Ah, PIPE7CTR 000A 007Ch, PIPE8CTR 000A 007Eh, PIPE9CTR 000A 0080h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	PID[1:0]	Response PID	b1 b0 0 0: NAK response 0 1: BUF response (depending on the buffer state) 1 0: STALL response 1 1: STALL response	R/W
b4 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	PBUSY	Pipe Busy Flag	0: The relevant pipe is not used at the USB bus. 1: The relevant pipe is used at the USB bus.	R
b6	SQMON	Sequence Toggle Bit Confirmation Flag	0: DATA0 1: DATA1	R
b7	SQSET	Sequence Toggle Bit Set*2	0: Invalid 1: Specifies DATA1.	R/W *1
b8	SQCLR	Sequence Toggle Bit Clear *2	0: Invalid 1: Specifies DATA0.	R/W *1
b9	ACLRM	Auto Buffer Clear Mode*2,*3	0: Auto buffer clear mode is disabled. 1: Auto buffer clear mode is enabled (all buffers are initialized)	R/W
b14 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	BSTS	Buffer Status Flag	0: Buffer access is disabled. 1: Buffer access is enabled.	R

Note 1. Only 0 can be read. Only 1 can be written.
Note 2. Write 1 to the SQCLR or SQSET bit while the PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.
Note 3. Modify the ACLRM bit while the PID[1:0] bits are 00b (NAK) and before the pipe is selected by the CURPIPE[3:0] bits in the port select register. Before modifying this bit after modifying the PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

PID[1:0] Bits (Response PID)

The PID[1:0] bits specify the response type for the next transaction of the relevant pipe.
The default setting of the PID[1:0] bits are 00b (NAK). Modify the setting of the PID[1:0] bits to 01b (BUF) to use the relevant pipe for USB transfer. Table 38.6 and Table 38.7 show the basic operation (operation when there are no errors in the transmitted and received packets) of the USB depending on the setting of the PID[1:0] bits.
After modifying the setting of the PID[1:0] bits through software from 01b (BUF) to 00b (NAK) during USB communication using the relevant pipe, check that the PBUSY flag is 1 to see if USB transfer using the relevant pipe has actually entered the NAK state. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.
The USB modifies the setting of the PID[1:0] bits in the following cases.

- The USB sets the PID[1:0] bits to 11b (STALL) on receiving a data packet with a payload exceeding the maximum packet size of the relevant pipe.
- The USB sets the PID[1:0] bits to 00b (NAK) on detecting a USB bus reset when the function controller is selected.
- The USB sets the PID[1:0] bits to 00b (NAK) on detecting a receive error, such as a CRC error, three consecutive times when the host controller is selected.
- The USB sets the PID[1:0] bits to 11b (STALL) on receiving the STALL handshake when the host controller is selected.

To specify each response type, set the PID[1:0] bits as follows.

- To make a transition from NAK (00b) to STALL, set 10b.
- To make a transition from BUF (01b) to STALL, set 11b.
- To make a transition from STALL (11b) to NAK, set 10b and then 00b.
- To make a transition from STALL (11b) to BUF, set 10b, 00b, and then 01b.
- To make a transition from STALL (10b) to BUF, set 00b and then 01b.

PBUSY Flag (Pipe Busy Flag)

The PBUSY flag indicates whether the relevant pipe is being currently used or not for the transaction.
The USB modifies the PBUSY flag from 0 to 1 upon start of the USB transaction for the relevant pipe, and modifies the PBUSY flag from 1 to 0 upon completion of one transaction.
Reading the PBUSY flag after the PID[1:0] bits has been set to 00b (NAK) by software allows checking whether modification of the pipe settings is possible.

SQMON Flag (Sequence Toggle Bit Confirmation Flag)

The SQMON flag indicates the expected value of the sequence toggle bit for the next transaction of the relevant pipe.
The USB allows the SQMON flag to toggle upon normal completion of the transaction. However, the SQMON flag is not allowed to toggle when a data PID mismatch occurs during the transfer in the receiving direction.

SQSET Bit (Sequence Toggle Bit Set)

The SQSET bit should be set to 1 to set DATA1 as the expected value of the sequence toggle bit for the next transaction of the relevant pipe.
Setting the SQSET bit through software allows the USB to set DATA1 as the expected value of the sequence toggle bit of the relevant pipe. The USB sets the SQSET bit to 0.

SQCLR Bit (Sequence Toggle Bit Clear)

The SQCLR bit should be set to 1 to clear the expected value (to set DATA0 as the expected value) of the sequence toggle bit for the next transaction of the relevant pipe.
Setting the SQCLR bit to 1 through software allows the USB to set DATA0 as the expected value of the sequence toggle bit of the relevant pipe. The USB sets the SQCLR bit to 0.

ACLRM Bit (Auto Buffer Clear Mode)

Enables or disables auto buffer clear mode for the relevant pipe.

To delete the information in the FIFO buffer assigned to the relevant pipe completely, write 1 and then 0 to the ACLRM bit continuously.

Table 38.10 shows the information cleared by writing 1 and 0 to the ACLRM bit continuously and the cases in which clearing the information is necessary.

BSTS Flag (Buffer Status Flag)

Indicates the FIFO buffer status for the relevant pipe.

The meaning of the BSTS flag depends on the settings of the PIPECFG.DIR bit, PIPECFG.BFRE bit, and DnFIFOSEL.DCLRM bits as shown in Table 38.9.

Table 38.10 Information Cleared by USB by Setting the ACLRM Bit = 1

No.	Information Cleared by ACLRM Bit Manipulation	Cases in which Clearing Information is Necessary
1	All the information in the FIFO buffer assigned to the selected pipe	When the pipe is to be initialized
2	The interval count value when the selected pipe is for interrupt transfer and the host controller is selected	When the interval count value is to be reset
3	Internal flags concerning the PIPECFG.BFRE bit	When the PIPECFG.BFRE setting is modified
4	Internal flags concerning the transaction count	When the transaction count function is forcibly terminated

38.2.33 PIPEn Transaction Counter Enable Register (PIPEnTRE) (n = 1 to 5)

Address(es): PIPE1TRE 000A 0090h, PIPE2TRE 000A 0094h, PIPE3TRE 000A 0098h, PIPE4TRE 000A 009Ch, PIPE5TRE 000A 00A0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	TRENB	TRCLR	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	TRCLR	Transaction Counter Clear	0: Invalid 1: The current counter value is cleared.	R/W
b9	TRENB	Transaction Counter Enable	0: Transaction counter is disabled. 1: Transaction counter is enabled.	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Modify each bit in the PIPEnTRE register while the PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

TRCLR Bit (Transaction Counter Clear)

Clears the current value of the transaction counter corresponding to the relevant pipe and then sets the TRCLR bit to 0.

TRENB Bit (Transaction Counter Enable)

Enables or disables the transaction counter.

For the pipe in the receiving direction, setting the TRENB bit to 1 after setting the total number of the packets to be received in the PIPEnTRN.TRNCNT[15:0] bits through software allows the USB to control hardware as described below on having received the number of packets equal to the setting of the TRNCNT[15:0] bits.

- While the PIPECFG.SHTNAK bit is 1, the USB modifies the PID[1:0] bits to 00b (NAK) for the corresponding pipe on having received the number of packets equal to the setting of the TRNCNT[15:0] bits.
- While the PIPECFG.BFRE bit is 1, the USB asserts the BRDY interrupt on having received the number of packets equal to the setting of the TRNCNT[15:0] bits and then reading the last received data.

For the pipe in the transmitting direction, set the TRENB bit to 0.

When the transaction counter is not used, set the TRENB bit to 0.

When the transaction counter is used, set the TRNCNT[15:0] bits before setting the TRENB bit to 1. Set the TRENB bit to 1 before receiving the first packet to be counted by the transaction counter.

38.2.34 PIPEn Transaction Counter Register (PIPEnTRN) (n = 1 to 5)

Address(es): PIPE1TRN 000A 0092h, PIPE2TRN 000A 0096h, PIPE3TRN 000A 009Ah, PIPE4TRN 000A 009Eh, PIPE5TRN 000A 00A2h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TRNCNT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TRNCNT[15:0]	Transaction Counter	• When written to: Specifies the total of packets (number of transactions) to be received in corresponding PIPE. • When read from: Indicates the specified number of transactions if the PIPEnTRE.TRENB bit is 0. Indicates the number of currently counted transactions if the PIPEnTRE.TRENB bit is 1.	R/W

The PIPEnTRN register retains the setting by a USB bus reset.

TRNCNT[15:0] Bits (Transaction Counter)

The USB increments the value of the TRNCNT[15:0] bits by one when all of the following conditions are satisfied on receiving the packet.

- The PIPEnTRE.TRENB bit = 1
- (TRNCNT[15:0] set value ≠ current counter value + 1) on receiving the packet.
- The payload of the received packet agrees with the setting of the PIPEMAXP.MXPS[8:0] bits.

The USB sets the value of the TRNCNT[15:0] bits to 0 when any of the following conditions are satisfied.

(1) All of the following conditions are satisfied.

- The PIPEnTRE.TRENB bit = 1
- (TRNCNT[15:0] set value = current counter value + 1) on receiving the packet.
- The payload of the received packet agrees with the setting of the PIPEMAXP.MXPS[8:0] bits.

(2) All of the following conditions are satisfied.

- The PIPEnTRE.TRENB bit = 1
- The USB has received a short packet.

(3) All of the following conditions are satisfied.

- The PIPEnTRE.TRENB bit = 1
- The PIPEnTRE.TRCLR bit has been set to 1 by software.

For the pipe in the transmitting direction, set the TRNCNT[15:0] bits to 0.
When the transaction counter is not used, set the TRNCNT[15:0] bits to 0.
Setting the number of transactions to be transferred to the TRNCNT[15:0] bits is only enabled when the PIPEnTRE.TRENB bit is 0. To modify the number of transactions to be transferred, set the TRCLR bit to 1 (to clear the current counter value) before setting the PIPEnTRE.TRENB bit to 1.

38.2.35 Device Address n Configuration Register (DEVADDn) (n = 0 to 5)

Address(es): DEVADD0 000A 00D0h, DEVADD1 000A 00D2h, DEVADD2 000A 00D4h, DEVADD3 000A 00D6h, DEVADD4 000A 00D8h, DEVADD5 000A 00DAh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	USBSPD[1:0]		—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7, b6	USBSPD[1:0]	Transfer Speed of Communication Target Device	b7 b6 0 0: DEVADDn is not used 0 1: Low-speed 1 0: Full-speed 1 1: Setting prohibited	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The DEVADDn register specifies the transfer speed of the peripheral device which is the communication target for PIPE0 to PIPE9.

When the host controller is selected, the bits in the DEVADDn register should be set before starting communication using each pipe.

The bits in the DEVADDn register should be modified while no valid pipes are using the settings of the bits. Valid pipes refer to the pipes satisfying both of the following conditions:

- The DEVADDn register is selected by the DEVSEL[3:0] bits.
- The PID[1:0] bits are set to 01b (BUF) for the selected pipe or the selected pipe is the DCP with the DCPCTR.SUREQ bit set to 1.

USBSPD[1:0] Bits (Transfer Speed of Communication Target Device)

The USBSPD[1:0] bits specify the USB transfer speed of the communication target peripheral device.

Set these bits to 10b when a full-speed device is connected via the HUB.

When the host controller is selected, the USB refers to the setting of the USBSPD[1:0] bits to generate packets.

When the function controller is selected, set these bits to 00b.

38.2.36 PHY Cross Point Adjustment Register (PHYSLEW)

Address(es): 000A 00F0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	SLEWR00	Driver Cross Point Adjustment 00	0: When the host controller is selected. 1: When the function controller is selected.	R/W
b1	SLEWR01	Driver Cross Point Adjustment 01	0: When the function controller is selected. 1: When the host controller is selected.	R/W
b2	SLEWF00	Driver Cross Point Adjustment 00	Set this bit to 1.	R/W
b3	SLEWF01	Driver Cross Point Adjustment 01	0: When the function controller is selected. 1: When the host controller is selected.	R/W
b31 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The PHYSLEW register adjusts the cross point of the driver.
Set the value (0000000Eh when the host controller is selected or 00000005h when the function controller is selected) to the register before starting the USB operation.

38.2.37 Deep Standby USB Transceiver Control/Pin Monitoring Register (DPUSR0R)

Address(es): 000A 0400h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	SRPC0	USB Single End Receiver Control	0: Input through the D+ and D– inputs is disabled. 1: Input through the D+ and D– inputs is enabled.	R/W
b1	RPUE0*1	D+ Pull-Up Resistor Control	0: Disables D+ pull-up resistor. 1: Enables D+ pull-up resistor.	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	DRPD0*1	D+/D– Pull-Down Resistor Control	0: Disables D+/D– pull-down resistor. 1: Enables D+/D– pull-down resistor.	R/W
b4	FIXPHY0	USB Transceiver Output Fix	0: The outputs are fixed in normal mode and on return from deep software standby mode. 1: The outputs are fixed on transitions to deep software standby mode.	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	DP0	USB D+ Input Flag	Indicates the D+ input signal of the USB.	R
b17	DM0	USB D– Input Flag	Indicates the D– input signal of the USB.	R
b19, b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20	DOVCA0	USB OVRCURA Input Flag	Indicates the OVRCURA input signal of the USB.	R
b21	DOVCB0	USB OVRCURB Input Flag	Indicates the OVRCURB input signal of the USB.	R
b22	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b23	DVBSTS0	USB VBUS Input Flag	Indicates the VBUS input signal of the USB.	R
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Use this bit during operation in deep standby mode. For details, refer to section 38.3.1.5, Release from Deep Software Standby Mode Due to USB Suspend/Resume Interrupts.

SRPC0 Bit (USB Single End Receiver Control)

The SRPC0 bit controls the D+ and D– inputs of the USB transceiver.

This bit is only valid when the FIXPHY0 bit is 1.

FIXPHY0 Bit (USB Transceiver Output Fix)

The FIXPHY0 bit keeps the outputs of the USB transceiver disabled.

38.2.38 Deep Standby USB Suspend/Resume Interrupt Register (DPUSR1R)

Address(es): 000A 0404h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit Name	Description	R/W
b0	DPINTE0	USB D+ Interrupt Enable/Clear	0: Recovery from deep software standby mode is disabled. 1: Recovery from deep software standby mode is enabled.	R/W
b1	DMINTE0	USB D– Interrupt Enable/Clear	0: Recovery from deep software standby mode is disabled. 1: Recovery from deep software standby mode is enabled.	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	DOVRCRAE0	USB OVRCURA Interrupt Enable/Clear	0: Recovery from deep software standby mode is disabled. 1: Recovery from deep software standby mode is enabled.	R/W
b5	DOVRCRBE0	USB OVRCURB Interrupt Enable/Clear	0: Recovery from deep software standby mode is disabled. 1: Recovery from deep software standby mode is enabled.	R/W
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	DVBSE0	USB VBUS Interrupt Enable/Clear	0: Recovery from deep software standby mode is disabled. 1: Recovery from deep software standby mode is enabled.	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	DPINT0	USB D+ Interrupt Source Recovery Flag	0: The system has not returned from deep software standby mode. 1: The system has returned from deep software standby mode.	R
b17	DMINT0	USB D– Interrupt Source Recovery Flag	0: The system has not returned from deep software standby mode. 1: The system has returned from deep software standby mode.	R
b19, b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20	DOVRCRA0	USB OVRCURA Interrupt Source Recovery Flag	0: The system has not returned from deep software standby mode. 1: The system has returned from deep software standby mode.	R
b21	DOVRCRB0	USB OVRCURB Interrupt Source Recovery Flag	0: The system has not returned from deep software standby mode. 1: The system has returned from deep software standby mode.	R
b22	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b23	DVBINT0	USB VBUS Interrupt Source Recovery Flag	0: The system has not returned from deep software standby mode. 1: The system has returned from deep software standby mode.	R
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

DPINTE0 Bit (USB D+ Interrupt Enable/Clear)

This bit enables or disables triggering of recovery from deep software standby mode by the D+ input of the USB. Writing 0 to the DPINTE0 bit while the DPINT0 flag is 1 sets the DPINT0 flag to 0.

DMINTE0 Bit (USB D– Interrupt Enable/Clear)

This bit enables or disables triggering of recovery from deep software standby mode by the D– input of the USB. Writing 0 to the DMINTE0 bit while the DMINT0 flag is 1 sets the DMINT0 flag to 0.

DOVRCRAE0 Bit (USB OVRCURA Interrupt Enable/Clear)

This bit enables or disables triggering of recovery from deep software standby mode by the OVRCURA input of the USB. Writing 0 to the DOVRCRAE0 bit while the DOVRCRA0 flag is 1 sets the DOVRCRA0 flag to 0.

DOVRCRBE0 Bit (USB OVRCURB Interrupt Enable/Clear)

This bit enables or disables triggering of recovery from deep software standby mode by the OVRCURB input of the USB. Writing 0 to the DOVRCRBE0 bit while the DOVRCRB0 flag is 1 sets the DOVRCRB0 flag to 0.

DVBSE0 Bit (USB VBUS Interrupt Enable/Clear)

This bit enables or disables triggering of recovery from deep software standby mode by the VBUS input of the USB. Writing 0 to the DVBSE0 bit while the DVBINT0 flag is 1 sets the DVBINT0 flag to 0.

DPINT0 Flag (USB D+ Interrupt Source Recovery Flag)

This bit indicates that the system has returned from deep software standby mode due to the D+ input of the USB. Recovery from deep software standby mode due to D+ input is only enabled when the DPINTE0 bit is 1.
Writing 0 to the DPINTE0 bit while the DPINT0 flag is 1 sets the DPINT0 flag to 0.

DMINT0 Flag (USB D– Interrupt Source Recovery Flag)

This bit indicates that the system has returned from deep software standby mode due to the D– input of the USB. Recovery from deep software standby mode due to D– input is only enabled when the DMINTE0 bit is 1.
Writing 0 to the DPINTE0 bit while the DMINT0 flag is 1 sets the DMINT0 flag to 0.

DOVRCRA0 Flag (USB OVRCURA Interrupt Source Recovery Flag)

This bit indicates that the system has returned from deep software standby mode due to the OVRCURA input of the USB. Recovery from deep software standby mode due to OVRCURA input is only enabled when the DOVRCRAE0 bit is 1.
Writing 0 to the DOVRCRAE0 bit while the DOVRCRA0 flag is 1 sets the DOVRCRA0 flag to 0.

DOVRCRB0 Flag (USB OVRCURB Interrupt Source Recovery Flag)

This bit indicates that the system has returned from deep software standby mode due to the OVRCURB input of the USB. Recovery from deep software standby mode due to OVRCURB input is only enabled when the DOVRCRBE0 bit is 1.
Writing 0 to the DOVRCRBE0 bit while the DOVRCRB0 flag is 1 sets the DOVRCRB0 flag to 0.

DVBINT0 Flag (USB VBUS Interrupt Source Recovery Flag)

This indicates that the system has returned from deep software standby mode due to the VBUS input of the USB. Recovery from deep software standby mode due to VBUS input is only enabled when the DVBSE0 bit is 1.
Writing 0 to the DVBSE0 bit while the DVBINT0 flag is 1 sets the DVBINT0 flag to 0.

38.3 Operation

38.3.1 System Control

This section describes the register settings that are necessary for initialization of this module and power consumption control.

38.3.1.1 Setting Data to the USB Related Register

Setting the SYSCFG.USBE bit to 1 after starting the clock supply to the USB (SYSCFG.SCKE bit = 1) enables and starts USB operation.

38.3.1.2 Controller Function Selection

For the USB, the host or function controller can be selected using the SYSCFG.DCFM bit. Note that the DCFM bit should be modified in the initial settings immediately after a reset is released or when pulling up of the D+ line and pulling down of the D+ and D– lines are disabled (the SYSCFG.DPRPU bit = 0 and DRPD bit = 0).

38.3.1.3 Controlling USB Data Bus Resistors

The USB has pull-up and pull-down resistors for the D+ and D– lines. Pull up or pull down these lines by setting the SYSCFG.DPRPU and DRPD bits.
When the function controller is selected, confirm that connection to the USB host is made, then set the SYSCFG.DPRPU bit to 1 and pull up the D+ line (during full-speed).
When the SYSCFG.DPRPU bit is set to 1 during communication with the PC, the USB module disables the pull-up resistor of the USB data line, thus notifying the USB host of disconnection.
When the host controller is selected, set the SYSCFG.DRPD bit and pull down the D+ and D– lines.

Table 38.11 USB Data Bus Resistor Control

SYSCFG register				
DRPD bit	**DPRPU bit**	**D–**	**D+**	**Function**
0	0	Open	Open	Not in use
0	1	Open	Pull-up	When operating as the function controller (in full-speed)
1	0	Pull-down	Pull-down	When operating as the host controller
1	1	—	—	Setting prohibited

38.3.1.4 Example of USB External Connection Circuit

Figure 38.2 shows an example of OTG connection of the USB connector in the self-powered state.
The USB controls the signals for enabling a pull-up resistor for the D+ signal and pull-down resistors for the D+ and D– signals. These signals can be pulled up or down using the SYSCFG.DPRPU and SYSCFG.DRPD bits.
When the function controller is selected and the DPRPU bit is set to 0 during communication with the host controller, the pull-up resistor of the USB data line is disabled, making it possible to notify the USB host of the device disconnection.

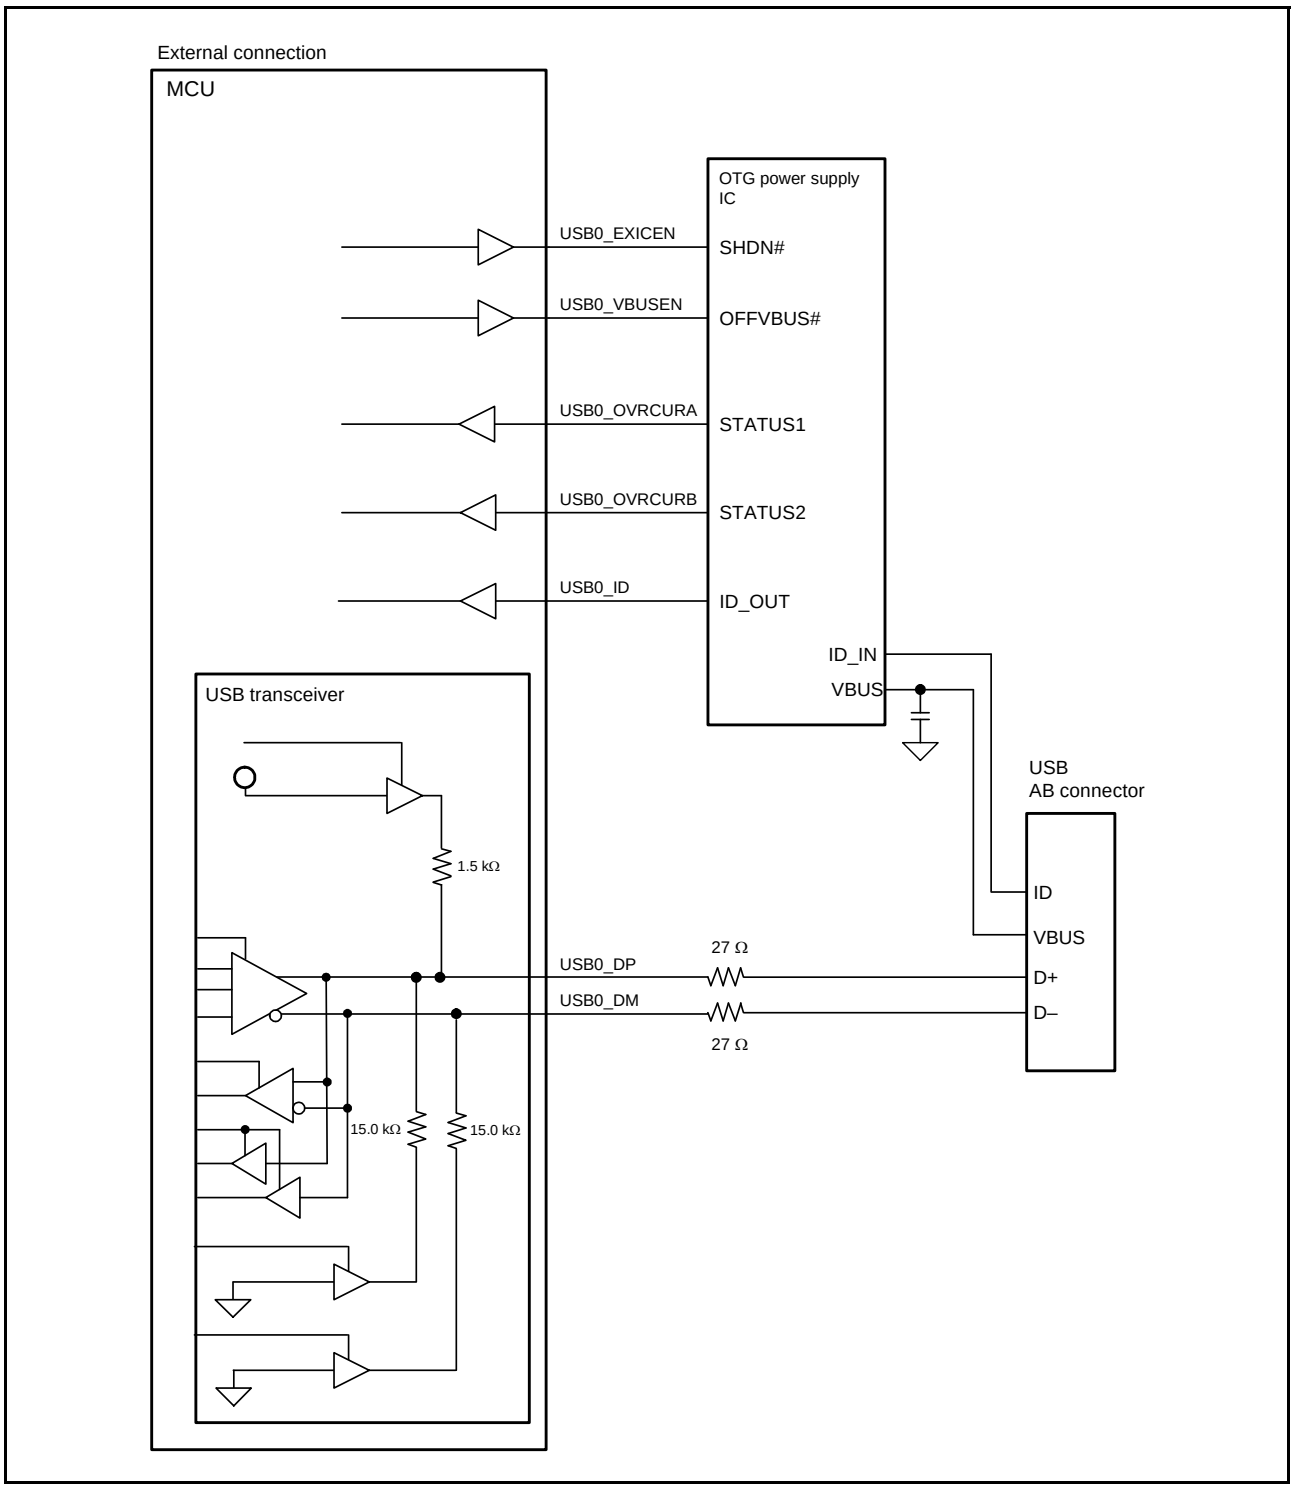

Figure 38.2 Sample OTG Connection of USB Connector in Self-Powered State

Figure 38.3 shows an example of functional connection of the USB connector in the self-powered state.

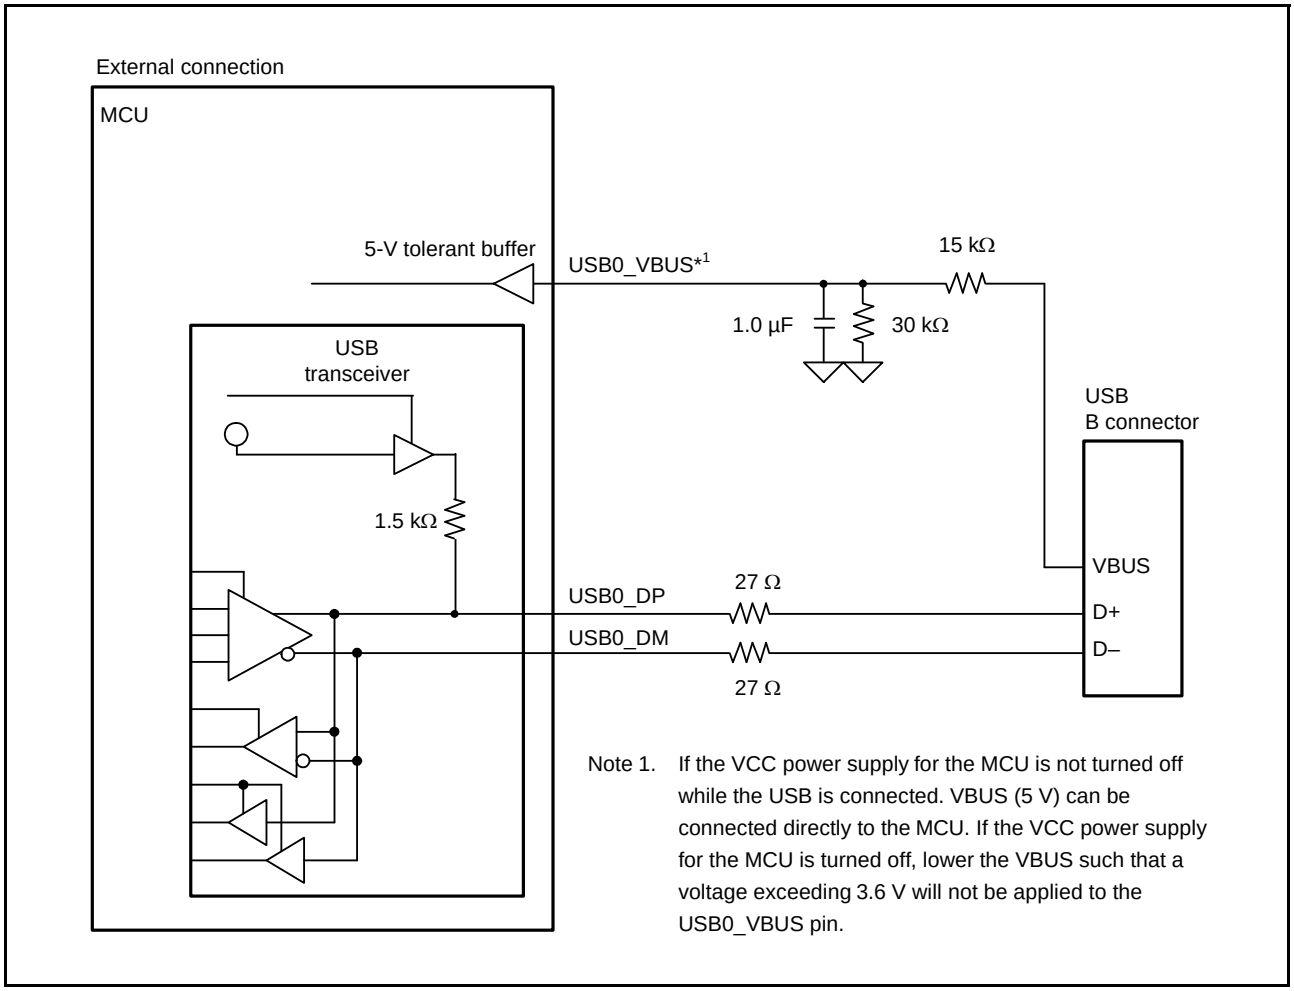

Figure 38.3 Functional Connection of USB Connector in Self-Powered State

Figure 38.4 shows an example of host connection of the USB connector.

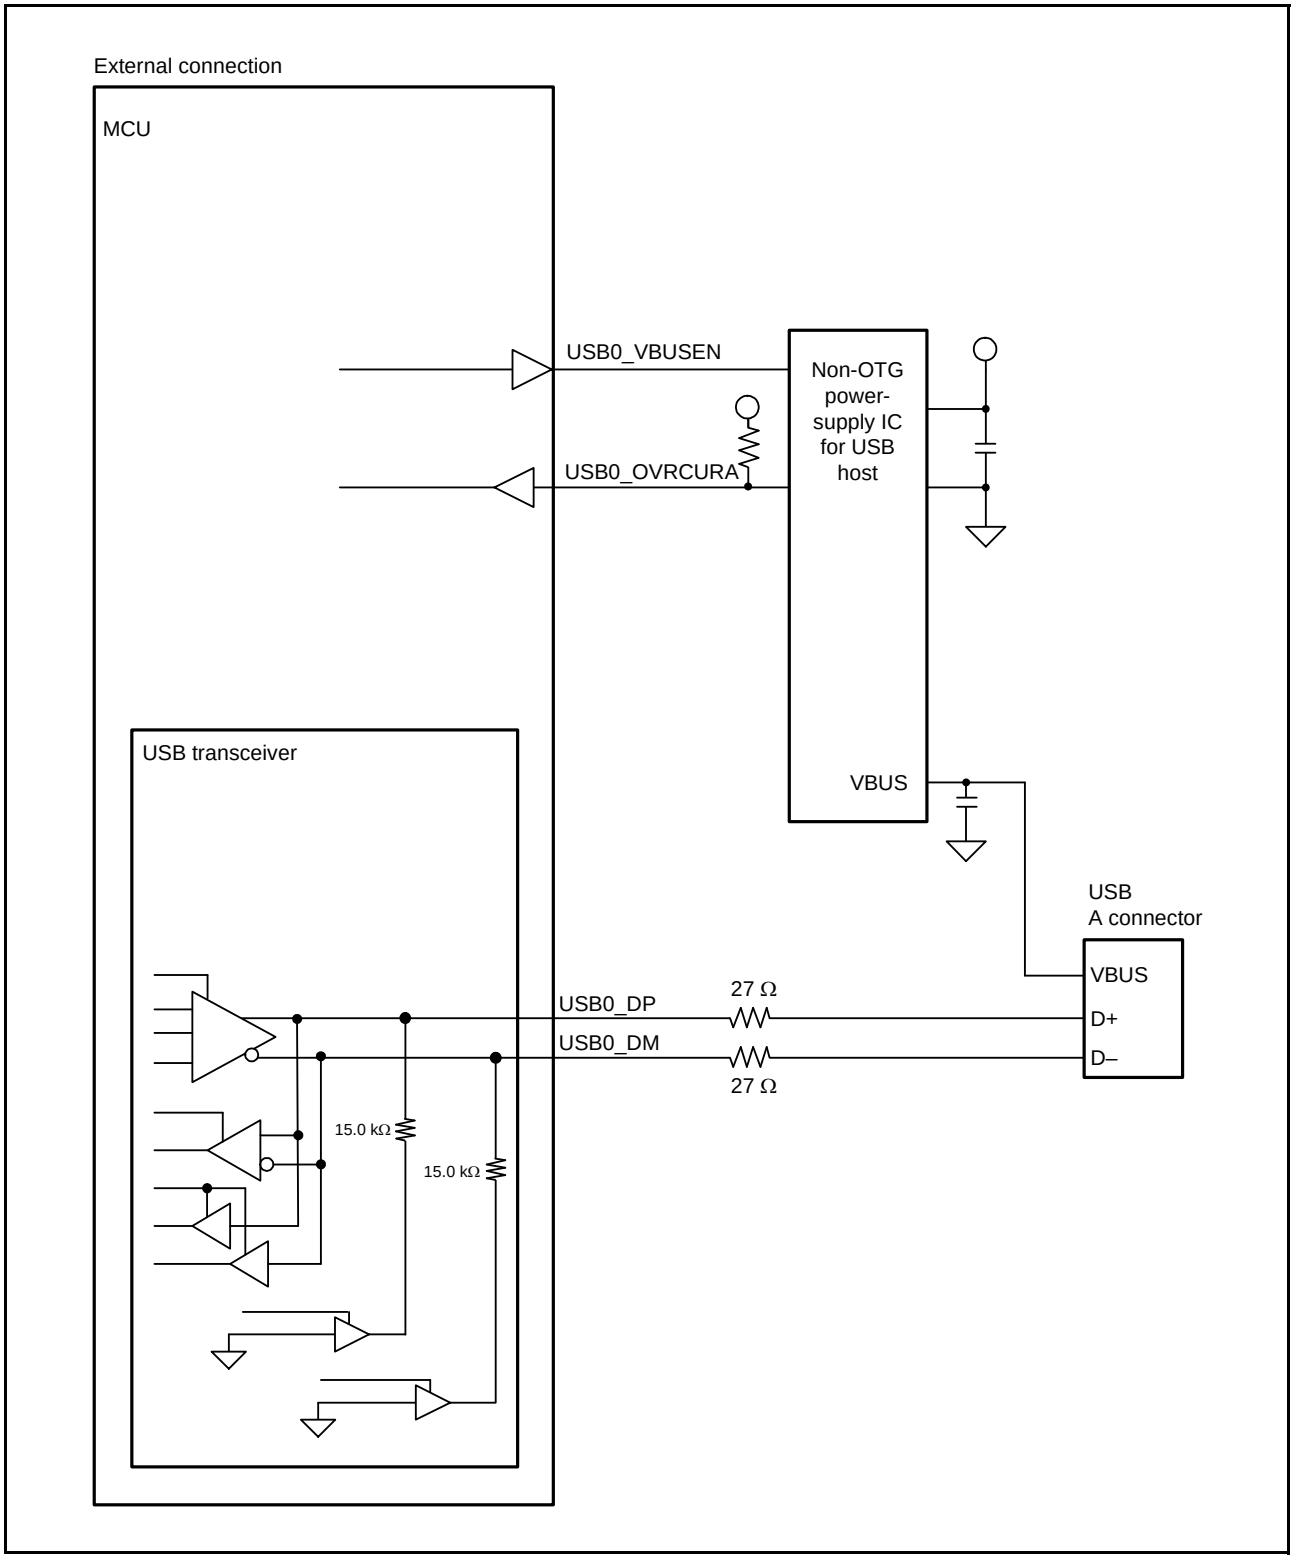

Figure 38.4 Sample Host Connection of USB Connector

Figure 38.5 shows an example of functional connection of the USB connector in bus powered state.

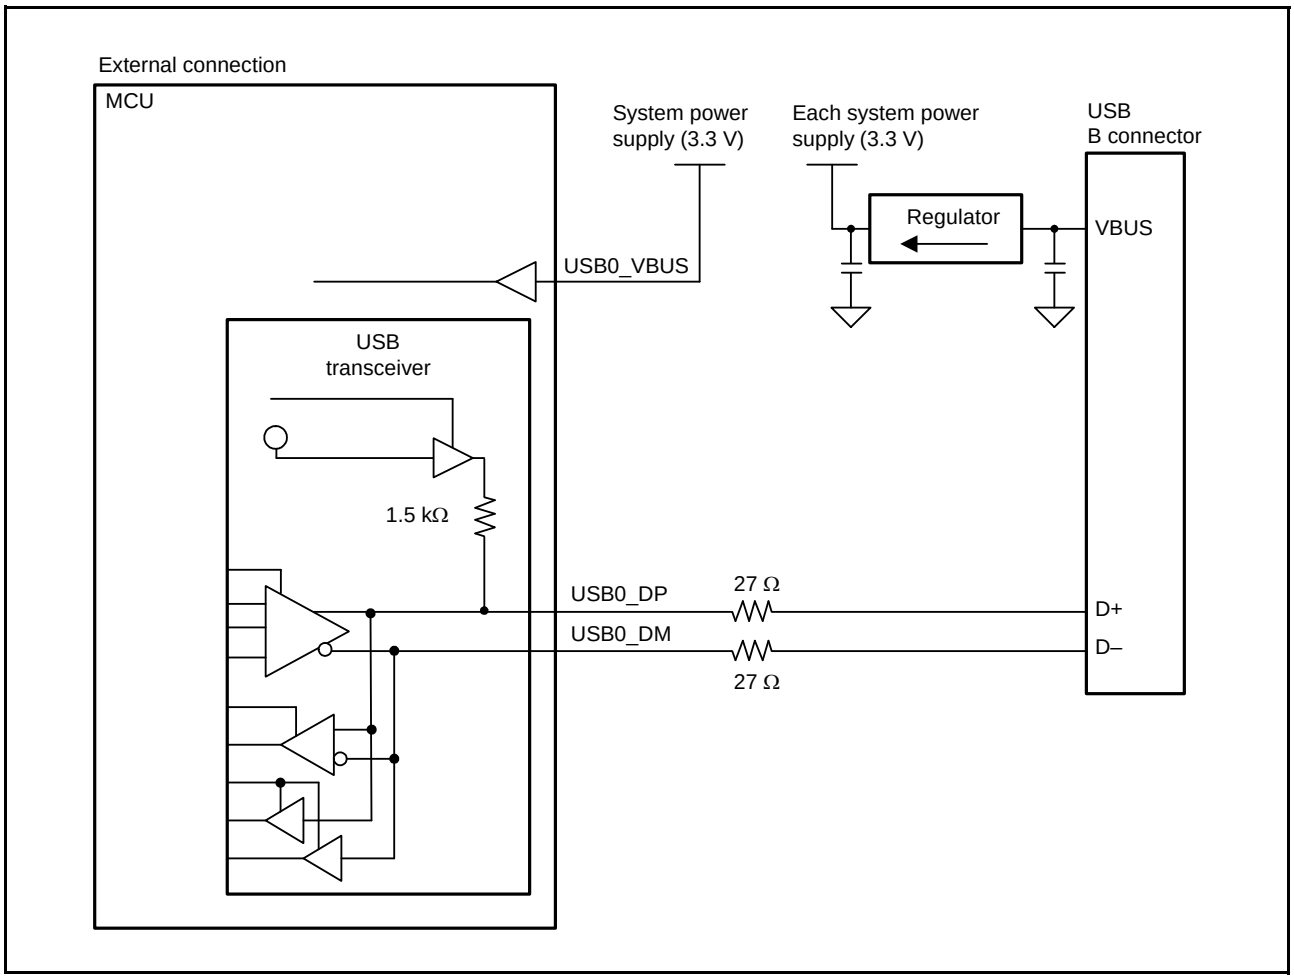

Figure 38.5 Functional Connection Sample of USB Connector in Bus Powered State

The examples of external circuits given in this section are simplified circuits, and their operation in every system is not guaranteed.

38.3.1.5 Release from Deep Software Standby Mode Due to USB Suspend/Resume Interrupts

Deep software standby mode can be canceled by a USB suspend/resume interrupt.
A USB suspend/resume interrupt is detected at the USB resume detecting unit. The USB resume detecting unit controls and monitors the I/O pins for USB to detect USB suspend/resume interrupts.
Figure 38.6 shows a schematic diagram of connection between the USB resume detecting unit and the I/O pins for USB.

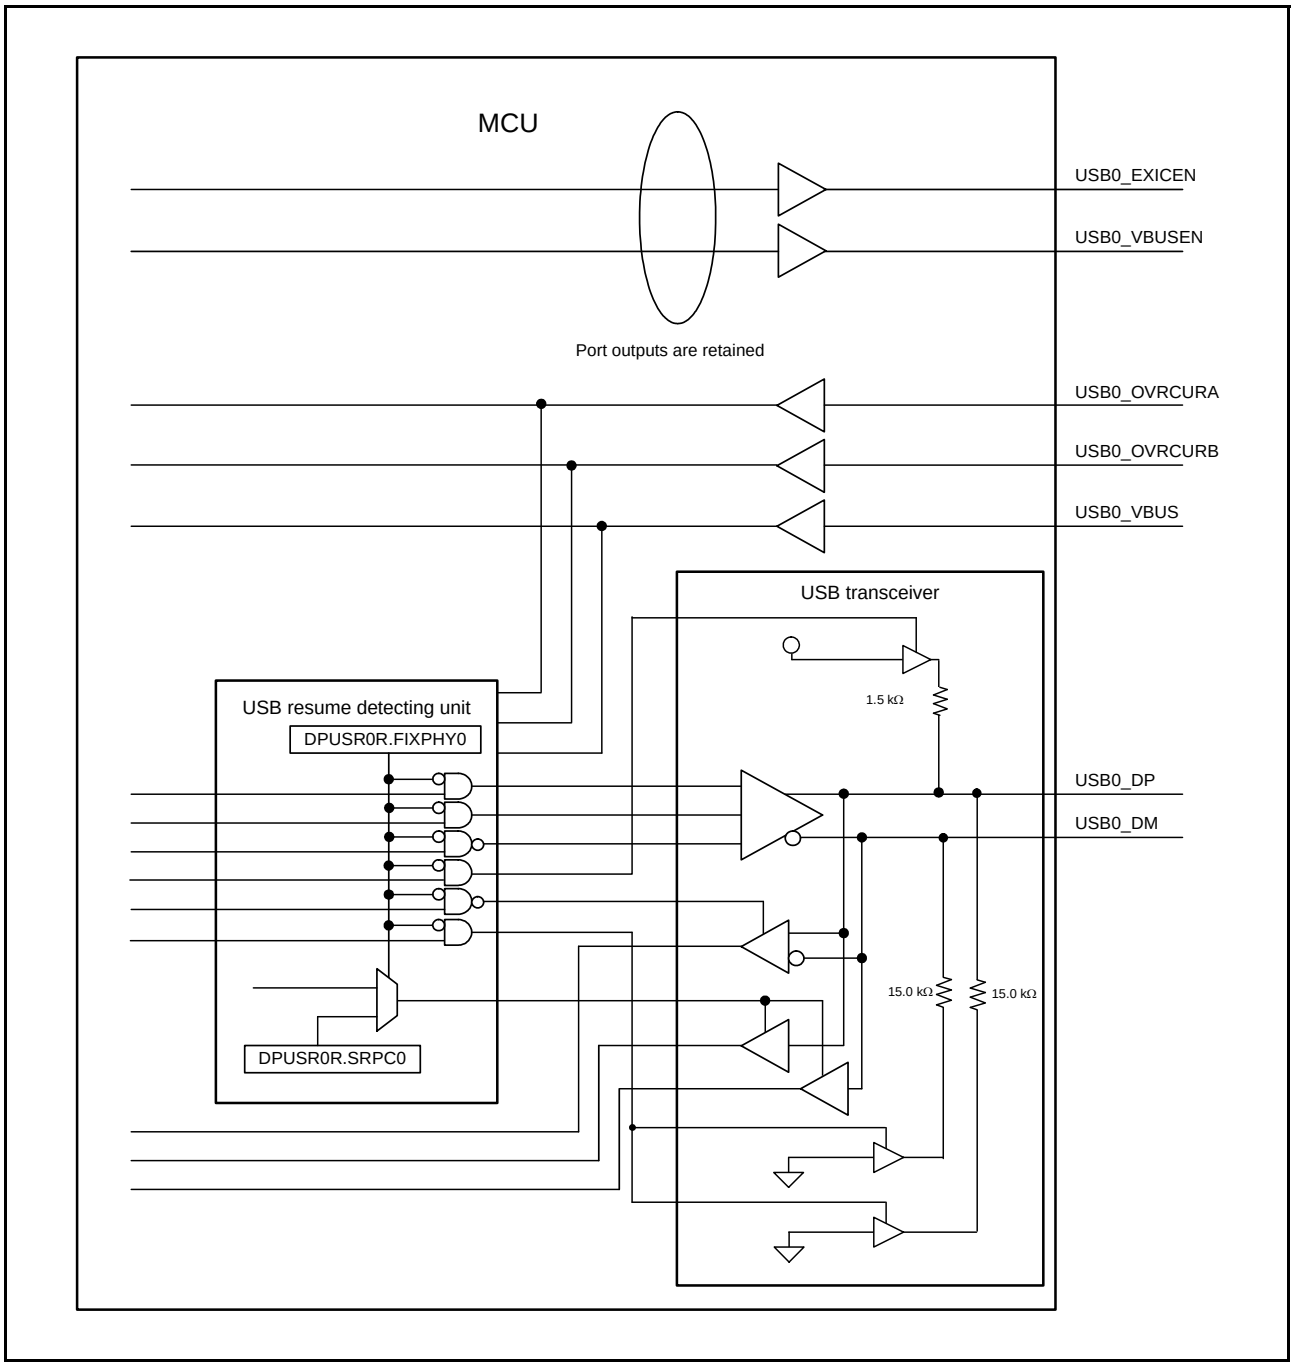

Figure 38.6 Overview of Connection between USB Resume Detecting Unit and USB I/O Pins

Table 38.12 shows the USB suspend/resume interrupt sources and their corresponding I/O pins.

Table 38.12 USB Suspend/Resume Interrupt Sources and Corresponding I/O Pins

USB Operating Mode	Source	Pin Name
Function/OTG	Resume	USB0_DP
Host/OTG	Connection/Disconnection	USB0_DP/USB0_DM
Function	Connection/Disconnection	USB0_VBUS
Host	Overcurrent detection	USB0_OVRCURA
OTG	Overcurrent detection	USB0_OVRCURA/USB0_OVRCURB

Figure 38.7 shows a flowchart for setting the USB when entering deep software standby mode while the host controller or function controller is selected. Figure 38.8 shows a flowchart for setting the USB when canceling deep software standby mode while the host controller is selected. Figure 38.9 shows a flowchart for setting the USB when canceling deep software standby mode while the function controller is selected.

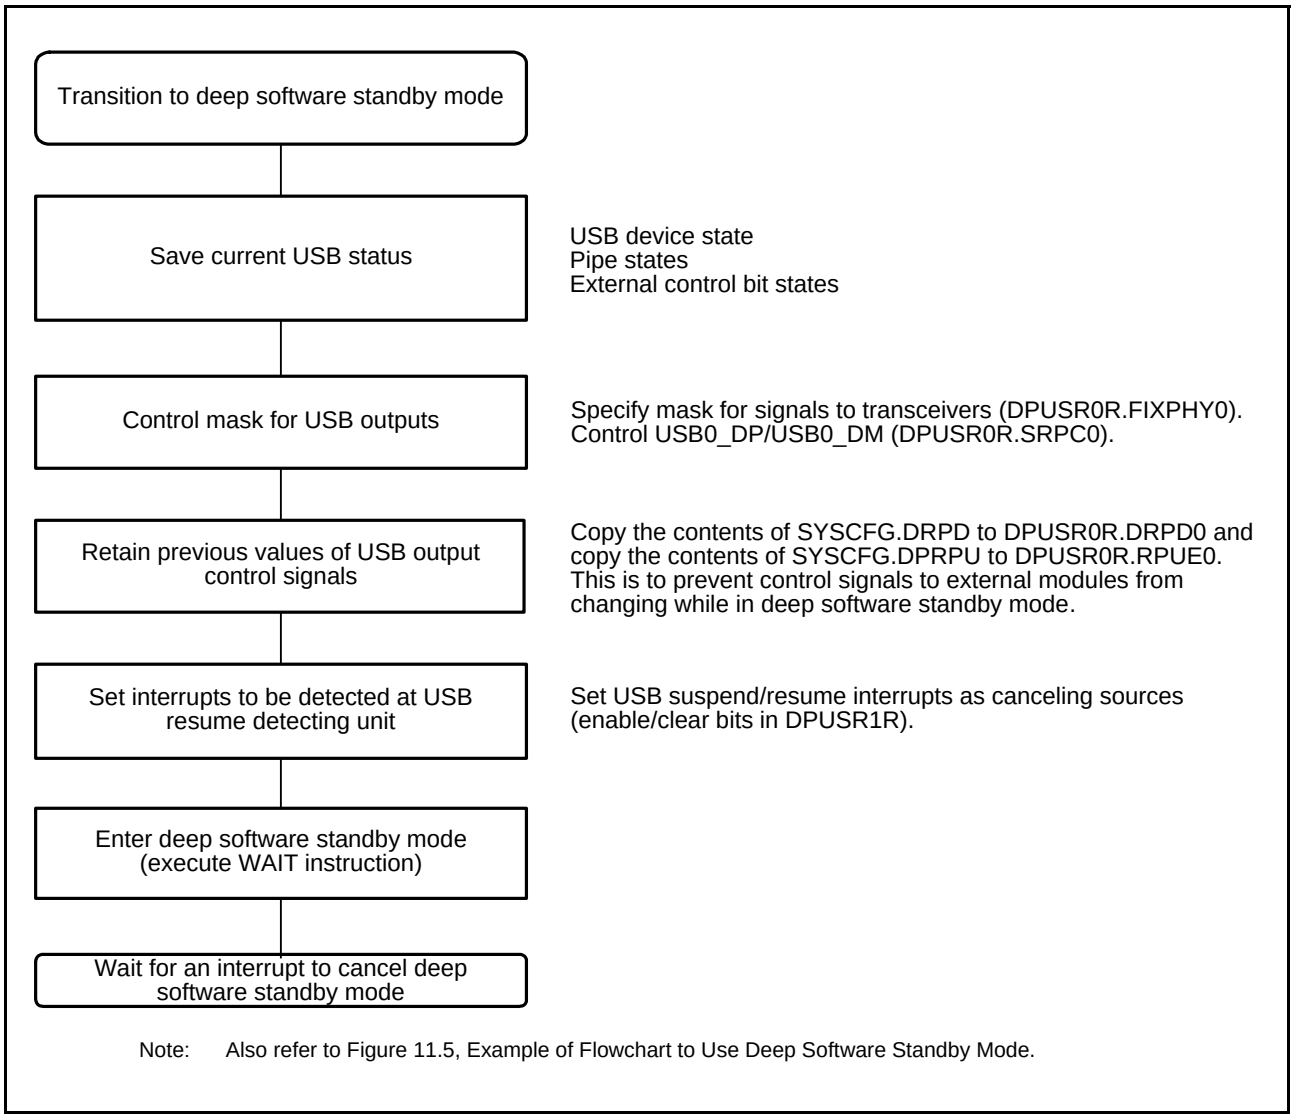

Figure 38.7 USB Setting Flowchart for Transition to Deep Software Standby Mode as Host/Function Controller

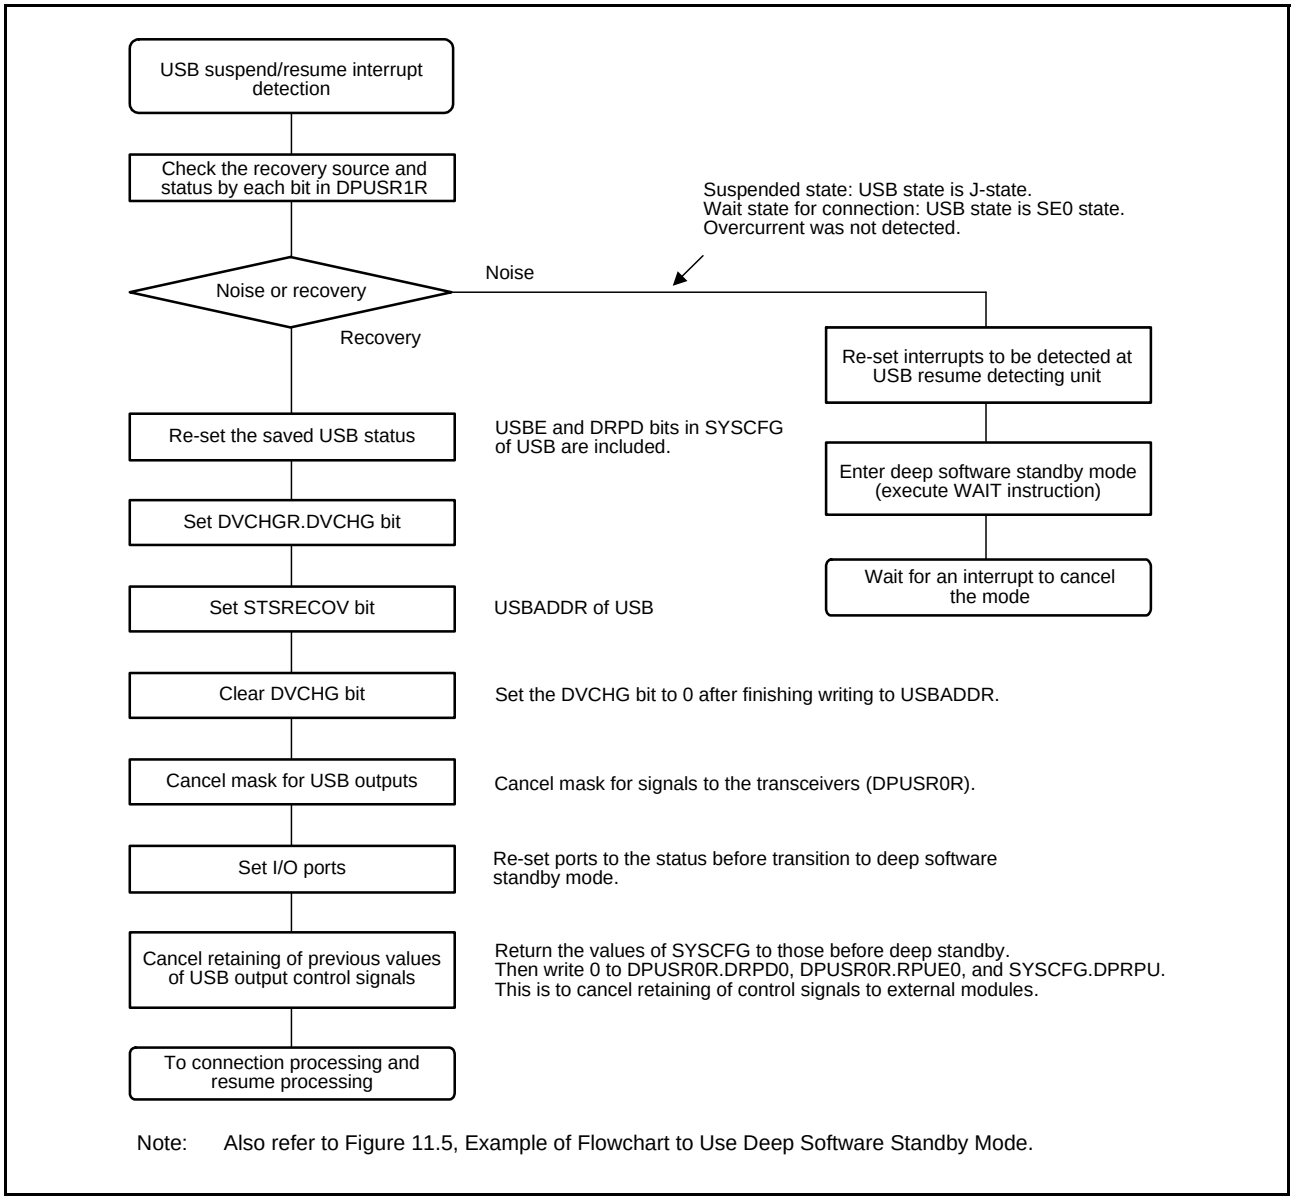

Figure 38.8 USB Setting Flowchart for Canceling Deep Software Standby Mode as Host Controller

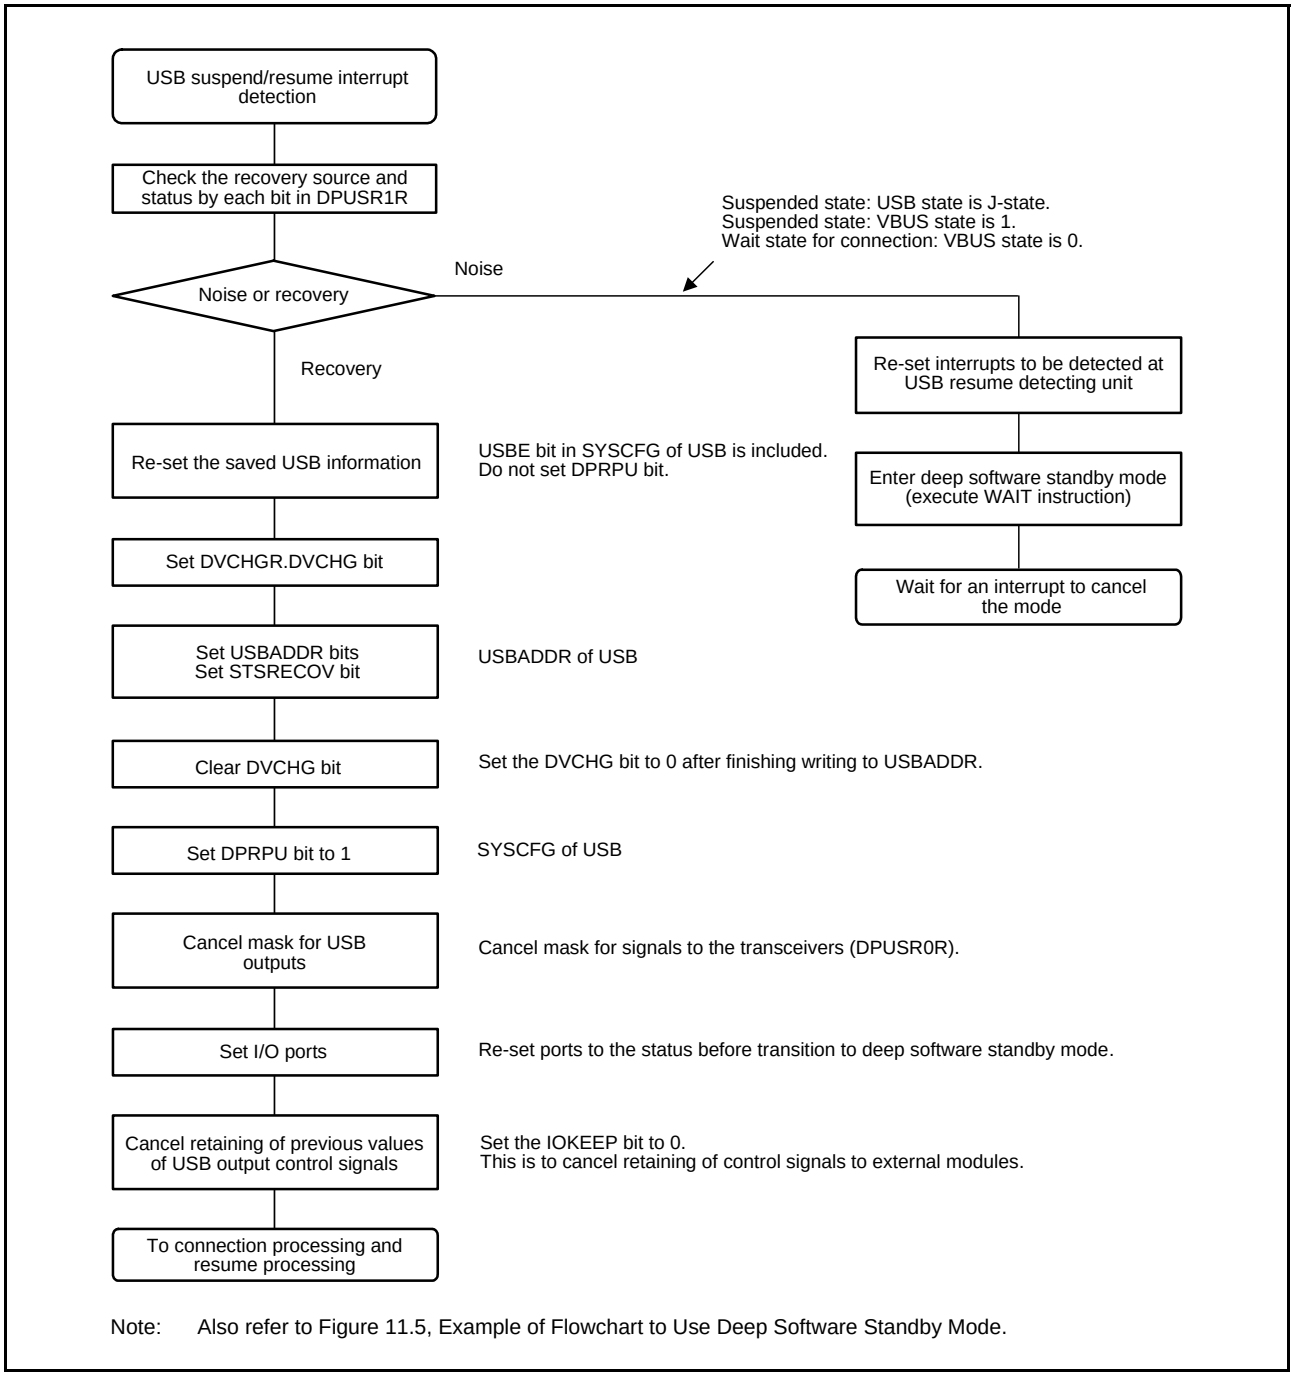

Note: Also refer to Figure 11.5, Example of Flowchart to Use Deep Software Standby Mode.

Figure 38.9 USB Setting Flowchart for Canceling Deep Software Standby Mode as Function Controller

38.3.2 Interrupt Sources

Table 38.13 lists the interrupt sources in the USB.

When an interrupt generation condition is satisfied and the interrupt output is enabled using the corresponding interrupt enable register, a USB interrupt request is issued the Interrupt Controller (ICU) and an USB interrupt will be generated.

Table 38.13 Interrupt Sources

Bit to be Set	Name	Interrupt Source	Function That Generates the Interrupt	Status Flag
VBINT	VBUS interrupt	• When a change in the state of the USB0_VBUS input pin has been detected (low to high or high to low)	Host/function*1	INTSTS0. VBSTS
RESM	Resume interrupt	• When a change in the state of the USB bus has been detected in the suspended state (J-state to K-state or J-state to SE0)	Function	—
SOFR	Frame number update interrupt	[Host controller is selected] • When an SOF packet with a different frame number has been transmitted [Function controller is selected] • When an SOF packet with a different frame number has been received	Host/function	—
DVST	Device state transition interrupt	• When a device state transition has been detected (any of the following conditions) A USB bus reset detected Suspend state detected SET_ADDRESS request received SET_CONFIGURATION request received	Function	INTSTS0. DVSQ[2:0]
CTRT	Control transfer stage transition interrupt	• When a stage transition has been detected in control transfer (any of the following conditions) Setup stage completed Control write transfer status stage transition Control read transfer status stage transition Control transfer completed A control transfer sequence error occurred	Function	INTSTS0. CTSQ[2:0]
BEMP	Buffer empty interrupt	• When transmission of all data in the buffer memory has been completed and the buffer has become empty • When a packet larger than the maximum packet size has been received	Host/function	BEMPSTS. PIPEnBEMP
NRDY	Buffer not ready interrupt	[Host controller is selected] • When STALL has been received from the peripheral device for the issued token • When a response has not been received correctly from the peripheral device for the issued token (no response was returned three consecutive times or a packet reception error occurred three consecutive times) • When an overrun/underrun occurred during isochronous transfer [Function controller is selected] • When NAK has been returned for an IN or OUT token while the PID[1:0] bits are 01b (BUF) • When a CRC error or a bit stuffing error occurred during data reception in isochronous transfer • When an overrun/underrun occurred during data reception in isochronous transfer	Host/function	NRDYSTS. PIPEnNRDY
BRDY	Buffer ready interrupt	• When the buffer has become ready (reading or writing is enabled)	Host/function	BRDYSTS. PIPEnBRDY
OVRCR	Overcurrent input change interrupt	• When a change in the state of the USB0_OVRCURA or USB0_OVRCURB input pin has been detected (low to high or high to low)	Host	INTSTS1. OVRCR
BCHG	Bus change interrupt	• When a change of USB bus state has been detected	Host/function	SYSSTS0. LNST[1:0]
DTCH	Disconnection detection during full-speed operation	• When disconnection of a peripheral device has been detected in full-speed operation	Host	DVSTCTR0. RHST[2:0]
ATTCH	Device connection detection	• When J-state or K-state is detected on the USB port for 2.5 µs. Used for checking whether a peripheral device is connected.	Host	—
EOFERR	EOF error detection	• When an EOF error of a peripheral device has been detected	Host	—
SACK	Normal setup operation	• When the normal response (ACK) for the setup transaction has been received	Host	—
SIGN	Setup error	• When a setup transaction error (no response or ACK packet corruption) was detected three consecutive times	Host	—

Note 1. Though this interrupt can be generated while the host function is selected, it is not usually used with the host function.

Figure 38.10 shows the circuits related to the interrupts in the USB.

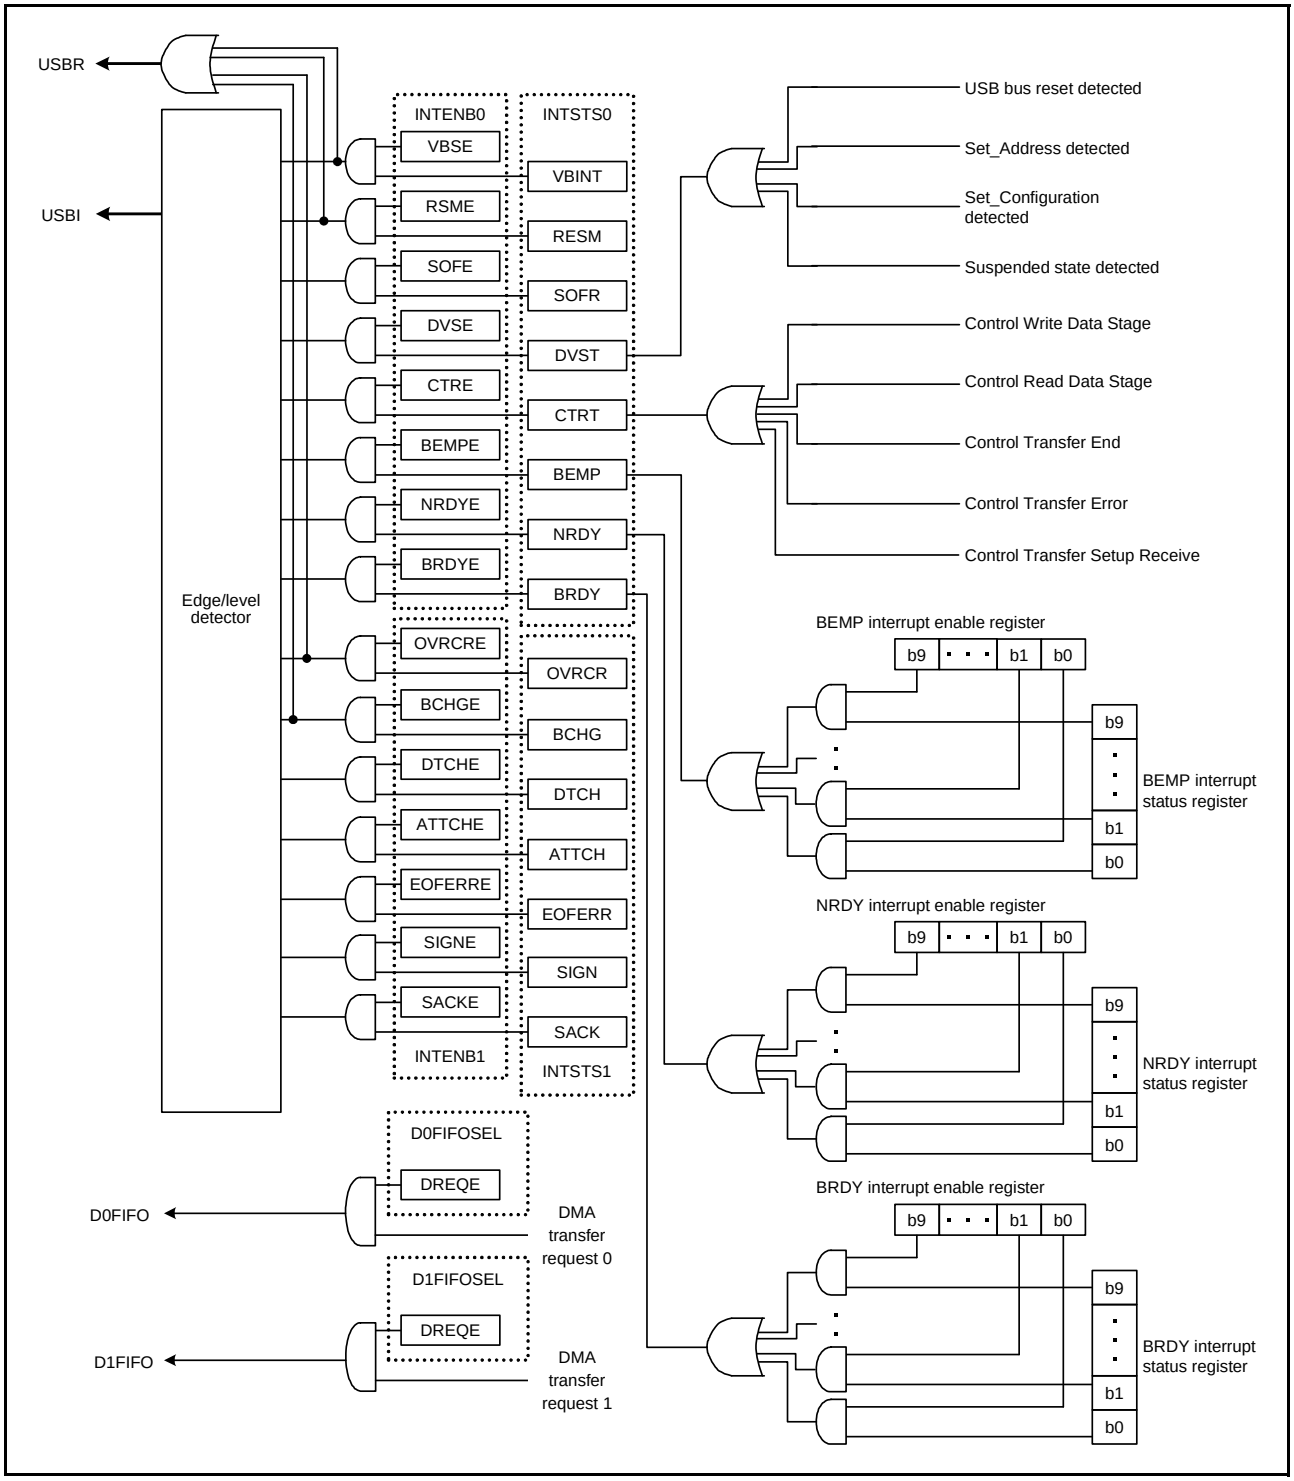

Figure 38.10 Circuits Related to Interrupts in USB

Table 38.14 shows the interrupts generated in the USB0.

Table 38.14 USB Interrupts

Interrupt Name	Interrupt Status Flag	DTC Activation	DMAC Activation	Priority
D0FIFO	DMA/DTC transfer request 0	Possible	Possible	High
D1FIFO	DMA/DTC transfer request 1	Possible	Possible	
USBI	VBUS interrupt, resume interrupt, frame number update interrupt, device state transition interrupt, control transfer stage transition interrupt, buffer empty interrupt, buffer not ready interrupt, buffer ready interrupt, overcurrent input change interrupt, bus change interrupt, disconnection detection during full-speed operation, device connection detection, EOF error detection, normal setup operation, and setup error	Not possible	Not possible	Low
USBR	VBUS interrupt, resume interrupt, overcurrent input change interrupt, and bus change interrupt	Not possible	Not possible	—

38.3.3 Interrupt Descriptions

38.3.3.1 BRDY Interrupt

The BRDY interrupt is generated when either of the host controller or function controller is selected. The following shows the conditions under which the USB sets 1 to a corresponding bit in the BRDYSTS register. Under this condition, the USB generates a BRDY interrupt if software has set 1 to the BRDYENB.PIPEnBRDYE bit that corresponds to the pipe and 1 to the INTENB0.BRDYE bit.
The conditions for generating and clearing the BRDY interrupt depend on the settings of the SOFCFG.BRDYM bit and PIPECFG.BFRE bit for each pipe as described below.

(1) When the SOFCFG.BRDYM Bit = 0 and the PIPECFG.BFRE Bit = 0

With these settings, the BRDY interrupt indicates that the FIFO port is accessible.
On any of the following conditions, the USB generates an internal BRDY interrupt request trigger and sets 1 to the BRDYSTS.PIPEnBRDY flag corresponding to the pertinent pipe.

(a) For the pipe in the transmitting direction:

- When the DIR bit is changed from 0 to 1 by software.
- When packet transmission is completed using the pertinent pipe while write-access from the CPU to the FIFO buffer for the pertinent pipe is disabled (when the BSTS flag is read as 0).
- When one FIFO buffer is empty on completion of writing data to the other FIFO buffer in double buffer mode.
- No request trigger is generated until completion of writing data to the currently-written FIFO buffer even if transmission to the other FIFO buffer is completed.
- When the hardware flushes the buffer of the pipe for isochronous transfers.
- When 1 is written to the PIPEnCTR.ACLRM bit, which causes the FIFO buffer to make transition from the write-disabled to write-enabled state.

No request trigger is generated for the DCP (that is, during data transmission for control transfers).

(b) For the pipe in the receiving direction:

- When packet reception is completed successfully thus enabling the FIFO buffer to be read while read-access from the CPU to the FIFO buffer for the pertinent pipe is disabled (when the BSTS flag is read as 0).
  No request trigger is generated for the transaction in which data PID mismatch has occurred.
- When one FIFO buffer is read-enabled on completion of reading data from the other FIFO buffer in double buffer mode.
  No request trigger is generated until completion of reading data from the currently-read FIFO buffer even if reception by the other FIFO buffer is completed.

When the function controller is selected, the BRDY interrupt is not generated in the status stage of control transfers.
The BRDY interrupt status of the pertinent pipe can be set to 0 by writing 0 to the corresponding PIPEnBRDY flag through software. In this case, 1s should be written to the PIPEnBRDY flags for the other pipes.
Clear the BRDY status before accessing the FIFO buffer.

(2) When the SOFCFG.BRDYM Bit = 0 and the PIPECFG.BFRE Bit = 1

With these settings, the USB generates a BRDY interrupt on completion of reading all data for a single transfer using the pipe in the receiving direction, and sets 1 to the bit in the BRDYSTS register corresponding to the pertinent pipe.
On any of the following conditions, the USB determines that the last data for a single transfer has been received.

- When a short packet including a zero-length packet is received.
- When the PIPEn transaction counter register (PIPEnTRN) is used and the number of packets specified by the PIPEnTRN.TRNCNT[15:0] bits are completely received.

When the pertinent data is completely read after any of the above conditions has been satisfied, the USB determines that all data for a single transfer has been completely read.
When a zero-length packet is received while the FIFO buffer is empty, the USB module determines that all data for a single transfer has been completely read when the FRDY flag in the FIFO port control register is 1 and the DTLN[8:0] flags are 0. In this case, to start the next transfer, write 1 to the BCLR bit in the corresponding port control register through software.
With these settings, the USB does not detect a BRDY interrupt for the pipe in the transmitting direction.
The BRDY interrupt status of the pertinent pipe can be set to 0 by writing 0 to the corresponding BRDYSTS.PIPEnBRDY flag through software. In this case, 1s should be written to the PIPEnBRDY flags for the other pipes.
In this mode, the PIPECFG.BFRE bit setting should not be modified until all data for a single transfer has been processed. When it is necessary to modify the PIPECFG.BFRE bit before completion of processing, all FIFO buffers for the pertinent pipe should be cleared using the PIPEnCTR.ACLRM bit.

(3) When the SOFCFG.BRDYM Bit = 1 and the PIPECFG.BFRE Bit = 0

With these settings, the BRDYSTS.PIPEnBRDY values are linked to the BSTS flag setting for each pipe. In other words, the BRDY interrupt status flags (PIPEnBRDY) are set to 1 or 0 by the USB depending on the FIFO buffer status.

(a) For the pipe in the transmitting direction:

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for write access, and are set to 0 when it is not ready.
However, the BRDY interrupt is not generated even if the DCP in the transmitting direction is ready for write access.

(b) For the pipe in the receiving direction:

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for read access, and are set to 0 when all data have been read (not ready for read access).
When a zero-length packet is received while the FIFO buffer is empty, the pertinent bit is set to 1 and the BRDY interrupt is continuously generated until BCLR = 1 is written through software.
With this setting, the PIPEnBRDY flag cannot be set to 0 through software.
When the SOFCFG.BRDYM bit is set to 1, all PIPECFG.BFRE bits (for all pipes) should be set to 0.

Figure 38.11 shows the timing of BRDY interrupt generation.

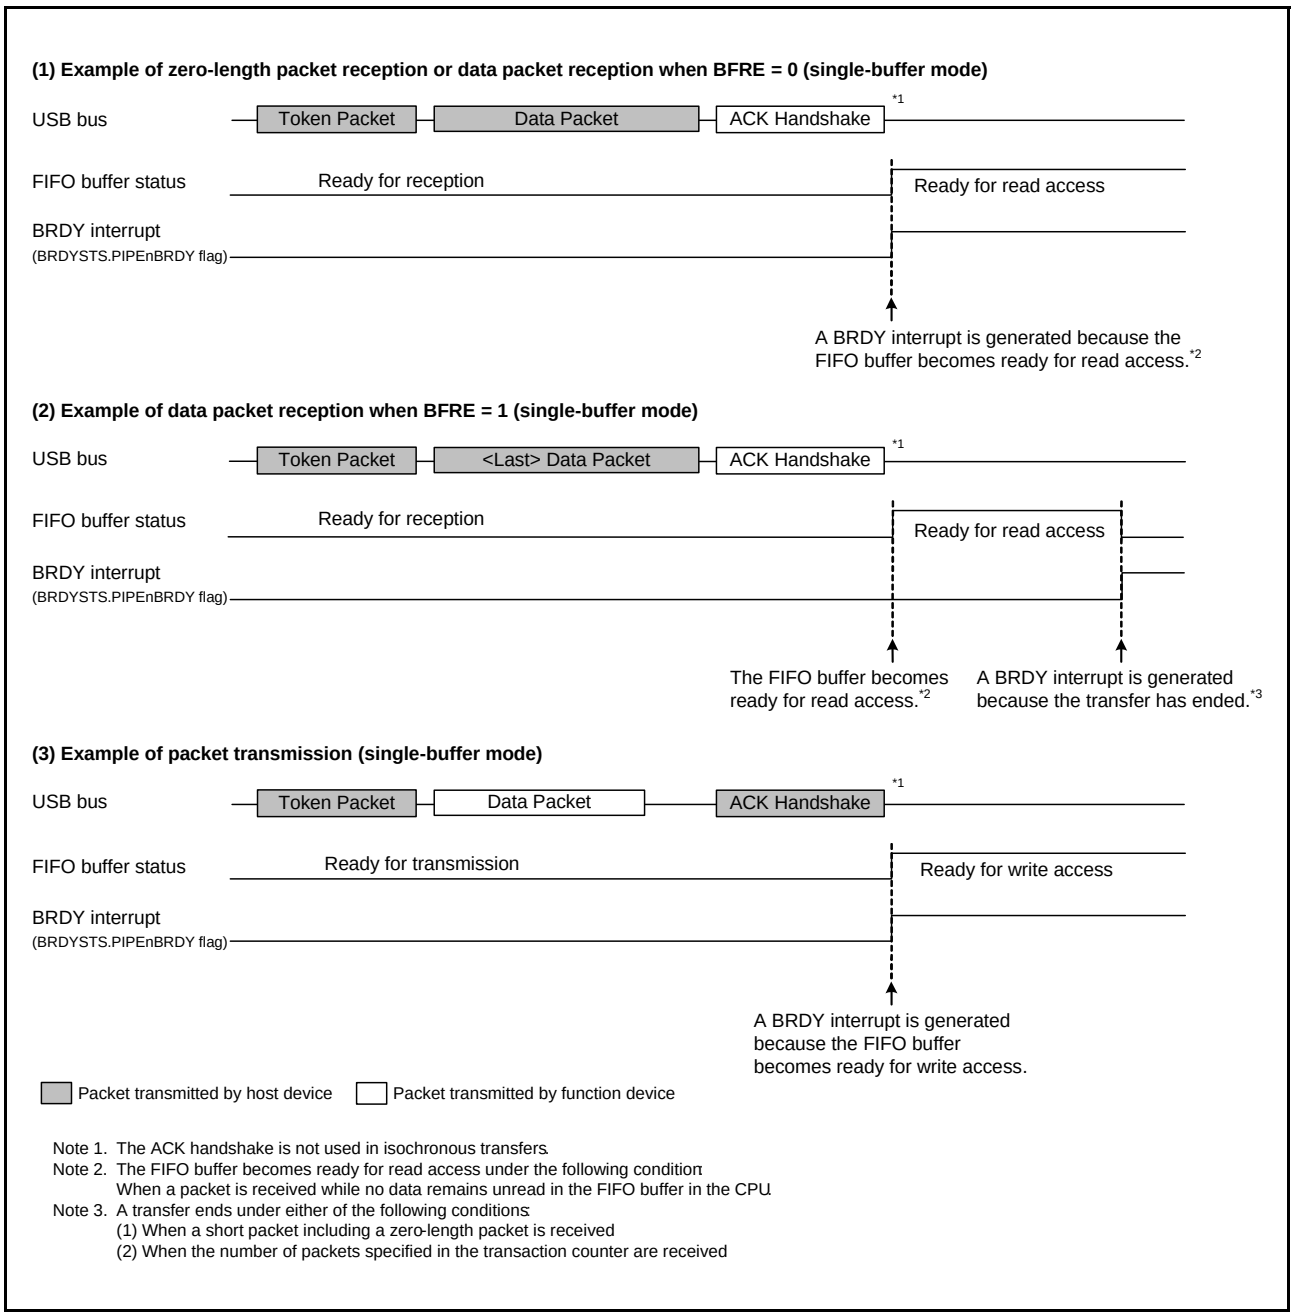

Figure 38.11 Timing of BRDY Interrupt Generation

The condition that USB clears the INTSTS0.BRDY flag depends on the SOFCFG.BRDYM bit setting. Table 38.15 shows the condition for clearing the BRDY flag.

Table 38.15 Condition for Clearing BRDY Flag

BRDYM Bit	Condition for Clearing BRDY Flag
0	The USB sets the BRDY flag to 0 when all bits in the BRDYSTS register have been set to 0 by software.
1	The USB sets the BRDY flag to 0 when the BSTS flags for all pipes have become 0.

38.3.3.2 NRDY Interrupt

On generating an internal NRDY interrupt request for the pipe whose PID[1:0] bits are set to 01b (BUF) by software, the USB sets the corresponding NRDYSTS.PIPEnNRDY flag to 1. If the corresponding bit in the NRDYENB register has been set to 1 by software, the USB sets the INTSTS0.NRDY flag to 1 and generates a USB interrupt.
The following describes the conditions on which the USB generates the internal NRDY interrupt request for a given pipe.
Note that the internal NRDY interrupt request is not generated during setup transaction execution when the host controller is selected. During setup transactions when the host controller is selected, the SACK or SIGN interrupt is detected.
The internal NRDY interrupt request is not generated during status stage execution of the control transfer when the function controller is selected.

(1) When Host Controller is Selected

(a) For the pipe in the transmitting direction:

On any of the following conditions, the USB detects an NRDY interrupt.

- For the pipe for isochronous transfers, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer.
  In this case, the USB transmits a zero-length packet following the OUT token and sets the bit corresponding to the NRDYSTS.PIPEnNRDY flag and the FRMNUM.OVRN flag to 1.
- During communications other than setup transactions using the pipe for the transfers other than isochronous transfers, when any combination of the following two cases occur three consecutive times: 1) no response is returned from the peripheral device (when timeout is detected before detection of the handshake packet from the peripheral device) and 2) an error is detected in the packet from the peripheral device.
  In this case, the USB sets the bit corresponding to the PIPEnNRDY flag to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 00b (NAK).
- During communications other than setup transactions, when the STALL handshake is received from the peripheral device.
  In this case, the USB sets the bit corresponding to the PIPEnNRDY flag to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 11b (STALL).

(b) For the pipe in the receiving direction:

- For the pipe for isochronous transfers, when the time to issue an IN token comes while there is no space available in the FIFO buffer.
  In this case, the USB discards the received data for the IN token and sets the PIPEnNRDY flag corresponding to the pipe and the OVRN flag to 1.
  When a packet error is detected in the received data for the IN token, the USB also sets the FRMNUM.CRCE flag to 1.
- For the pipe for the transfers other than isochronous transfers, when any combination of the following two cases occur three consecutive times: 1) no response is returned from the peripheral device for the IN token issued by the USB (when timeout is detected before detection of the DATA packet from the peripheral device) and 2) an error is detected in the packet from the peripheral device.
  In this case, the USB sets the PIPEnNRDY flag corresponding to the pipe to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 00b (NAK).
- For the pipe for isochronous transfers, when no response is returned from the peripheral device for the IN token (when timeout is detected before detection of the DATA packet from the peripheral device) or an error is detected in the packet from the peripheral device.
  In this case, the USB sets the PIPEnNRDY flag corresponding to the pipe to 1. (The setting of the PID[1:0] bits of the pipe is not modified.)

- For the pipe for isochronous transfers, when a CRC error or a bit stuffing error is detected in the received data packet.
  In this case, the USB sets the PIPEnNRDY flag corresponding to the pipe and the CRCE flag to 1.
- When the STALL handshake is received.
  In this case, the USB sets the PIPEnNRDY flag corresponding to the pipe to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 11b (STALL).

(2) When Function Controller is Selected

(a) For the pipe in the transmitting direction:

- When an IN token is received while there is no data to be transmitted in the FIFO buffer.
  In this case, the USB generates a NRDY interrupt request at the reception of the IN token and sets the NRDYSTS.PIPEnNRDY flag to 1.
  For the pipe for the isochronous transfers in which an interrupt is generated, the USB transmits a zero-length packet and sets the FRMNUM.OVRN flag to 1.

(b) For the pipe in the receiving direction:

- When an OUT token is received while there is no space available in the FIFO buffer.
  For the pipe for the isochronous transfers in which an interrupt is generated, the USB generates a NRDY interrupt request at the reception of the OUT token and sets the PIPEnNRDY flag to 1 and OVRN flag to 1.
  For the pipe for the transfers other than isochronous transfers in which an interrupt is generated, the USB generates a NRDY interrupt request when a NAK handshake is transferred after the data following the OUT token is received, and sets the PIPEnNRDY flag to 1.
  However, during re-transmission (due to data PID mismatch), the NRDY interrupt request is not generated. In addition, if an error occurs in the DATA packet, the NRDY interrupt request is not generated.
- For the pipe for isochronous transfers, when a token is not received successfully within an interval frame.
  In this case, the USB generates a NRDY interrupt request when SOF is received, and sets the PIPEnNRDY flag to 1.

Figure 38.12 shows the timing of NRDY interrupt generation when the function controller is selected.

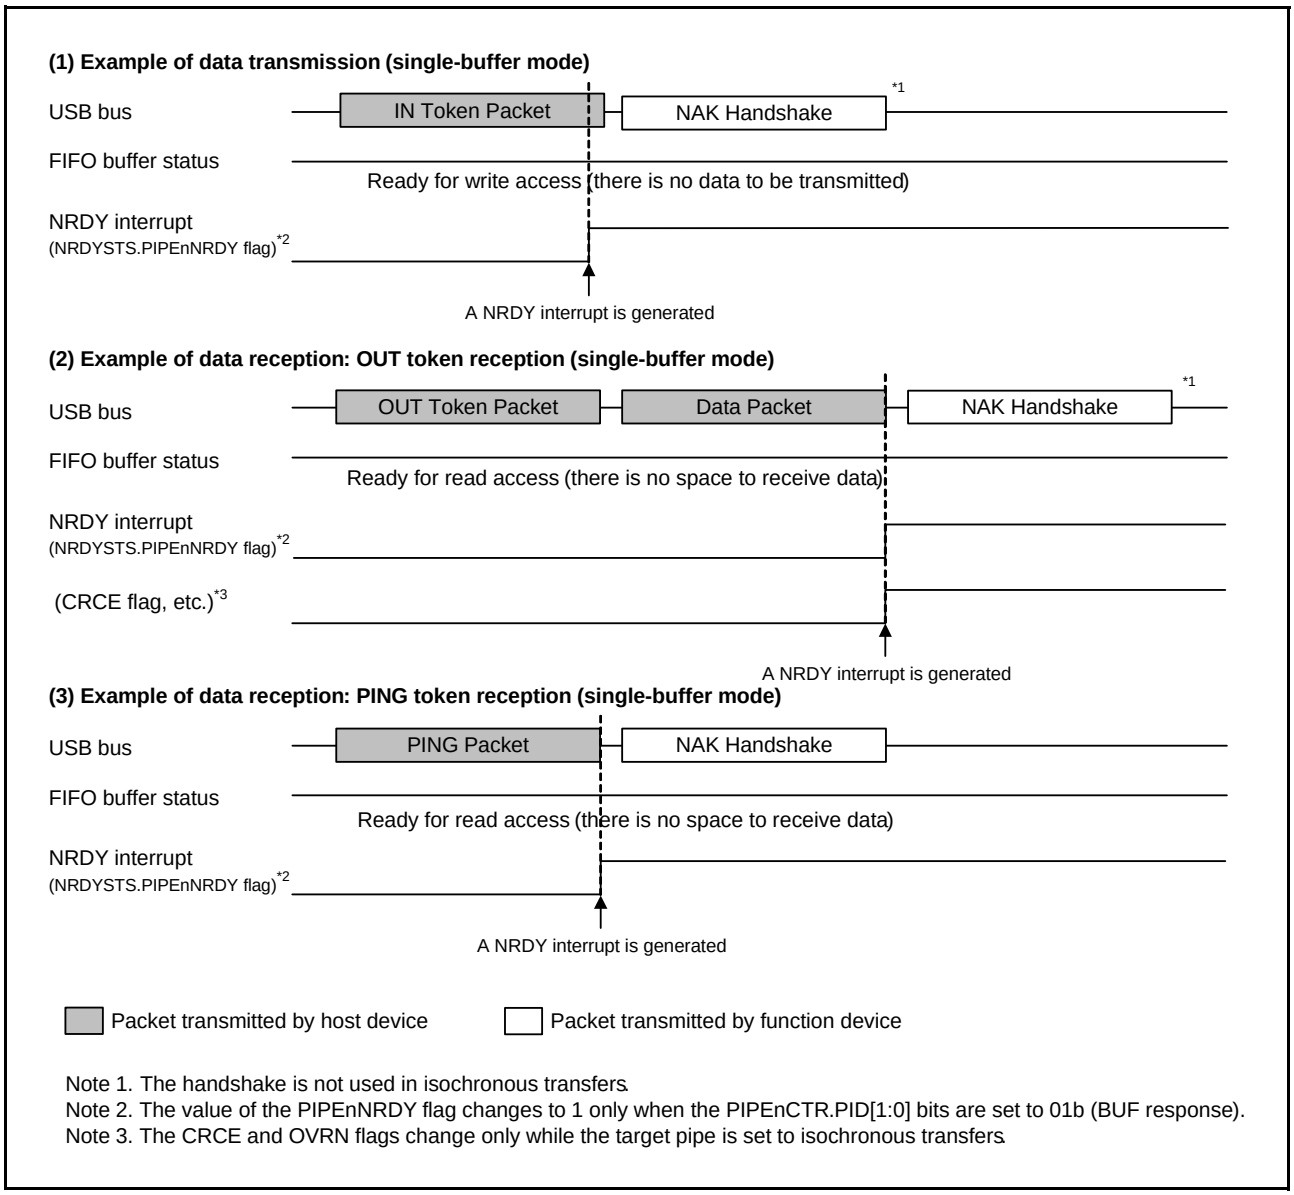

Figure 38.12 Timing of NRDY Interrupt Generation (When Function Controller is Selected)

38.3.3.3 BEMP Interrupt

On detecting a BEMP interrupt for the pipe whose PID[1:0] bits are set to 01b (BUF) by software, the USB sets the corresponding BEMPSTS.PIPEnBEMP flag to 1. If the corresponding bit in the BEMPENB register has been set to 1 by software, the USB sets the INTSTS0.BEMP flag to 1 and generates a USB interrupt.

The following describes the conditions on which the USB generates an internal BEMP interrupt request.

(1) For the pipe in the transmitting direction:

When the FIFO buffer of the corresponding pipe is empty on completion of transmission (including zero-length packet transmission).
In single buffer mode, an internal BEMP interrupt request is generated simultaneously with the BRDY interrupt for the pipe other than DCP. However, the internal BEMP interrupt request is not generated on any of the following conditions.

- When the CPU or DMAC/DTC has already started writing data to the FIFO buffer of the CPU on completion of transmitting data from one FIFO buffer in double buffer mode.
- When the buffer is cleared (emptied) by setting the PIPEnCTR.ACLRM or the BCLR bit in the port control register to 1.
- When IN transfer (zero-length packet transmission) is performed during the control transfer status stage while the function controller is selected.

(2) For the pipe in the receiving direction:

When the successfully-received data packet size exceeds the specified maximum packet size.
In this case, the USB generates a BEMP interrupt request, sets the corresponding BEMPSTS.PIPEnBEMP flag to 1, discards the received data, and modifies the setting of the PID[1:0] bits of the corresponding pipe to 11b (STALL). Here, the USB returns no response when used as the host controller, and returns STALL response when used as the function controller.
However, the internal BEMP interrupt request is not generated on any of the following conditions.

- When a CRC error or a bit stuffing error is detected in the received data.
- When a setup transaction is being performed,
  Writing 0 to the BEMPSTS.PIPEnBEMP flag clears the status.
  Writing 1 to the BEMPSTS.PIPEnBEMP flag has no effect.

Figure 38.13 shows the timing of BEMP interrupt generation when the function controller is selected.

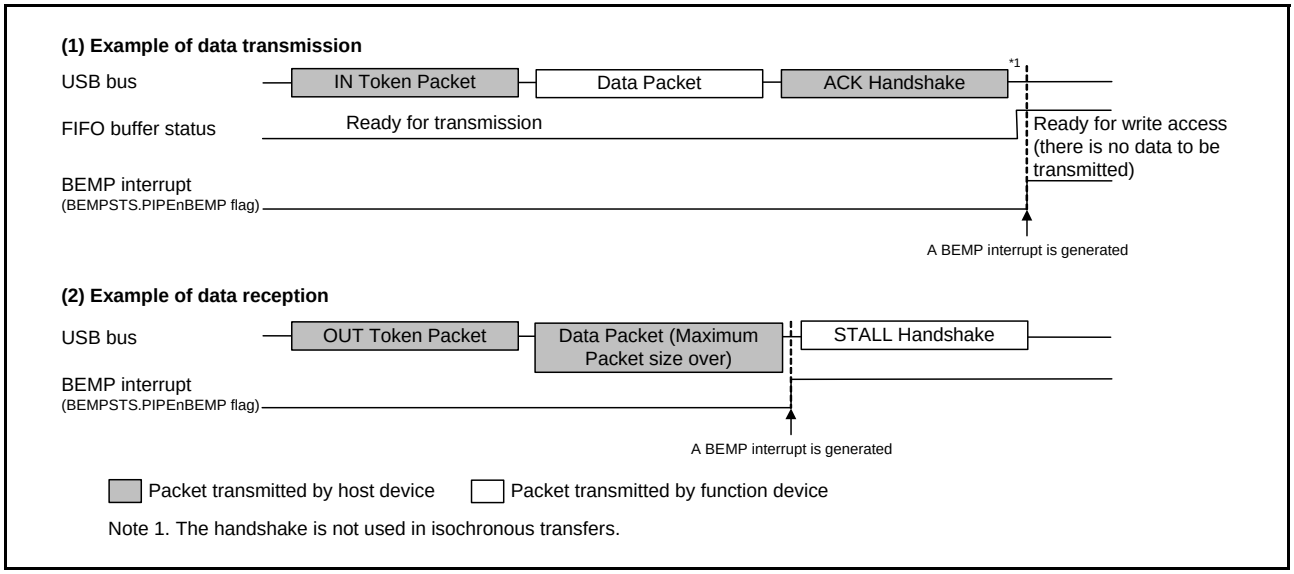

Figure 38.13 Timing of BEMP Interrupt Generation (When Function Controller is Selected)

38.3.3.4 Device State Transition Interrupt

Figure 38.14 is a diagram of device state transitions in the USB. The USB controls device state and generates device state transition interrupts. However, recovery from the suspended state (resume signal detection) is detected by means of the resume interrupt. The device state transition interrupts can be enabled or disabled individually using INTENB0. The device state to which a transition was made can be confirmed using the INTSTS0.DVSQ[2:0] flags.

When a transition is made to the default state, a device state transition interrupt is generated after a USB bus reset is detected.

Device state can be controlled only when the function controller is selected. The device state transition interrupts can also be generated only when the function controller is selected.

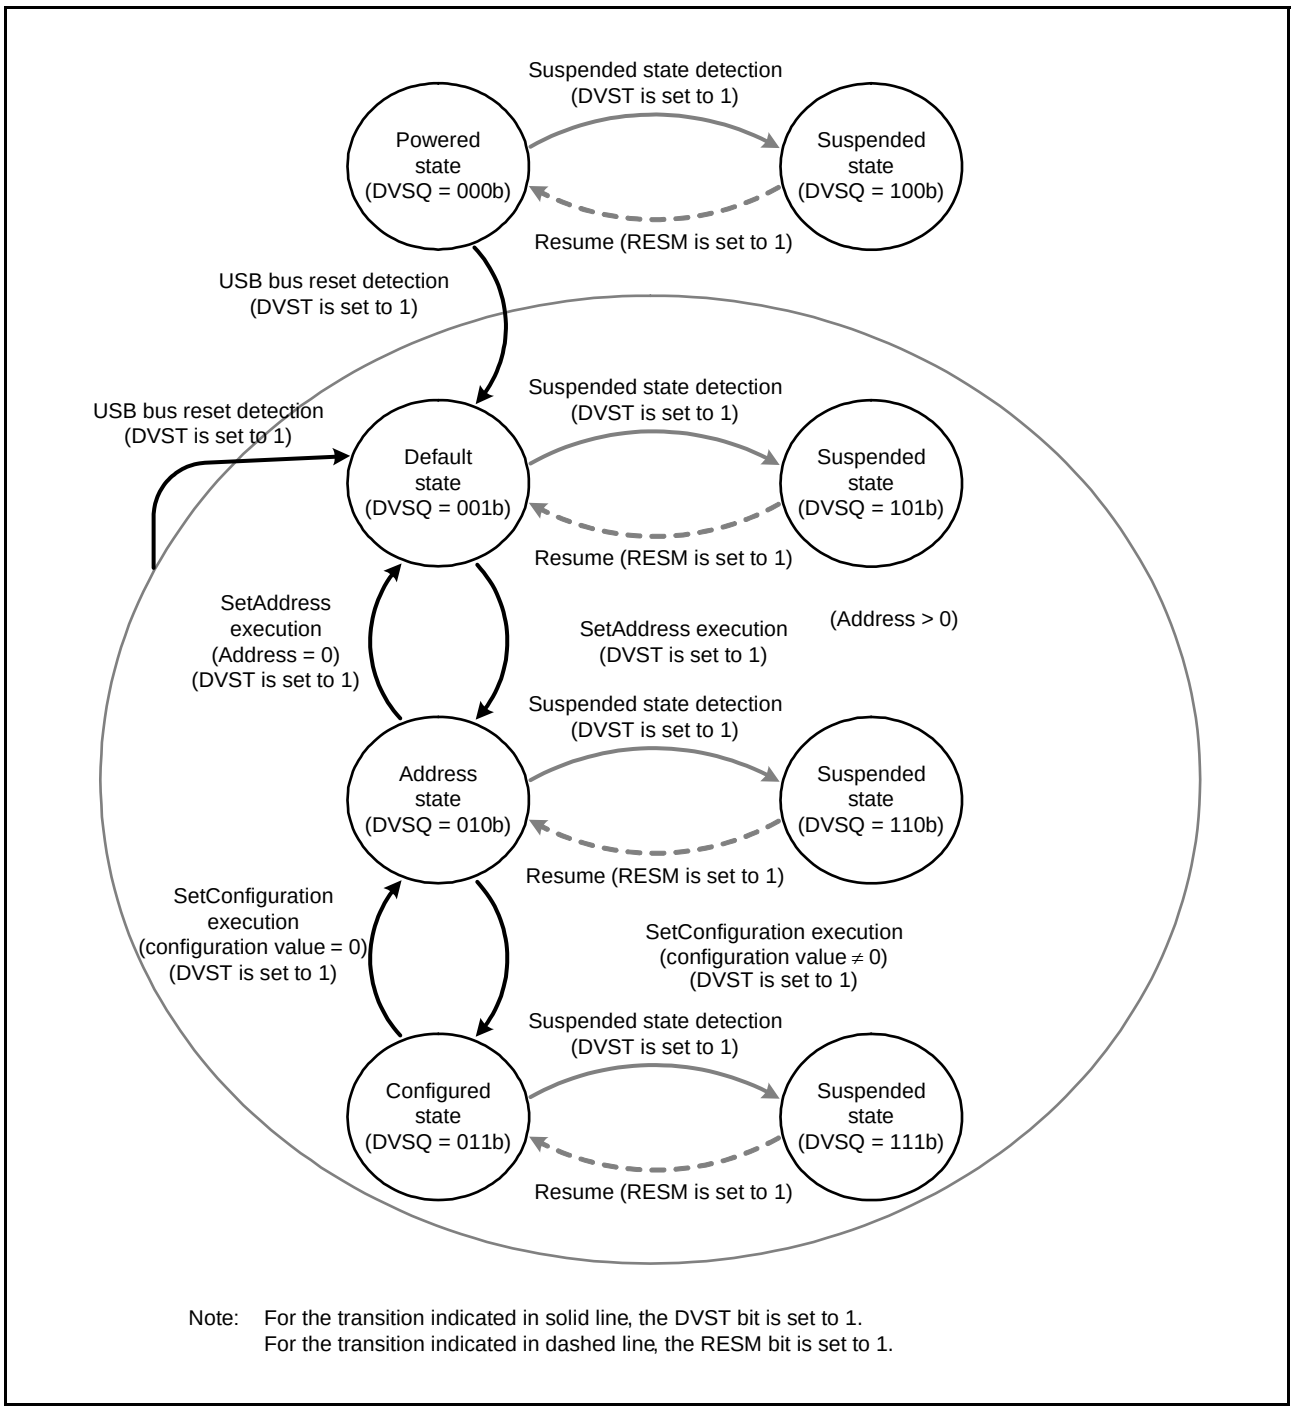

Figure 38.14 Device State Transitions

38.3.3.5 Control Transfer Stage Transition Interrupt

Figure 38.15 is a diagram of control transfer stage transitions in the USB. The USB controls the control transfer sequence and generates control transfer stage transition interrupts. The control transfer stage transition interrupts can be enabled or disabled individually using INTENB0. The transfer stage to which a transition was made can be confirmed using the INTSTS0.CTSQ[2:0] flags.

Control transfer stage transition interrupts are generated only when the function controller is selected.

The control transfer sequence errors are listed below. If an error occurs, the DCPCTR.PID[1:0] bits are set to 1xb (STALL response).

During control read transfer:

- An OUT token is received while no data has been transferred for the IN token at the data stage.
- An IN token is received at the status stage.
- A data packet with PID = DATA0 is received at the status stage.

During control write transfer:

- An IN token is received while no ACK response has been returned for the OUT token at the data stage.
- A data packet with PID = DATA0 is received for the first data packet at the data stage.
- An OUT token is received at the status stage

During no-data control transfers:

- An OUT token is received at the status stage.

At the control write transfer data stage, if the number of receive data exceeds the wLength value of the USB request, it cannot be recognized as a control transfer sequence error. At the control read transfer status stage, packets other than zero-length packets are received by an ACK response and the transfer ends normally.

When a CTRT interrupt occurs in response to a sequence error (INTSTS0.CTRT = 1), CTSQ[2:0] = 110b value is retained until the CTRT flag = 0 is written from the system (the interrupt status is cleared). Therefore, while CTSQ[2:0] = 110b is being held, the CTRT interrupt that ends the setup stage will not be generated even if a new USB request is received. (The USB retains the setup stage end, and after the interrupt status has been cleared by software, a setup stage end interrupt is generated.)

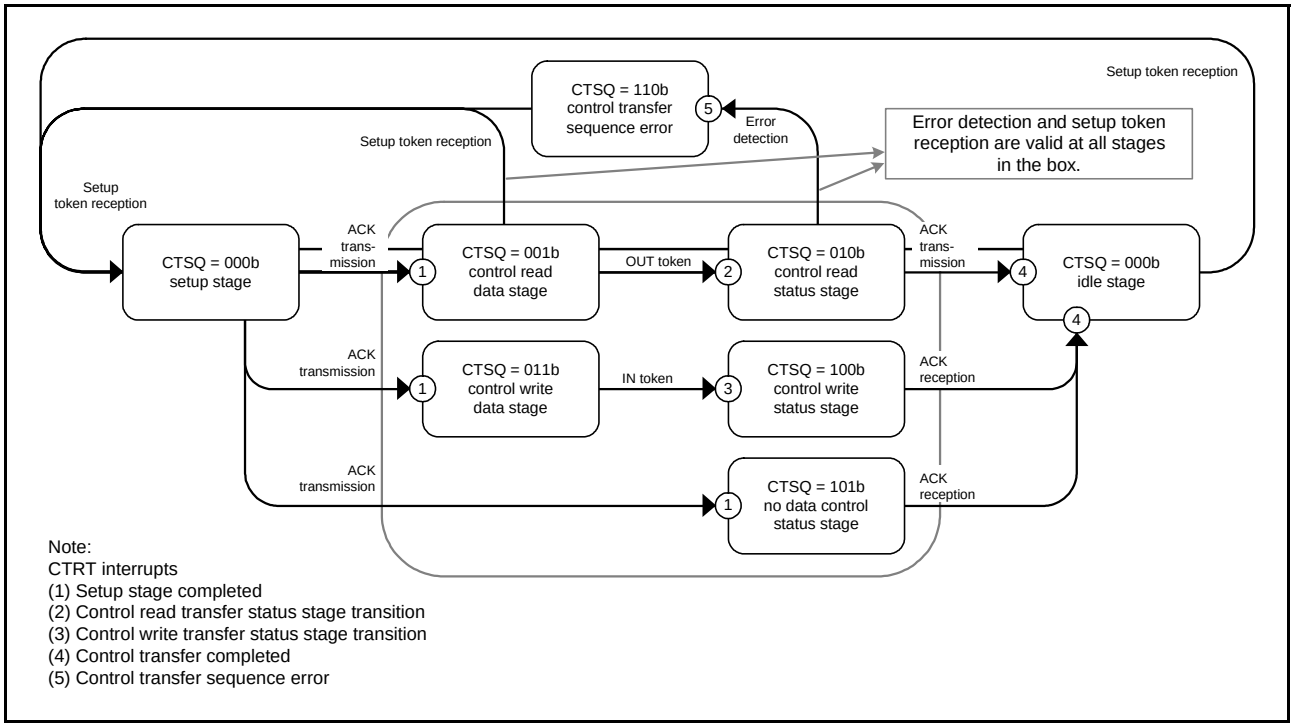

Figure 38.15 Control Transfer Stage Transitions

38.3.3.6 Frame Update Interrupt

With the host controller selected, an interrupt is generated at the timing when the frame number is updated. With the function controller selected, an SOFR interrupt is generated when the frame number is updated.
When the function controller is selected, the USB updates the frame number and generates an SOFR interrupt if it detects a new SOF packet during full-speed operation.

38.3.3.7 VBUS Interrupt

When the USB0_VBUS pin level changes, a VBUS interrupt is generated. The level of the USB0_VBUS pin can be checked with the INTSTS0.VBSTS flag. Whether the host controller is connected or disconnected can be confirmed using the VBUS interrupt. However, if the system is activated with the host controller connected, the first VBUS interrupt is not generated because there is no change in the USB0_VBUS pin level.

38.3.3.8 Resume Interrupt

When the function controller is selected, a resume interrupt is generated when the device state is the suspended state and the USB bus state has changed (from J-state to K-state, or from J-state to SE0). Recovery from the suspended state is detected by means of the resume interrupt.
When the host controller is selected, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

38.3.3.9 OVRCR Interrupt

An OVRCR interrupt is generated when the USB0_OVRCURA or USB0_OVRCURB pin level has changed. The levels of the USB0_OVRCURA and USB0_OVRCURB pins can be checked with the SYSSTS0.OVCMON[1:0] bits. The external power supply IC can check whether overcurrent has been detected using the OVRCR interrupt.
For OTG connection, whether a change has been detected in the VBUS comparator can be checked using the OVRCR interrupt.

38.3.3.10 BCHG Interrupt

A BCHG interrupt is generated when the USB bus state has changed. The BCHG interrupt can be used to detect whether the peripheral device is connected and can also be used to detect a remote wakeup when the host controller is selected. The BCHG interrupt is generated regardless of whether the host controller or function controller is selected.

38.3.3.11 DTCH Interrupt

A DTCH interrupt is generated when disconnection of the USB bus is detected while the host controller is selected. The USB detects bus disconnection based on USB Specification 2.0.
After detecting a DTCH interrupt, the USB controls hardware as described below (irrespective of the value set in the corresponding interrupt enable bit). All pipes in which communications are currently carried out for the pertinent port should be terminated by software and make a transition to the wait state for bus connection to the pertinent port (wait state for ATTCH interrupt generation).

- Modifies the DVSTCTR0.UACT bit for the port in which a DTCH interrupt has been detected to 0.
- Puts the port in which a DTCH interrupt has been generated into the idle state.

38.3.3.12 SACK Interrupt

A SACK interrupt is generated when an ACK response for the transmitted setup packet has been received from the peripheral device with the host controller selected. The SACK interrupt can be used to confirm that the setup transaction has been completed successfully.

38.3.3.13 SIGN Interrupt

A SIGN interrupt is generated when an ACK response for the transmitted setup packet has not been correctly received from the peripheral device three consecutive times with the host controller selected. The SIGN interrupt can be used to detect no ACK response transmitted from the peripheral device or corruption of an ACK packet.

38.3.3.14 ATTCH Interrupt

An ATTCH interrupt is generated when J-state or K-state of the full-speed signal level is detected on the USB port for 2.5 µs with the host controller selected. To be more specific, an ATTCH interrupt is detected on any of the following conditions.

- When K-state, SE0, or SE1 changes to J-state, and J-state continues 2.5 µs.
- When J-state, SE0, or SE1 changes to K-state, and K-state continues 2.5 µs.

38.3.3.15 EOFERR Interrupt

An EOFERR interrupt is generated when it is detected that communication is not completed at the EOF2 timing prescribed in USB Specification 2.0.
After detecting an EOFERR interrupt, the USB controls hardware as described below (irrespective of the value set in the corresponding interrupt enable bit). All pipes in which communications are currently carried out for the pertinent port should be terminated by software and perform re-enumeration of the pertinent port.

- Modifies the DVSTCTR0.UACT bit for the port in which an EOFERR interrupt has been detected to 0.
- Puts the port in which an EOFERR interrupt has been generated into the idle state.

38.3.4 Pipe Control

Table 38.16 lists the pipe settings for the USB. With USB data transfer, data transfer is carried out using the pipe that the software has associated with the endpoint. The USB has ten pipes that are used for data transfer.
Appropriate settings should be made for each of the pipes according to the specifications of the system.

Table 38.16 Pipe Settings

Register Name	Bit Name	Setting	Remarks
DCPCFG PIPECFG	TYPE[1:0]	Specifies the transfer type	PIPE1 to PIPE9: Can be set
	BFRE	Selects the BRDY interrupt mode	PIPE1 to PIPE5: Can be set
	DBLB	Selects double buffer mode	PIPE1 to PIPE5: Can be set
	DIR	Selects transfer direction	IN or OUT can be set
	EPNUM[3:0]	Endpoint number	PIPE1 to PIPE9: Can be set A value other than 0000b should be set when the pipe is used.
	SHTNAK	Selects disabled state for pipe when transfer ends	PIPE1 and PIPE2: Can be set (only when bulk transfer has been selected) PIPE3 to PIPE5: Can be set
DCPMAXP PIPEMAXP	DEVSEL[3:0]	Selects a device	Referenced only when the host controller is selected.
	MXPS[8:0]	Maximum packet size	Compliant with USB Specification 2.0.
PIPEPERI	IFIS	Buffer flush	PIPE1 and PIPE2: Can be set (only when isochronous transfer has been selected) PIPE3 to PIPE9: Cannot be set
	IITV[2:0]	Interval counter	PIPE1 and PIPE2: Can be set (only when isochronous transfer has been selected) PIPE3 to PIPE5: Cannot be set PIPE6 to PIPE9: Can be set (only when the host controller has been selected)
DCPCTR PIPEnCTR	BSTS	Buffer status	For the DCP, receive buffer status and transmit buffer status are switched with the ISEL bit.
	INBUFM	IN buffer monitor	Available only for PIPE1 to PIPE5.
	SUREQ	SETUP request	Can be set only for the DCP. Can be controlled only when the host controller has been selected.
	SUREQCLR	SUREQ clear	Can be set only for the DCP. Can be controlled only when the host controller has been selected.
	ATREPM	Auto response mode	PIPE1 to PIPE5: Can be set Can be set only when the function controller has been selected.
	ACLRM	Auto buffer clear	PIPE1 to PIPE9: Can be set
	SQCLR	Sequence clear	Clears the data toggle bit.
	SQSET	Sequence set	Sets the data toggle bit.
	SQMON	Sequence monitor	Monitors the data toggle bit.
	PBUSY	Pipe busy status	
	PID[1:0]	Response PID	Refer to section 38.3.4.6, Response PID.
PIPEnTRE	TRENB	Transaction counter enable	PIPE1 to PIPE5: Can be set
	TRCLR	Current transaction counter clear	PIPE1 to PIPE5: Can be set
PIPEnTRN	TRNCNT[15:0]	Transaction counter	PIPE1 to PIPE5: Can be set

38.3.4.1 Pipe Control Register Switching Procedures

The following bits in the pipe control registers can be modified only when USB communication is prohibited (PID[1:0] = 00b (NAK)).

The following shows the registers and bits that should not be modified when USB communication is enabled (PID[1:0] = 01b (BUF)).

- Bits in the DCPCFG and DCPMAXP registers
- The SQCLR and SQSET bits in the DCPCTR register
- Bits in registers PIPECFG, PIPEMAXP, and PIPEPERI
- The ATREPM, ACLRM, SQCLR, and SQSET bits in the PIPEnCTR register
- Bits in the PIPEnTRE and PIPEnTRN registers

In order to modify the above bits in the USB communication enabled (PID[1:0] = 01b (BUF)) state, follow the procedure shown below:

1. A request to modify bits in the pipe control register occurs.
2. Modify the PID[1:0] bits corresponding to the pipe to 00b (NAK).
3. Wait until the corresponding PBUSY flag is set to 0.
4. Modify the bits in the pipe control register.

The following bits in the pipe control registers can be modified only when the pertinent pipe information has not been set by the CURPIPE[3:0] bits in registers CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Registers that should not be set when the CURPIPE[3:0] bits are set:

- Bits in the DCPCFG and DCPMAXP register
- Bits in registers PIPECFG, PIPEMAXP and PIPEPERI

In order to modify pipe information, the CURPIPE[3:0] bits in the port select registers should be set to a pipe other than the pipe to be modified. For the DCP, the buffer should be cleared using the BCLR bit in the port control register after the pipe information is modified.

38.3.4.2 Transfer Types

The PIPECFG.TYPE[1:0] bits are used to specify the transfer type for each pipe. The transfer types that can be set for the pipes are as follows.

- DCP: No setting is necessary (fixed at control transfer).
- PIPE1 and PIPE2: These should be set to bulk transfer or isochronous transfer.
- PIPE3 to PIPE5: These should be set to bulk transfer.
- PIPE6 to PIPE9: These should be set to interrupt transfer.

38.3.4.3 Endpoint Number

The PIPECFG.EPNUM[3:0] bits are used to set the endpoint number for each pipe. The DCP is fixed at endpoint 0. The other pipes can be set from endpoint 1 to endpoint 15.

- DCP: No setting is necessary (fixed at endpoint 0).
- PIPE1 to PIPE9: The endpoint numbers from 1 to 15 should be selected and set.
  These should be set so that the combination of the PIPECFG.DIR bit and EPNUM[3:0] bits is unique.

38.3.4.4 Maximum Packet Size Setting

The DCPMAXP.MXPS[6:0] bits and the PIPEMAXP.MXPS[8:0] bits are used to specify the maximum packet size for each pipe. DCP and PIPE1 to PIPE5 can be set to any of the maximum pipe sizes defined by USB Specification 2.0. For PIPE6 to PIPE9, 64 bytes are the upper limit of the maximum packet size. The maximum packet size should be set before beginning the transfer (PID[1:0] = 01b (BUF)).

- DCP: Set 8, 16, 32, or 64.
- PIPE1 to PIPE5: Set 8, 16, 32, or 64 when using bulk transfer.
- PIPE1 and PIPE2: Set a value between 1 and 256 when using isochronous transfer.
- PIPE6 to PIPE9: Set a value between 1 and 64.

38.3.4.5 Transaction Counter (For PIPE1 to PIPE5 in Reading Direction)

When the specified number of transactions has been completed in the data packet receiving direction, the USB recognizes that the transfer has ended. Two transaction counters are provided: one is the PIPEnTRN register that specifies the number of transactions to be executed and the other is the current counter that internally counts the number of executed transactions. With the PIPECFG.SHTNAK bit set to 1, when the current counter value matches the specified number of transactions, the corresponding PIPEnCTR.PID[1:0] bits are set to 00b (NAK) and the subsequent transfer is disabled. The transactions can be counted again from the beginning by initializing the current counter of the transaction counter function through the PIPEnTRE.TRCLR bit. The information read from PIPEnTRN differs depending on the setting of the PIPEnTRE.TRENB bit.

- The TRENB bit = 0: The specified transaction counter value can be read.
- The TRENB bit = 1: The current counter value indicating the internally counted number of executed transactions can be read.

When operating the TRCLR bit, the following should be noted.

- If the transactions are being counted and PID[1:0] = 01b (BUF), the current counter cannot be cleared.
- If there is any data left in the buffer, the current counter cannot be cleared.

38.3.4.6 Response PID

The PID[1:0] bits in the DCPCTR and PIPEnCTR registers are used to set the response PID for each pipe.
The following shows the USB operation with various response PID settings:

(1) Response PID settings when the host controller is selected:

The response PID is used to specify the execution of transactions.

- NAK setting: Using pipes is disabled. No transaction is executed.
- BUF setting: Transactions are executed based on the status of the buffer memory.
  For OUT direction: If there are transmit data in the buffer memory, an OUT token is issued.
  For IN direction: If there is an area to receive data in the buffer memory, an IN token is issued.
- STALL setting: Using pipes is disabled. No transaction is executed.

Note: Setup transactions for the DCP are set with the DCPCTR.SUREQ bit.

(2) Response PID settings when the function controller is selected:

The response PID is used to specify the response to transactions from the host.

- NAK setting: The NAK response is returned in response to the generated transaction.
- BUF setting: Responses are made to transactions according to the status of the buffer memory.
- STALL setting: The STALL response is returned in response to the generated transaction.

Note: For setup transactions, an ACK response is returned regardless of the PID[1:0] bits setting, and the USB request is stored in the register.

The USB may write to the PID[1:0] bits, depending on the results of the transaction as described below.

(3) When the host controller has been selected and the response PID is set by hardware:

- NAK setting: In the following cases, PID[1:0] = 00b (NAK) is set and issuing of tokens is automatically stopped:
  When a transfer other than isochronous transfer has been performed and an NRDY interrupt is generated.
  (For details, refer to section 38.3.3.2, NRDY Interrupt.)
  - If a short packet is received when the PIPECFG.SHTNAK bit has been set to 1 for bulk transfer.
  - If the transaction counting ends when the SHTNAK bit has been set to 1 for bulk transfer.
- BUF setting: There is no BUF writing by the USB.
- STALL setting: In the following cases, PID[1:0] = 1xb (STALL) is set and issuing of tokens is automatically stopped:
  When STALL is received in response to the transmitted token.
  When the size of the receive data packet exceeds the maximum packet size.

(4) When the function controller has been selected and the response PID is set by hardware:

- NAK setting: In the following cases, PID[1:0] = 00b (NAK) is set and NAK is returned in response to transactions:
  When the SETUP token is received normally (DCP only).
  If the transaction counting ends or a short packet is received when the PIPECFG.SHTNAK bit has been set to 1 for bulk transfer.
- BUF setting: There is no BUF writing by the USB.
- STALL setting: In the following cases, PID[1:0] = 1xb (STALL) is set and STALL is returned in response to transactions:
  When a maximum packet size exceeded error is detected in the received data packet.
  When a control transfer sequence error has been detected (DCP only).

38.3.4.7 Data PID Sequence Bit

The USB automatically toggles the sequence bit in the data PID when data is transferred successfully in the control transfer data stage, bulk transfer, and interrupt transfer. The sequence bit of the next data PID to be transmitted can be confirmed with the SQMON flag in the DCPCTR and PIPEnCTR registers. When data is transmitted, the sequence bit switches at the timing of ACK handshake reception. When data is received, the sequence bit switches at the timing of ACK handshake transmission. The DCPCTR.SQCLR bit and the PIPEnCTR.SQSET bit can be used to change the data PID sequence bit.

When the function controller has been selected and control transfer is used, the USB automatically sets the sequence bit when a stage transition is made. DATA1 is returned when the setup stage is ended. The sequence bit is not referenced and PID = DATA1 is returned in a status stage. Therefore, software settings are not required. However, when the host controller has been selected and control transfer is used, the sequence bit should be set by software at a stage transition. For the ClearFeature request transmission or reception, the data PID sequence bit should be set by software regardless of whether the host controller or function controller is selected.

38.3.4.8 Response PID = NAK Function

The USB has a function that disables pipe operation (response PID = NAK) at the timing at which the final data packet of a transaction is received (the USB automatically distinguishes this based on reception of a short packet or the transaction counter) by setting the PIPECFG.SHTNAK bit to 1.

When the double buffer mode is being used for the buffer memory, using this function enables reception of data packets in transfer units. If pipe operation has been disabled, software should set the pipe to the enabled state again (response PID = BUF).

The response PID = NAK function can be used only when bulk transfers are used.

38.3.4.9 Auto Response Mode

With the pipes for bulk transfer (PIPE1 to PIPE5), when the PIPEnCTR.ATREPM bit is set to 1, a transition is made to auto response mode. During an OUT transfer (the PIPECFG.DIR bit = 0), OUT-NAK mode is entered, and during an IN transfer (the DIR bit = 1), null auto response mode is entered.

38.3.4.10 OUT-NAK Mode

With the pipes for bulk OUT transfer, NAK is returned in response to an OUT token and an NRDY interrupt is output when the PIPEnCTR.ATREPM bit is set to 1. To make a transition from normal mode to OUT-NAK mode, OUT-NAK mode should be specified in the pipe operation disabled state (response PID = NAK) before enabling pipe operation (response PID = BUF). After pipe operation has been enabled, OUT-NAK mode becomes valid. However, if an OUT token is received immediately before pipe operation is disabled, the token data is normally received, and an ACK is returned to the host.

To make a transition from OUT-NAK mode to normal mode, OUT-NAK mode should be canceled in the pipe operation disabled state (response PID = NAK) before enabling pipe operation (response PID = BUF). In normal mode, reception of OUT data is enabled.

38.3.4.11 Null Auto Response Mode

With the pipes for bulk IN transfer, zero-length packets are continuously transmitted when the PIPEnCTR.ATREPM bit is set to 1.

To make a transition from normal mode to null auto response mode, null auto response mode should be set in the pipe operation disabled state (response PID = NAK) before enabling pipe operation (response PID = BUF). After pipe operation has been enabled, null auto response mode becomes valid. Before setting null auto response mode, the PIPEnCTR.INBUFM = 0 should be confirmed because the mode can be set only when the buffer is empty. If the INBUFM flag is 1, the buffer should be emptied with the PIPEnCTR.ACLRM bit. While a transition to null auto response mode is being made, data should not be written from the FIFO port.

To make a transition from null auto response mode to normal mode, pipe operation disabled state (response PID = NAK) should be retained for the period of zero-length packet transmission (about 10 µs) before canceling null auto response mode. In normal mode, data can be written from the FIFO port; therefore, packet transmission to the host is enabled by enabling pipe operation (response PID = BUF).

38.3.5 FIFO Buffer Memory

38.3.5.1 FIFO Buffer Memory

The USB has FIFO buffer memory for data transfer. The memory area used for each pipe is managed by the USB. The FIFO buffer memory has two states depending on whether the access right is assigned to the system (CPU side) or the USB (SIE side).

(1) Buffer Status

Table 38.17 and Table 38.18 show the buffer status in the USB. The buffer memory status can be confirmed using the DCPCTR.BSTS flag and the PIPEnCTR.INBUFM flag. The transfer direction for the buffer memory can be specified using either the PIPECFG.DIR bit or the CFIFOSEL.ISEL bit (when DCP is selected).

The INBUFM flag is valid for PIPE0 to PIPE5 in the transmitting direction.

When a transmitting pipe uses the double buffer configuration, software can read the BSTS flag to monitor the buffer memory status on the CPU side and the INBUFM flag to monitor the buffer memory status on the SIE side. When the BEMP interrupt may not show the buffer empty status because the write access to the FIFO port by the CPU or DMAC/DTC is slow, software can use the INBUFM flag to confirm the end of transmission.

Table 38.17 Buffer Status Indicated by the BSTS Flag

ISEL or DIR	BSTS	Buffer Memory Status
0 (receiving direction)	0	There is no received data, or data is being received. Reading from the FIFO port is disabled.
0 (receiving direction)	1	There is received data, or a zero-length packet has been received. Reading from the FIFO port is allowed. Note that when a zero-length packet is received, reading is not possible and the buffer must be cleared.
1 (transmitting direction)	0	The transmission has not been completed. Writing to the FIFO port is disabled.
1 (transmitting direction)	1	The transmission has been completed. CPU write is allowed.

Table 38.18 Buffer Status Indicated by the INBUFM Flag

DIR	INBUFM	Buffer Memory Status
0 (receiving direction)	Invalid	Invalid
1 (transmitting direction)	0	The transmission has been completed. There is no waiting data to be transmitted.
1 (transmitting direction)	1	The FIFO port has written data to the buffer. There is data to be transmitted.

38.3.5.2 FIFO Buffer Clearing

Table 38.19 shows the clearing of the FIFO buffer memory by the USB. The buffer memory can be cleared using the BCLR, DnFIFOSEL.DCLRM, and PIPEnCTR.ACLRM bit in the port control register.
Either a single or double buffer configuration can be selected for PIPE1 to PIPE5, using the PIPECFG.DBLB bit.

Table 38.19 List of Buffer Clearing Methods

FIFO Buffer Clearing Mode	Clearing Buffer Memory on CPU Side	Mode for Automatically Clearing Buffer Memory after Reading Specified Pipe Data	Auto Buffer Clear Mode for Discarding All Received Packets
Register used	CFIFOCTR DnFIFOCTR	DnFIFOSEL	PIPEnCTR
Bit used	BCLR	DCLRM	ACLRM
Clearing condition	Cleared by writing 1	1: Mode valid 0: Mode invalid	1: Mode valid 0: Mode invalid

(1) Auto Buffer Clear Mode Function

With the USB, all received data packets are discarded if the PIPEnCTR.ACLRM bit is set to 1. If a correct data packet has been received, the ACK response is returned to the host controller. The auto buffer clear mode function can be set only in the buffer memory reading direction.
If the ACLRM bit is set to 1 and then to 0, the buffer memory of the selected pipe can be cleared regardless of the access direction.
An access cycle of at least 100 ns is required for the internal hardware sequence processing time between ACLRM = 1 and ACLRM = 0.

38.3.5.3 FIFO Port Functions

Table 38.20 shows the settings for the FIFO port functions of the USB. In write access, writing data until the maximum packet size is reached automatically enables transmission of the data. To enable transmission before the maximum packet size is reached, the BVAL bit in the port control register should be set to end writing. To send a zero-length packet, the BCLR bit in the register should be used to clear the buffer and then the BVAL bit set in order to end writing.
In reading, reception of new packets is automatically enabled when all data has been read. Data cannot be read when a zero-length packet has been received (the DTLN[8:0] flags = 0), so the BCLR bit in the register should be used to clear the buffer. The length of the receive data can be confirmed using the DTLN[8:0] flags in the port control register.

Table 38.20 FIFO Port Function Settings

Register Name	Bit Name	Description
CFIFOSEL, DnFIFOSEL (n = 0, 1)	RCNT	Selects DTLN read mode.
	REW	Buffer memory rewind (re-read, rewrite).
	DCLRM	Automatically clears receive data for a specified pipe after the data has been read (only for DnFIFO).
	DREQE	Enables DMA/DTC transfers (only for DnFIFO).
	MBW	FIFO port access bit width.
	BIGEND	Selects FIFO port endian.
	ISEL	FIFO port access direction (only for DCP).
	CURPIPE	Selects the current pipe.
CFIFOCTR, DnFIFOCTR (n = 0, 1)	BVAL	Ends writing to the buffer memory.
	BCLR	Clears the buffer memory on the CPU side.
	DTLN	Checks the length of receive data.

(1) FIFO Port Selection

Table 38.21 shows the pipes that can be selected with the various FIFO ports. The pipe to be accessed should be selected using the CURPIPE[3:0] bits in the port select register. After the pipe is selected, whether the written value can be correctly read from the CURPIPE[3:0] bits should be checked. (If the previous pipe number is read, it indicates that the pipe modification is being executed by the USB controller.) Then, the FRDY flag in a port control register = 1 is checked.
In addition, the bus width to be accessed should be selected using the MBW bit in the port select register. The buffer memory access direction conforms to the PIPECFG.DIR bit. Only for the DCP, the ISEL bit in the port select register determines the direction.

Table 38.21 FIFO Port Access Categorized by Pipe

Pipe	Access Method	Port that can be Used
DCP	CPU access	CFIFO port register
PIPE1 to PIPE9	CPU access	CFIFO port register D0FIFO/D1FIFO port register
	DMAC/DTC access	D0FIFO/D1FIFO port register

(2) REW Bit

It is possible to temporarily stop access to the pipe currently being accessed, access a different pipe, and then continue processing for the current pipe again. The REW bit in the port select register is used for this processing.
If a pipe is selected through the CURPIPE[3:0] bits in the port select register with the REW bit set to 1, the pointer used for reading from and writing to the buffer memory is reset, and reading or writing can be carried out from the first byte.
If a pipe is selected with 0 set for the REW bit, data can be read and written in continuation from the previous selection, without the pointer being reset.
To access the FIFO port, the FRDY flag in the port control register = 1 should be checked after selecting a pipe.

38.3.5.4 DMA Transfers (D0FIFO and D1FIFO Ports)

(1) Overview of DMA Transfers

For PIPE1 to PIPE9, the FIFO port can be accessed using the DMAC. When accessing the buffer for the pipe targeted for DMA transfer is enabled, a DMA transfer request is issued.
The unit of transfer to the FIFO port should be selected using the DnFIFOSEL.MBW bit and the pipe targeted for the DMA transfer should be selected using the DnFIFOSEL.CURPIPE[3:0] bits. The selected pipe should not be changed during the DMA transfer.

(2) DnFIFO Auto Clear Mode (D0FIFO and D1FIFO Port Reading Direction)

If 1 is set in the DnFIFOSEL.DCLRM bit, the USB automatically clears the buffer memory of the selected pipe when reading of data from the buffer memory has been completed.
Table 38.22 shows the packet reception and buffer memory clearing processing by software for each of the various settings. As shown in Table 38.22, the buffer clearing conditions depend on the value set in the PIPECFG.BFRE bit. Using the DnFIFOSEL.DCLRM bit eliminates the need for the buffer to be cleared by software in any situation that requires buffer clearing. This enables DMA transfers without involving software.
The DnFIFO auto clear mode can be set only in the buffer memory reading direction.

Table 38.22 Packet Reception and Buffer Memory Clearing Processing by Software

Buffer Status When Packet is Received	Register Setting			
	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1
Buffer full	Clearing is not necessary	Clearing is not necessary	Clearing is not necessary	Clearing is not necessary
Zero-length packet reception	Clearing is necessary	Clearing is necessary	Clearing is not necessary	Clearing is not necessary
Normal short packet reception	Clearing is not necessary	Clearing is necessary	Clearing is not necessary	Clearing is not necessary
Transaction count end	Clearing is not necessary	Clearing is necessary	Clearing is not necessary	Clearing is not necessary

38.3.6 Control Transfers Using DCP

In the data stage of control transfers, data is transferred using the default control pipe (DCP).
The DCP buffer memory is a 64-byte single buffer and is a fixed area that is shared for both control reading and control writing. The buffer memory can be accessed only through the CFIFO port.

38.3.6.1 Control Transfers When the Host Controller is Selected

(1) Setup Stage

Registers USBREQ, USBVAL, USBINDX, and USBLENG are the registers that are used to transmit a USB request for setup transactions. Writing setup packet data to the registers and writing 1 to the DCPCTR.SUREQ bit transmits the specified data for setup transactions. Upon completion of the transaction, the SUREQ bit is set to 0. The above USB request registers should not be modified while SUREQ = 1.
After the attached state of the connected function device is detected, the first setup transaction for the device should be issued by using the sequence described above with the DCPMAXP.DEVSEL[3:0] bits set to 0 and the DEVADD0.USBSPD[1:0] bits set appropriately.
After the connected function device is shifted to the Address state, setup transactions should be issued by using the sequence described above with the assigned USB address set in the DEVSEL[3:0] bits and the bits in the DEVADDn register corresponding to the specified USB address set appropriately. For example, when PIPEMAXP.DEVSEL[3:0] = 0010b, make appropriate settings in the DEVADD2 register; when PIPEMAXP.DEVSEL[3:0] = 0101b, make appropriate settings in the DEVADD5 register.
When the setup transaction data has been sent, an interrupt request is generated according to the response received from the peripheral device (SIGN or SACK flag in the INTSTS1 register), by means of which the result of the setup transactions can be confirmed.
A data packet of DATA0 (USB request) is transmitted as the data packet for a setup transaction regardless of the setting of the DCPCTR.SQMON flag.

(2) Data Stage

Data is transferred using the DCP buffer memory.
The access direction of the DCP buffer memory should be specified using the CFIFOSEL.ISEL bit. The transfer direction should be specified using the DCPCFG.DIR bit.
For the first data packet of the data stage, the data PID should be transferred as DATA1. Set data PID = DATA1 in the DCPCTR.SQSET bit and the PID[1:0] bits = 01b (BUF). Completion of data transfer is detected using the BRDY or BEMP interrupt.
For control write transfers, when the number of data bytes to be sent is an integer multiple of the maximum packet size, software should control so as to send a zero-length packet at the end.

(3) Status Stage

Zero-length packet data is transferred in the direction opposite to that in the data stage. As in the data stage, data is transferred using the DCP buffer memory. Transactions are done in the same manner as the data stage.
For the data packets of the status stage, the data PID should be set to DATA1 using the DCPCTR.SQSET bit.
For reception of a zero-length packet, the received data length should be confirmed using the CFIFOCTR.DTLN[8:0] flags after a BRDY interrupt is generated, and the buffer memory should then be cleared using the CFIFOCTR.BCLR bit.

38.3.6.2 Control Transfers When the Function Controller is Selected

(1) Setup Stage

The USB sends an ACK response for a correct setup packet targeted to the USB. The operation of the USB in the setup stage is described below.
When receiving a new setup packet, the USB sets the following bits.

- Set the INTSTS0.VALID flag to 1.
- Set the DCPCTR.PID[1:0] bits to 00b (NAK).
- Set the DCPCTR.CCPL bit to 0.

When receiving a data packet right after the setup packet, the USB stores the USB request parameters in registers USBREQ, USBVAL, USBINDX, and USBLENG.

Response processing with respect to the control transfer should be carried out after setting the VALID flag = 0. In the VALID flag = 1 state, PID[1:0] = 01b (BUF) cannot be set, and the data stage cannot be terminated.
Using the function of the VALID flag, the USB can suspend the current request processing when receiving a new USB request during a control transfer, and can send a response to the newest request.
In addition, the USB automatically detects the direction bit (bit 8 of bmRequestType) and the request data length (wLength) of the received USB request, distinguishes between control read transfer, control write transfer, and no-data control transfer, and controls stage transitions. For a wrong sequence, the sequence error of the control transfer stage transition interrupt is generated, and the software is notified of occurrence of the error. For the stage control of the USB, refer to Figure 38.15.

(2) Data Stage

Data transfers corresponding to received USB requests should be done using the DCP. Before accessing the DCP buffer memory, the access direction should be specified using the CFIFOSEL.ISEL bit.
If the transfer data is larger than the size of the DCP buffer memory, the data transfer should be carried out using the BRDY interrupt for control write transfers and the BEMP interrupt for control read transfers.

(3) Status Stage

Control transfers are terminated by setting the DCPCTR.CCPL bit to 1 while the DCPCTR.PID[1:0] bits are set to 01b (BUF).
After the above settings have been made, the USB automatically executes the status stage in accordance with the data transfer direction determined at the setup stage. The specific procedure is as follows.

- For control read transfers
  A zero-length packet is received from the USB host and an ACK response is sent.
- For control write transfers and no-data control transfers
  A zero-length packet is transmitted and an ACK response is received from the USB host.

(4) Control Transfer Auto Response Function

The USB automatically responds to a correct SET_ADDRESS request. If any of the following errors occurs in the SET_ADDRESS request, a response from the software is necessary.

- bmRequestType is not 00h: Any transfer other than a control write transfer
- wIndex is not 00h: Request error
- wIndex is not 00h: Any transfer other than a no-data control transfer
- wValue is larger than 7Fh: Request error
- INTSTS0.DVSQ[2:0] are 011b (Configured state): Control transfer of a device state error

For all requests other than the SET_ADDRESS request, a response is required from the corresponding software.

38.3.7 Bulk Transfers (PIPE1 to PIPE5)

The buffer memory usage (single/double buffer setting) can be selected for bulk transfers. The USB provides the following functions for bulk transfers.

- BRDY interrupt function (PIPECFG.BFRE bit: refer to section 38.3.3.1, (2) When the SOFCFG.BRDYM Bit = 0 and the PIPECFG.BFRE Bit = 1
- Transaction count function
  (PIPEnTRE.TRENB, TRCLR, and PIPEnTRN.TRNCNT[15:0] bits: refer to section 38.3.4.5, Transaction Counter (For PIPE1 to PIPE5 in Reading Direction)
- Response PID = NAK function (PIPECFG.SHTNAK bit: refer to section 38.3.4.8, Response PID = NAK Function
- Auto response mode (PIPEnCTR.ATREPM bit: refer to section 38.3.4.9, Auto Response Mode)

38.3.8 Interrupt Transfers (PIPE6 to PIPE9)

When the function controller is selected, the USB carries out interrupt transfers in accordance with the timing controlled by the host controller.
When the host controller is selected, the timing of issuing a token can be specified using the interval counter.

38.3.8.1 Interval Counter during Interrupt Transfers When the Host Controller is Selected

For interrupt transfers, intervals between transactions are set in the PIPEPERI.IITV[2:0] bits. The USB controller issues interrupt transfer tokens based on the specified intervals.

(1) Counter Initialization

The interval counter is initialized when the MCU is reset or when the PIPEnCTR.ACLRM bit is set to 1. Note that the PIPEPERI.IITV[2:0] bits are not initialized when the ACLRM bit is used for initialization.

Note that the interval counter is not initialized in the following case.

- USB bus reset or USB suspended
  The IITV[2:0] bits are not initialized. Setting 1 to the DVSTCTR0.UACT bit starts counting from the value before entering the USB bus reset state or USB suspended state.

(2) Operation When Transmission/Reception is Impossible at Token Issuance Timing

The USB cannot issue tokens even at token issuance timing in the following cases. In such a case, the USB attempts transactions at the subsequent interval.

- When the PID[1:0] bits are set to 00b (NAK) or 1xb (STALL).
- When the buffer memory is full at the token sending timing in the receiving (IN) direction.
- When there is no data to be sent in the buffer memory at the token sending timing in the transmitting (OUT) direction.

38.3.9 Isochronous Transfers (PIPE1 and PIPE2)

The USB has the following functions for isochronous transfers.

- Notification of isochronous transfer error information
- Interval counter (specified by the PIPEPERI.IITV[2:0] bits)
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function (specified by the PIPEPERI.IFIS bit)

38.3.9.1 Error Detection in Isochronous Transfers

The USB has a function for detecting the error information described below, so that when errors occur in isochronous transfers, they can be controlled by software. Table 38.23 and Table 38.24 show the priority in which errors are confirmed and the interrupts generated corresponding to errors.

(a) PID errors

- If the PID of the received packet is illegal.

(b) CRC errors and bit stuffing errors

- If an error occurs in the CRC of the received packet or the bit stuffing is illegal.

(c) Maximum packet size exceeded

- The data of the received packet is larger than the specified maximum packet size.

(d) Overrun and underrun errors

- When the host controller is selected
  When the buffer memory is full at the token sending timing in the IN (receiving) direction.
  When there is no data to be sent in the buffer memory at the token sending timing in the OUT (transmitting) direction.
- When the function controller is selected
  When there is no data to be sent in the buffer memory at the token receiving timing in the IN (transmitting) direction.
  When the buffer memory is full at the token receiving timing in the OUT (receiving) direction.

(e) Interval errors

An interval error is generated on any of the following conditions when the function controller is selected.

- During an isochronous IN transfer, an IN token could not be received in the interval frame.
- During an isochronous OUT transfer, an OUT token could not be received in the interval frame.

Table 38.23 Error Detection When a Token is Received

Detection Priority	Error	Generated Interrupt and Status
1	PID errors	No interrupts are generated in both cases when the host controller is selected and the function controller is selected (ignored as a corrupted packet).
2	CRC errors and bit stuffing errors	No interrupts generated in both cases when the host controller is selected and the function controller is selected (ignored as a corrupted packet).
3	Overrun and underrun errors	An NRDY interrupt is generated to set the FRMNUM.OVRN flag to 1 in both cases when the host controller is selected and function controller is selected. When the function controller is selected, a zero-length packet is transmitted in response to IN token. However, no data packets are received in response to OUT token.
4	Interval errors	An NRDY interrupt is generated when the function controller is selected. It is not generated when the host controller is selected.

Table 38.24 Error Detection When a Data Packet is Received

Detection Priority	Error	Generated Interrupt and Status
1	PID errors	No interrupts are generated (ignored as a corrupted packet).
2	CRC errors and bit stuffing errors	An NRDY interrupt is generated to set the FRMNUM.CRCE to 1 bit in both cases when the host controller is selected and the function controller is selected.
3	Maximum packet size exceeded errors	A BEMP interrupt is generated to set the PID[1:0] bits to 1xb (STALL) in both cases when the host controller is selected and the function controller is selected.

38.3.9.2 Data PID

When the function controller is selected, the USB operates as follows in response to the received PID.
IN direction

- DATA0: Sent as data packet PID
- DATA1: Not sent
- DATA2: Not sent
- mDATA: Not sent

OUT direction

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Packets are ignored
- mDATA: Packets are ignored

38.3.9.3 Interval Counter

The isochronous transfer interval can be set using the PIPEPERI.IITV[2:0] bits. The interval counter enables the functions shown in Table 38.25 when the function controller is selected. When the host controller is selected, the USB generates the token issuance timing. When the host controller is selected, the interval counter operation is the same as that in the interrupt transfer.

Table 38.25 Interval Counter Function When the Function Controller is Selected

Transfer Direction	Function	Conditions for Detection
IN	Flushes transmit buffer	When an IN token cannot be successfully received in the interval frame during an isochronous IN transfer
OUT	Notifies that a token not being received	When an OUT token cannot be successfully received in the interval frame during an isochronous OUT transfer

The interval count is carried out when an SOF is received or for interpolated SOFs, so the isochronism can be maintained even if an SOF is damaged. The frame interval that can be set is the $2^{IITV[2:0]}$ frames.

(1) Counter Initialization When the Function Controller is Selected

The interval counter is initialized when the MCU is reset or when the PIPEnCTR.ACLRM bit is set to 1. Note that the PIPEPERI.IITV[2:0] bits are not initialized when the ACLRM bit is used for initialization.

After the interval counter has been initialized, counting is started under either of the following conditions 1 and 2 when a packet has been transferred successfully.

1. An SOF is received after transmission of data in response to an IN token while the PID[1:0] bits are 01b (BUF).
2. An SOF is received after reception of data of an OUT token while the PID[1:0] bits are 01b (BUF).

Note that the interval counter is not initialized under the following conditions.

- When the PID[1:0] bits are set to 00b (NAK) or 1xb (STALL)
  The interval timer does not stop. The USB attempts transactions at the subsequent interval.
- When the USB bus is reset or USB is suspended
  The IITV[2:0] bits are not initialized. When an SOF has been received, counting is restarted from the value prior to the reception of the SOF.

(2) Interval Counting and Transfer Control When the Host Controller is Selected

The USB controls the interval between token issuance operations based on the PIPEPERI.IITV[2:0] bit settings. Specifically, the USB issues a token for a selected pipe once every $2^{IITV[2:0]}$ frames.
The USB starts counting the token issuance interval at the frame following the frame in which the PID[1:0] bits have been set to 01b (BUF) by software.

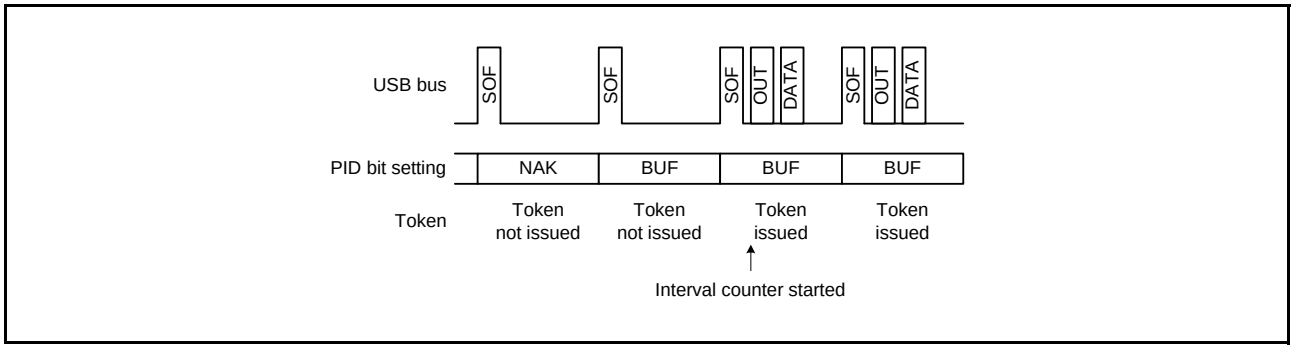

Figure 38.16 Token Issuance When IITV[2:0] = 000b

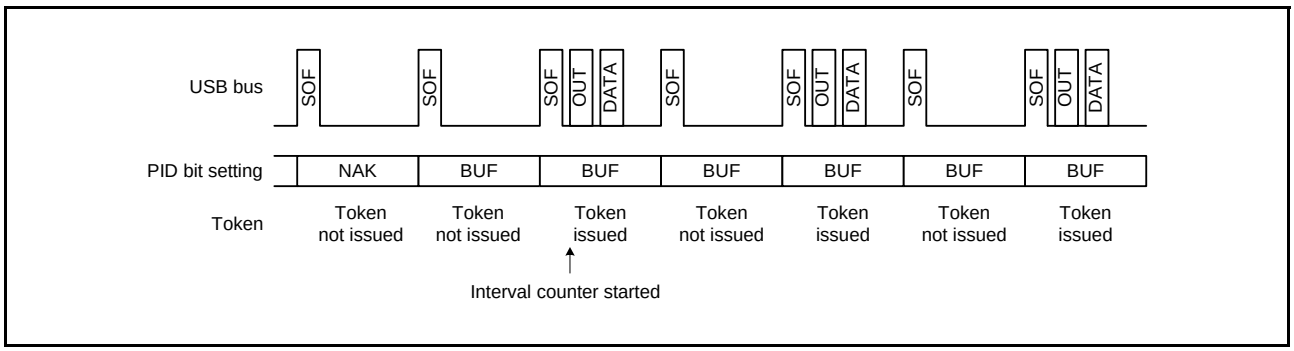

Figure 38.17 Token Issuance When IITV[2:0] = 001b

When the selected pipe is set for isochronous transfers, the USB carries out the following operation in addition to controlling the token issuance interval. The USB issues a token even when the NRDY interrupt generation condition is satisfied.

(a) When the selected pipe is for isochronous IN transfers

The USB generates an NRDY interrupt when the USB issues an IN token but does not receive a packet successfully from a peripheral device (no response or packet error).
The USB sets the FRMNUM.OVRN flag to 1 generating an NRDY interrupt when the time to issue an IN token comes while the USB cannot receive data because the FIFO buffer is full (due to the fact that the CPU or DMAC/DTC is too slow to read data from the FIFO buffer).

(b) When the selected pipe is for isochronous OUT transfers

The USB sets the OVRN flag to 1 generating an NRDY interrupt and transmitting a zero-length packet when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer (because the CPU or DMAC/DTC is too slow to write data to the FIFO buffer).
The token issuance interval is reset on any of the following conditions.

- When the USB is reset through a reset pin
  (The IITV[2:0] bits are also set to 0).
- When the PIPEnCTR.ACLRM bit has been set to 1 by software.

(3) Interval Counting and Transfer Control When the Function Controller is Selected

(a) When the selected pipe is for isochronous OUT transfers

The USB generates an NRDY interrupt when the USB fails to receive a data packet within the interval set by the PIPEPERI.IITV[2:0] bits.
The USB also generates an NRDY interrupt when the USB fails to receive data because of a CRC error or other errors contained in the data packet or because of the FIFO buffer being full.
The NRDY interrupt is generated at the timing of SOF packet reception. Even if the SOF packet is corrupted, the internal interpolation allows the interrupt to be generated at the timing to receive the SOF packet.
However, when the IITV[2:0] bits are set to a value other than 0, the USB generates an NRDY interrupt on receiving an SOF packet for every interval after starting interval counting operation.
When the PID[1:0] bits are set to 00b (NAK) by software after starting the interval timer, the USB does not generate an NRDY interrupt on receiving an SOF packet.
The timing to start interval counting depends on the setting of IITV[2:0] bits as shown below.

- When the IITV[2:0] = 000b: The interval counting starts when software has set the PID[1:0] bits for the selected pipe to 01b (BUF).

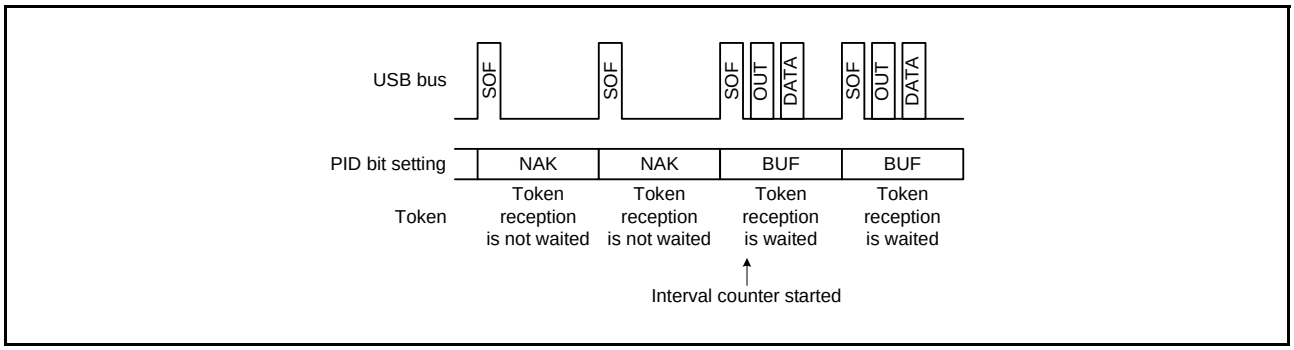

Figure 38.18 Relationship between Frames and Expected Token Reception When IITV[2:0] = 000b

- When the IITV[2:0] ≠ 000b: The interval counting starts on completion of successful reception of the first data packet after the PID[1:0] bits for the selected pipe have been modified to 01b (BUF).

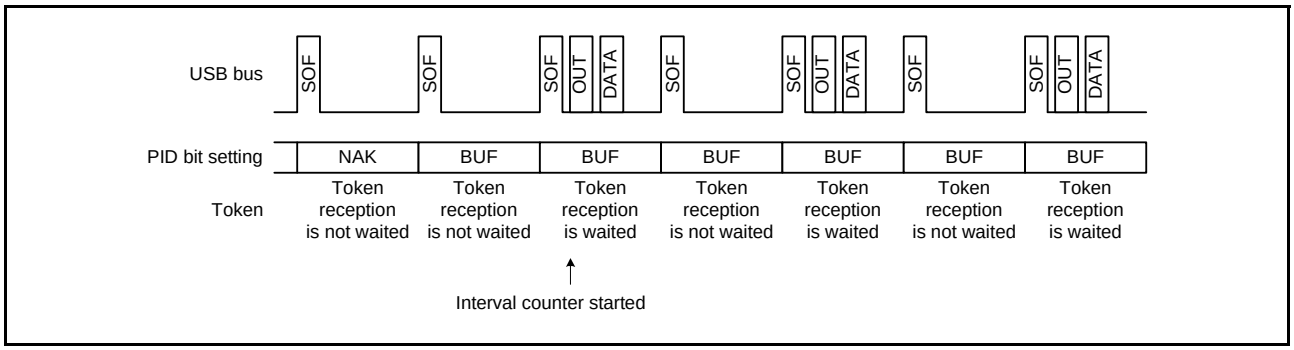

Figure 38.19 Relationship between Frames and Expected Token Reception When IITV[2:0] ≠ 000b

(b) When the selected pipe is for isochronous IN transfers

The PIPEPERI.IFIS bit should be 1 for this use. When IFIS = 0, the USB transmits a data packet in response to the received IN token irrespective of the setting of the PIPEPERI.IITV[2:0] bits.
When IFIS = 1, the USB clears the FIFO buffer when the USB fails to receive an IN token in the frame at the interval set by the IITV[2:0] bits while there is data to be transmitted in the FIFO buffer.
The USB also clears the FIFO buffer when the USB fails to receive an IN token successfully because of a bus error such as a CRC error contained in the IN token.
The FIFO buffer is cleared at the timing of SOF packet reception. Even if the SOF packet is corrupted, the internal interpolation allows the FIFO buffer to be cleared at the timing to receive the SOF packet.

The timing to start interval counting depends on the setting of the IITV[2:0] bits (similar to the timing during OUT transfers).
The interval is counted on any of the following conditions in function controller mode.

- When a hardware-reset is applied to the USB (here, the IITV[2:0] bits are also set to 000b).
- When the PIPEnCTR.ACLRM bit is set to 1 by software.
- When the USB detects a USB bus reset.

(4) Setup of Data to be Transmitted Using Isochronous Transfer When the Function Controller is Selected

With isochronous data transmission using the USB in the function controller, after data has been written to the buffer memory, a data packet can be transmitted with the next frame after the frame in which an SOF packet is detected. This function is called the isochronous transfer transmission data setup function, and it makes it possible to designate the frame from which transmission began.

In a double buffer configuration, even after the writing of data to both buffers has been completed, transmission will be enabled for only one buffer to which data writing was completed first. Accordingly, even if multiple IN tokens are received, only one packet of data is transmitted from a single buffer.

When an IN token is received, if the buffer memory is in the transmission enabled state, the USB transmits data as a normal response. If the buffer memory is not in the transmission enabled state, however, a zero-length packet is sent and an underrun error occurs.

Figure 38.20 shows an example of transmission using the isochronous transfer transmission data setup function with the USB when IITV[2:0] = 000b (every frame) has been set.

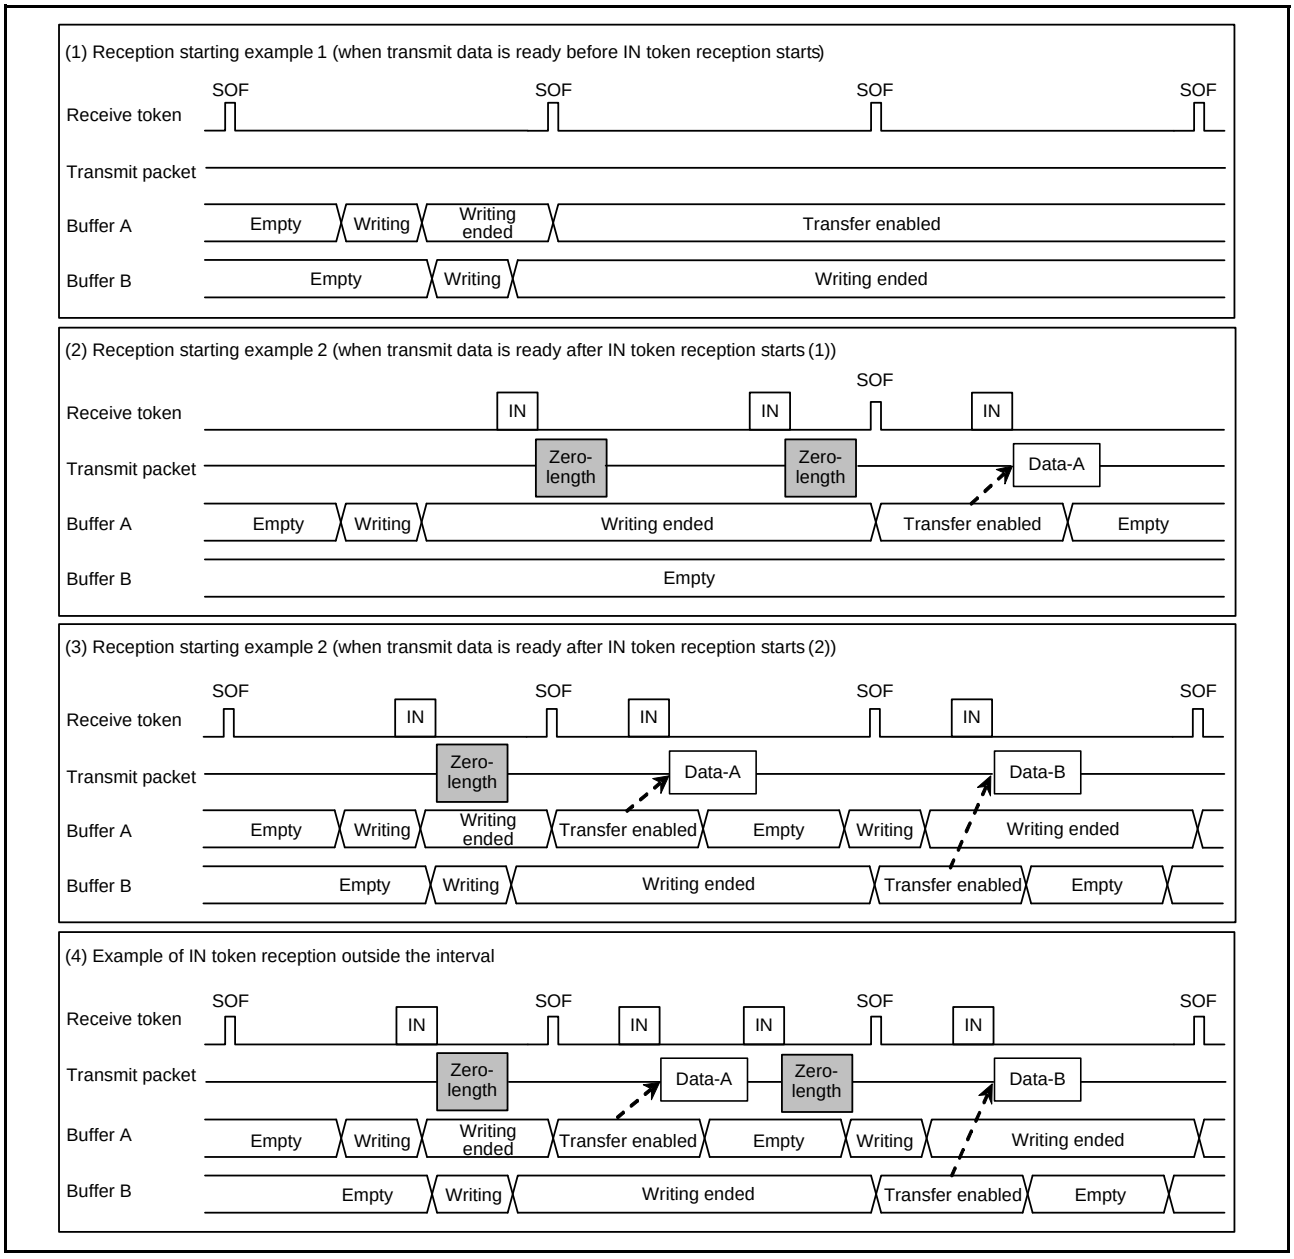

Figure 38.20 Example of Data Setup Function Operation

(5) Isochronous Transfer Transmission Buffer Flush When the Function Controller is Selected

If an SOF packet of the next frame is received without receiving an IN token in an interval frame during isochronous data transmission, the USB operates as if an IN token had been corrupted, and clears the buffer for which transmission is enabled, putting that buffer in the writing enabled state.
If a double buffer configuration is used and writing to both buffers has been completed, the buffer memory that was cleared is assumed as the data having been sent in the interval frame, and transmission is enabled for the buffer memory that is not cleared with SOF packet reception.
The timing of the buffer flush function depends on the setting of the PIPEPERI.IITV[2:0] bits.

- When the IITV[2:0] = 000b
  The buffer flush operation starts from the next frame after the pipe becomes valid.
- When the IITV[2:0] ≠ 000b
  The buffer flush operation is carried out after the first successful transaction.

Figure 38.21 shows an example of the buffer flush function in the USB. When an unanticipated token is received before the interval frame, the USB sends the write data or a zero-length packet as an underrun error according to the data setup state.

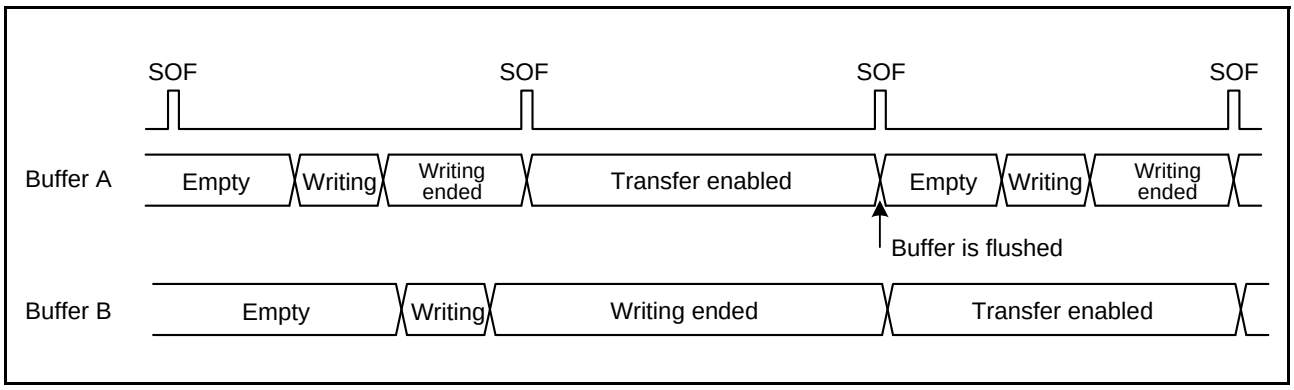

Figure 38.21 Example of Buffer Flush Operation

Figure 38.22 shows an example of interval error occurrence in the USB. There are five types of interval errors, as shown below. The interval error is generated at the timing indicated by ① in the figure, and the buffer flush function is activated.

If an interval error occurs during an IN transfers, the buffer flush function is activated; if it occurs during an OUT transfer, an NRDY interrupt is generated.

The FRMNUM.OVRN flag should be used to distinguish between NRDY interrupts such as received packet errors and overrun errors.

In response to tokens that are shaded in the figure, responses are sent according to the buffer memory status.

IN direction

- If the buffer is in the transmission enabled state, the data is transferred as a normal response.
- If the buffer is in the transmission disabled state, a zero-length packet is sent and an underrun error occurs.

OUT direction

- If the buffer is in the reception enabled state, the data is received as a normal response.
- If the buffer is in the reception disabled state, the data is discarded and an overrun error occurs.

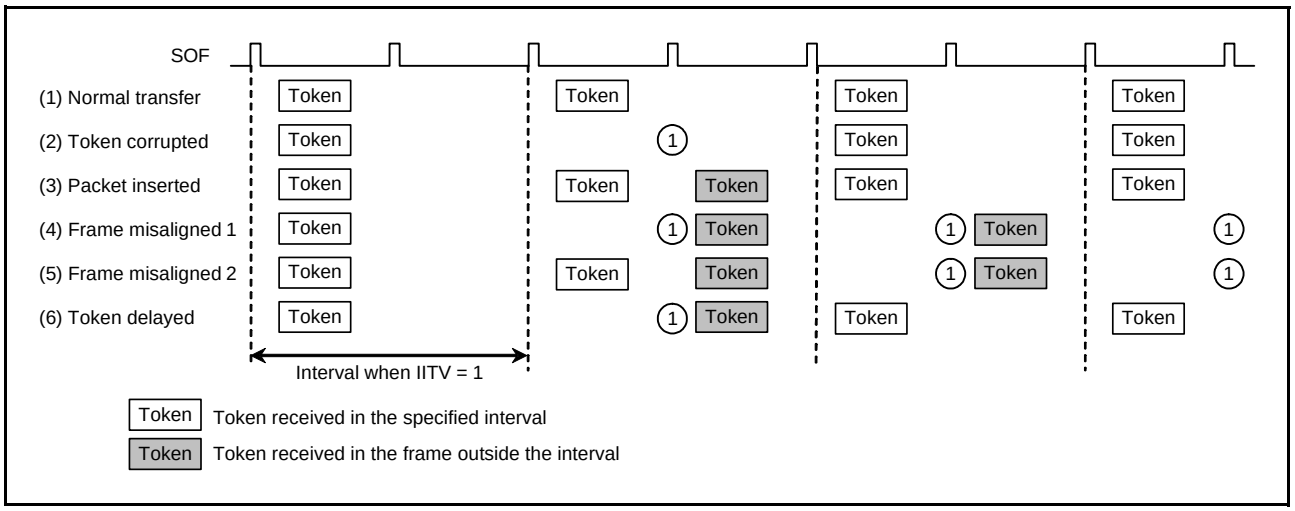

Figure 38.22 Example of Interval Error Occurrence When IITV[2:0] = 001b

38.3.10 SOF Interpolation Function

When the function controller is selected and if data could not be received at intervals of 1 ms because an SOF packet was corrupted or missing, the USB interpolates the SOF. The SOF interpolation operation begins when the USBE and SCKE bits in the SYSCFG register have been set to 1 and an SOF packet is received. The interpolation function is initialized under the following conditions.

- MCU reset
- USB bus reset
- Suspended state detected

The SOF interpolation operates as follows.

- The interpolation function is not activated until an SOF packet is received.
- After the first SOF packet is received, interpolation is carried out by counting 1 ms with an internal clock of 48 MHz.
- After the second and subsequent SOF packets are received, interpolation is carried out at the previous reception interval.
- Interpolation is not carried out in the suspended state or while a USB bus reset is being received.

The USB supports the following functions based on the SOF packet reception. These functions also operate normally with SOF interpolation, if the SOF packet was missing.

- Updating of the frame number
- SOFR interrupt timing
- Isochronous transfer interval count

If an SOF packet is missing during full-speed operation, the FRMNUM.FRNM[10:0] flags are not updated.

38.3.11 Pipe Schedule

38.3.11.1 Conditions for Generating a Transaction

When the host controller is selected and the DVSTCTR0.UACT bit has been set to 1, the USB generates a transaction under the conditions shown in Table 38.26.

Table 38.26 Conditions for Generating a Transaction

	Conditions for Generation				
Transaction	**DIR**	**PID[1:0]**	**IITV[0]**	**Buffer State**	**SUREQ**
Setup	—*1	—*1	—*1	—*1	1 setting
Control transfer data stage, status stage, bulk transfer	IN	BUF	Invalid	Receive area exists	—*1
	OUT	BUF	Invalid	Transmit data exists	—*1
Interrupt transfer	IN	BUF	Valid	Receive area exists	—*1
	OUT	BUF	Valid	Transmit data exists	—*1
Isochronous transfer	IN	BUF	Valid	*2	—*1
	OUT	BUF	Valid	*3	—*1

Note 1. Symbols (—) in the table indicate that the condition is unrelated to the generating of tokens. "Valid" indicates that, for interrupt transfers and isochronous transfers, a transaction is generated only in transfer frames that are based on the interval counter. "Invalid" indicates that a transaction is generated regardless of the interval counter.
Note 2. This indicates that a transaction is generated regardless of whether there is a receive area. If there is no receive area, however, the received data is discarded.
Note 3. This indicates that a transaction is generated regardless of whether there is any data to be transmitted. If there is no data to be transmitted, however, a zero-length packet is transmitted.

38.3.11.2 Transfer Schedule

This section describes the transfer scheduling within a frame of the USB. After the USB sends an SOF, the transfer is carried out in the sequence described below.

1. Execution of periodic transfers
   A pipe is searched in the order of PIPE1 → PIPE2 → PIPE6 → PIPE7 → PIPE8 → PIPE9, and then, if there is a pipe for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.
2. Setup transactions for control transfers
   The DCP is checked, and if a setup transaction is possible, it is sent.
3. Execution of bulk transfers, control transfer data stages, and control transfer status stages
   A pipe is searched in the order of DCP → PIPE1 → PIPE2 → PIPE3 → PIPE4 → PIPE5, and then, if there is a pipe for which a transaction for a bulk transfer, a control transfer data stage, or a control transfer status stage can be generated, the transaction is generated.
   When a transaction is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral device is ACK or NAK. If there is time for transfer within the frame, step 3 is repeated.

38.3.11.3 Enabling USB Communication

Setting the DVSTCTR0.UACT bit to 1 initiates SOF transmission and transaction generation is enabled.
Setting the UACT bit to 0 stops SOF transmission and a suspend state is entered. If the setting of the UACT bit is changed from 1 to 0, processing stops after the next SOF is sent.

38.4 Usage Notes

38.4.1 Setting the Module Stop Function

Operation of the USB module can be disabled or enabled using module stop control register B (MSTPCRB). The setting after a reset is for operation of the USB module to be stopped. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

39. USB2.0 Full-Speed Host/Function Module (USBA)

39.1 Overview

This MCU incorporates a USB2.0 full-speed host/function module (USBA). The USBA is a USB controller that is equipped to operate as a host controller or a function controller. As a host controller, the USBA supports full-speed transfer and low-speed transfer as defined in the Universal Serial Bus Specification Revision 2.0 (hereinafter referred to as USB 2.0). As a function controller, the USBA supports full-speed transfer as defined in USB 2.0. The USBA has an internal USB transceiver and supports all of the transfer types defined in USB 2.0. The USBA has FIFO buffers for data transfer, providing a maximum of 10 pipes. Any endpoint numbers can be assigned to pipes 1 to 9, based on the peripheral devices or user system for communication.

This chapter includes the following initialisms:

- BESL: Best Effort Service Latency
- HIRD: Host Initiated Resume Duration
- UTMI: USB Transceiver Macrocell Interface
- PHY: USB physical layer transceiver

Table 39.1 USBA Specifications

Item	Specifications
Features	• Incorporates a USB device controller (UDC) and transceiver for USB 2.0 The host controller and function controller operations are provided and the On-The-Go (OTG) function is supported. • Host controller and function controller operations are switched by software.
	In host controller operation: • Supports full-speed transfer (12 Mbps) and low-speed transfer (1.5 Mbps) • Automatic scheduling for Start-of-Frame (SOF) packets and other packet transmissions • Programmable intervals for isochronous and interrupt transfers • Communications with multiple peripheral devices connected via a single hub
	In function controller operation: • Supports full-speed transfer (12 Mbps) • Control transfer stage control function • Device state control function • Auto response function for SetAddress() request • SOF recovery function
Communication data transfer types	• Control transfer • Bulk transfer • Interrupt transfer • Isochronous transfer
Internal bus interface	• Connected to internal peripheral bus 3
Pipe configuration	• FIFO buffer of up to 8.5 Kbytes for USB communications is available. • Up to 10 pipes can be selected (including the default control pipe). • Programmable pipe configurations • Endpoint numbers can be assigned flexibly to pipes 1 to 9.
	• Transfer conditions that can be set for each pipe: Pipe 0 (default control pipe): Control transfer, 64-byte fixed single buffer Pipes 1 and 2: Bulk transfer/isochronous transfer in continuous transfer mode. Programmable buffer size up to 2 Kbytes. Selectable single buffer or double buffer mode. Pipes 3 to 5: Bulk transfer in continuous transfer mode. Programmable buffer size up to 2 Kbytes. Selectable single buffer or double buffer mode. Pipes 6 to 9: Interrupt transfer, 64-byte fixed single buffers
Other features	• Transfer ending function using transaction count • Function that changes the BRDY interrupt event notification timing • Function that automatically clears the FIFO buffer after the data for the pipe specified at the D0FIFO port or D1FIFO port has been read • NAK setting function for response packet ID (PID) generated by end of transfer • Internal pull-up and pull-down resistors for D+ and D– • Supports the USB 2.0 Engineering Change Notice for Link Power Management (LPM). A new sleep state (referred to as the L1 state) is available. • Supports Battery Charging Specification Revision 1.2 • To reduce power consumption, a classic-only mode where operation is only in accord with the USB 1.1 standard is selectable.

Figure 39.1 shows a block diagram of the USBA.

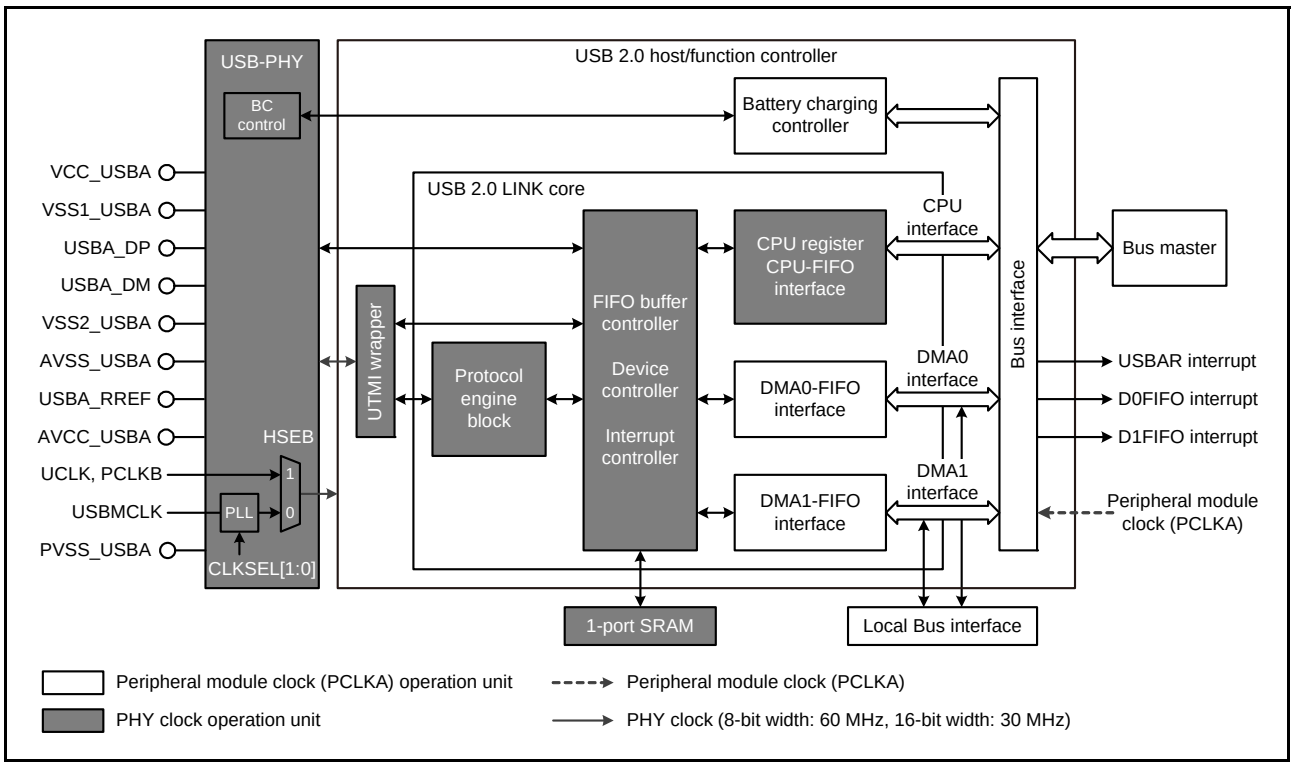

Figure 39.1 USBA Block Diagram

Table 39.2 lists the I/O pins of the USBA.

Table 39.2 Pin Configuration

Pin Symbol	I/O	Function
VCC_USBA	Input	Power supply pin for the USBA
VSS1_USBA VSS2_USBA	Input	Ground pin for the USBA
AVCC_USBA	Input	Analog power supply pin for the USBA
AVSS_USBA	Input	Analog ground pin for the USBA. Must be shorted to the PVSS_USBA pin.
PVSS_USBA	Input	PLL circuit ground pin for the USBA. Must be shorted to the AVSS_USBA pin.
USBA_RREF	I/O	Reference current source pin for the USBA. This pin should be connected to the AVSS_USBA pin through a resistor of 2.2 kΩ (±1%).
USBA_DP	I/O	I/O pin for the D+ data line of the USB bus
USBA_DM	I/O	I/O pin for the D– data line of the USB bus
USBA_EXICEN	Output	This pin should be connected to the OTG power supply IC.
USBA_ID	Input	This pin should be connected to the OTG power supply IC.
USBA_VBUSEN	Output	VBUS power enable pin for USB
USBA_OVRCURA USBA_OVRCURB	Input	Overcurrent pin for USB
USBA_VBUS	Input	USB cable connection monitor input pin

39.2 Register Descriptions

39.2.1 System Configuration Control Register (SYSCFG)

Address: 000D 0400h

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	—	—	—	—	CNEN
Value after reset:	x	x	x	x	x	x	x	0
	b7	b6	b5	b4	b3	b2	b1	b0
	—	DCFM	DRPD	DPRPU	—	—	—	USBE
Value after reset:	0	0	1	0	x	x	x	0

Bit	Symbol	Bit Name	Description	R/W
b0	USBE	USB Operation Enable	0: USB operation is disabled. 1: USB operation is enabled.	R/W
b3 to b1	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b4	DPRPU	D+ Line Resistor Control	0: Pulling up the line is disabled. 1: Pulling up the line is enabled.	R/W
b5	DRPD	D+/D– Line Resistor Control	0: Pulling down the line is disabled. 1: Pulling down the line is enabled.	R/W
b6	DCFM	Controller Operation Select	0: Function controller operation is selected. 1: Host controller operation is selected.	R/W
b7	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b8	CNEN	Single End Receiver Enable	0: Single end receiver operation is disabled. 1: Single end receiver operation is enabled.	R/W
b15 to b9	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

The SYSCFG register can be write accessed even when the LPSTS.SUSPENDM bit is 0 (PHY clock is stopped). Note, however, that written values are only reflected in the SYSCFG register after the LPSTS.SUSPENDM bit is set to 1 (PHY clock is supplied to the LINK).

USBE Bit (USB Operation Enable)

The USBE bit enables and disables USBA operation. Use the PHYSET.CLKSEL[1:0] bits to specify the input clock and verify that the PLLSTA.PLLLOCK flag is 1 before setting the USBE bit to 1. When operating in classic-only mode, set the PHYSET.HSEB bit to 1 before setting the USBE bit to 1. At that time, the UCLK must be set to 48 MHz and PCLKB must be set to 60 MHz. Refer to section 39.3.3 for details on setting clocks.

In host controller operation, set the DRPD bit to 1, eliminate chattering of the SYSSTS0.LNST[1:0] flags, and confirm that the USB bus state is stable before setting the USBE bit to 1.

When modifying the USBE bit from 1 to 0, some bits are initialized. Refer to Table 39.3 for a list of the bits initialized from setting the USBE bit to 0.

Table 39.3 Bits Initialized by Writing 0 to the SYSCFG.USBE Bit

Selected Function	Bits	Remarks
Function controller operation (when the DCFM bit is 0)	SYSSTS0.LNST[1:0]	The value is retained in host controller operation.
	DVSTCTR0.RHST[2:0]	
	INTSTS0.DVSQ[2:0]	The value is retained in host controller operation.
	USBADDR.USBADDR[6:0]	The value is retained in host controller operation.
	USBREQ.BREQUEST[7:0] and BMREQUESTTYPE[7:0]	The value is retained in host controller operation.
	USBVAL.WVALUE[15:0]	The value is retained in host controller operation.
	USBINDX.WINDEX[15:0]	The value is retained in host controller operation.
	USBLENG.WLENGTH[15:0]	The value is retained in host controller operation.
Host controller operation (when the DCFM bit is 1)	DVSTCTR0.RHST[2:0]	
	FRMNUM.FRNM[10:0]	The value is retained in function controller operation.

DPRPU Bit (D+ Line Resistor Control)

In function controller operation, the DPRPU bit enables and disables pulling up the D+ line.
When the DPRPU bit is set to 1 in function controller operation, the USBA pulls up the D+ line and notifies the USB host of the attached state. Modifying the DPRPU bit from 1 to 0 stops the USBA from pulling up the D+ line, thus it appears that the USBA is detached from the USB host.
Set the DPRPU bit to 1 in function controller operation, and set it to 0 in host controller operation.

DRPD Bit (D+/D– Line Resistor Control)

In host controller operation, the DRPD bit enables and disables pulling down the D+ and D– lines.
Set the DRPD bit to 1 in host controller operation. Set the DRPD bit to 0 when OTG is not used in function controller operation.

DCFM Bit (Controller Operation Select)

The DCFM bit selects the function of the USBA. Modify this bit when both the DPRPU and DRPD bits are 0.

CNEN Bit (Single End Receiver Enable)

Setting the CNEN bit to 1 enables single-ended receiver operation and enables the SYSSTS0.LNST[1:0] flags to monitor the states of the D+ and D– lines.
When the USBA is detached, the CNEN bit is used to prevent through-current damage which may occur from a single-ended receiver floating.
In host controller operation, verify that the PHY clock is being supplied before setting this bit to 1. In function controller operation, set this bit to 1 when the VBUS is detected due to a VBUS interrupt, and set the bit to 0 when the VBUS is removed.

39.2.2 CPU Bus Wait Register (BUSWAIT)

Address: 000D 0402h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	BWAIT[3:0]			
Value after reset:	x	x	0	0	1	1	1	1	x	x	0	0	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	BWAIT[3:0]	CPU Bus Access Wait Select	b3 b0 0 0 0 0: 0 waits (2 access cycles) 0 0 0 1: 1 wait (3 access cycles) 0 0 1 0: 2 waits (4 access cycles) 0 0 1 1: 3 waits (5 access cycles) 0 1 0 0: 4 waits (6 access cycles) 0 1 0 1: 5 waits (7 access cycles) 0 1 1 0: 6 waits (8 access cycles) 0 1 1 1: 7 waits (9 access cycles) 1 0 0 0: 8 waits (10 access cycles) 1 0 0 1: 9 waits (11 access cycles) 1 0 1 0: 10 waits (12 access cycles) 1 0 1 1: 11 waits (13 access cycles) 1 1 0 0: 12 waits (14 access cycles) 1 1 0 1: 13 waits (15 access cycles) 1 1 1 0: 14 waits (16 access cycles) 1 1 1 1: 15 waits (17 access cycles) (initial value)	R/W
b5, b4	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b7, b6	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b11 to b8	—	Reserved	These bits are 1 when read. Set them to 1 when writing.	R/W
b13, b12	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b15, b14	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

BWAIT[3:0] Bits (CPU Bus Access Wait Select)

The BWAIT[3:0] bits specify the wait period to access registers associated with the USBA.

Among the registers associated with the USBA, when consecutively accessing registers allocated to address 000D 0404h and higher, the access cycle time must be at least 67 ns. Though the initial value of the BWAIT[3:0] bits is 1111b (17 access cycles), satisfy this condition by setting the best value for wait period in accordance with the frequency of the CPU clock. This setting is the same as the waits in accesses to the FIFO port register. The maximum speed for accessing the FIFO port registers is as follows:

MBW[1:0] bits are 00b (8-bit width): 15 Mbytes/s

MBW[1:0] bits are 01b (16-bit width): 30 Mbytes/s

MBW[1:0] bits are 10b (32-bit width): 60 Mbytes/s

39.2.3 System Configuration Status Register (SYSSTS0)

Address: 000D 0404h

	b15	b14	b13	b12	b11	b10	b9	b8
	OVCMON[1:0]		—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x

	b7	b6	b5	b4	b3	b2	b1	b0
	—	HTACT	SOFEA	—	—	IDMON	LNST[1:0]	
Value after reset:	x	0	0	x	x	x	x	x

Bit	Symbol	Bit Name	Description	R/W
b1, b0	LNST[1:0]	USB Data Line Status Monitor Flags	These flags indicate the status of the USB data line. See Table 39.4 for details.	R
b2	IDMON	USBA_ID Pin Monitor Flag	0: Low is input to the USBA_ID pin. 1: High is input to the USBA_ID pin.	R
b4, b3	—	Reserved	These bits are undefined when read.	R
b5	SOFEA	SOF Active Monitor Flag While in Host Controller Operation	0: SOF output is stopped. 1: SOF output is continued.	R
b6	HTACT	Host Sequencer Status Monitor Flag	0: Host sequencer is stopped. 1: Host sequencer is operating.	R
b13 to b7	—	Reserved	These bits are undefined when read.	R
b15, b14	OVCMON[1:0]	USBA_OVRCURA/USBA_OVRCURB Pin Monitor Flags	The OVCMON[1] flag indicates the status of the USBA_OVRCURA pin. The OVCMON[0] flag indicates the status of the USBA_OVRCURB pin.	R

LNST[1:0] Flags (USB Data Line Status Monitor Flags)

These flags indicate the state of the USB data lines (D+ line and D– line). See Table 39.4 for details. In function controller operation, set the SYSCFG.CNEN and USBE bits to 1 before reading the LNST[1:0] flags. In host controller operation, set the SYSCFG.DRPD bit to 1 before reading the LNST[1:0] flags.
However, for hardware-based contact checking using the battery charging function in function controller operation, set the SYSCFG.DRPD, SYSCFG.CNEN, and BCCTRL.IDPSRCE bits to 1 before reading the LNST[1:0] flags. Refer to section 39.3.15, Battery Charging Detection Processing for details.

Table 39.4 Status of USB Data Bus Lines

LNST[1:0] Flags	During Low-Speed Operation (Only in Host Controller Operation)	During Full-Speed Operation
00b	SE0	SE0
01b	K state	J state
10b	J state	K state
11b	SE1	SE1

SOFEA Flag (SOF Active Monitor Flag While in Host Controller Operation)

When the USB bus enters the Suspend state by setting the DVSTCTR0.UACT bit to 0 in host controller operation, the SOFEA flag is used to check whether the output of the last SOF is completed. If the SYSCFG.USBE bit is set to 0 to stop the USBA module and the LPSTS.SUSPENDM bit is set to 0 to stop supply of the clock signal while communications are in progress in host controller operation, make sure the HTACT and SOFEA flags are set to 0.

HTACT Flag (Host Sequencer Status Monitor Flag)

The HTACT flag is set to 0 when the host sequencer of the USBA is completely stopped. In host controller operation, make sure the HTACT flag is set to 0 when setting the DVSTCTR0.UACT bit to 0 to place the USBA interface in the USB bus Suspend state or setting the LPSTS.SUSPENDM bit to 0 to stop the clock. In addition, when communicating in host controller operation, make sure the HTACT flag and SOFEA flag are both 0 when setting the SYSCFG.USBE bit to 0 to stop the USBA, or when setting the LPSTS.SUSPENDM bit to 0 to stop the clock.

OVCMON[1:0] Flags (USBA_OVRCURA/USBA_OVRCURB Pin Monitor Flags)

The OVCMON[1] flag indicates the status of the USBA_OVRCURA pin, and the OVCMON[0] flag indicates the status of the USBA_OVRCURB pin.

39.2.4 PLL Status Register (PLLSTA)

Address: 000D 0406h

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	PLLLOCK
Value after reset:	x	x	x	x	x	x	x	0

Bit	Symbol	Bit Name	Description	R/W
b0	PLLLOCK	PLL Lock Flag	0: PLL is not locked. 1: PLL is locked.	R
b15 to b1	—	Reserved	These bits are undefined when read.	R

PLLLOCK Flag (PLL Lock Flag)

Indicates whether the UTMI-PHY internal PLL is locked or not. When classic-only mode is not used, make sure the PLL is locked before starting USB communication.

39.2.5 Device State Control Register 0 (DVSTCTR0)

Address: 000D 0408h

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	—	HNPBTOA	EXICEN	VBUSEN	WKUP
Value after reset:	x	x	x	x	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	RWUPE	USBRST	RESUME	UACT	—	RHST[2:0]		
Value after reset:	0	0	0	0	x	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	RHST[2:0]	USB Reset Handshake Status Flags	• In host controller operation b2 b0 0 0 0: Communication speed not determined (powered state or disconnected) 0 0 1: Low-speed connection 0 1 0: Full-speed connection 0 1 1: Reserved 1 0 0: USB reset handshake in progress 1 0 1: USB reset handshake in progress 1 1 0: USB reset handshake in progress 1 1 1: USB reset handshake in progress • In function controller operation b2 b0 0 0 0: Communication speed not determined (powered state or disconnected) 0 0 1: Reserved 0 1 0: Full-speed connection 0 1 1: Reserved 1 0 0: Reserved 1 0 1: Reserved 1 1 0: Reserved 1 1 1: Reserved	R
b3	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b4	UACT	USB Bus Operation Enable for Host Controller Operation	0: Downstream port is disabled (SOF transmission is disabled). 1: Downstream port is enabled (SOF transmission is enabled).	R/W
b5	RESUME	Resume Signal Output for Host Controller Operation	0: Resume signal is not output. 1: Resume signal is output.	R/W
b6	USBRST	USB Bus Reset Output for Host Controller Operation	0: USB bus reset signal is not output. 1: USB bus reset signal is output.	R/W
b7	RWUPE	Remote Wakeup Detection Enable for Host Controller Operation	0: Downstream port remote wakeup detection is disabled 1: Downstream port remote wakeup detection is enabled	R/W
b8	WKUP	Remote Wakeup Output for Function Controller Operation	0: Remote wakeup signal is not output. 1: Remote wakeup signal is output.	R/W
b9	VBUSEN	USBA_VBUSEN Output Pin Control	0: The external USBA_VBUSEN pin outputs the low level. 1: The external USBA_VBUSEN pin outputs the high level.	R/W
b10	EXICEN	USBA_EXICEN Output Pin Control	0: The external USBA_EXICEN pin outputs the low level. 1: The external USBA_EXICEN pin outputs the high level.	R/W
b11	HNPBTOA	Host Negotiation Protocol (HNP) Control	0: HNP not enabled 1: HNP is enabled	R/W
b15 to b12	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

RHST[2:0] Flags (USB Reset Handshake Status Flags)

These flags indicate that a reset handshake is in progress.

1. In host controller operation
   When the USBRST bit is set to 1, the RHST[2:0] flags become 100b and then become 110b or 101b. When the USBRST bit is set to 0, the USBA stops the USB bus reset signal, and the USBA fixes the RHST[2:0] flag value.
2. In function controller operation
   When the USBA detects a USB bus reset, the RHST[2:0] flags become 010b. After the USBA detects the USB bus reset, when the RHST[2:0] flags are confirmed to be 010b, the device state transition interrupt is generated.

UACT Bit (USB Bus Operation Enable for Host Controller Operation)

When the UACT bit is set to 1 in host controller operation, the USBA enables the USB bus for the USB port.
The USBA starts the output of an SOF packet within one frame period after the UACT bit is set to 1.
If the UACT bit is set to 0, the USBA enters the Idle state after an SOF packet is output.
The USBA sets the UACT bit to 0 on either of the following conditions.

- A DTCH interrupt is detected
- An EOFERR interrupt is detected

Set the UACT bit to 1 either when the USB bus reset processing is complete (USBRST bit is set to 0), or when the USBA has exited the Suspend state (RESUME bit is set to 0).
When the HL1CTRL1.L1REQ bit is set to 1 to issue an LPM token and an ACK response is received, the USBA sets the UACT bit to 0. In addition, after exiting the L1 state, the USBA sets the UACT bit to 1.
In function controller operation, set the UACT bit to 0.

RESUME Bit (Resume Signal Output for Host Controller Operation)

This bit controls the output of the resume signal in host controller operation.
If the RESUME bit set to 1 while in the Suspend state, the USBA outputs the resume signal to the USB port. In addition, if the RWUPE bit is 1 and a remote wakeup signal is detected while in the Suspend state, the USBA sets the RESUME bit to 1, and USBA outputs the resume signal to the USB port.
The USBA continues outputting the resume signal until the RESUME bit is set to 0 by software. Ensure that the period the RESUME bit is 1 (resume period) complies with the time defined in USB 2.0. In addition, set the UACT bit to 1 at the same time the resume processing is complete (RESUME bit is set to 0).
If the RESUME bit to 1 during the L1 state, the USBA outputs the resume signal to the USB port. The resume period is the period indicated by the HL1CTRL2.HIRD[3:0] bits. The USBA sets the RESUME bit to 0 at the end of the resume period.
Only set the RESUME bit is 1 while in the Suspend state or L1 state. In addition, set the RESUME bit to 0 in function controller operation.

USBRST Bit (USB Bus Reset Output for Host Controller Operation)

In host controller operation, this bit controls the output of the USB bus reset signal.
In host controller operation, if the USBRST bit is set to 1, the USBA performs a USB bus reset on the USB port.
The USBA continues outputting the bus reset signal until the USBRST bit is set to 0 by software. Ensure that the period the USBRST bit is 1 (USB bus reset period) complies with the time defined in USB 2.0.
When setting the USBRST bit to 1 either during communication (UACT bit is 1), or during the resume processing (RESUME bit is 1), the USBA prevents the USB but reset processing from starting until both the UACT and RESUME bits become 0. Set the UACT bit to 1 at the same time the USB bus reset processing is complete (USBRST bit is set to 0).
In function controller operation, set the USBRST bit to 0.

RWUPE Bit (Remote Wakeup Detection Enable for Host Controller Operation)

In host controller operation, this bit enables and disables remote wakeup signals (resume signals) from peripheral devices connected to downstream ports.
While the RWUPE bit set to 1, the USBA performs resume processing (resume signal is output) when a remote wakeup signal (K state for 2.5 µs) is detected from a peripheral device connected to a downstream port.
While the RWUPE bit is 0, even if the USBA detects a remote wakeup signal from a peripheral device connected to the USB port, the remote wakeup signal is ignored.
When the RWUPE bit is set to 1, do not stop the PHY clock even in the Suspend state (keep the LPSTS.SUSPENDM bit to 1). Also, executing a USB bus reset (setting the USBRST bit to 1) while in the Suspend state is prohibited in USB 2.0.
In addition, the RWUPE bit is used to enable and disable detection of the remote wakeup signal while in the L1 state.
In function controller operation, set the RWUPE bit to 0.

WKUP Bit (Remote Wakeup Output for Function Controller Operation)

In function controller operation, this bit is used to output the remote wakeup signal (resume signal) to the USB port.
The USBA controls the output time of the remote wakeup signal. When the WKUP bit is set to 1, the USBA sets this bit to 0 after outputting a 10-ms remote wakeup signal.
According to USB 2.0, the USBA must be in the USB bus Idle state for at least 5 ms before the remote wakeup signal is transmitted. For this reason, even if the WKUP bit is set to 1 immediately after the USB bus is detected as being in the suspended state, the USBA waits 2 ms before outputting the remote wakeup signal.
Only set the WKUP bit to 1 when the device state is in the suspended state (INTSTS0.DVSQ[2:0] flags are 1xxb) and the remote wakeup signaling is enabled by the USB host.
Also, when the WKUP bit is set to 1, do not stop the PHY clock even if the USBA is in the suspended state (keep the LPSTS.SUSPENDM bit to 1).
If the WKUP bit is set to 1 while the USBA is in the L1 state, the USBA outputs the remote wakeup signal for 50 µs and then sets the WKUP bit to 0.
In host controller operation, set the WKUP bit to 0.

HNPBTOA Bit (Host Negotiation Protocol (HNP) Control)

When the USBA is used as an OTG device B, set this bit to switch from function controller operation to host controller operation.
If the HNPBTOA bit is 1, the USBA remains in the suspended state until HNP processing is complete even if the SYSCFG.DPRPU bit is set to 0 or the SYSCFG.DCFM bit is set to 1. At this time, a resume interrupt is not generated even if a falling edge on the D+ line is detected.
After setting the HNPBTOA bit to 1, when attachment of a host is detected (due to pulling up by the other party) or if a timeout occurs during HNP processing, set the HNPBTOA bit to 0 to end HNP processing.

39.2.6 FIFO Port Registers (CFIFO, D0FIFO, D1FIFO)

(1) FIFO port register values when the MBW[1:0] bits are 10b (32-bit width)

Addresses CFIFO 000D 0414h, D0FIFO 000D 0418h, D1FIFO 000D 041Ch

Bit	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol																																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	FIFO Port	From this port, receive data is read from the FIFO buffer and transmit data is written to the FIFO buffer.	R/W

(2) FIFO port register values when the MBW[1:0] bits are 01b (16-bit width) and the BIGEND bit is 0 (Little endian)

Addresses CFIFO 000D 0416h, D0FIFO 000D 041Ah, D1FIFO 000E 041Eh

Bit	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	H[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	H[15:0]	FIFO Port	From this port, receive data is read from the FIFO buffer and transmit data is written to the FIFO buffer.	R/W

(3) FIFO port register values when the MBW[1:0] bits are 01b (16-bit width) and the BIGEND bit is 1 (Big endian)

Addresses CFIFO 000D 0414h, D0FIFO 000D 0418h, D1FIFO 000D 041Ch

Bit	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	L[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	L[15:0]	FIFO Port	From this port, receive data is read from the FIFO buffer and transmit data is written to the FIFO buffer.	R/W

(4) FIFO port register values when the MBW[1:0] bits are 00b (8-bit width) and the BIGEND bit is 0 (Little endian)

Addresses CFIFO 000D 0417h, D0FIFO 000D 041Bh, D1FIFO 000F 041Fh

Bit	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	HH[7:0]							
Value after reset	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	HH[7:0]	FIFO Port	From this port, receive data is read from the FIFO buffer and transmit data is written to the FIFO buffer.	R/W

(5) FIFO port register values when the MBW[1:0] bits are 00b (8-bit width) and the BIGEND bit is 1 (Big Endian)

Addresses CFIFO 000D 0414h, D0FIFO 000D 0418h, D1FIFO 000D 041Ch

Bit	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	LL[7:0]							
Value after reset	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	LL[7:0]	FIFO Port	From this port, receive data is read from the FIFO buffer and transmit data is written to the FIFO buffer.	R/W

There are three FIFO ports: CFIFO, D0FIFO, and D1FIFO. Each FIFO port is configured of a FIFO port register, FIFO port select register, and a FIFO port control register. The FIFO port registers (CFIFO, D0FIFO, and D1FIFO) read data from and write data to the FIFO buffers. The FIFO port select registers (CFIFOSEL, D0FIFOSEL, and D1FIFOSEL) are used to select the pipe assigned to the FIFO port. The FIFO port control registers are CFIFOCTR, D0FIFOCTR, and D1FIFOCTR.

The following are features and precautions pertaining to the FIFO ports:

- Access the FIFO buffer for the default control pipe (control transfer) through the CFIFO port.
- Accessing a FIFO buffer using DMA/DTC transfer should be performed through the D0FIFO or D1FIFO port.
- The D0FIFO and D1FIFO ports can also be accessed by the CPU.
- When using functions specific to a FIFO port such as a DMA/DTC transfer function, the pipe number (current pipe) set in the CURPIPE[3:0] bits of the FIFO port select register cannot be changed.
- Registers configuring one FIFO port do not affect other FIFO ports.
- The same pipe should not be assigned to two or more FIFO ports.
- Access rights for a FIFO buffer can be on the CPU side or on the serial interface engine (SIE) side. When the access right for a FIFO buffer is on the SIE side, the FIFO buffer cannot be accessed from the CPU.

FIFO Port Bits

Using the FIFO port bits, the received data can be read from the FIFO buffer and the transmit data can be written to the FIFO buffer. The FIFO port registers can only be accessed when the FRDY flag in the corresponding FIFO port control register is 1. Valid bits in the FIFO port registers depend on the MBW[1:0] and BIGEND bit values in the corresponding FIFO port select register. When the MBW[1:0] bits are 01b or 10b, data allocation changes in relation to the MDE.MDE[2:0] bit value and the CFIFOSEL.BIGEND, D0FIFOSEL.BIGEND, and D1FIFOSEL.BIGEND bits. Table 39.5 and Table 39.6 show the various data allocation.

Table 39.5 Data Allocation in a 32-Bit Access (MBW[1:0] Bits are 10b)

MDE[2:0] Bits	BIGEND Bit	b31 to b24	b23 to b16	b15 to b8	b7 to b0	Remarks
000b (big endian)	0 (little endian)	Address N+3	Address N+2	Address N+1	Address N+0	Data is transmitted sequentially from address N+3. Data received is stored sequentially from address N+3.
	1 (big endian)	Address N+0	Address N+1	Address N+2	Address N+3	Data is transmitted sequentially from address N+0. Data received is stored sequentially from address N+0.
111b (little endian)	0 (little endian)	Address N+3	Address N+2	Address N+1	Address N+0	Data is transmitted sequentially from address N+0. Data received is stored sequentially from address N+0.
	1 (big endian)	Address N+0	Address N+1	Address N+2	Address N+3	Data is transmitted sequentially from address N+3. Data received is stored sequentially from address N+3.

Table 39.6 Data Allocation in a 16-Bit Access (MBW[1:0] Bits are 01b)

MDE[2:0] Bits	BIGEND Bit	b15 to b8	b7 to b0	Remarks
000b (big endian)	0 (little endian)	Address N+1	Address N+0	Access the H[15:0] bits. Data is transmitted sequentially from address N+1. Data received is stored sequentially from address N+1.
	1 (big endian)	Address N+0	Address N+1	Access the L[15:0] bits. Data is transmitted sequentially from address N+0. Data received is stored sequentially from address N+0.
111b (little endian)	0 (little endian)	Address N+1	Address N+0	Access the H[15:0] bits. Data is transmitted sequentially from address N+0. Data received is stored sequentially from address N+0.
	1 (big endian)	Address N+0	Address N+1	Access the L[15:0] bits. Data is transmitted sequentially from address N+1. Data received is stored sequentially from address N+1.

39.2.7 CFIFO Port Select Register (CFIFOSEL)

Address: 000D 0420h

	b15	b14	b13	b12	b11	b10	b9	b8

b13, b12	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b14	REW	Buffer Pointer Rewind	Set this bit to 1 to rewind the buffer pointer. Writing 0 has no effect.	R/W
b15	RCNT	Read Count Mode	0: The CFIFOCTR.DTLN[11:0] flags are set to 000h when all of the receive data has been read from the CFIFO register. 1: The CFIFOCTR.DTLN[11:0] flags are decremented each time the receive data is read from the CFIFO register.	R/W

The same pipe number should not be set to the CURPIPE[3:0] bits in registers CFIFOSEL, D0FIFOSEL, and D1FIFOSEL. In addition, do not change the pipe number while DMA or DTC transfer is enabled.

CURPIPE[3:0] Bits (FIFO Port Access Pipe Select)

The CURPIPE[3:0] bits specify the current pipe number for which data is read or written through the CFIFO port. When modifying the CURPIPE[3:0] bits, first set them to 0000b, and then set the desired pipe number. After setting the desired pipe number, read the CURPIPE[3:0] bits, confirm that the value set and the value read match, and then proceed to the next processing.

Do not set the same pipe number in the CURPIPE[3:0] bits in registers CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

If the CURPIPE[3:0] bits are modified while accessing the FIFO buffer, access until that point is retained, and after the CURPIPE[3:0] bits are modified back to the original setting, access can be resumed.

ISEL Bit (FIFO Port Access Direction When Default Control Pipe is Selected)

If the ISEL bit is modified while the default control pipe is the current pipe, read the bit to confirm it has been modified. Set the ISEL bit and the CURPIPE[3:0] bits simultaneously.

BIGEND Bit (FIFO Port Endian Control)

Set this bit to specify the byte endian of the CFIFO port.

MBW[1:0] Bits (CFIFO Port Access Bit Width)

Set this bit to specify the bit width for accessing the CFIFO port.
When the transfer direction of the current pipe is receiving, if the MBW[1:0] bits are set to start reading data from the FIFO buffer, do not modify the MBW[1:0] bits until all the data has been read. When modifying the MBW[1:0] bits, set the CURPIPE[3:0] bits and MBW[1:0] bits simultaneously after setting the CURPIPE[3:0] bits to 0000b.
When the transfer direction of the current pipe is transmitting, while data is being written to the FIFO buffer, the bit width cannot be changed from 8-bit width to 16- or 32-bit width, and 16-bit width cannot be changed to 32-bit width. Also, even when 16-bit or 32-bit width is selected, an odd number of bytes can be written by byte access.

REW Bit (Buffer Pointer Rewind)

When the transfer direction of the current pipe is receiving, if the REW bit is set to 1 while reading data from the FIFO buffer, the FIFO buffer can be reread from the first data. In double buffer mode, the buffer that was being read can be reread from the first data.
Do not modify the CURPIPE[3:0] bits when setting the REW bit to 1. Also, confirm that the FRDY flag is 1 before setting the REW bit to 1.
For pipes in the receiving transfer direction, to rewrite to the FIFO buffer from the first data, set the BCLR bit.

RCNT Bit (Read Count Mode)

When the RCNT bit is set to 0, when all data has been read from the FIFO buffer (in double buffer mode, when a single plane is done being read) for the pipe specified by the CURPIPE[3:0] bits, the USBA sets the CFIFOCTR.DTLN[11:0] flags to 000h.
When the RCNT bit set to 1, each time data is read from the FIFO buffer for the pipe specified by the CURPIPE[3:0] bits, the USBA decrements the value of the CFIFOCTR.DTLN[11:0] flags.

39.2.8 D0FIFO Port Select Register (D0FIFOSEL)
D1FIFO Port Select Register (D1FIFOSEL)

Addresses: D0FIFOSEL 000D 0428h, D1FIFOSEL 000D 042Ch

b14	REW	Buffer Pointer Rewind	Set this bit to 1 to rewind the buffer pointer. Writing 0 has no effect.	R/W
b15	RCNT	Read Count Mode	0: The DTLN[11:0] flags in the D0FIFOCTR/D1FIFOCTR register are set to 000h when all of the receive data has been read from D0FIFO/D1FIFO (after reading a single plane in double buffer mode). 1: The DTLN[11:0] flags in the D0FIFOCTR/D1FIFOCTR register are decremented each time the receive data is read from D0FIFO/D1FIFO.	R/W

The same pipe number should not be set to the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. In addition, a pipe is not assigned if the setting of the D0FIFOSEL/D1FIFOSEL.CURPIPE[3:0] bits is 0000b. Do not change the pipe number while DMA or DTC transfer is enabled.

CURPIPE[3:0] Bits (FIFO Port Access Pipe Select)

The CURPIPE[3:0] bits specify the current pipe number for which data is read or written through the D0FIFO or D1FIFO port.

When modifying the CURPIPE[3:0] bits, write a value to the CURPIPE[3:0] bits, then read the bits to confirm that the value written and the value read match written value agree, and then proceed to the next processing.

Do not set the same pipe number in the CURPIPE[3:0] bits in registers CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

If the CURPIPE[3:0] bits are modified while accessing the FIFO buffer, access until that point is retained, and after the CURPIPE[3:0] bits are modified back to the original setting, access can be resumed.

BIGEND Bit (FIFO Port Endian Control)

Set this bit to specify the byte endian of the D0FIFO and D1FIFO port.

MBW[1:0] Bits (FIFO Port Access Bit Width)

This bit specifies the bit width for accessing the D0FIFO or D1FIFO port.
When the current pipe is in the receiving direction, once reading data from the FIFO buffer is started after setting the MBW[1:0] bits, these bits should not be modified until all the data has been read. When modifying the MBW[1:0] bits, set the CURPIPE[3:0] bits and the MBW[1:0] bits simultaneously after setting the CURPIPE[3:0] bits to 0000b.
When the current pipe is in the transmitting direction, the bit width cannot be changed from 8-bit width to 16-bit/32-bit width or 16-bit width to 32-bit width while data is being written to the FIFO buffer. An odd number of bytes can also be written through byte-access control even when 16-bit or 32-bit width is selected.

DREQE Bit (DMA/DTC Transfer Request Enable)

This bit enables or disables the DMA/DTC transfer request. To enable the DMA/DTC transfer request, set this bit to 1 after setting the CURPIPE[3:0] bits. To change the setting of the CURPIPE[3:0] bits, do it after setting this bit to 0.

DCLRM Bit (Automatic FIFO Buffer Clear Mode after Current Pipe is Read)

This bit enables or disables the automatic FIFO buffer clear after data in the current pipe is read. When the DCLRM bit is set to 1 on receiving a zero-length packet while the FIFO buffer assigned to the current pipe is empty, or when reading the received short packet is completed while the PIPECFG.BFRE bit is 1, the USBA sets the BCLR bit in a FIFO port control register to 1. Set the DCLRM bit to 0 when the SOFCFG.BRDYM bit 1.

REW Bit (Buffer Pointer Rewind)

When the current pipe is in the receiving direction, setting the REW bit to 1 while the FIFO buffer is being read allows re-reading the FIFO buffer from the first data. When double-buffering is in use and reading is already in progress, reading either FIFO buffer from the first entry is possible. Do not set the REW bit to 1 simultaneously with modifying the CURPIPE[3:0] bits. Before setting the REW bit to 1, be sure to check that the FRDY flag is 1. To rewrite to the FIFO buffer again from the first data for the pipe in the transmitting direction, use the BCLR bit.

RCNT Bit (Read Count Mode)

With the RCNT bit set to 0, the USBA sets the DTLN[11:0] flags in the D0FIFOCTR/D1FIFOCTR register to 000h upon finishing reading all the received data in the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits (after reading a single plane in double buffer mode). With the RCNT bit set to 1, the USBA decrements the value indicated by the DTLN[11:0] flags each time it reads data received from the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits. Set the RCNT bit to 0 when accessing D0FIFO/D1FIFO with the PIPECFG.BFRE bit set to 1.

39.2.9 CFIFO Port Control Register (CFIFOCTR)
D0FIFO Port Control Register (D0FIFOCTR)
D1FIFO Port Control Register (D1FIFOCTR)

Addresses: CFIFOCTR 000D 0422h, D0FIFOCTR 000D 042Ah, D1FIFOCTR 000D 042Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BVAL	BCLR	FRDY	—	DTLN[11:0]											
Value after reset:	0	0	0	x	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	DTLN[11:0]	Receive Data Length Flags	These flags indicate the length of the receive data. The meaning of the value of these flags differs with the setting of the RCNT bit in the FIFO port select register. For details, see the more detailed description of the DTLN[11:0] flags below.	R
b12	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b13	FRDY	FIFO Port Ready Flag	0: FIFO port access is disabled 1: FIFO port access is enabled	R
b14	BCLR	CPU Buffer Clear	This bit should be set to 1 to clear the FIFO buffer on the CPU side for the pipe specified by the CUREPIPE[3:0] bits. Writing 0 has no effect. This bit is 0 when read.	R/W
b15	BVAL	FIFO Buffer Valid	This bit should be set to 1 when data has been completely written to the FIFO buffer on the CPU side for the pipe specified by the CURPIPE[3:0] bits. Writing 0 has no effect.	R/W

The CFIFOCTR, D0FIFOCTR, and D1FIFOCTR registers respectively correspond to the CFIFO, D0FIFO, and D1FIFO buffers.

DTLN[11:0] Flags (Receive Data Length Flags)

These flags indicate the length of the receive data. While data is being read from the FIFO buffer, the value of the DTLN[11:0] flags differs according to the setting of the RCNT bit in the FIFO port select registers as described below.

- When the RCNT bit is 0
  The USBA sets the DTLN[11:0] flags to indicate the length of the receive data until the CPU or DMAC/DTC has read all the received data in the FIFO buffer (until a single plane has been read in double buffer mode).
  When the PIPECFG.BFRE bit for the current pipe is set to 1, the USBA retains the length of the receive data until the BCLR bit is set to 1 even after all the data has been read.
- When the RCNT bit is 1
  The USBA decrements the value indicated by the DTLN[11:0] flags each time the CPU or DMAC/DTC reads the receive data from the FIFO buffer. (The value is decremented by one when the MBW[1:0] bits are 00b, by two when the MBW[1:0] bits are 01b, and by four when the MBW[1:0] bits are 10b.)
  The DTLN[11:0] flags become 000h when all the data has been read from the FIFO buffer. However, in double buffer mode, if data reception is completed in one FIFO buffer plane before all the data has been read from the other plane, the DTLN[11:0] flags indicate the length of the receive data in the latter plane when all the data has been read from the former plane.
  In addition, updating the DTLN[11:0] flags can take up to 150 ns. After reading the FIFO buffer, wait at least 150 ns before reading the DTLN[11:0] flags.

FRDY Flag (FIFO Port Ready Flag)

This flag indicates whether the FIFO port can be accessed by the CPU or DMAC/DTC.
In the cases below, the FRDY flag also becomes 1, but data cannot be read via the FIFO port because there is no data to be read. In these cases, set the BCLR bit to 1 to clear the FIFO buffer, and enable transmission and reception of the next data.

- A zero-length packet is received when the FIFO buffer assigned to the current pipe is empty.
- When the PIPECFG.BFRE bit for the current pipe is 1, a short packet is received and the data read operation is complete.

BCLR Bit (CPU Buffer Clear)

Set the BCLR bit to 1 to clear the FIFO buffer on the CPU side of the current pipe.
When double buffer mode is set for the FIFO buffer assigned to the current pipe, the USBA only clears one plane of the FIFO buffer even when both planes are readable.
When the current pipe is the default control pipe, setting the BCLR bit to 1 clears the FIFO buffer regardless of whether the FIFO buffer access rights are on the CPU side or the SIE side. To clear the FIFO buffer when the SIE has the access right, set the DCPCTR.PID[1:0] bits to 00b (NAK response) and then set the BCLR bit to 1.
When the current pipe is a pipe other than the default control pipe, set the BCLR bit to 1 when the FRDY flag in a FIFO port control register is 1.

BVAL Bit (FIFO Buffer Valid)

When the transfer direction of the pipe specified by the CURPIPE[3:0] bits is transmitting, set the BVAL bit to 1 in the cases listed below. When the BVAL bit is set to 1, the USBA switches the FIFO buffer access right from the CPU side to the SIE side, enabling transmission.

- To transmit a short packet, set this bit to 1 after transmit data has been written.
- To transmit a zero-length packet, set this bit to 1 before transmit data is written.
- For pipes in continuous transfer mode, set this bit to 1 after writing data that is an integral multiple of the maximum packet size and less than the buffer size.

When the BVAL bit and BCLR bit are set to 1 simultaneously, the USBA clears the data already written and enables the transmission of a zero-length packet. For pipes in discontinuous transfer mode, when the maximum packet size of data is written, the USBA sets the BVAL bit to 1, and switches the FIFO buffer access right from the CPU side to the SIE side, enabling transmission.
Set the BVAL bit to 1 while the FRDY flag is 1.
When the transfer direction of the current pipe is receiving, do not set the BVAL bit to 1.

39.2.10 Interrupt Enable Register 0 (INTENB0)

Address: 000D 0430h

b14	RSME	Resume Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled	R/W
b15	VBSE	VBUS Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled	R/W

Note: The CTRE bit, DVSE bit, and RSME bit can only be set to 1 in function controller operation. Set these bits to 0 in host controller operation.

When a status flag in the INTSTS0 register becomes 1, if the corresponding interrupt request enable bit in the INTENB0 register is 1, the USBA requests the USBAR interrupt.
Regardless of the INTENB0 register setting, if the conditions for each status are satisfied, the status flags corresponding to the INTSTS0 register become 1.
When the status flags in the INTSTS0 register are 1, if a corresponding interrupt request enable bit in the INTENB0 register is rewritten from 0 to 1, the USBAR interrupt request is generated.

39.2.11 Interrupt Enable Register 1 (INTENB1)

Address: 000D 0432h

	b15	b14	b13	b12	b11	b10	b9	b8
	OVRCRE	BCHGE	—	DTCHE	ATTCHE	—	L1RSMENDE	LPMENDE
Value after reset:	0	0	x	0	0	x	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	—	EOFERRE	SIGNE	SACKE	—	—	—	PDDETINTE
Value after reset:	x	0	0	0	x	x	x	0

Bit	Symbol	Bit Name	Description	R/W
b0	PDDETINTE	Portable Device Detection Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled	R/W
b3 to b1	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b4	SACKE	Setup Transaction Normal Response Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W
b5	SIGNE	Setup Transaction Error Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W
b6	EOFERRE	End-of-Frame Error Detection Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W
b7	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b8	LPMENDE	LPM Transaction End Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W
b9	L1RSMENDE	L1 Resume End Interrupt Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W
b10	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b11	ATTCHE	Device Connection Detection Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W
b12	DTCHE	Device Disconnection Detection Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W
b13	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b14	BCHGE	Bus Change Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W
b15	OVRCRE	Overcurrent Change Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W

Note 1. This bit can only be set to 1 in host controller operation. Set this bit to 0 in function controller operation.

When a status flag in the INTSTS1 register becomes 1, if the corresponding interrupt request enable bit in the INTENB1 register is 1, the USBA requests the USBAR interrupt.
Regardless of the INTENB1 register setting, if the conditions for each status are satisfied, the status flags corresponding to the INTSTS1 register become 1.
When the status flags in the INTSTS1 register are 1, if a corresponding interrupt request enable bit in the INTENB1 register is rewritten from 0 to 1, the USBAR interrupt request is generated.

39.2.12 BRDY Interrupt Enable Register (BRDYENB)

Address: 000D 0436h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPEBRDYE[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	PIPEBRDYE[9:0]	Pipe 9 to Pipe 0 BRDY Interrupt Request Enable *1	0: Interrupt request output disabled 1: Interrupt request output enabled	R/W
b15 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. Each bit corresponds to a pipe number (e.g. pipe 9 corresponds to the PIPEBRDYE[9] bit, pipe 8 corresponds to the PIPEBRDYE[8] bit, etc.).

When a flag in the BRDYSTS register becomes 1, if the corresponding BRDYENB.PIPEBRDYE[9:0] bit is 1, the INTSTS0.BRDY flag becomes 1.
In this case, if the INTENB0.BRDYE bit is 1, the USBA requests the USBAR interrupt.
When any of the BRDYSTS.PIPEBRDY[9:0] flags is 1, if the corresponding interrupt request enable bit in the BRDYENB register is rewritten from 0 to 1, the INTSTS0.BRDY flag becomes 1.

39.2.13 NRDY Interrupt Enable Register (NRDYENB)

Address: 000D 0438h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPENRDYE[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	PIPENRDYE[9:0]	Pipe 9 to Pipe 0 NRDY Interrupt Enable *1	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b15 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. Each bit corresponds to a pipe number (e.g. pipe 9 corresponds to the PIPENRDYE[9] bit, pipe 8 corresponds to the PIPENRDYE[8] bit, etc.).

When a flag in the NRDYSTS register becomes 1, if the corresponding NRDYENB.PIPENRDYE[9:0] bit is 1, the INTSTS0.NRDY flag becomes 1.
In this case, if the INTENB0.NRDYE bit is 1, the USBA requests the USBAR interrupt.
When any of the NRDYSTS.PIPENRDY[9:0] flags is 1, if the corresponding interrupt request enable bit in the NRDYENB register is rewritten from 0 to 1, the INTSTS0.NRDY flag becomes 1.

39.2.14 BEMP Interrupt Enable Register (BEMPENB)

Address: 000D 043Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPEBEMPE[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	PIPEBEMPE[9:0]	Pipe 9 to Pipe 0 BEMP Interrupt Enable *1	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b15 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. Each bit corresponds to a pipe number (e.g. pipe 9 corresponds to the PIPEBEMPE[9] bit, pipe 8 corresponds to the PIPEBEMPE[8] bit, etc.).

When a flag in the BEMPSTS register becomes 1, if the corresponding BEMPENB.PIPEBEMPE[9:0] bit is 1, the INTSTS0.BEMP flag becomes 1.
In this case, if the INTENB0.BEMPE bit is 1, the USBA requests the USBAR interrupt.
When any of the BEMPSTS.PIPEBEMP[9:0] flags is 1, if the corresponding interrupt request enable bit in the BEMPENB register is rewritten from 0 to 1, the INTSTS0.BEMP flag becomes 1.

39.2.15 SOF Output Configuration Register (SOFCFG)

Address: 000D 043Ch

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	—	—	—	—	TRNENSEL
Value after reset:	x	x	x	x	x	x	x	0

	b7	b6	b5	b4	b3	b2	b1	b0
	—	BRDYM	INTL	EDGESTS	—	—	—	—
Value after reset:	x	0	0	0	0	0	x	x

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b4	EDGESTS	Interrupt Edge Processing Status Flag *1	This flag is 1 when the USBA outputs an edge interrupt request signal.	R
b5	INTL	Interrupt Signal Output Method Select *2	0: Do not set this value (edge output) 1: Level output	R/W
b6	BRDYM	PIPEBRDY Interrupt Status Clear Timing *3	0: The PIPEBRDY[9:0] flags are set to 0 by software. 1: The PIPEBRDY[9:0] flags are set to 0 by reading the FIFO buffer or writing to the FIFO buffer.	R/W
b7	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b8	TRNENSEL	Transaction-Enabled Time Select *4	0: Not low-speed compatible 1: Low-speed compatible	R/W
b15 to b9	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

Note 1. Confirm that the EDGESTS flag is 0 before stopping the clock supplied to the USBA.
Note 2. Set this bit to 1 before operating the USBA.
Note 3. When setting the BRDYM bit to 1, set the INTL bit to 1.
Note 4. The TRNENSEL bit setting is only valid in host controller operation.

EDGESTS Flag (Interrupt Edge Processing Status Flag)

This flag is enabled when the INTL bit is 0 (edge output).
When multiple interrupt requests are generated, if one of the interrupt requests is cleared, the USBA temporarily negates the interrupt request signal, after waiting 666.6 μs, the interrupt request signal is reasserted. While the interrupt request signal is negated, the EDGESTS flag becomes 1.
Confirm the EDGESTS flag is 0 when stopping the PHY clock.

BRDYM Bit (PIPEBRDY Interrupt Status Clear Timing)

This bit specifies the timing to clear the BRDY interrupt status (BRDYSTS.PIPEBRDY[9:0] flags) for each pipe.

TRNENSEL Bit (Transaction-Enabled Time Select)

When the USB port is in use for full-speed or low-speed communications, this bit specifies the timing with which the USBA issues tokens in a frame (transaction-enabled time).
Set the TRNENSEL bit to 1 when a low-speed device is connected.
The TRNENSEL bit is only valid in host controller operation.
Set this bit to 0 in function controller operation.

39.2.16 PHY Setting Register (PHYSET)

Address: 000D 043Eh

	b15	b14	b13	b12	b11	b10	b9	b8
	HSEB	—	—	—	—	—	REPSEL[1:0]	
Value after reset:	0	x	x	x	0	x	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	CLKSEL[1:0]		CDPEN	—	PLLRESET	DIRPD
Value after reset:	x	x	1	1	0	x	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	DIRPD	Power-Down Control	0: Power-down control not performed 1: Power-down control performed	R/W
b1	PLLRESET	PLL Reset Control *1	0: Disable PLL reset control for UTMI-PHY 1: Enable PLL reset control for UTMI-PHY	R/W
b2	—	Reserved	This bit is read as 0. Set it to 0 when writing.	R/W
b3	CDPEN	Charging Downstream Port Enable	0: Disable the charging downstream port 1: Enable the charging downstream port	R/W
b5, b4	CLKSEL[1:0]	Input System Clock Frequency	b5 b4 0 0: Do not set this value. 0 1: Do not set this value. 1 0: 20 MHz 1 1: 24 MHz	R/W
b7, b6	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b9, b8	REPSEL[1:0]	Terminating Resistance Adjustment	b9 b8 0 0: Disable the terminating resistance adjustment 0 1: Enable the terminating resistance adjustment 1 0: Do not set this value. 1 1: Do not set this value.	R/W
b14 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b15	HSEB	Classic-Only Mode *2	0: Classic-only mode is disabled. 1: Classic-only mode is enabled.	R/W

Note 1. Since the PLLRESET bit is 1 after a reset, changing the setting after release from the reset state is not required because of PLL reset control. Setting the PLLRESET bit to 1 after setting it to 0 may cause the USBA operate erroneously.
Note 2. Do not set the HSEB bit to 0 after setting it to 1. Doing so may cause the USBA operate erroneously.

CLKSEL[1:0] Bits (Input System Clock Frequency)

These bits select the frequency of the PLL clock source (USBMCLK) necessary for generating the USBA PHY clock. The USBA PHY clock is generated by the PLL embedded in the USB-PHY. The CLKSEL[1:0] bits set the frequency of the clock source (USBMCLK) supplied to the PLL. The USBMCLK is input from the EXTAL pin, but the clock specification must follow the clock standard in the USB 2.0. In classic-only mode, the PLL in the USB-PHY is stopped, so writing to the CLKSEL[1:0] bits is invalid (refer to the HSEB bit description for details).
Refer to section 39.3.3, Supplying Clocks for details on setting clocks.

REPSEL[1:0] Bits (Terminating Resistance Adjustment)

These bits automatically adjust the terminating resistance. Before operating the USBA, set the REPSEL[1:0] bits to 01b to enable the automatic adjustment function for the terminating resistance. Note that the automatic adjustment function for the terminating resistance is stopped when the HSEB bit is 1 (classic-only mode is enabled).

HSEB Bit (Classic-Only Mode)

This bit selects the method to supply the PHY clock.
When the HSEB bit is set to 0, the clock generated by the PLL embedded in the USB-PHY is used as the PHY clock.
When the HSEB bit is set to 1, the clock generated by the clock generator is used as the PHY clock. When the HSEB bit is set to 1, the UCLK must be set to 48 MHz, and PCLKB must be set to 60 MHz. Refer to section 9, Clock Generation Circuit for details on supplying the clock. Refer to section 39.3.3 for details on setting clocks.

39.2.17 Interrupt Status Register 0 (INTSTS0)

Address: 000D 0440h

	b15	b14	b13	b12	b11	b10	b9	b8
	VBINT	RESM	SOFR	DVST	CTRT	BEMP	NRDY	BRDY
Value after reset:	0	0	0	0/1 *1	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	VBSTS		DVSQ[2:0]		VALID		CTSQ[2:0]	
Value after reset:	x	0	0	0/1 *1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CTSQ[2:0]	Control Transfer Stage Flag *2	b2 b0 0 0 0: Idle state or setup stage 0 0 1: Control read data stage 0 1 0: Control read status stage 0 1 1: Control write data stage 1 0 0: Control write status stage 1 0 1: Control write (no data) status stage 1 1 0: Control transfer sequence error 1 1 1: Reserved	R
b3	VALID	USB Request Reception Flag *2	0: Setup packet is not received 1: Setup packet is received	R/(W)
b6 to b4	DVSQ[2:0]	Device State Flag *2	b6 b4 0 0 0: Powered state 0 0 1: Default state 0 1 0: Address state 0 1 1: Configured state 1 0 0: Suspended state 1 0 1: Suspended state 1 1 0: Suspended state 1 1 1: Suspended state	R
b7	VBSTS	VBUS Input Status Flag	0: The USBA_VBUS pin is low 1: The USBA_VBUS pin is high	R
b8	BRDY	BRDY Interrupt Status Flag	0: BRDY interrupt not requested 1: BRDY interrupt requested	R
b9	NRDY	NRDY Interrupt Status Flag	0: NRDY interrupt not requested 1: NRDY interrupt requested	R
b10	BEMP	BEMP Interrupt Status Flag	0: BEMP interrupt not requested 1: BEMP interrupt requested	R
b11	CTRT	Control Transfer Stage Transition Interrupt Status Flag *3	0: Control transfer stage transition interrupt not requested 1: Control transfer stage transition interrupt requested	R/(W) *4
b12	DVST	Device State Transition Interrupt Status Flag *3	0: Device state transition interrupt not requested 1: Device state transition interrupt requested	R/(W) *4
b13	SOFR	Frame Number Refresh Interrupt Status Flag	0: Frame number refresh interrupt not requested 1: Frame number refresh interrupt requested	R/(W) *4
b14	RESM	Resume Interrupt Status Flag *3	0: Resume interrupt not requested 1: Resume interrupt requested	R/(W) *4
b15	VBINT	VBUS Interrupt Status Flag *5	0: VBUS interrupt is not requested on detecting a change in the USBA_VBUS pin. 1: VBUS interrupt is requested on detecting a change in the USBA_VBUS pin.	R/(W) *4

Note 1. The value is 0 when the MCU is reset, and 1 when a USB bus reset occurs.
Note 2. The CTSQ[2:0], VALID, and DVSQ[2:0] flags are only valid in function controller operation.
Note 3. The CTRT, DVST, and RESM flags are only changed in function controller operation. Set the corresponding interrupt enable bits to 0 (disabled) in host controller operation.
Note 4. To clear the CTRT, DVST, SOFR, RESM, or VBINT flags, write 0 only to the flags to be cleared, and write 1 to the other flags. Do not write 0 to the status flags indicating 0.
Note 5. The USBA detects a change in the status indicated by the VBINT flag even while the clock supply is stopped (while the LPSTS.SUSPENDM bit is 0), and requests the USBAR interrupt when the corresponding interrupt enable bit is 1. Clear these flags after supplying the PHY clock.

BRDY Flag (BRDY Interrupt Status Flag)

This flag indicates the state of the BRDY interrupt. Refer to section 39.2.12 for conditions of the BRDY flag becoming 1. The BRDY flag becomes 0 when 0 is written to the BRDYSTS.PIPEBRDY[9:0] flags for all pipes for which the BRDYENB.PIPEBRDYE[9:0] bits are 1 (interrupt request output enabled). The BRDY flag does not become 0 even when set to 0 by software.

NRDY Flag (NRDY Interrupt Status Flag)

This flag indicates the state of the NRDY interrupt. Refer to section 39.2.13 for conditions of the NRDY flag becoming 1. The NRDY flag becomes 0 when 0 is written to the NRDYSTS.PIPENRDY[9:0] flags for all pipes for which the NRDYENB.PIPENRDYE[9:0] bits are 1 (interrupt request output enabled). The NRDY flag does not become 0 even when set to 0 by software.

BEMP Flag (BEMP Interrupt Status Flag)

This flag indicates the state of the BEMP interrupt. Refer to section 39.2.14 for conditions of the BEMP flag becoming 1. The BEMP flag becomes 0 when 0 is written to the BEMPSTS.PIPEBEMP[9:0] flags for all pipes for which the BEMPENB.PIPEBEMPE[9:0] bits are 1 (interrupt request output enabled). The BEMP flag does not become 0 even when set to 0 by software.

CTRT Flag (Control Transfer Stage Transition Interrupt Status Flag)

In function controller operation, the USBA updates the value of the CTSQ[2:0] flags and sets the CTRT flag to 1 on detecting a transition in the control transfer stage. When a control transfer stage transition interrupt is generated, set the CTRT flag to 0 before the USBA detects the next control transfer stage transition. Values read from the CTRT flag are invalid in host controller operation.

DVST Flag (Device State Transition Interrupt Status Flag)

In function controller operation, the USBA updates the value of the DVSQ[2:0] flags and sets the DVST flag to 1 when a change in the device state is detected. When a device state transition interrupt is generated, set the DVST flag to 0 before the USBA detects the next device state transition. Values read from the DVST flag are invalid in host controller operation.

SOFR Flag (Frame Number Refresh Interrupt Status Flag)

- In host controller operation
  When the DVSTCTR0.UACT bit is 1, the SOFR flag becomes 1 (a frame number refresh interrupt is detected every millisecond) when the frame number is updated.
- In function controller operation
  The USBA sets the SOFR flag to 1 (a frame number refresh interrupt is detected every millisecond) when the frame number is updated. The USBA can detect a frame number refresh interrupt using the SOF recovery function even when a corrupted SOF packet is received from the USB host. Refer to section 39.3.13 for details on the SOF recovery function.

RESM Flag (Resume Interrupt Status Flag)

In function controller operation, the RESM flag becomes 1 when the USBA detects the resume signal in the suspended state (DVSQ[2:0] flags are 1xxb). Values read from the RESM flag are invalid in host controller operation.

VBINT Flag (VBUS Interrupt Status Flag)

The VBINT flag becomes 1 when a level change (high to low or low to high) is detected in the USBA_VBUS pin input signal. The USBA sets the VBSTS flag to indicate the USBA_VBUS pin input level. When the VBUS interrupt request is generated, eliminate chattering by reading the VBSTS flag several times by software and checking that the values read are the same.

39.2.18 Interrupt Status Register 1 (INTSTS1)

Address: 000D 0442h

	b15	b14	b13	b12	b11	b10	b9	b8
	OVRCR	BCHG	—	DTCH	ATTCH	—	L1RSMEND	LPMEND
Value after reset:	0	0	x	0	0	x	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	—	EOFERR	SIGN	SACK	—	—	—	PDDETINT
Value after reset:	x	0	0	0	x	x	x	0

Bit	Symbol	Bit Name	Description	R/W
b0	PDDETINT	Portable Device Detection Interrupt Status Flag *1	0: Portable Device detection interrupt not requested 1: Portable Device detection interrupt requested	R/(W) *2
b3 to b1	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b4	SACK	Setup Transaction Normal Response Interrupt Status Flag *3	0: SACK interrupt not requested 1: SACK interrupt requested	R/(W) *2
b5	SIGN	Setup Transaction Error Interrupt Status Flag *3	0: SIGN interrupt not requested 1: SIGN interrupt requested	R/(W) *2
b6	EOFERR	End-of-Frame Error Detection Interrupt Status Flag *3	0: EOFERR interrupt not requested 1: EOFERR interrupt requested	R/(W) *2
b7	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b8	LPMEND	LPM Transaction End Interrupt Status Flag *3	0: LPMEND interrupt not requested 1: LPMEND interrupt requested	R/(W) *2
b9	L1RSMEND	L1 Resume End Interrupt Status Flag *3	0: L1RSMEND interrupt not requested 1: L1RSMEND interrupt requested	R/(W) *2
b10	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b11	ATTCH	Device Attach Detection Interrupt Status Flag *3	0: ATTCH interrupt not requested 1: ATTCH interrupt requested	R/(W) *2
b12	DTCH	Device Detach Detection Interrupt Status Flag *3	0: DTCH interrupt not requested 1: DTCH interrupt requested	R/(W) *2
b13	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b14	BCHG	Bus Change Interrupt Status Flag *3	0: BCHG interrupt not requested 1: BCHG interrupt requested	R/(W) *2
b15	OVRCR	Overcurrent Change Interrupt Status Flag *1, *3	0: OVRCR interrupt not requested 1: OVRCR interrupt requested	R/(W) *2

Note 1. If a change in the status indicated by the PDDETINT or OVRCR flag is detected even while the clock is stopped (when the LPSTS.SUSPENDM bit is 0), and if the corresponding interrupt enable bit is 1, the USBAR interrupt is requested. Supply the PHY clock before setting these flags to 0. Interrupts indicated by flags other than the PDDETINT and OVRCR flags are not detected while the PHY clock is stopped (when the LPSTS.SUSPENDM bit is 0).

Note 2. To clear the flags in the INTSTS1 register, write 0 only to the flags to be cleared; write 1 to the other flags.

Note 3. Only enable interrupts other than the Portable Device detection interrupt in host controller operation.

PDDETINT Flag (Portable Device Detection Interrupt Status Flag)

In host controller operation, this flag indicates the status of the Portable Device detection interrupt.

The PDDETINT flag becomes 1 when the USBA detects a Portable Device. The USBA indicates the D+ line status in the BCCTRL.PDDETSTS flag. When the Portable Device detection interrupt is generated, eliminate chattering by reading the BCCTRL.PDDETSTS flag several times by software and checking that the values read are the same.

SACK Flag (Setup Transaction Normal Response Interrupt Status Flag)

In host controller operation, this flag indicates the status of the setup transaction normal response interrupt (SACK interrupt). When the USBA issues a setup transaction, if an ACK response is received from a peripheral device, the SACK flag becomes 1. At this time, if the INTENB1.SACKE bit is 1, the USBA requests the SACK interrupt.
In function controller operation, the SACK flag read value is invalid.

SIGN Flag (Setup Transaction Error Interrupt Status Flag)

In host controller operation, this flag indicates the status of the setup transaction error interrupt (SIGN interrupt). When the USBA issues a setup transaction, if an ACK response is not returned from a peripheral device three consecutive times, the SIGN flag becomes 1. At this time, if the INTENB1.SIGNE bit is 1, the USBA requests the SIGN interrupt. If any of the following conditions occurs three times consecutively, the USBA detects the setup transaction error

- A timeout is detected by the USBA when there is no response from a peripheral device
- An ACK packet is corrupted.
- A handshake other than ACK (i.e. NAK, NYET, or STALL) is received

In function controller operation, the SIGN flag read value is invalid.

EOFERR Flag (End-of-Frame Error Detection Interrupt Status Flag)

In host controller operation, this flag indicates the status of the EOF error detection interrupt (EOFERR interrupt). When communication is detected as not being complete at the EOF2 timing prescribed in USB 2.0, the EOFERR flag becomes 1. At this time, if the INTENB1.EOFERRE bit is 1, the USBA requests the EOFERR interrupt. After detecting the EOF error, regardless of the INTENB1.EOFERRE bit setting, the USBA sets the DVSTCTR0.UACT bit to 0 and enters the Idle state. controls hardware as described below. Use software to end all communication currently being performed on pipes, and repeat enumeration.
In function controller operation, the EOFERR flag read value is invalid.

LPMEND Flag (LPM Transaction End Interrupt Status Flag)

When the HL1CTRL1.L1REQ bit is set to 1, the USBA transmits an LPM token. When the LPM transaction is ended because a response from the peripheral device or a timeout is detected, the LPMEND flag becomes 1.
In function controller operation, the LPMEND flag read value is invalid.

L1RSMEND Flag (L1 Resume End Interrupt Status Flag)

When performing processing to exit the L1 state, the L1RSMEND flag becomes 1 when the processing is completed.
In function controller operation, the L1RSMEND flag read value is invalid.

ATTCH Flag (Device Attach Detection Interrupt Status Flag)

In host controller operation, this flag indicates the status of the device attach detection interrupt (ATTCH interrupt). When the USBA detects J state or K state of the full-speed or low-speed signal level for 2.5 µs on the port, the USBA detects that a device has been attached, and sets the ATTCH flag to 1. At this time, if the INTENB1.ATTCHE bit is 1, the USBA requests the USBAR interrupt.
The conditions for the USBA to detect a device being attached are as follows:

- The K state, SE0, or SE1 changes to the J state, and the J state continues for 2.5 µs
- The J state, SE0, or SE1 changes to the K state, and the K state continues for 2.5 µs

In function controller operation, the ATTCH flag read value is invalid.

DTCH Flag (Device Detach Detection Interrupt Status Flag)

In host controller operation, this flag indicates the status of the device detach detection interrupt (DTCH interrupt).
When a USB bus device disconnect is detected, the USBA detects device disconnection, and the DTCH flag becomes 1. At this time, if the INTENB1.DTCHE bit is set to 1, the USBA requests the USBAR interrupt.
The USBA detects bus disconnection based on USB 2.0.
After device disconnect is detected, regardless of the INTENB1.DTCHE bit setting, the USBA sets the DVSTCTR0.UACT bit to 0 and enters the Idle state. Use software to end all communication currently being performed on pipes, and transition to the wait for attach (ATTCH interrupt generated) state.
In function controller operation, the DTCH flag read value is invalid.

BCHG Flag (Bus Change Interrupt Status Flag)

This flag indicates the status of the bus change interrupt (BCHG interrupt).
When a status change to full-speed or low-speed occurs on the USB port (when the J state, K state, or SE0 changes to the J state, K state, or SE0), the USBA detects a change in the bus status, and the BCHG flag becomes 1. At this time, if the INTENB1.BCHGE bit is 1, the USBA requests the USBAR interrupt.
The SYSSTS0.LNST[1:0] flags indicate the current state of the USB port. When the BCHG interrupt is generated, in order to eliminate chattering, read the LNST[1:0] flags several times by software and confirm that the values read are the same.
In function controller operation, the BCHG flag read value is invalid.

OVRCR Flag (Overcurrent Change Interrupt Status Flag)

This flag indicates the status change interrupt (OVRCR interrupt) for the USBA_OVRCURA pin or USBA_OVRCURB pin.
If there is a change in the input of either the USBA_OVRCURA pin or USBA_OVRCURB pin (from high to low or low to high), the USBA detects a change in the overcurrent pin, and the OVRCR flag becomes 1. At this time, if the INTENB1.OVRCRE bit is 1, the USBA requests the USBAR interrupt.
The SYSSTS0.OVCMON[1:0] flags to indicate the current status of the USBA_OVRCURA and USBA_OVRCURB pins.
In host controller operation, if an overcurrent notification signal (from the power supply IC which supplies VBUS to the peripheral devices) is connected to the USBA_OVRCURA or USBA_OVRCURB pin, software can detect an occurrence of overcurrent.

39.2.19 BRDY Interrupt Status Register (BRDYSTS)

Address: 000D 0446h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPEBRDY[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	PIPEBRDY[9:0]	Pipe 9 to Pipe 0 BRDY Interrupt Status Flags *1	0: Interrupt not generated 1: Interrupt generated	R/(W) *2
b15 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. Each bit corresponds to a pipe number (e.g. pipe 9 corresponds to the PIPEBRDY[9] bit, pipe 8 corresponds to the PIPEBRDY[8] bit, etc.).

Note 2. When the SOFCFG.BRDYM bit is 0, to clear the status indicated by the PIPEBRDY[9:0] flags, write 0 only to the flags to be cleared; write 1 to the other flags.
When the SOFCFG.BRDYM bit is set to 0, clear the BRDY interrupt before accessing the FIFO buffer.

PIPEBRDY[9:0] Flags (Pipe 9 to Pipe 0 BRDY Interrupt Status Flags)

When the BRDY interrupt is detected, the USBA sets the bits corresponding to the PIPEBRDY[9:0] flags to 1. Refer to section 39.3.6.1 for details on the BRDY interrupt.

39.2.20 NRDY Interrupt Status Register (NRDYSTS)

Address: 000D 0448h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPENRDY[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	PIPENRDY[9:0]	Pipe 9 to Pipe 0 NRDY Interrupt Status Flags *1	0: Interrupt not generated 1: Interrupt generated	R/(W) *2
b15 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. Each bit corresponds to a pipe number (e.g. Pipe 9 corresponds to the PIPENRDY[9] bit, pipe 8 corresponds to the PIPENRDY[8] bit, etc.).

Note 2. To clear the status indicated by the PIPENRDY[9:0] flags, write 0 only to the flags to be cleared; write 1 to the other flags.

PIPENRDY[9:0] Flags (Pipe 9 to Pipe 0 NRDY Interrupt Status Flags)

If an NRDY interrupt source is detected while the PID[1:0] bits in a pipe control register are 01b (BUF response), the USBA module sets the bits corresponding to the PIPENRDY[9:0] flags to 1. Refer to section 39.3.6.2 for details on the NRDY interrupt.

39.2.21 BEMP Interrupt Status Register (BEMPSTS)

Address: 000D 044Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPEBEMP[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	PIPEBEMP[9:0]	Pipe 9 to Pipe 0 BEMP Interrupt Status Flags *1	0: Interrupt not generated 1: Interrupt generated (n = 0 to 9)	R/(W) *2
b15 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. Each bit corresponds to a pipe number (e.g. pipe 9 corresponds to the PIPEBEMP[9] bit, pipe 8 corresponds to the PIPEBEMP[8] bit, etc.).

Note 2. To clear the status indicated by the PIPEBEMP[9:0] flags, write 0 only to the flags to be cleared; write 1 to the other flags.

PIPEBEMP[9:0] Flags (Pipe 9 to Pipe 0 BEMP Interrupt Status Flags)

If a BEMP interrupt is detected while the PID[1:0] bits in a pipe control register are 01b (BUF response), the USBA module sets the bits corresponding to the PIPEBEMP[9:0] flags to 1. Refer to section 39.3.6.3 for details on the BEMP interrupt.

39.2.22 Frame Number Register (FRMNUM)

Address: 000D 044Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVRN	CRCE	—	—	—	FRNM[10:0]										
Value after reset:	0	0	x	x	x	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b10 to b0	FRNM[10:0]	Frame Number Flags	Latest frame number	R
b13 to b11	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b14	CRCE	CRC Error Detection Status Flag	0: No error occurred 1: Error occurred	R/(W) *2
b15	OVRN	Overrun/Underrun Detection Status Flag *1	0: No error occurred 1: Error occurred	R/(W) *2

Note 1. The OVRN flag is used for debugging. Design the timing so that no overrun or underrun occurs in the system.
Note 2. When setting this flag to 0, write 0 only to the flags to be cleared; write 1 to the other flags.

FRNM[10:0] Flags (Frame Number Flags)

An SOF packet is issued or received every millisecond. Each time an SOF packet is issued or received, the USBA rewrites these flags to indicate the latest frame number.

CRCE Flag (CRC Error Detection Status Flag)

This flag becomes 1 when a CRC error or bit stuffing error occurs during isochronous transfer. Write 0 to the CRCE flag to clear it. When writing 0 to the CRCE flag, write 1 to the other flags in the FRMNUM register. When a CRC error is detected, the USBA generates an internal NRDY interrupt request.

OVRN Flag (Overrun/Underrun Detection Status Flag)

This flag becomes 1 when an overrun or underrun error occurs during isochronous transfer. Write 0 to the OVRN flag to clear it. When writing 0 to the OVRN flag, write 1 to the other flags in the FRMNUM register.

(1) In host controller operation

The USBA sets the OVRN flag to 1 when either of the following conditions is satisfied.

- For pipes set to isochronous transfer for transmitting, the timing to issue an OUT token comes before all the transmit data has been written to the FIFO buffer.
- For pipes set to isochronous transfer for receiving, the timing to issue an IN token comes while no FIFO buffer plane is empty.

(2) In function controller operation

The USBA sets the OVRN flag to 1 when any of the following conditions is satisfied.

- For pipes set to isochronous transfer for transmitting, the IN token is received before all the transmit data has been written to the FIFO buffer.
- For pipes set to isochronous transfer for receiving, the OUT token is received while no FIFO buffer plane is empty.

39.2.23 USB Address Register (USBADDR)

Address: 000D 0450h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	USBADDR[6:0]						
Value after reset:	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	USBADDR[6:0]	USB Address Flags	In function controller operation, these flags indicate the USB address assigned by the host when the USBA processed the SetAddress() request successfully.	R
b15 to b7	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

USBADDR[6:0] Flags (USB Address Flags)

In function controller operation, these flags indicate the USB address received in the USBADDR[6:0] flags when the USBA processed the SetAddress() request successfully. The USBADDR[6:0] flags indicate 00h when a USB bus reset is detected.

In host controller operation, the USBA does not use the USBADDR[6:0] flags.

39.2.24 USB Request Type Register (USBREQ)

Address: 000D 0454h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BREQUEST[7:0]								BMREQUESTTYPE[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	BMREQUESTTYPE[7:0]	Request Type	USB request *bmRequestType* value	R/W *1
b15 to b8	BREQUEST[7:0]	Request	USB request *bRequest* value	R/W *1

Note 1. In function controller operation, these bits are readable but writing to them is invalid. In host controller operation, these bits are both readable and writable.

BMREQUESTTYPE[7:0] Bits (Request Type)

These bits store the *bmRequestType* value of USB requests.

- In host controller operation
  Set these bits to the value of the USB request data in setup transactions to be transmitted. Do not modify these bits when the DCPCTR.SUREQ bit is 1.
- In function controller operation
  These bits indicate the value of the USB request data in setup transactions to be received. Writing to these bits is invalid.

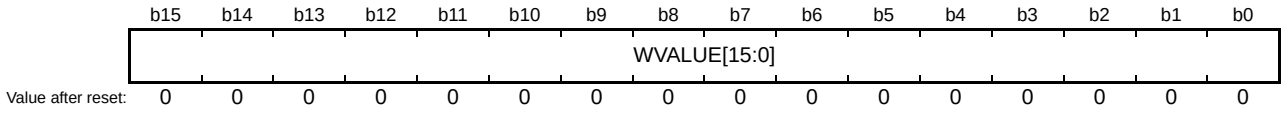
BREQUEST[7:0] Bits (Request)

These bits store the *bRequest* value of USB requests.

- In host controller operation
  Set these bits to the value of the USB request data in setup transactions to be transmitted. Do not modify these bits when the DCPCTR.SUREQ bit is 1.
- In function controller operation
  These bits indicate the value of the USB request data in setup transactions to be received. Writing to these bits is invalid.

39.2.25 USB Request Value Register (USBVAL)

Address: 000D 0456h



Bit	Symbol	Bit Name	Description	R/W
b15 to b0	WVALUE[15:0]	Value	Value of the USB request *wValue*	R/W *1

Note 1. In function controller operation, these bits are readable but writing to them is invalid. In host controller operation, these bits are both readable and writable.

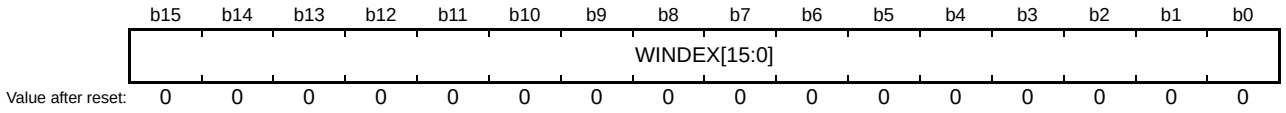
WVALUE[15:0] Bits (Value)

These bits store the *wValue* value of USB requests.

- In host controller operation
  Set the *wValue* value of USB requests in setup transactions to be transmitted. Do not modify these bits when the DCPCTR.SUREQ bit is 1.
- In function controller operation
  These bits indicate the *wValue* value of USB requests in setup transactions to be received. Writing to these bits is invalid.

39.2.26 USB Request Index Register (USBINDX)

Address: 000D 0458h



Bit	Symbol	Bit Name	Description	R/W
b15 to b0	WINDEX[15:0]	Index	Value of the USB request *wIndex*	R/W *1

Note 1. In function controller operation, these bits are readable but writing to them is invalid. In host controller operation, these bits are both readable and writable.

WINDEX[15:0] Bits (Index)

These bits store the *wIndex* value of USB requests.

- In host controller operation
  Set the *wIndex* value of USB requests in setup transactions to be transmitted. Do not modify these bits when the DCPCTR.SUREQ bit is 1.
- In function controller operation
  These bits indicate the *wIndex* value of USB requests in setup transactions to be received. Writing to these bits is invalid.

39.2.27 USB Request Length Register (USBLENG)

Address: 000D 045Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WLENGTH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	WLENGTH[15:0]	Length	Value of the USB request *wLength*	R/W *1

Note 1. In function controller operation, these bits are readable but writing to them is invalid. In host controller operation, these bits are both readable and writable.

WLENGTH[15:0] Bits (Length)

These bits store the *wLength* value of USB requests.

- In host controller operation
  Set the *wLength* value of USB requests in setup transactions to be transmitted. Do not modify these bits when the DCPCTR.SUREQ bit is 1.
- In function controller operation
  These bits indicate the *wLength* value of USB requests in setup transactions to be received. Writing to these bits is invalid.

39.2.28 Default Control Pipe Configuration Register (DCPCFG)

Address: 000D 045Ch

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	—	—	—	—	CNTMD
Value after reset:	x	x	x	x	x	x	x	0

	b7	b6	b5	b4	b3	b2	b1	b0
	SHTNAK	—	—	DIR	—	—	—	—
	0	x	x	0	x	x	x	x

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b4	DIR	Transfer Direction *1	0: Receive data 1: Transmit data	R/W
b6, b5	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b7	SHTNAK	Pipe Disabled at End of Transfer *1	0: The pipe is continued at the end of transfer. 1: The pipe is disabled at the end of transfer.	R/W
b8	CNTMD	Continuous Transfer Mode	0: Discontinuous transfer mode 1: Continuous transfer mode	R/W
b15 to b9	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

Note 1. Only change the settings of bits in the DCPCFG register when the DCPCTR.PID[1:0] bits are 00b (NAK response). Only change the DCPCTR.PID[1:0] bits from 01b (BUF response) to 00b (NAK response) after confirming that the value of the DCPCTR.PBUSY flag is 0. However, the PBUSY flag does not need to be checked by software if the USBA changes the PID[1:0] bits to 00b (NAK response).

DIR Bit (Transfer Direction)

In host controller operation, this bit sets the transfer direction of the data stage and status stage for control transfer.
In function controller operation, set this bit to 0.

SHTNAK Bit (Pipe Disabled at End of Transfer)

When the control transfer direction is receiving, this bit specifies whether the DCPCTR.PID[1:0] bits are changed from 00b (NAK response) when transfer is complete.
The SHTNAK bit is valid when the default control pipe transfer direction is receiving.
When the SHTNAK bit is 1, the DCPCTR.PID[1:0] bits become 00b (NAK response) when the USBA transfer is complete. The USBA determines that transfer is complete when short packet data (including the zero-length packet) is received successfully.

CNTMD Bit (Continuous Transfer Mode)

This bit specifies whether the default control pipe communicates in continuous transfer mode or not.

39.2.29 Default Control Pipe Maximum Packet Size Register (DCPMAXP)

Address: 000D 045Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DEVSEL[3:0]				—	—	—	—	—	MXPS[6:0]						
Value after reset:	0	0	0	0	x	x	x	x	x	1	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	MXPS[6:0]	Maximum Packet Size *1	These bits specify the maximum data payload (maximum packet size) for the default control pipe.	R/W
b11 to b7	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b15 to b12	DEVSEL[3:0]	Device Select *2	b15 b12 0 0 0 0: Address 0000b 0 0 0 1: Address 0001b 0 0 1 0: Address 0010b 0 0 1 1: Address 0011b 0 1 0 0: Address 0100b 0 1 0 1: Address 0101b 0 1 1 0: Address 0110b 0 1 1 1: Address 0111b 1 0 0 0: Address 1000b 1 0 0 1: Address 1001b 1 0 1 0: Address 1010b Only set the values listed above.	R/W

Note 1. Only change the MXPS[6:0] bit setting when the DCPCTR.PID[1:0] bits are 00b (NAK response), and the CFIFOSEL.CURPIPE[3:0] bits are 0000b. When changing the setting after changing the DCPCTR.PID[1:0] bits from 01b (BUF response) to 00b (NAK response), confirm the DCPCTR.PBUSY flag is 0 before modifying these bits. However, when the USBA changes the DCPCTR.PID[1:0] bits from 01b (BUF response) to 00b (NAK response), the PBUSY flag does not need to be checked by software. In addition, after the MXPS[6:0] bit setting is changed, set the CFIFOSEL.BCLR bit to 1 to perform buffer clear processing.

Note 2. Only change the DEVSEL[3:0] bit setting when the DCPCTR.PID[1:0] bits are 00b (NAK response), and the DCPCTR.SUREQ bit is 0. Only change the DCPCTR.PID[1:0] bits of the default control pipe from 01b (BUF response) to 00b (NAK response) after confirming the value of the DCPCTR.PBUSY flag is 0. However, the PBUSY flag does not need to be checked by software if the USBA changes the DCPCTR.PID[1:0] bits to 00b (NAK response).

MXPS[6:0] Bits (Maximum Packet Size)

Set the default control pipe's maximum data payload (maximum packet size) to the MXPS[6:0] bits. The initial value is 40h (64 bytes).

The value set to the MXPS[6:0] bits must be compliant with USB 2.0.

When the MXPS[6:0] bits are set to 00h, do not write to the FIFO buffer and do not set the DCPCTR.PID[1:0] bits to 01b (BUF response).

DEVSEL[3:0] Bits (Device Select)

In host controller operation, these bits specify the peripheral device address of the communication target for control transfer.

Set the DEVADDm register corresponding to the value set in the DEVSEL[3:0] bits, and then set the DEVSEL[3:0] bits (m = 0 to A). For example, to set the DEVSEL[3:0] bits to 0010b, set the address in the DEVADD2 register.

In function controller operation, set the DEVSEL[3:0] bits to 0000b.

39.2.30 Default Control Pipe Control Register (DCPCTR)

Address: 000D 0460h

	b15	b14	b13	b12	b11	b10	b9	b8
	BSTS	SUREQ	—	—	SUREQCLR	—	—	SQCLR
Value after reset:	0	0	0	0	x	x	x	0

	b7	b6	b5	b4	b3	b2	b1	b0
	SQSET	SQMON	PBUSY	—	—	CCPL	PID[1:0]	
Value after reset:	0	0	0	0	x	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	PID[1:0]	Response PID	b1 b0 0 0: NAK response 0 1: BUF response (depending on the FIFO buffer state) 1 0: STALL response 1 1: STALL response	R/W
b2	CCPL	Control Transfer End Enable	0: Completion of control transfer is disabled. 1: Completion of control transfer is enabled.	R/W
b4, b3	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b5	PBUSY	Pipe Busy Flag	0: The default control pipe is not used for the USB bus. 1: The default control pipe is in use for the USB bus.	R
b6	SQMON	Sequence Toggle Bit Monitor Flag	0: DATA0 1: DATA1	R
b7	SQSET	Sequence Toggle Bit Set *1	This bit allows setting for the expected value of the sequence toggle bit of the next transaction for data 1 in default control pipe transfer. Writing 0 has no effect. This bit is read as 0.	R/W
b8	SQCLR	Sequence Toggle Bit Clear *1	This bit allows setting for the expected value of the sequence toggle bit of the next transaction for data 0 in default control pipe transfer. Writing 0 has no effect. This bit is read as 0.	R/W
b10, b9	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b11	SUREQCLR	SUREQ Bit Clear	In host controller operation, the SUREQ bit becomes 0 when this bit is set to 1. Writing 0 has no effect. This bit is read as 0.	R/W
b12	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R
b13	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b14	SUREQ	SETUP Token Transmission	In host controller operation, setting this bit to 1 transmits the setup packet. Writing 0 has no effect.	R/W
b15	BSTS	Buffer Status Flag	0: Buffer access is disabled. 1: Buffer access is enabled.	R

Note 1. Only write 1 to bits SQSET and SQCLR while the DCPCTR.PID[1:0] bits are 00b (NAK response). Only change the DCPCTR.PID[1:0] bits from 01b (BUF response) to 00b (NAK response) after confirming that the value of the DCPCTR.PBUSY flag is 0. However, the PBUSY flag does not need to be checked by software if the USBA changes the DCPCTR.PID[1:0] bits to 00b (NAK response).

PID[1:0] Bits (Response PID)

The DCPCTR.PID[1:0] bits control the USB response for control transfer.

(1) In host controller operation

Perform the following to modify the DCPCTR.PID[1:0] bits from 00b (NAK response) to 01b (BUF response).

- When transmitting
  Write all the transmit data to the FIFO buffer while the DVSTCTR0.UACT bit is 1 and the DCPCTR.PID[1:0] bits are 00b (NAK response), and then set the DCPCTR.PID[1:0] bits to 01b (BUF response). After the DCPCTR.PID[1:0] bits have been set to 01b (BUF response), the USBA executes the OUT transaction.
- When receiving
  Confirm that the FIFO buffer is empty (or empty the buffer) while the DVSTCTR0.UACT bit is 1 and the DCPCTR.PID[1:0] bits are 00b (NAK response), and then set the DCPCTR.PID[1:0] bits to 01b (BUF response). After the DCPCTR.PID[1:0] bits have been set to 01b (BUF response), the USBA executes the IN transaction.

The USBA modifies the value of the DCPCTR.PID[1:0] bits in the following cases.

- When the DCPCTR.PID[1:0] bits are set to 01b (BUF response) and the USBA has received data exceeding the maximum packet size, the USBA sets the DCPCTR.PID[1:0] bits to 11b (STALL response).
- When a reception error such as CRC error is detected three times in succession, the USBA sets the DCPCTR.PID[1:0] bits to 00b (NAK response).
- When a STALL handshake is received, the USBA sets the DCPCTR.PID[1:0] bits to 11b (STALL response).

(2) In function controller operation

The USBA modifies the value of the DCPCTR.PID[1:0] bits in the following cases.

- When a setup packet is received, the USBA modifies the DCPCTR.PID[1:0] bits to 00b (NAK response). At this time, the USBA sets the INTSTS0.VALID flag to 1, and the DCPCTR.PID[1:0] bits cannot be modified by software until the VALID flag is set to 0 by software.
- When the DCPCTR.PID[1:0] bits are set to 01b (BUF response) and the USBA receives data exceeding the maximum packet size, the USBA sets the DCPCTR.PID[1:0] bits to 11b (STALL response).
- When the USBA detects a control transfer sequence error, the DCPCTR.PID[1:0] bits are set to 10b or 11b (STALL response).
- When the USBA detects a USB bus reset, the DCPCTR.PID[1:0] bits are set to 00b (NAK response).

The USBA does not check the setting of the DCPCTR.PID[1:0] bits during the SetAddress() request processing (automatic processing).

CCPL Bit (Control Transfer End Enable)

In function controller operation, setting this bit to 1 enables completion of the status stage of the control transfer.
If the CCPL bit is set to 1 while the corresponding DCPCTR.PID[1:0] bits are 01b (BUF response), the USBA completes the status stage of the control transfer.
During a control read transfer, the USBA transmits an ACK handshake for the OUT transaction from the USB host.
During a control write or no-data control transfer, the USBA transmits a zero-length packet for the IN transaction from the USB host. However, when the SetAddress() request is detected, the USBA performs automatic responses from the SETUP stage until the status stage is completed regardless of the setting of the CCPL bit.
When a new setup packet is received, the USBA modifies the CCPL bit from 1 to 0.
When the INTSTS0.VALID flag is 1, the CCPL bit cannot be set to 1.
The CCPL bit is initialized by the USB bus reset.
In host controller operation, set the CCPL bit to 0.

PBUSY Flag (Pipe Busy Flag)

When the USBA starts a USB transaction using the default control pipe, the USBA changes the PBUSY flag from 0 to 1.
The USBA switches the PBUSY flag back to 0 at the end of the transaction.
After the DCPCTR.PID[1:0] bits are set to 00b (NAK response), the read value of the PBUSY flag indicates whether or not changes to pipe settings can proceed. Refer to section 39.3.7.1 for details.

SQMON Flag (Sequence Toggle Bit Monitor Flag)

This flag indicates the value of the sequence toggling bit for the next transaction in default control pipe transfer. When a transaction is processed successfully, the USBA toggles the SQMON flag. However, the SQMON flag is not toggled when data PID mismatch occurs during data reception. In function controller operation, the USBA sets the SQMON flag to 1 (setting the expected value for DATA1) when a setup packet is received successfully. In addition, in function controller operation, the USBA does not check the SQMON flag during IN or OUT transactions in the status stage, and the flag is not toggled even at the end of a successful processing.

SQSET Bit (Sequence Toggle Bit Set)

This bit sets the value of the sequence toggling bit to DATA1 for the next transaction in default control pipe transfer. Do not set bits SQCLR and SQSET to 1 at the same time.

SQCLR Bit (Sequence Toggle Bit Clear)

This bit sets the value of the sequence toggling bit to DATA0 for the next transaction in default control pipe transfer. Do not set bits SQCLR and SQSET to 1 at the same time.

SUREQCLR Bit (SUREQ Bit Clear)

In host controller operation, the SUREQ bit can be cleared by setting the SUREQCLR bit to 1. If transfer stops while the SUREQ bit is set to 1 in a SETUP transaction, set the SUREQCLR bit to 1 by software. This is not necessary at the end of a successful setup transaction because the USBA will automatically set the SUREQ bit to 0. Use the SUREQCLR bit to control the SUREQ bit when transfer stops while the DVSTCTR0.UACT bit is set to 0 or transfer is not proceeding because detaching of the port has been detected. Set the SUREQCLR bit to 0 in function controller operation.

SUREQ Bit (SETUP Token Transmission)

In host controller operation, a setup packet is transmitted when the SUREQ bit is set to 1. After the SETUP transaction processing is completed, the USBA generates the SACK interrupt or SIGN interrupt and sets the SUREQ bit to 0. When the SUREQCLR bit is set to 1, the SUREQ bit becomes 0.
Set the SUREQ bit to 1 after a USB request to be transmitted in the setup transaction is set in the DCPMAXP.DEVSEL[3:0] bits and registers USBREQ, USBVAL, USBINDX, and USBLENG. Before setting the SUREQ bit to 1, confirm that the DCPCTR.PID[1:0] bits are set to 00b (NAK response). In addition, after the SUREQ bit is set to 1, until the setup transaction ends (SUREQ bit is 1), do not modify the DCPMAXP.DEVSEL[3:0] bits or values of registers USBREQ, USBVAL, USBINDX, and USBLENG. Set the SUREQ bit to 1 only when issuing a SETUP token. In other cases, be sure to write 0 to this bit. Set the SUREQ bit to 0 in function controller operation.

BSTS Flag (Buffer Status Flag)

This flag indicates whether the default control pipe's FIFO buffer can be accessed.
The meaning of the BSTS flag varies depending on the setting of the CFIFOSEL.ISEL bit.

- When the ISEL bit is 0, the BSTS flag indicates whether receive data can be read.
- When the ISEL bit is 1, the BSTS flag indicates whether transmit data can be written.

39.2.31 Pipe Window Select Register (PIPESEL)

Address: 000D 0464h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	PIPESEL[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	PIPESEL[3:0]	Pipe Window Select	b3 b0 0 0 0 0: No pipe selected 0 0 0 1: Pipe 1 0 0 1 0: Pipe 2 0 0 1 1: Pipe 3 0 1 0 0: Pipe 4 0 1 0 1: Pipe 5 0 1 1 0: Pipe 6 0 1 1 1: Pipe 7 1 0 0 0: Pipe 8 1 0 0 1: Pipe 9 Only set the values listed above.	R/W
b15 to b4	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

Set pipes 1 to 9 using registers PIPESEL, PIPECFG, PIPEBUF, PIPEMAXP, PIPEPERI, PIPEnCTR (n = 1 to 9), PIPEnTRE (n = 1 to 5), and PIPEnTRN (n = 1 to 5). After selecting the pipe to be set by the PIPESEL register, each pipe setting is performed by the PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI registers. In addition, the PIPEnCTR, PIPEnTRE, and PIPEnTRN registers can be set regardless of the pipe selection by the PIPESEL register.

PIPESEL[3:0] Bits (Pipe Window Select)

When the pipe number is specified in the PIPESEL[3:0] bits, the pipe information is indicated in the PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI registers. Perform the pipe setting by modifying these registers.
When the PIPESEL[3:0] bits are set to 0000b, reading bits in the PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI registers returns 0. Writing has no effect.

39.2.32 Pipe Configuration Register (PIPECFG)

Address: 000D 0468h

	b15	b14	b13	b12	b11	b10	b9	b8

R/W

Note 1. Only change the settings of the TYPE[1:0], SHTNAK, and EPNUM[3:0] bits while the PIPEnCTR.PBUSY flag is 0, and the PIPEnCTR.PID[1:0] bits are 00b (NAK response). Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag is 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBA changes the PID[1:0] bits to 00b (NAK response).

Note 2. Only change the setting of the BFRE, DBLB, CNTMD, and DIR bits while the PIPEnCTR.PBUSY flag is 0, and the PIPEnCTR.PID[1:0] bits are 00b (NAK response) with the pipe not specified in the CURPIPE[3:0] bits of a FIFO port select register. Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag is 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBA changes the PID[1:0] bits to 00b (NAK response).

Note 3. When the setting of the BFRE, DBLB, CNTMD, and DIR bits are modified after USB communications have been carried with the selected pipe, write 1 and 0 to the PIPEnCTR.ACLRM bit continuously by software and clear the FIFO buffer assigned to the selected pipe, in addition to the note described in Note 2.

EPNUM[3:0] Bits (Endpoint Number)

These bits specify the endpoint number for the selected pipe. Setting 0000b indicates the pipe not used. Set these bits so that the combination of the settings of the DIR and EPNUM[3:0] bits is different from the settings of other pipes. (The EPNUM[3:0] bits being set to 0000b can be set for all pipes.)

DIR Bit (Transfer Direction)

This bit specifies the transfer direction for the selected pipe. When the DIR bit is set to 0, the USBA uses the selected pipe to receive data. When the DIR bit is set to 1, the USBA uses the selected pipe to transmit data.

SHTNAK Bit (Pipe Disabled at End of Transfer)

This bit selects whether to modify the PIPEnCTR.PID[1:0] bits to 00b (NAK response) at the end of transfer when receiving direction is set for the selected pipe. This bit is valid when the default control pipe is in the receiving direction. When software processing sets this bit to 1 for a pipe in the receiving direction, the USBA modifies the PIPEnCTR.PID[1:0] bits corresponding to the selected pipe to 00b (NAK response) on determining the end of the transfer. The USBA determines that the transfer has ended from the following conditions.

- Short packet data (including a zero-length packet) is received successfully.
- The transaction counter is used and packets of the number specified by the transaction counter are received successfully.

CNTMD Bit (Continuous Transfer Mode)

This bit is valid when the selected pipe is pipe 1 to 5 of the bulk transfer type. According to the setting of this bit, the USBA determines the completion of transmission or reception for the FIFO buffer allocated to the selected pipe as shown in Table 39.7.

Table 39.7 Relationship Between the CNTMD Bit Setting and Methods for Determining Completion of FIFO Buffer Transmission/Reception

CNTMD Bit Setting	Method for Determining Readability and Transmittability
0	Conditions for FIFO buffer readable state when receiving direction is set (DIR bit is 0): The USBA has received one packet.
	Conditions for FIFO buffer transmittable state when transmitting direction is set (DIR bit is 1): When (1) or (2) is satisfied. (1) CPU (or DMAC/DTC) has written data of the maximum packet size to the FIFO buffer. (2) CPU (or DMAC/DTC) has written data of the short packet size (including 0 bytes) to the FIFO buffer and has set the BVAL bit in the FIFO port control register to 1.
1	Conditions for FIFO buffer readable state when receiving direction is set (DIR bit is 0): (1) The byte count of data received in the FIFO buffer allocated to the selected pipe is equal to the allocated byte count ((BUFSIZE + 1) × 64). (2) While there is no data stored in the FIFO buffer allocated to the selected pipe, the USBA has received a short packet except for a zero-length packet. (3) The USBA has received a zero-length packet when data is already contained in the FIFO buffer allocated to the selected pipe. (4) The number of packets specified by the transaction counter set for the selected pipe have been received.
	Conditions for FIFO buffer transmittable state when transmitting direction is set (DIR bit is 1): When (1) or (2) is satisfied. (1) CPU (or DMAC/DTC) has written data that is equal to the size of the FIFO buffer allocated to the selected pipe. (2) CPU (or DMAC/DTC) has written data of size smaller than the size of the FIFO buffer allocated to the selected pipe (including 0 bytes) and has set the BVAL bit in the FIFO port control register to 1.

DBLB Bit (Double Buffer Mode)

This bit specifies single buffer or double buffer for the FIFO buffer used by the selected pipe. This bit is valid when the selected pipe is pipe 1 to 5. When this bit is set to 1, the USBA allocates twice the FIFO buffer size specified by the PIPEBUF.BUFSIZE[4:0] bits for the selected pipe. The FIFO buffer size that the USBA allocates to the selected pipe is (PIPEBUF.BUFSIZE[4:0] + 1) × 64 × (DBLB + 1) [bytes].

BFRE Bit (BRDY Interrupt Operation Specification)

This bit specifies the timing for transmitting the BRDY interrupt. When this bit is set to 1 and the selected pipe is used in the receiving direction, the USBA detects the end of the transfer and issues a BRDY interrupt upon reading the packet. When a BRDY interrupt is generated with this setting, set the BCLR bit in a FIFO port control register to 1. Until the BCLR bit is set to 1, the FIFO buffer allocated to the selected pipe does not become the receivable state. When software processing sets this bit to 1 and the selected pipe is used in the transmitting direction, the USBA generates no BRDY interrupt. Refer to section 39.3.6.1 for details.

TYPE[1:0] Bits (Transfer Type)

These bits specify the transfer type of the pipe specified by the PIPESEL.PIPESEL[3:0] bits. Before modifying the PIPEnCTR.PID[1:0] bits of the selected pipe to 01b (BUF response) (before starting the USB communication with the selected pipe), set the TYPE[1:0] bits to a value other than 00b.

39.2.33 Pipe Buffer Register (PIPEBUF)

Address: 000D 046Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	BUFSIZE[4:0]					—	—	BUFNMB[7:0]							
Value after reset:	x	0	0	0	0	0	x	x	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description			R/W
b7 to b0	BUFNMB[7:0]	Buffer Number *1	These bits specify the start block of the FIFO buffer allocated to the selected pipe (04h to 87h).			R/W
b9, b8	—	Reserved	These bits are undefined when read. Set them to 0 when writing.			R/W
b14 to b10	BUFSIZE[4:0]	Buffer Size *1	00h: 64 bytes 01h: 128 bytes 02h: 192 bytes 03h: 256 bytes 04h: 320 bytes 05h: 384 bytes 06h: 448 bytes 07h: 512 bytes 08h: 576 bytes 09h: 640 bytes 0Ah: 704 bytes	0Bh: 768 bytes 0Ch: 832 bytes 0Dh: 896 bytes 0Eh: 960 bytes 0Fh: 1,024 bytes 10h: 1,088 bytes 11h: 1,152 bytes 12h: 1,216 bytes 13h: 1,280 bytes 14h: 1,344 bytes 15h: 1,408 bytes	16h: 1,472 bytes 17h: 1,536 bytes 18h: 1,600 bytes 19h: 1,664 bytes 1Ah: 1,728 bytes 1Bh: 1,792 bytes 1Ch: 1,856 bytes 1Dh: 1,920 bytes 1Eh: 1,984 bytes 1Fh: 2,048 bytes	R/W
b15	—	Reserved	This bit is undefined when read. Set it to 0 when writing.			R/W

Note 1. Only change the settings of bits in the PIPEBUF register while the PIPEnCTR.PID[1:0] bits are 00b (NAK response) and the CURPIPE[3:0] bits in the D0FIFOSEL/D1FIFOSEL register are 0000b. Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag is 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBA changes the PID[1:0] bits to 00b (NAK response).

BUFNMB[7:0] Bits (Buffer Number)

Specify the first block number of the FIFO buffer to be allocated to the selected pipe. Blocks of the FIFO buffer that the USBA allocates to the selected pipe are shown below.
Block number: BUFNMB[7:0] to block number: BUFNMB[7:0] + (PIPEBUF.BUFSIZE[4:0] + 1) × (DBLB + 1) -1

Set the BUFNMB[7:0] bits to a value that observes the conditions below, and has a allocated block number between 04h and 87h (8.5 Kbytes of the on-chip memory).

- 00h is for default control pipe only.
- 04h is for pipe 6 only, but is available for other pipes when pipe 6 is not used. When pipe 6 is selected, writing a value to these bits is disabled. The USBA automatically allocates 04h to the BUFNMB[7:0] bits for pipe 6.
- 05h is for pipe 7 only, but is available for other pipes when pipe 7 is not used. When pipe 7 is selected, writing a value to these bits is disabled. The USBA automatically allocates 05h to the BUFNMB[7:0] bits for pipe 7.
- 06h is for pipe 8 only, but is available for other pipes when pipe 8 is not used. When pipe 8 is selected, writing a value to these bits is disabled. The USBA automatically allocates 06h to the BUFNMB[7:0] bits for pipe 8.
- 07h is for pipe 9 only, but is available for other pipes when pipe 9 is not used. When pipe 9 is selected, writing a value to these bits is disabled. The USBA automatically allocates 07h to the BUFNMB[7:0] bits for pipe 9.

BUFSIZE[4:0] Bits (Buffer Size)

Specify the FIFO buffer size (number of blocks) to be allocated to the selected pipe. One block is 64 bytes.
When the DBLB bit is set to 1, the USBA allocates twice the FIFO buffer size specified by these bits for the selected pipe. Setting the DBLB bit to 1 is effective only when the selected pipe is pipe 1 to 5. The FIFO buffer size that the USBA allocates to the selected pipe is shown below.

(BUFSIZE[4:0] + 1) × 64 × (DBLB + 1) [bytes]

Set a value within the following range for the BUFSIZE[4:0] bits.

(1) When the selected pipe is pipe 1 to 5, a value of 00h to 1Fh can be set (up to 2 Kbytes).
(2) When the selected pipe is pipe 6 to 9, only a value of 00h (64 bytes) can be set.

39.2.34 Pipe Maximum Packet Size Register (PIPEMAXP)

Address: 000D 046Ch

Bit	Symbol	Bit Name	Description	R/W
b10 to b0	MXPS[10:0]	Maximum Packet Size *1, *2	• For pipes 1 and 2 1 byte (001h) to 1,023 bytes (3FFh) • For pipes 3 to 5 8 bytes (008h), 16 bytes (010h), 32 bytes (020h), 64 bytes (040h) • For pipes 6 to 9 1 byte (001h) to 64 bytes (040h)	R/W
b11	—	Reserved	This bit is read as 0. Set it to 0 when writing.	R/W
b15 to b12	DEVSEL[3:0]	Device Select *3	b15 b12 0 0 0 0: Address 0000b 0 0 0 1: Address 0001b 0 0 1 0: Address 0010b 0 0 1 1: Address 0011b 0 1 0 0: Address 0100b 0 1 1 0: Address 0110b 0 1 1 1: Address 0111b 1 0 0 0: Address 1000b 1 0 0 1: Address 1001b 1 0 1 0: Address 1010b 1011 to 1111: Reserved	R/W

Note 1. The initial value of the MXPS[10:0] bits is 000h when the PIPESEL.PIPESEL[3:0] bits are 0000b, or 040h when the PIPESEL[3:0] bits are 0001b to 1001b.

Note 2. Only change the settings of the MXPS[10:0] bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK response) and the CURPIPE[3:0] bits in the D0FIFOSEL/D1FIFOSEL register are 0000b. Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming the value of the PIPEnCTR.PBUSY flag is 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBA changes the PID[1:0] bits to 00b (NAK response).

Note 3. Only change the settings of the DEVSEL[3:0] bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK response) and the CURPIPE[3:0] bits in the D0FIFOSEL/D1FIFOSEL register are 0000b. Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag is 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBA changes the PID[1:0] bits to 00b (NAK response).

MXPS[10:0] Bits (Maximum Packet Size)

These bits set the maximum data payload (maximum packet size) for the selected pipe. Set the value of the MXPS[10:0] bits compliant with USB 2.0 for each transfer type. While the MXPS[10:0] bits are 000h, do not write data to the FIFO buffer or set the PIPEnCTR.PID[1:0] bits to 01b (BUF response).

DEVSEL[3:0] Bits (Device Select)

In host controller operation, set the address of the communication target USB device for these bits. Set these bits after the settings for the DEVADDm register corresponding to the set value of the DEVSEL[3:0] bits has been made (m = 0 to A). When setting the DEVSEL[3:0] bits to 0010b, for example, set the DEVADD2 register. In function controller operation, set the DEVSEL[3:0] bits to 0000b.

39.2.35 Pipe Cycle Control Register (PIPEPERI)

Address: 000D 046Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	IFIS	—	—	—	—	—	—	—	—	—	IITV[2:0]		
Value after reset:	x	x	x	0	x	x	x	x	x	x	x	x	x	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	IITV[2:0]	Interval Error Detection Interval *1	These bits specify the interval error detection interval for the selected pipe as 2^n of the frame timing.	R/W
b11 to b3	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b12	IFIS	Isochronous IN Buffer Flush	0: The buffer is not flushed. 1: The buffer is flushed.	R/W
b15 to b13	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. Only change the settings of the IITV[2:0] bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK response). Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag is 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBA changes the PID[1:0] bits to 00b (NAK response).

IITV[2:0] Bits (Interval Error Detection Interval)

To modify these bits to another value after these bits have been set and USB communication has been performed, set the PIPEnCTR.PID[1:0] bits to 00b (NAK response) and then set the PIPEnCTR.ACLRM bit to 1 to initialize the interval timer. The IITV[2:0] bits are not provided for pipes 3 to 5. Write 000b to bit positions of the IITV[2:0] bits corresponding to pipes 3 to 5.

The IITV[2:0] bit function differs in host controller operation and function control operation. Refer to section 39.3.11 and section 39.3.12 for details.

IFIS Bit (Isochronous IN Buffer Flush)

This bit specifies whether to flush the buffer when the pipe specified by the PIPESEL.PIPESEL[3:0] bits is used for isochronous IN transfer.

In function controller operation, this bit provides a buffer flush function for the USBA to automatically clear the FIFO buffer if the USBA does not receive IN token from the USB host in frames at each interval set by the IITV[2:0] bits for the selected pipe of isochronous transfer type in the IN transfer direction.

When double buffer is specified (PIPECFG.DBLB bit is 1), the USBA only clears the data in the plane used earlier.

The USBA clears the FIFO buffer on receiving the SOF packet immediately after the frame in which the USBA has expected to receive IN token. Even if the SOF packet is corrupted, the FIFO buffer is cleared by the recovery function at the timing when the SOF packet should be received.

In host controller operation, set the IITV[2:0] bits to 000b.

Set the IITV[2:0] bits to 000b when the selected pipe is not for isochronous transfer.

39.2.36 Pipe n Control Register (PIPEnCTR) (n = 1 to 9)

Addresses: PIPE1CTR 000D 0470h, PIPE2CTR 000D 0472h, PIPE3CTR 000D 0474h, PIPE4CTR 000D 0476h, PIPE5CTR 000D 0478h, PIPE6CTR 000D 047Ah, PIPE7CTR 000D 047Ch, PIPE8CTR 000D 047Eh, PIPE9CTR 000D 0480h

b10	ATREPM	Auto Response Mode *1, *3	0: Auto response mode is disabled. 1: Auto response mode is enabled	R/W
b13 to b11	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b14	INBUFM	Transmit Buffer Monitor Flag *3	0: No transmittable data is present in the FIFO buffer. 1: Transmittable data is present in the FIFO buffer.	R
b15	BSTS	Buffer Status Flag	0: Buffer access is disabled. 1: Buffer access is enabled.	R

Note 1. Only change the settings of the ATREPM bit and write 1 to the SQCLR or SQSET bit while the PIPEnCTR.PID[1:0] bits are 00b (NAK response). Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag is 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBA changes the PIPEnCTR.PID[1:0] bits to 00b (NAK response).

Note 2. Only change the settings of the ACLRM bit while the PIPEnCTR.PID[1:0] bits are 00b (NAK response) and the CURPIPE[3:0] bits in the D0FIFOSEL/D1FIFOSEL register are 0000b. Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag is 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBA changes the PID[1:0] bits to 00b (NAK response).

Note 3. The ATREPM bit and the INBUFM flag in registers PIPE6CTR to PIPE9CTR are reserved. This bit is undefined when read. Set it to 0 when writing.

PID[1:0] Bits (Response PID)

These bits specify the response type for the next transaction of pipe n.
The initial setting of the PIPEnCTR.PID[1:0] bits is 00b (NAK response). Modify these bits to 01b (BUF response) to use pipe n for USB transfer. The basic operation (with no error in communication packets) of the USBA according to the setting of the PIPEnCTR.PID[1:0] bits is shown in Table 39.8 and Table 39.9.
After modifying the setting of the PIPEnCTR.PID[1:0] bits from 01b (BUF response) to 00b (NAK response) during communication using pipe n, check that the PBUSY flag is 0 to confirm that the USB transfer using pipe n has actually entered the NAK state.

The USBA modifies the PIPEnCTR.PID[1:0] bits in the following cases.

- If pipe n is in the receiving direction, and the PIPECFG.SHTNAK bit for the selected pipe is set to 1, when the USBA sets the PIPEnCTR.PID[1:0] bits to 00b (NAK response) on recognizing the completion of transfer.
- The USBA sets the PIPEnCTR.PID[1:0] bits to 11b (STALL response) on receiving a data packet with a payload exceeding the maximum packet size of pipe n.
- The USBA sets the PIPEnCTR.PID[1:0] bits to 00b (NAK response) on detecting a USB bus reset in function controller operation.
- The USBA sets the PIPEnCTR.PID[1:0] bits to 00b (NAK response) on detecting a reception error, such as a CRC error, three consecutive times in host controller operation.
- The USBA sets the PIPEnCTR.PID[1:0] bits to 11b (STALL response) on receiving the STALL handshake in host controller operation.

The PIPEnCTR.PID[1:0] bits should be set according to the procedure below.

- To make a transition from 00b (NAK response) to 10b (STALL response), write 10b.
- To make a transition from 01b (BUF response) to 11b (STALL response), write 11b.
- To make a transition from 11b (STALL response) to 00b (NAK response), write 10b and then 00b.
- To make a transition from 11b (STALL response) to 01b (BUF response), modify the bits to 00b (NAK response) and then to 01b (BUF response).

Table 39.8 USBA Operation According to the PIPEnCTR.PID[1:0] Bit Setting (In Host Controller Operation)

PID[1:0] Bit Value	Transfer Type (TYPE[1:0] Bit Value)	Transfer Direction (DIR Bit Value)	USBA Operation
00b (NAK response)	Does not depend on the setting.	Does not depend on the setting.	Does not issue tokens.
01b (BUF response)	Bulk or Interrupt	Does not depend on the setting.	Issues tokens when the DVSTCTR0.UACT bit is 1 and the FIFO buffer corresponding to the relevant pipe is ready for transmission and reception. Does not issue tokens when the DVSTCTR0.UACT bit is 0 or the FIFO buffer corresponding to the relevant pipe is not ready for transmission or reception.
	Isochronous	Does not depend on the setting.	Issues tokens when the DVSTCTR0.UACT bit is 1, regardless of the state of the FIFO buffer corresponding to pipe n. Does not issue tokens when UACT is 0.
10b or 11b (STALL response)	Does not depend on the setting.	Does not depend on the setting.	Does not issue tokens.

Table 39.9 USBA Operation According to the PIPEnCTR.PID[1:0] Bit Setting (In Function Controller Operation)

PID[1:0] Bit Value	Transfer Type (TYPE[1:0] Bit Value)	Transfer Direction (DIR Bit Value)	USBA Operation
00b (NAK response)	Bulk or Interrupt	Does not depend on the setting.	Returns a NAK response to the token from the USB host.
	Isochronous	Receiving direction (DIR bit is 0)	Returns no response to the token from the USB host.
		Transmitting direction (DIR bit is 1)	Transmits a zero-length packet in response to the token from the USB host.
01b (BUF response)	Bulk	Receiving direction (DIR bit is 0)	Receives data and returns an ACK response in response to the OUT token from the USB host if the FIFO buffer corresponding to the relevant pipe is ready for reception. Otherwise, returns a NAK response.
	Interrupt	Receiving direction (DIR bit is 0)	Receives data and returns an ACK response in response to the OUT token from the USB host if the FIFO buffer corresponding to the relevant pipe is ready for reception. Otherwise, returns a NAK response.
	Bulk or Interrupt	Transmitting direction (DIR bit is 1)	Transmits data in response to the token from the USB host if the corresponding FIFO buffer is ready for transmission. Otherwise, returns a NAK response.
	Isochronous	Receiving direction (DIR bit is 0)	Receives data in response to the OUT token from the USB host if the corresponding FIFO buffer is ready for reception. Otherwise, discards data.
		Transmitting direction (DIR bit is 1)	Transmits data in response to the token from the USB host if the corresponding FIFO buffer is ready for transmission. Otherwise, transmits a zero-length packet.
10b or 11b (STALL response)	Bulk or Interrupt	Does not depend on the setting.	Returns a STALL response to the token from the USB host.
	Isochronous	Does not depend on the setting.	Returns no response to the token from the USB host.

PBUSY Flag (Pipe Busy Flag)

This flag indicates whether pipe n is being used for the current transaction. The USBA modifies the PBUSY flag from 0 to 1 at the beginning of a USB transaction for pipe n, and modifies the PBUSY flag from 1 to 0 upon successful completion of one transaction. After setting the PIPEnCTR.PID[1:0] bits to 00b (NAK response), reading the PBUSY flag allows checking whether modification of the pipe setting is possible. Refer to section 39.3.7.1 for details.

SQMON Flag (Sequence Toggle Bit Monitor Flag)

This flag indicates the value of the sequence toggle bit for the next transaction of pipe n. When pipe n is not the isochronous transfer type, the USBA toggles the SQMON flag upon successful completion of the transaction. However, the USBA does not toggle the SQMON flag when a data PID inconsistency occurs during transfer in the receiving direction.

SQSET Bit (Sequence Toggle Bit Set)

This bit is set to 1 when the value of the sequence toggle bit for the next transaction of pipe n is set for DATA1. When the SQSET bit is set to 1, the USBA sets the expected value of the sequence toggle bit of pipe n for DATA1.

SQCLR Bit (Sequence Toggle Bit Clear)

This bit is set to 1 when the value of the sequence toggle bit for the next transaction of pipe n is returned to DATA0. When the SQCLR bit is set to 1, the USBA sets the expected value of the sequence toggle bit of pipe n for DATA0.

ACLRM Bit (Auto Buffer Clear Mode)

This bit enables or disables auto buffer clear mode for pipe n. To completely clear the information in the FIFO buffer allocated to pipe n, write 1 and then 0 to the ACLRM bit continuously. Also, allow 100 ns between modifying the ACLRM bit from 1 to 0 as sequence execution time for the internal hardware. The following lists the information cleared by the USBA by writing 1 and 0 continuously to the ACLRM bit.

(a) All data in the FIFO buffer allocated to pipe n (both planes in double buffer mode).

(b) The interval counter value when the transfer type for pipe n is isochronous transfer or interrupt transfer.

Perform this processing when the following conditions are satisfied:

(a) When all data in the FIFO buffer allocated to pipe n needs to be cleared.

(b) When the interval counter value needs to be reset.

(c) When modifying the PIPECFG.DIR, DBLB, or BFRE bit.

(d) When the transaction count function is forcibly ended.

ATREPM Bit (Auto Response Mode)

This bit enables or disables the auto response of pipe n.

When the transfer type of pipe n is set to bulk IN function controller operation, this bit can be set to 1.

When this bit is set to 1, the USBA responds as follows to the token from the USB host.

(1) When pipe n is bulk IN transfer type (PIPECFG.TYPE[1:0] bits are 01b and the PIPECFG.DIR bit is 1)
When the ATREPM bit is 1 and the PIPEnCTR.PID[1:0] bits are 01b (BUF response), the USBA transmits a zero-length packet in response to IN token. The USBA updates (toggles) the sequence toggle bit (data PID) each time the USBA receives ACK from the USB host (in a single transaction, IN token is received, zero-length packet is transmitted, and then ACK is received). In this case, the USBA generates no BRDY interrupt or BEMP interrupt.

(2) When pipe n is bulk OUT transfer type (PIPECFG.TYPE[1:0] bits are 01b and the PIPECFG.DIR bit is 0)
When the ATREPM bit is 1 and the PIPEnCTR.PID[1:0] bits are 01b (BUF response), the USBA returns a NAK response to OUT token and generates an NRDY interrupt. When performing USB communication with this bit set to 1, set this bit while the FIFO buffer is empty. Do not write data to the FIFO buffer during USB communication with this bit set to 1. Be sure to set this bit to 0 when pipe n is used for isochronous transfer. In host controller operation, be sure to set this bit to 0.

INBUFM Flag (Transmit Buffer Monitor Flag)

This flag indicates the FIFO buffer status for pipe n in the transmitting direction. With pipe n set in the transmitting direction (PIPECFG.DIR bit is 1), the USBA sets the INBUFM flag to 1 when the CPU or DMAC/DTC has completed writing data to at least one FIFO buffer plane. The USBA sets the INBUFM flag to 0 when the USBA has completely transmitted the data from the FIFO buffer plane to which all the data has been written. In double buffer mode (PIPECFG.DBLB bit is 1), the USBA sets the INBUFM flag to 0 when the USBA has completely transmitted data from the two FIFO buffer planes before the CPU or DMAC/DTC completes writing data to one FIFO buffer plane. The INBUFM flag indicates the same value as the BSTS flag when pipe n is in the receiving direction (PIPECFG.DIR bit is 0).

BSTS Flag (Buffer Status Flag)

This flag indicates the FIFO buffer status for pipe n. The meaning of the BSTS flag varies as shown in Table 39.10 depending on the settings of the PIPECFG.DIR bit, PIPECFG.BFRE bit, and DCLRM bit in the D0FIFOSEL/ D1FIFOSEL register.

Table 39.10 Operation of the BSTS Flag

DIR Bit Value	BFRE Bit Value	DCLRM Bit Value	Meaning of the BSTS Flag
0	0	0	Becomes 1 when receive data can be read from the FIFO buffer, and becomes 0 upon completion of data read.
		1	Do not set this combination.
	1	0	Becomes 1 when receive data can be read from the FIFO buffer, and becomes 0 when the BCLR bit is set in a FIFO port control register to 1 after the data read has been completed.
		1	Becomes 1 when receive data can be read from the FIFO buffer, and becomes 0 upon completion of data read.
1	0	0	Becomes 1 when transmit data can be written to the FIFO buffer, and becomes 0 upon completion of data write.
		1	Do not set this combination.
	1	0	Do not set this combination.
		1	Do not set this combination.

39.2.37 Pipe n Transaction Counter Enable Register (PIPEnTRE) (n = 1 to 5)

Addresses: PIPE1TRE 000D 0490h, PIPE2TRE 000D 0494h, PIPE3TRE 000D 0498h, PIPE4TRE 000D 049Ch, PIPE5TRE 000D 04A0h

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	—	—	—	TRENB	TRCLR
Value after reset:	x	x	x	x	x	x	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b8	TRCLR	Transaction Counter Clear	This bit is set to 1 when the transaction counter is reset. Writing 0 has no effect. This bit is read as 0.	R/W
b9	TRENB	Transaction Counter Enable	0: The transaction count function is disabled. 1: The transaction count function is enabled.	R/W
b15 to b10	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

Note: Only change the settings of the PIPEnTRE register while the PIPEnCTR.PID[1:0] bits are 00b (NAK response). Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag is 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBA changes the PID[1:0] bits to 00b (NAK response).

TRCLR Bit (Transaction Counter Clear)

The USBA clears the current count value of the transaction counter corresponding to pipe n and then sets the TRCLR bit to 0.

TRENB Bit (Transaction Counter Enable)

This bit enables or disables the transaction counter.

When the total number of packets is set in the PIPEnTRN.TRNCNT[15:0] bits and then the TRENB bit is set to 1 for the pipe in the receiving direction, the USBA performs the following control upon completion of receiving packets as many as the value of the TRNCNT[15:0] bits.

- In continuous transfer mode (CNTMD bit is 1), the USBA toggles the TRENB bit to the CPU side even if the FIFO buffer is not full at the end of reception.
- When the PIPECFG.SHTNAK bit is 1, the USBA modifies the PIPEnCTR.PID[1:0] bits of the corresponding pipe to 00b (NAK response) upon completion of receiving packets as many as the value of the TRNCNT[15:0] bits.
- When the PIPECFG.BFRE bit is 1, the USBA asserts the BRDY interrupt upon completion of reading the final data after receiving packets as many as the value of the TRNCNT[15:0] bits.

For pipes in the transmitting direction, set the TRENB bit to 0.

When the transaction count function is not used, set the TRENB bit to 0.

When the transaction count function is used, set the TRNCNT[15:0] bits and then set the TRENB bit to 1. Furthermore, set the TRENB bit to 1 before receiving the first packet to be counted by the transaction counter.

39.2.38 Pipe n Transaction Counter Register (PIPEnTRN) (n = 1 to 5)

Addresses: PIPE1TRN 000D 0492h, PIPE2TRN 000D 0496h, PIPE3TRN 000D 049Ah, PIPE4TRN 000D 049Eh, PIPE5TRN 000D 04A2h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TRNCNT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TRNCNT[15:0]	Transaction Counter *1	• When writing to the register These bits specify the number of total packets (number of transactions) to be received by the relevant pipe. • When reading the register When the PIPEnTRE.TRENB bit is 0, these bits indicate the specified number of transactions. When the PIPEnTRE.TRENB bit is 1, these bits indicate the number of transaction in the current count (current count value).	R/W

Note 1. Only change the settings of the TRNCNT[15:0] bits while the PIPEnTRE.TRENB bit is 0 and the PIPEnCTR.PID[1:0] bits are 00b (NAK response). Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag is 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBA changes the PID[1:0] bits to 00b (NAK response).

The value set to the PIPEnTRN register is retained even if a USB bus reset occurs.

TRNCNT[15:0] Bits (Transaction Counter)

The USBA increments the value of the TRNCNT[15:0] bits (current counter value) when all of the following conditions for reception state are satisfied.

- The PIPEnTRE.TRENB bit is 1.
- When receiving a packet, the value of the TRNCNT[15:0] bits is different from the current counter value + 1.
- The payload of the received packet matches the value set to the PIPEMAXP.MXPS[10:0] bits.

The USBA sets the value of the TRNCNT[15:0] bits (current counter value) to 0 when any of the following conditions is satisfied.

(1) All of the following conditions are satisfied.
- The PIPEnTRE.TRENB bit is 1.
- When receiving a packet, the value of the TRNCNT[15:0] bits is the same as the current counted value + 1.
- The payload of the received packet matches the value set to the PIPEMAXP.MXPS[10:0] bits.

(2) Both of the following conditions are satisfied.
- The PIPEnTRE.TRENB bit is 1.
- The USBA has received a short packet.

(3) The following condition is satisfied.
- The PIPEnTRE.TRCLR bit is set to 1.

For pipes in the transmitting direction, set the TRNCNT[15:0] bits to 0. When the transaction count function is not used, set the TRNCNT[15:0] bits to 0. The number of transactions can be set to the TRNCNT[15:0] bits only when the PIPEnTRE.TRENB bit is 0. If the specified number of transactions is modified, set the PIPEnTRE.TRCLR bit to 1 (the current counter is cleared) before setting the PIPEnTRE.TRENB bit to 1 (count starts).

39.2.39 Device Address m Configuration Register (DEVADDm) (m = 0 to A)

Addresses: DEVADD0 000D 04D0h, DEVADD1 000D 04D2h, DEVADD2 000D 04D4h, DEVADD3 000D 04D6h, DEVADD4 000D 04D8h, DEVADD5 000D 04DAh, DEVADD6 000D 04DCh, DEVADD7 000D 04DEh, DEVADD8 000D 04E0h, DEVADD9 000D 04E2h, DEVADDA 000D 04E4h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	USBSPD[1:0]		—	—	—	—	—	—
Value after reset:	x	0	0	0	0	0	0	0	0	0	x	x	x	x	x	x

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b7, b6	USBSPD[1:0]	Transfer Speed of Communication Target Device	b7 b6 0 0: DEVADDm register is not used. 0 1: Low-speed 1 0: Full-speed 1 1: Reserved	R/W
b15 to b8	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

The DEVADDm register specifies the communication speed of the communication target peripheral device for pipes 0 to 9. In host controller operation, set each bit in the DEVADDm register before communications start to pipes.
Modify each bit in the DEVADDm register while there is no valid pipe specified by such a bit. The valid pipe is defined as the pipe satisfying both the conditions listed below.

- The DEVSEL[3:0] bits specify the DEVADDm register.
- The PIPEnCTR.PID[1:0] bits of the selected pipe are 01b (BUF response), or the default control pipe is the selected pipe and the DCPCTR.SUREQ bit is set to 1.

In function controller operation, set each bit in this register to 0.

USBSPD[1:0] Bits (Transfer Speed of Communication Target Device)

In host controller operation, the USBA generates a packet according to the value of these bits.

39.2.40 Low Power Control Register (LPCTRL)

Address: 000D 0500h

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	0

Value after reset:	0	x	x	x	x	x	x	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b7	HWUPM	Return Mode Setting	0: Hardware return is not made while the CPU clock is stopped. 1: Hardware return is made while the CPU clock is stopped.	R/W
b8	—	Reserved	This bit is read as 0. Set it to 0 when writing.	R/W
b15 to b9	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

HWUPM Bit (Return Mode Setting)

This bit specifies whether to enable the hardware processing for return from a low power state of the LPM L1 state even while the CPU clock is stopped. In function controller operation, the processing for return from low power mode upon detecting resume signal is enabled even while the CPU clock is stopped. The HWUPM bit specifies whether to detect resume signal while the CPU clock is stopped. The PL1CTRL1.L1EXTMD bit controls whether to make hardware return. To make hardware return from a low power state of the LPM L1 state while the CPU clock is stopped, set the HWUPM bit and the PL1CTRL1.L1EXTMD bit to 1.

39.2.41 Low Power Status Register (LPSTS)

Address: 000D 0502h

	b15	b14	b13	b12	b11	b10	b9	b8
	—	SUSPENDM	—	—	—	—	—	—
Value after reset:	x	0	x	0	x	x	x	0

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	0	x	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b2	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b3	—	Reserved	This bit is read as 0. Set it to 0 when writing.	R/W
b7 to b4	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b8	—	Reserved	This bit is read as 0. Set it to 0 when writing.	R/W
b11 to b9	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b12	—	Reserved	This bit is read as 0. Set it to 0 when writing.	R/W
b13	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b14	SUSPENDM	SuspendM Control	0: Suspend mode 1: Normal mode	R/W
b15	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W

SUSPENDM Bit (SuspendM Control)

This bit controls the SuspendM signal output to the PHY. The initial value is 0 and the PHY is in suspend mode. To supply the PHY clock to operate the USB2.0 host/function controller, set this bit to 1. Refer to section 39.3.3 for details on setting clocks.

When the SUSPENDM bit is 0, the registers in the USBA are not writable, but are readable. However, registers listed in Table 39.11 below are write accessible even when the SUSPENDM bit is 0.

Table 39.11 Registers That Can be Written by Software when the SUSPENDM Bit is 0

Address	Register/Bit
000D 0400h	SYSCFG register
000D 0402h	BUSWAIT register
000D 0432h	INTENB1.PDDETINTE bit
000D 043Eh	PHYSET register
000D 0500h	LPCTRL register
000D 0502h	LPSTS register
000D 0540h	BCCTRL register

However, the value written to the SYSCFG register while the PHY clock is stopped is updated after the PHY clock is oscillated. The PHY clock is oscillated in the following cases.

(1) The SUSPENDM bit is set to 1 and then the PLLSTA.PLLLOCK flag is set to 1 after the predetermined time has passed.

(2) 48 and 60 MHz are supplied to the USBA from the main clock with the SUSPENDM bit set to 0 (Refer to section 39.2.16 for details on classic-only mode.)

While the PL1CTRL1.L1EXTMD bit is 0, the SUSPENDM bit must be controlled by software. When the PL1CTRL1.L1EXTMD bit is 1, when transitioning to the L1 or L2 state (suspended state), the SUSPENDM bit must be set to 0 by software, but when exiting the L1 or L2 state, the USBA sets the SUSPENDM bit to 1.

39.2.42 Battery Charging Control Register (BCCTRL)

Address: 000D 0540h

Note 1. Valid when the IDMSINKE bit is 1.
Note 2. Valid when the IDPSINKE bit is 1.

IDPSRCE Bit (D+ Line IDPSRC Output Control)

In function controller operation, set this bit to 1 to perform Data Contact Detect. In the Battery Charging Specification Revision 1.2, there are two methods to handle Data Contact Detect; the method realized by software wait and the method to contact the data line by hardware. The IDPSRCE bit adopts the latter method. When the IDPSRCE bit is set to 1, the USBA enables the IDP_SRC circuit and, at the same time, controls D– line pull-down.

IDMSINKE Bit (D– Line 0.6 V Input Detection (Comparator and Sink) Control)

In function controller operation, the following can be detected when the IDMSINKE bit is set to 1:

- During Primary Detection, VDMSRC (0.6 V) is input to the USBA_DM pin from the host
- During Primary Detection, VDPSRC (0.6 V) output from the USBA to the USBA_DP pin is input to the USBA_DM pin via the USB host

VDPSRCE Bit (D+ Line VDPSRC (0.6 V) Output Control)

In function controller operation, if Primary Detection is executed, this bit controls VDPSRC (0.6 V) output from the USBA_DP pin.

IDPSINKE Bit (D+ Line 0.6 V Input Detection (Comparator and Sink) Control)

When the IDPSINKE bit is set to 1, the following states can be detected:

- In host controller operation
  During Primary Detection, VDPSRC (0.6 V) is input to the USBA_DP pin from a peripheral device.
- In function controller operation
  During Secondary Detection, VDPSRC (0.6 V) output from the USBA to the USBA_DM pin is input to the USBA_DP pin via the host.

VDMSRCE Bit (D– Line VDMSRC (0.6 V) Output Control)

- In host controller operation
  During Primary Detection, this bit controls VDMSRC (0.6 V) output from the USBA_DM pin.
- In function controller operation
  During Secondary Detection, this bit controls VDMSRC (0.6 V) output from the USBA_DM pin.

CHGDETSTS Flag (D– Line 0.6 V Input Detection Status Flag)

In function controller operation, this flag is enabled when the IDPSINKE bit is 1.
The CHGDETSTS flag becomes 1 under the following conditions:

- During Primary Detection, VDMSRC (0.6 V) is input to the USBA_DM pin from the USB host.
- During Primary Detection, the VDPSRC (0.6 V) output from the USBA to the USBA_DP pin is input to the USBA_DM pin via the USB host.

PDDETSTS Flag (D+ Line 0.6 V Input Detection Status Flag)

The PDDETSTS flag is enabled when the IDPSINKE bit is 1.
The PDDETSTS flag becomes 1 under the following conditions:

- In host controller operation
  During Primary Detection, VDPSRC (0.6 V) is input to the USBA_DP pin from a peripheral device.
- In function controller operation
  During Secondary Detection, the VDMSRC (0.6 V) output from the USBA to the USBA_DM pin is input to the USBA_DP pin via the host.

39.2.43 Function L1 Control Register 1 (PL1CTRL1)

Address: 000D 0544h

	b15	b14	b13	b12	b11	b10	b9	b8
	—	L1EXTMD	—	—	HIRDTHR[3:0]			
Value after reset:	x	0	x	x	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	DVSQ[3]	DVSQ[2:0]			L1NEGOMD	L1RESPMD[1:0]		L1RESPEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	L1RESPEN	L1 Response Enable	0: LPM is not supported. 1: LPM is supported.	R/W
b2, b1	L1RESPMD[1:0]	L1 Response Mode	b2 b1 0 0: NYET response 0 1: ACK response 1 0: STALL response 1 1: Comply with the L1NEGOMD bit	R/W
b3	L1NEGOMD	L1 Response Negotiation Control *1	0: When the received HIRD field is larger than the HIRDTHR[3:0] bit value, an ACK response is returned. When the received HIRD field is smaller than or equal to the value set to the HIRDTHR[3:0] bits, an NYET response is returned. 1: When the received HIRD field is smaller than the HIRDTHR[3:0] bit value, an ACK response is returned. When the received HIRD field is greater than or equal to the value set to the HIRDTHR[3:0] bits, an NYET response is returned.	R/W
b6 to b4	DVSQ[2:0]	Extension Device State Flag	These flags indicate the same value with the INTSTS0.DVSQ[2:0] flags.	R
b7	DVSQ[3]		This flag indicates the L1 state together with the INTSTS0.DVSQ[2:0] flags. 0000: Powered state 0001: Default state 0010: Address state 0011: Configured state 0100: Suspended state 0101: Suspended state 0110: Suspended state 0111: Suspended state 1000 to 1011: L1 state	R
b11 to b8	HIRDTHR[3:0]	L1 Response Negotiation Threshold Value *1	HIRD threshold value used when the L1RESPMD[1:0] bits are 11b. The format is the same as the HIRD field in the HL1CTRL2 register.	R/W
b13, b12	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b14	L1EXTMD	PHY Control Mode at L1 Return	0: The LPSTS.SUSPENDM bit is not set by hardware when exiting the L1 state. 1: The LPSTS.SUSPENDM bit is set by hardware when exiting the L1 state.	R/W
b15	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W

Note 1. The L1NEGOMD bit is only valid when the L1RESPMD[1:0] bits are 11b.

L1RESPEN Bit (L1 Response Enable)

When the L1RESPEN bit is 0, even if the LPM token is received, the USBA returns no response in regards to the LPM token. When the L1RESPEN bit is 1, if the LPM token is received, the USBA returns a response in accordance with the L1RESPMD[1:0] bit setting.

L1RESPMD[1:0] Bits (L1 Response Mode)

When the L1RESPEN bit is set to 1, the USBA returns a response to the LPM token in accordance with the L1RESPMD[1:0] bit setting.

L1NEGOMD Bit (L1 Response Negotiation Control)

The L1NEGOMD bit sets the response conditions for the HIRD[3:0] bit value. The L1NEGOMD bit is valid when the L1RESPMD[1:0] bits are 11b.

DVSQ[2:0] Flags (DVSQ Extension Flag)

These flags mirror the INTSTS0.DVSQ[2:0] flags.

DVSQ[3] Flag (DVSQ Extension Flag)

This flag is the fourth bit of the device state flags (DVSQ[2:0] flags).

HIRDTHR[3:0] Bits (L1 Response Negotiation Threshold Value)

The HIRDTHR[3:0] bits specify the HIRD threshold value used by the HIRD[3:0] bit value in the negotiation. The HIRDTHR[3:0] bits are valid when the L1RESPMD[1:0] bits are 11b.
The format of the set value is the same as the HL1CTRL2.HIRD[3:0] bits.

L1EXTMD Bit (PHY Control Mode at L1 Return)

In the L1 state, with the LPSTS.SUSPENDM bit set to 0 to stop the PHY clock, this bit specifies the LPSTS.SUSPENDM bit control method when receiving the resume signal.
When supporting the L1 state, set the L1EXTMD bit to 1 during the initialization process.
When entering the L1 state, the LPSTS.SUSPENDM bit must be set to 0 by software regardless of the L1EXTMD bit value.
When the L1EXTMD bit is set to 1, the USBA also sets the LPSTS.SUSPENDM bit to 1 when exiting the L2 state (suspended state).

39.2.44 Function L1 Control Register 2 (PL1CTRL2)

Address: 000D 0546h

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	RWEMON	HIRDMON[3:0]			
Value after reset:	x	x	x	0	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b11 to b8	HIRDMON[3:0]	HIRD Value Monitor Flag	These bits reflect the HIRD field value of the recently received LPM token.	R/W
b12	RWEMON	bRemoteWake Value Monitor Flag	This bit reflects the bRemoteWake bit value of the recently received LPM token.	R/W
b15 to b13	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

HIRDMON[3:0] Flags (HIRD Value Monitor Flag)

These flags monitor the HIRD field value of the received LPM token. These bits reflect the HIRD field value of the recently received LPM token.

RWEMON Flag (bRemoteWake Value Monitor Flag)

This flag monitors the bRemoteWake field value of the received LPM token. This flag reflects the bRemoteWake field value of the recently received LPM token.

39.2.45 Host L1 Control Register 1 (HL1CTRL1)

Address: 000D 0548h

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	L1STATUS[1:0]		L1REQ
Value after reset:	x	x	x	x	x	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	L1REQ	L1 Transition Request	Set this bit to 1 when making a request that a peripheral device transition to the L1 state. This bit is automatically set to 0 when the LPM transaction is completed.	R/W
b2, b1	L1STATUS[1:0]	L1 Request Completion Status	b2 b1 0 0: ACK response received 0 1: NYET response received 1 0: STALL response received 1 1: Transaction error occur ed	R/W
b15 to b3	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

L1REQ Bit (L1 Transition Request)

Set this bit to 1 to transition a peripheral device to the L1 state. When the L1REQ bit is set to 1, the USBA starts the LPM transaction, and when the transaction is complete, the L1REQ bit is set to 0.

L1STATUS[1:0] Bits (L1 Request Completion Status)

These bits reflect the result of the LPM transaction executed by the L1REQ bit.

39.2.46 Host L1 Control Register 2 (HL1CTRL2)

Address: 000D 054Ah

	b15	b14	b13	b12	b11	b10	b9	b8
	BESL	—	—	L1RWE	HIRD[3:0]			
Value after reset:	0	x	x	0	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	L1ADDR[3:0]			
Value after reset:	x	x	x	x	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	L1ADDR[3:0]	LPM Token Device Address	These bits specify the value to be set in the ADDR field of the LPM token.	R/W
b7 to b4	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b11 to b8	HIRD[3:0]	LPM Token HIRD	These bits specify the value to be set in the BESL field of the LPM token.	R/W
b12	L1RWE	LPM Token L1 Remote Wakeup Enable	These bits specify the value to be set in the bRemoteWake field of the LPM token.	R/W
b14, b13	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b15	BESL	BESL & Alternate HIRD	This bit selects the resume signal output period when exiting the L1 state.	R/W

L1ADDR[3:0] Bits (LPM Token Device Address)

When the HL1CTRL1.L1REQ bit is set to 1, these bits specify the value to be set in the ADDR field of the LPM token transmitted by the USBA.

HIRD[3:0] Bits (LPM Token HIRD)

When the HL1CTRL1.L1REQ bit is set to 1, these bits specify the value to be set in the BESL field of the LPM token transmitted by the USBA. Table 39.12 indicates the Relationship Between the Values Set to the HIRD[3:0] and BESL Bits With the HIRD and BESL Values.

Table 39.12 Relationship Between the Values Set to the HIRD[3:0] and BESL Bits With the HIRD and BESL Values

Value Set to the HIRD[3:0] Bits	When the BESL Bit is 0	When the BESL Bit is 1	
	HIRD value	HIRD value	BESL value
0000b	50 µs (do not set this value)	75 µs	125 µs
0001b	125 µs	100 µs	150 µs
0010b	200 µs	150 µs	200 µs
0011b	275 µs	250 µs	300 µs
0100b	350 µs	350 µs	400 µs
0101b	425 µs	450 µs	500 µs
0110b	500 µs	950 µs	1000 µs
0111b	575 µs	1,950 µs	2,000 µs
1000b	650 µs	2,950 µs	3,000 µs
1001b	725 µs	3,950 µs	4,000 µs
1010b	800 µs	4,950 µs	5,000 µs
1011b	875 µs	5,950 µs	6,000 µs
1100b	950 µs	6,950 µs	7,000 µs
1101b	1,025 µs (do not set this value)	7,950 µs	8,000 µs
1110b	1,100 µs (do not set this value)	8,950 µs	9,000 µs
1111b	1,175 µs (do not set this value)	9,950 µs	10,000 µs

Note: In host controller operation, the HIRD[3:0] bit setting value is used for the resume signal output period when exiting the L1 state.

L1RWE Bit (LPM Token L1 Remote Wakeup Enable)

When the HL1CTRL1.L1REQ bit is set to 1, this bit specifies the value to be set in the bRemoteWake field of the LPM token transmitted by the USBA. Depending on the L1RWE bit setting, the USBA does not control detection of the remote wakeup signal in the L1 state. The remote wakeup signal is controlled by the DVSTCTR0.RWUPE bit as is the case when the USBA is in the suspended state.

BESL Bit (BESL & Alternate HIRD)

In host controller operation, this bit selects the resume signal output period when exiting the L1 state. Refer to the description of the HIRD[3:0] bits for details.

39.2.47 Deep Standby USB Transceiver Control/Pin Monitor Register (DPUSR0R)

b3 to b0	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b4	DOVCAHE	OVRCURA Interrupt Enable/Clear	0: Exit from deep software standby mode disabled, and the DOVCAH flag is cleared 1: Exit from deep software standby mode enabled	R/W
b5	DOVCBHE	OVRCURB Interrupt Enable/Clear	0: Exit from deep software standby mode disabled, and the DOVCBH flag is cleared 1: Exit from deep software standby mode enabled	R/W
b6	—	Reserved	This bit is read as 0. Set it to 0 when writing.	R/W
b7	DVBSTSHE	VBUS Interrupt Enable/Clear	0: Exit from deep software standby mode disabled, and the DVBSTSH flag is cleared 1: Exit from deep software standby mode enabled	R/W
b19 to b8	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b20	DOVCAH	OVRCURA Interrupt Source Return Status Flag *1	0: USBA is in deep software standby mode 1: USBA exited deep software standby mode	R
b21	DOVCBH	OVRCURB Interrupt Source Return Status Flag *2	0: USBA is in deep software standby mode 1: USBA exited deep software standby mode	R
b22	—	Reserved	This bit is read as 0. Set it to 0 when writing.	R/W
b23	DVBSTSH	VBUS Interrupt Source Return Status Flag *3	0: USBA is in deep software standby mode 1: USBA exited deep software standby mode	R
b31 to b24	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. This bit becomes 0 when the DOVCAHE bit is set to 0.
Note 2. This bit becomes 0 when the DOVCBHE bit is set to 0.
Note 3. This bit becomes 0 when the DVBSTSHE bit is set to 0.

39.3 Operation

39.3.1 System Control

This section describes register settings necessary to initialize the USBA and registers necessary for power consumption control.

39.3.1.1 Setting Registers Associated with the USBA

After supplying the PHY clock, set the SYSCFG.USBE bit to 1 to enable USBA operation.
Refer to section 39.3.3 for details on supplying the PHY clock.

39.3.1.2 Selecting the Controller Function

The USBA can be used in host controller operation or function controller operation. Set the SYSCFG.DCFM bit to select a controller operation. However, modify the DCFM bit in the initial settings immediately after a reset, or when pulling up the D+ line is disabled, and pulling down the D+ and D– lines is disabled (both SYSCFG.DPRPU bit and SYSCFG.DRPD bit are 0).

39.3.2 Controlling the USB Data Bus Resistors

The USBA incorporates pull-up and pull-down resistors for the D+ and D– lines. Set the SYSCFG.DPRPU bit and SYSCFG.DRPD bit to select pull up or pull down.
In function controller operation, confirm there is a connection to the USB host, then set the SYSCFG.DPRPU bit to 1 to pull up the D+ line.
If the SYSCFG.DPRPU bit is set to 0 while communicating with a personal computer, the pull-up resistor for the USB data line is disabled, and the USB host can be notified that the device has been disconnected.
In host controller operation, set the SYSCFG.DRPD bit to 1 to pull down the D+ and D– lines.
Table 39.13 lists the settings for the USB data bus resistors. Set the DRPD and DPRPU bits to select the USB data bus resistors.

Table 39.13 Controlling the USB Data Bus Resistors (Excluding OTG Operation)

Settings		USB Data Bus Resistor Control		
DRPD bit	DPRPU bit	D– line	D+ line	Remarks
0	0	Open	Open	When the resistor is not used
0	1	Open	Pull-up	When operating as the function controller
1	0	Pull-down	Pull-down	When operating as the host controller
1	1	—	—	Do not set this value except for OTG operation

39.3.3 Supplying Clocks

The two input clocks required for the USBA are shown in Table 39.14.

Table 39.14 Input Clocks

Input Clock Name	Description
Peripheral module clock (PCLKA)	PCLKA is used to access USBA registers from the CPU, DMAC, and DTC. The clock frequency has no restrictions on the USBA side.
PHY clock	Generating the PHY clock: External input or internal supply • External input A 20 MHz or 24 MHz clock is supplied to the EXTAL pin from outside the MCU, and the PHY clock is generated by the PLL in the UTMI-PHY. Specifications for the external clock must be strictly followed, especially the jitter characteristics of ±50 ppm. • Internal supply The PHY clock is supplied when 48 and 60 MHz are supplied to the UTMI-PHY module and the PHYSET.HSEB bit is set to 1 (classic-only mode is enabled).

Figure 39.2 shows the PHY Clock Settings in Classic-Only Mode.

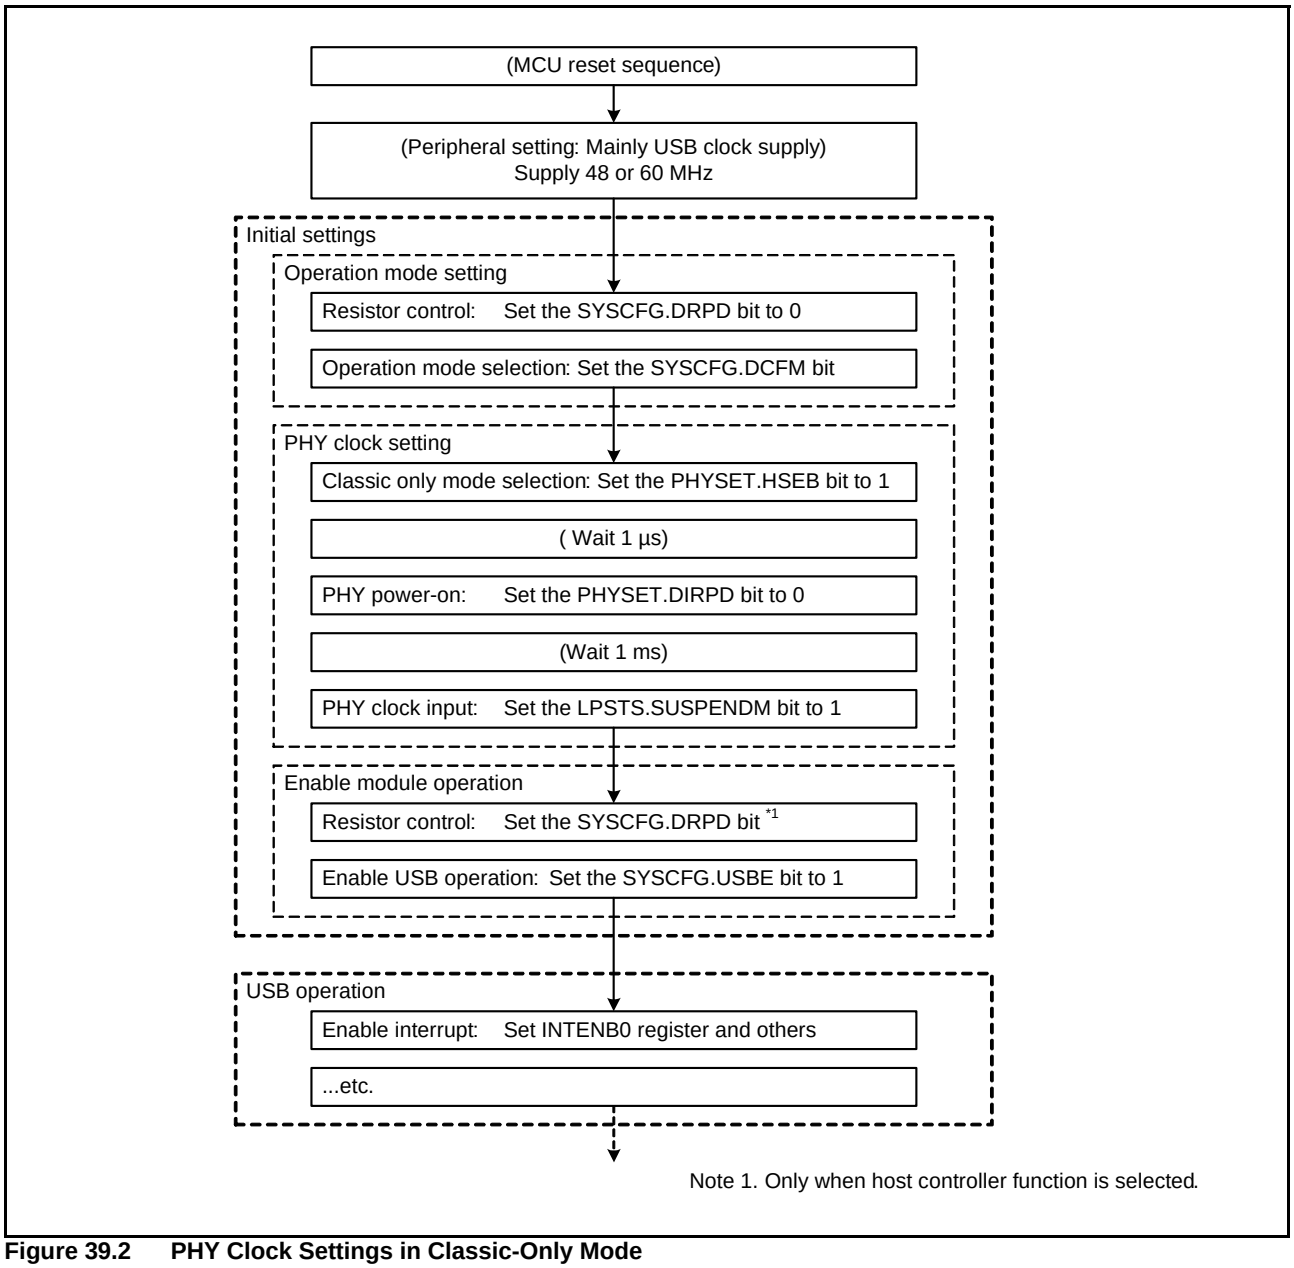

Figure 39.2 PHY Clock Settings in Classic-Only Mode

Figure 39.3 shows the PHY Clock Settings When Not Using Classic-Only Mode.

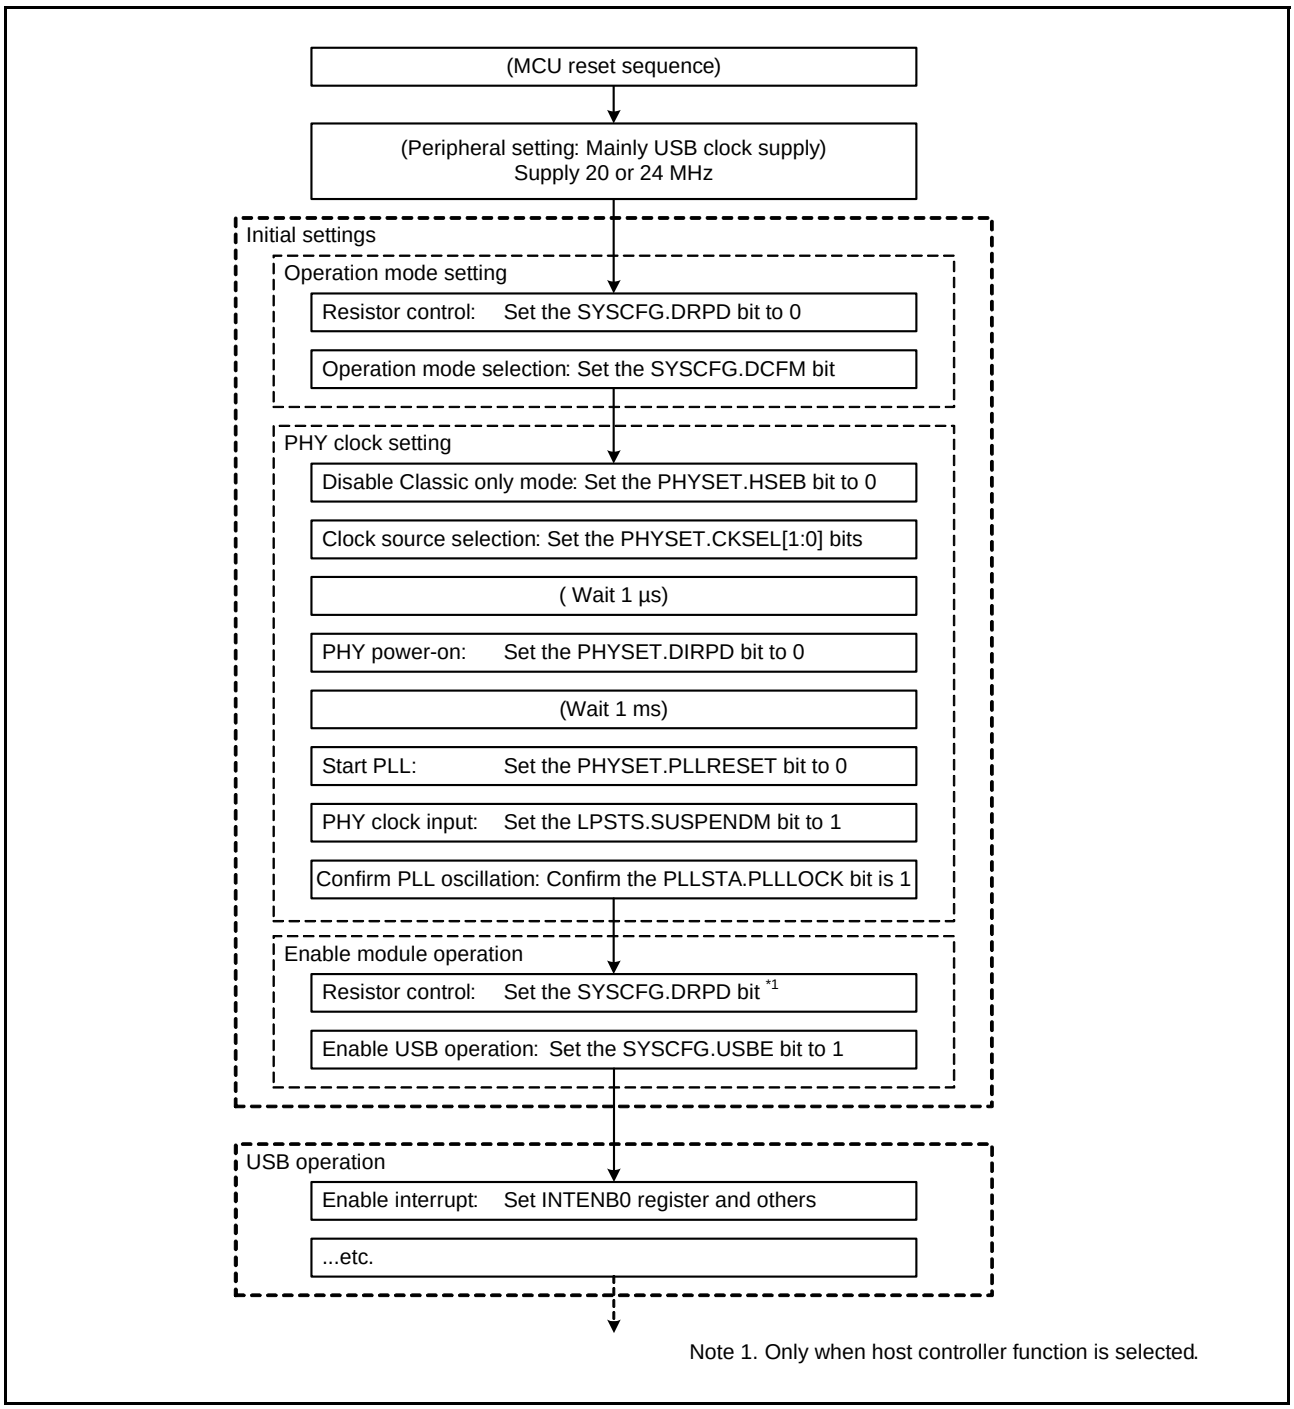

Figure 39.3 PHY Clock Settings When Not Using Classic-Only Mode

39.3.4 Notes on Stopping Clock

The CPU clock and PHY clock can be stopped when a device is disconnected or the USBA is in the suspend state. However, in function controller operation, if either of these clocks are stopped while the USBA is in the suspended state, they must be resupplied when exiting the suspended state. The PHY clock must be resupplied within 9.5 ms of generating the resume interrupt.

39.3.5 Interrupts

Table 39.15 lists the interrupt functions of the USBA. When a condition to generate an interrupt is satisfied, and the interrupt output is enabled using the corresponding interrupt enable register, the USBA issues a USBAR interrupt request to the interrupt controller (ICU).

Table 39.15 List of Interrupt Functions (1/2)

Flag That Becomes 1	Interrupt	Interrupt Source	Function Generated	Status Flag
VBINT	VBUS interrupt	• VBUS input pin state change was detected (from low to high and from high to low).	Host *1, function	INTSTS0. VBSTS
RESM	Resume interrupt	• USB bus state change was detected in the suspended state. (J state to K state or J state to SE0)	Function	—
SOFR	Frame number refresh interrupt	In host controller operation • An SOF packet with a different frame number was transmitted In function controller operation • An SOF packet with a different frame number was received. • Failed to receive an SOF packet due to packet corruption.	Host, function	—
DVST	Device state transition interrupt	• When device state transition was detected USB bus reset detection Suspension detection SetAddress() request received SetConfiguration request received	Function	INTSTS0. DVSQ[2:0]
CTRT	Control transfer stage transition interrupt	• When control transfer stage transition was detected Completed setup stage Transition to control write transfer status stage Transition to control read transfer status stage Completed control transfer A control transfer sequence error occurred	Function	INTSTS0. CTSQ[2:0]
BEMP	Buffer empty interrupt (BEMP interrupt)	• The buffer was empty after all FIFO buffer data was transmitted. • A packet exceeding the maximum packet size was received.	Host, function	BEMPSTS. PIPEBEMP[9:0]
NRDY	Buffer not ready interrupt (NRDY interrupt)	In host controller operation • The STALL response from the function was received in response to the token issued. • The response from the function in response to the issued token was not received successfully (no response three times in succession or packet receive error three times in succession). • An overrun or underrun error occurred during isochronous transfer. In function controller operation • When NAK has been returned for an IN or OUT token while the PID[1:0] bits are set to 01b (BUF response) • A CRC error or bit stuffing error occurred during data reception in isochronous transfer. • An interval error occurred during data reception in isochronous transfer.	Host, function	NRDYSTS. PIPENRDY[9:0]
BRDY	Buffer ready interrupt (BRDY interrupt)	• The buffer is ready (readable or writable state).	Host, function	BRDYSTS. PIPEBRDY[9:0]
OVRCR	Overcurrent change interrupt (OVRCR interrupt)	• USBA_OVRCURA pin or USBA_OVRCURB pin state change was detected (both low to high and high to low).	Host, function	SYSSTS0. OVCMON[1:0]
BCHG	Bus change interrupt (BCHG interrupt)	• USB bus state change was detected.	Host, function	SYSSTS0. LNST[1:0]
DTCH	Device disconnection detect interrupt (DTCH interrupt)	• Disconnection of peripheral device was detected.	Host	SYSSTS0. RHST[2:0]
ATTCH	Device connection detect interrupt (ATTCH interrupt)	• The J state (continuous USB bus state for 2.5 µs) or K state (continuous USB bus state for 2.5 µs) was detected. This interrupt can be used for detecting connection of peripheral device.	Host	—
EOFERR	EOF error detect interrupt (EOFERR interrupt)	• EOF error of peripheral device was detected.	Host	—

Table 39.15 List of Interrupt Functions (2/2)

Flag That Becomes 1	Interrupt	Interrupt Source	Function Generated	Status Flag
SACK	SETUP transaction normal response interrupt (SACK interrupt)	• The SETUP transaction normal response (ACK) was received.	Host	—
SIGN	SETUP transaction error interrupt (SIGN interrupt)	• A SETUP transaction error (no response or corrupted ACK packet) was detected three times in succession.	Host	—
PDDETINT	Portable Device detection interrupt	• Portable Device connection was detected.	Host	BCCTRL. PDDETSTS
LPMEND	LPM transaction end interrupt (LPMEND interrupt)	• LPM transaction has been completed.	Host	INTSTS0. DVSQ[2:0]
L1RSMEND	L1 resume end interrupt (L1RSMEND interrupt)	• Resume processing from L1 state has been completed.	Host	—

Note 1. Though this interrupt can be generated in host controller operation, it is not usually used in host controller operation.

39.3.5.1 Setting the USBAR Interrupt Signal Output Method

The USBAR interrupt signal output method can be selected by setting the SOFCFG.INTL bit. However, since the detection method for detecting USBAR interrupts in this MCU is level sense, set the INTL bit to 1 (level output).

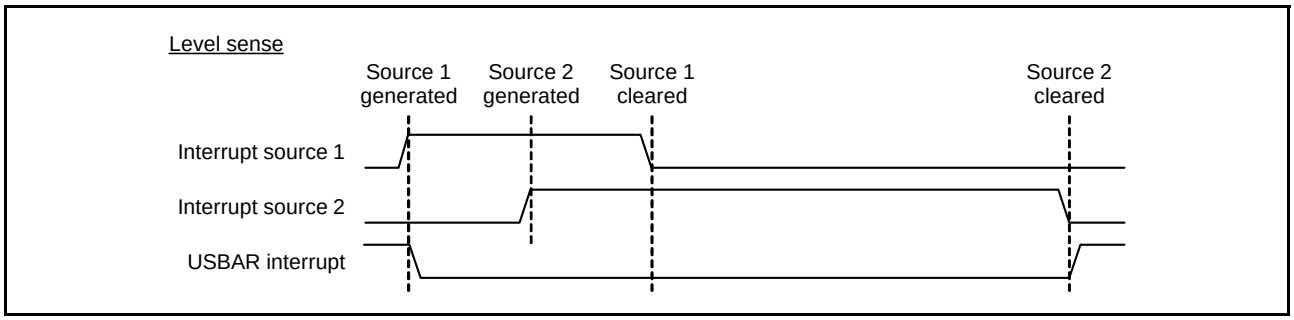

Figure 39.4 USBAR Interrupt Operation

Figure 39.5 shows the Interrupt Association Diagram.

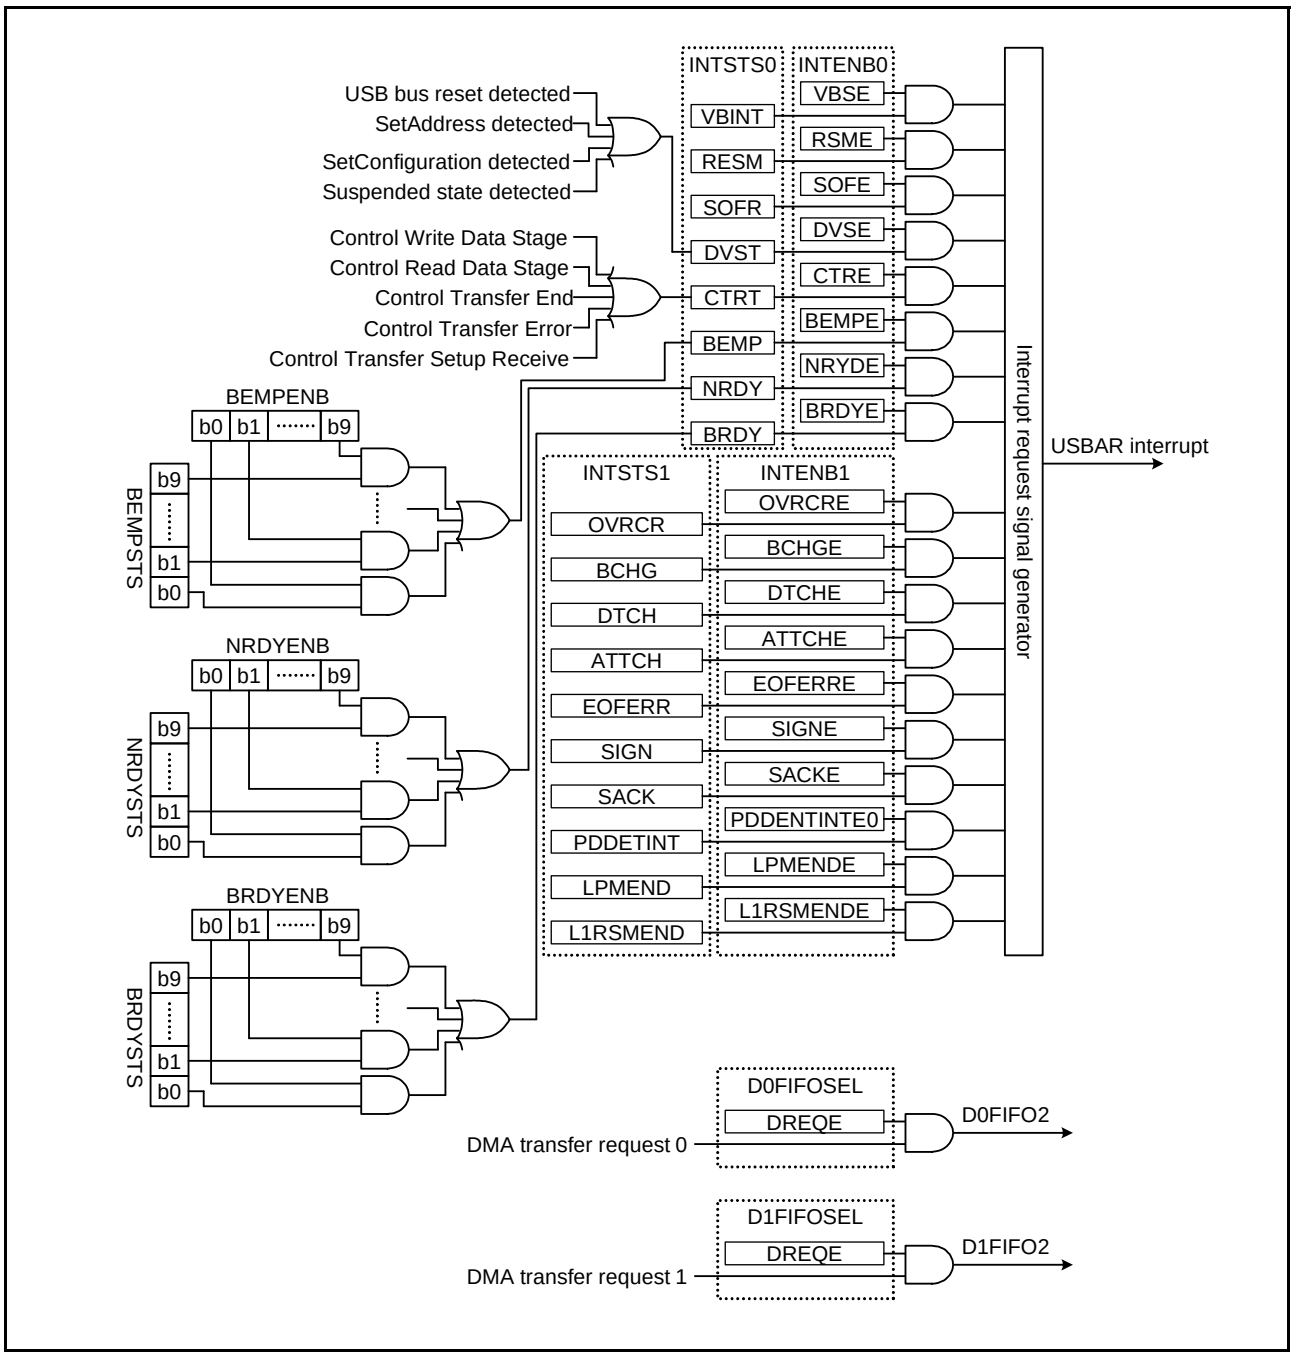

Figure 39.5 Interrupt Association Diagram

Table 39.16 lists the USBA Interrupt Sources.

Table 39.16 USBA Interrupt Sources

Interrupt	Interrupt Status Flag	DTC/DMAC Triggerable	Priority
D0FIFO2	DMA/DTC transfer request 0	Yes	High
D1FIFO2	DMA/DTC transfer request 1	Yes	↑
USBAR	VBUS interrupt, resume interrupt, frame number refresh interrupt, device state transition interrupt, control transfer stage transition interrupt, buffer empty interrupt, buffer not ready interrupt, buffer ready interrupt, OVRCR interrupt, bus change interrupt, device disconnection detection, device connection detection, EOF error detection, normal SETUP operation, SETUP error, PDDETSTS change detection, LPM transaction end interrupt, and L1 resume end interrupt	No	Low

39.3.6 Interrupt Descriptions

39.3.6.1 BRDY Interrupt

The BRDY interrupt is generated in both host controller operation and function controller operation. When each pipe satisfies the conditions listed below, the USBA sets the corresponding bit in the BRDYSTS register to 1. Under these conditions, if a bit in the BRDYENB register that corresponds to a given pipe and the INTENB0.BRDYE bit are 1, the USBA generates the BRDY interrupt request.
The conditions for generating and method for clearing the BRDY interrupt depend on the settings of the SOFCFG.BRDYM bit, and the PIPECFG.BFRE bit for each pipe as described below.

(1) When the SOFCFG.BRDYM Bit is 0 and the PIPECFG.BFRE Bit is 0

With these settings, the BRDY interrupt indicates that the FIFO port is accessible. On any of the following conditions, the USBA generates an internal BRDY interrupt request trigger and sets the BRDYSTS.PIPEBRDY[9:0] flag corresponding to the pertinent pipe to 1.

(a) For pipes set to transmit:

- When the DIR bit is changed from 0 to 1.
- When writing by the CPU to the FIFO buffer for a given pipe is disabled (when the BSTS flag is read as 0) and the USBA module has completed packet transmission.
  In continuous transfer mode, the BRDY interrupt is generated when data from one FIFO buffer is done being transmitted.
- If a FIFO buffer is specified as a double buffer, when data is done being written to one plane of the FIFO buffer, the other plane becomes empty.
- While data is being written to one plane of a FIFO buffer, even if the other plane is done transmitting, a request trigger is not generated until the data being written to the current plane is complete.
- When the hardware flushes the buffer of the pipe for isochronous transfers.
- Setting the PIPEnCTR.ACLRM bit to 1 changes the state of the FIFO buffer from write disabled to write enabled.

A request trigger is not generated for the default control pipe (during data transmission for control transfers).

(b) For pipes set to receive:

- When packet reception is completed successfully thus enabling the FIFO buffer to be read while read-access from the CPU to the FIFO buffer for the pertinent pipe is disabled (when the BSTS flag is 0).
  However, no request trigger is generated for the transaction in which data PID mismatch has occurred.
  In continuous transfer mode, when the maximum packet size of data is received and there is still space in the FIFO buffer, the request trigger is not generated. When a short packet is received, the request trigger is generated even if the FIFO buffer has available space. When the transaction counter is used, the request trigger is generated on receiving the specified number of packets. In this case, the request trigger is generated even if the FIFO buffer has available space.
- When one FIFO buffer is read-enabled on completion of reading data from the other FIFO buffer in double buffer mode. No request trigger is generated until completion of reading data from the currently-read FIFO buffer even if reception by the other FIFO buffer is completed.

In function controller operation, the BRDY interrupt is not generated in the status stage of control transfers. The PIPEBRDY interrupt status of the pertinent pipe can be set to 0 by writing 0 to the corresponding PIPEBRDY flag. In this case, 1's should be written to the corresponding bits for the other pipes. Clear the BRDY status before accessing the FIFO buffer.

(2) When the SOFCFG.BRDYM Bit is 0 and the PIPECFG.BFRE Bit is 1

With these settings, the USBA determines that a BRDY interrupt is generated on completion of reading all data for a single transfer using the pipe in the receiving direction, and sets 1 to the flag in the BRDYSTS register corresponding to the pertinent pipe.
On any of the following conditions, the USBA determines that the last data for a single transfer has been received.

- When a short packet including a zero-length packet is received.
- When the PIPEnTRN register is used and the number of packets specified by the PIPEnTRN.TRNCNT[15:0] bits are completely received.

When the pertinent data is completely read after any of the above conditions has been satisfied, the USBA determines that all data for a single transfer has been completely read. When a zero-length packet is received while the FIFO buffer is empty, the USBA determines that all data for a single transfer has been completely read when the FRDY flag in a FIFO port control register is 1 and the DTLN[11:0] flags are 000h. In this case, to start the next transfer, write 1 to the BCLR bit in the corresponding FIFO port control register. With these settings, the USBA does not detect a BRDY interrupt for the pipe in the transmitting direction. The PIPEBRDY interrupt status of the pertinent pipe can be set to 0 by writing 0 to the corresponding BRDYSTS.PIPEBRDY[9:0] flag. In this case, 1's should be written to the corresponding bits for the other pipes. In this mode, the PIPECFG.BFRE bit setting should not be modified until all data for a single transfer has been processed. When it is necessary to modify the PIPECFG.BFRE bit before completion of processing, all FIFO buffers for the pertinent pipe should be cleared using the PIPEnCTR.ACLRM bit.

(3) When the SOFCFG.BRDYM Bit is 1 and the PIPECFG.BFRE Bit is 0

With these settings, the BRDYSTS.PIPEBRDY[9:0] flag values are linked to the BSTS flag setting for each pipe. The BRDY interrupt status bits are set to 1 or 0 by the USBA depending on the FIFO buffer status.

(a) For the pipe in the transmitting direction:

The BRDY interrupt status bits are set to 1 when the FIFO port is ready for write access, and are set to 0 when it is not ready. However, the BRDY interrupt is not generated even if the default control pipe in the transmitting direction is ready for write access.

(b) For the pipe in the receiving direction:

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for read access, and are set to 0 when all data have been read (not ready for read access). When a zero-length packet is received while the FIFO buffer is empty, the pertinent bit is set to 1 and the BRDY interrupt is continuously generated until 1 is written to BCLR bit.

With this setting, the PIPEBRDY[9:0] flags cannot be set to 0 by software. When the SOFCFG.BRDYM bit is set to 1, the PIPECFG.BFRE bit (for all pipes) should be set to 0, and the SOFCFG.INTL bit should be set to 1 (level control).

Figure 39.6 shows the BRDY Interrupt Generation Timing.

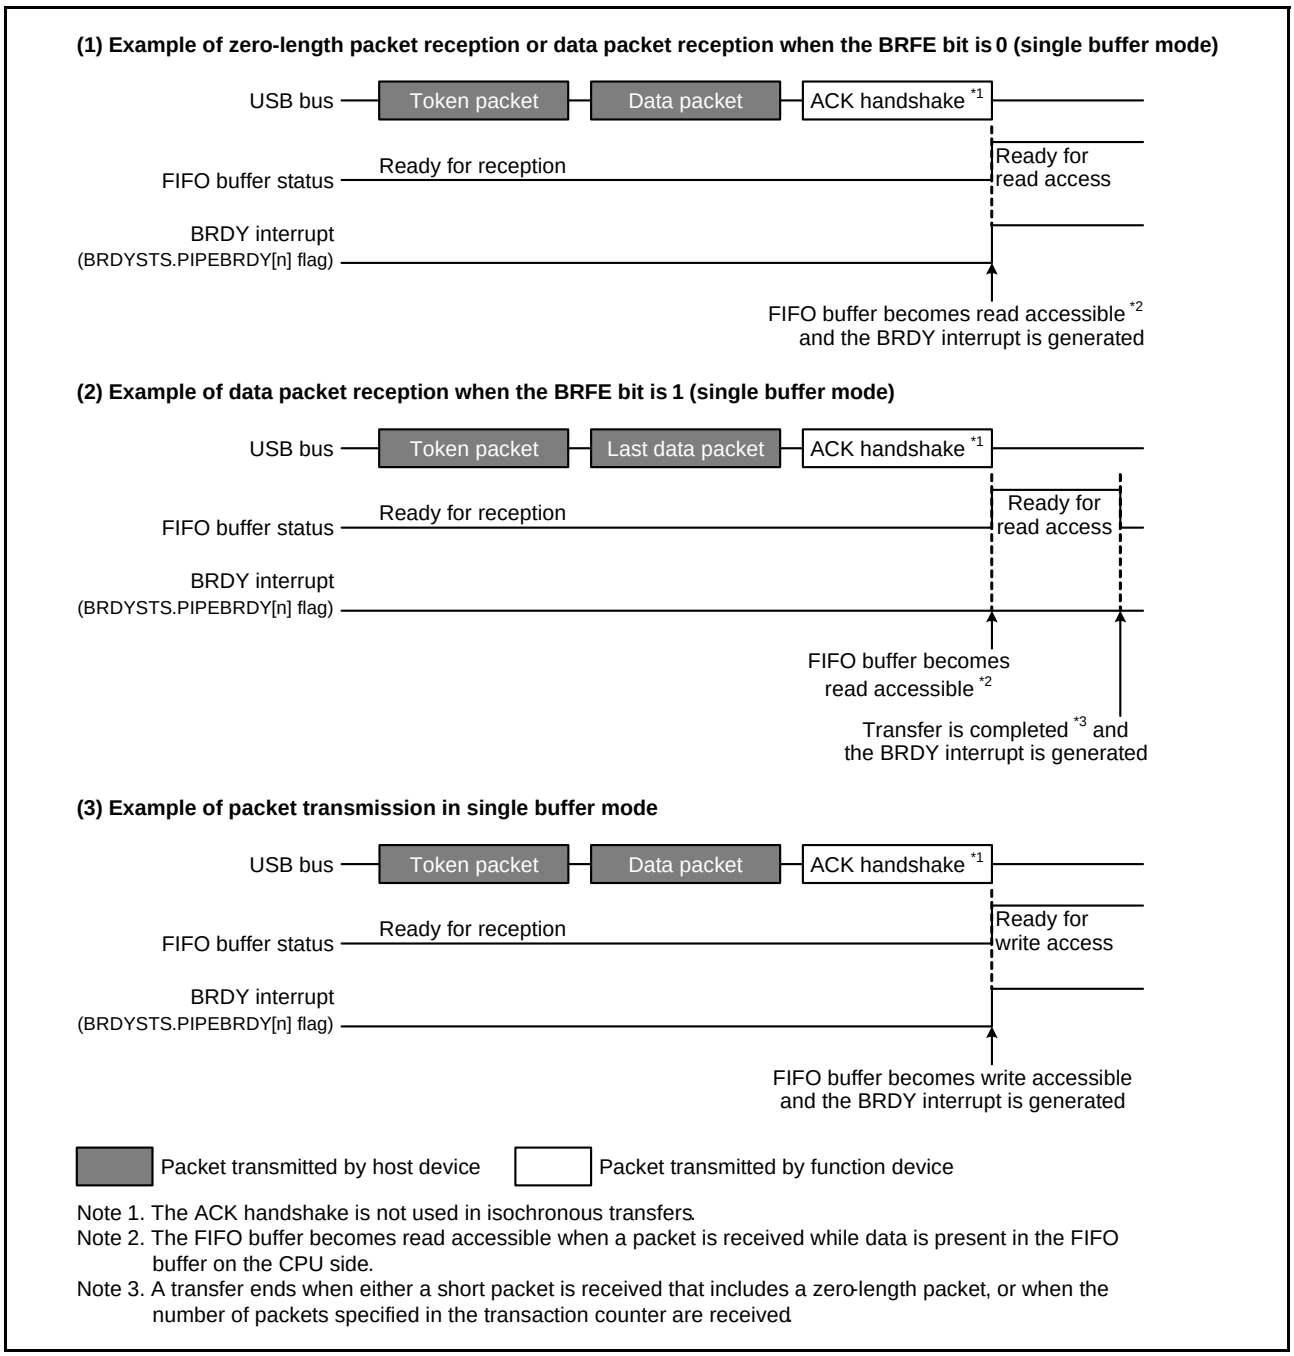

Figure 39.6 BRDY Interrupt Generation Timing

The condition that the USBA clears the INTSTS0.BRDY flag depends on the SOFCFG.BRDYM bit setting value. Table 39.17 shows the condition for clearing the BRDY flag.

Table 39.17 Condition for Clearing BRDY Flag

BRDYM Bit	Condition for Clearing the BRDY Flag
0	The USBA sets the BRDY flag to 0 when all flags in the BRDYSTS register have been set to 0 by software.
1	The USBA sets the BRDY flag to 0 when the BSTS flags for all pipes have become 0.

39.3.6.2 NRDY Interrupt

On generating an internal NRDY interrupt request for the pipe whose PID[1:0] bits are set to 01b (BUF response), the USBA sets the bit corresponding to the NRDYSTS.PIPENRDY[9:0] flag to 1. If the corresponding bit in NRDYENB has been set to 1, the USBA sets the INTSTS0.NRDY flag to 1 and generates a USBAR interrupt request.
The following describes the conditions in which the USBA generates the internal NRDY interrupt request for a given pipe.
Note that the internal NRDY interrupt request is not generated during setup transaction execution in host controller operation. During setup transactions in host controller operation, the SACK or SIGN interrupt is detected.
The internal NRDY interrupt request is not generated during status stage execution of the control transfer in function controller operation.

(1) In Host Controller Operation

(a) For the pipe in the transmitting direction:

On any of the following conditions, the USBA detects an NRDY interrupt.

- For the pipe for isochronous transfers, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer.
  In this case, the USBA transmits a zero-length packet following the OUT token and sets the bit corresponding to the NRDYSTS.PIPENRDY[9:0] flag and the FRMNUM.OVRN flag to 1.
- During communications other than setup transactions using the pipe for transfers other than isochronous transfers, when any combination of the following two cases occur three consecutive times: 1) no response is returned from the peripheral device (when timeout is detected before detection of the handshake packet from the peripheral device) and 2) an error is detected in the packet from the peripheral device.
  In this case, the USBA sets the bit corresponding to the PIPENRDY[9:0] flag to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 00b (NAK response).
- During communications other than setup transactions, when the STALL handshake is received from the peripheral device.
  In this case, the USBA sets the bit corresponding to the PIPENRDY[9:0] flag to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 11b (STALL response).

(b) For the pipe in the receiving direction:

- For the pipe for isochronous transfers, when the time to issue an IN token comes while there is no space available in the FIFO buffer.
  In this case, the USBA discards the received data for the IN token and sets the PIPENRDY[9:0] flag corresponding to the pipe and the OVRN flag to 1. When a packet error is detected in the received data for the IN token, the USBA also sets the FRMNUM.CRCE flag to 1.
- For the pipe for transfers other than isochronous transfers, when any combination of the following two cases occur three consecutive times: 1) no response is returned from the peripheral device for the IN token issued by the USBA (when timeout is detected before detection of the data packet from the peripheral device) and 2) an error is detected in the packet from the peripheral device.
  In this case, the USBA sets the PIPENRDY[9:0] flag corresponding to each pipe to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 00b (NAK response).
- For the pipe for isochronous transfers, when no response is returned from the peripheral device for the IN token (when timeout is detected before detection of the data packet from the peripheral device) or an error is detected in the packet from the peripheral device.
  In this case, the USBA sets the NRDYSTS.PIPENRDY[9:0] flag corresponding to each pipe to 1. (The setting of the PID[1:0] bits of the pipe is not modified.)
- For the pipe for isochronous transfers, when a CRC error or a bit stuffing error is detected in the received data packet.
  In this case, the USBA sets the NRDYSTS.PIPENRDY[9:0] flag corresponding to each pipe and the CRCE flag to 1.
- When the STALL handshake is received.
  In this case, the USBA sets the NRDYSTS.PIPENRDY[9:0] flag corresponding to each pipe to 1 and modifies the

setting of the PID[1:0] bits of the corresponding pipe to STALL.

(2) In Function Controller Operation

(a) For the pipe in the transmitting direction:

- When an IN token is received while there is no data to be transmitted in the FIFO buffer.
  In this case, the USBA generates an NRDY interrupt request at the reception of the IN token and sets the NRDYSTS.PIPENRDY[9:0] flag to 1. For the pipe for isochronous transfers in which an interrupt is generated, the USBA transmits a zero-length packet and sets the FRMNUM.OVRN flag to 1.

(b) For the pipe in the receiving direction:

- When an OUT token is received while there is no space available in the FIFO buffer.
  For the pipe for isochronous transfers in which an interrupt is generated, the USBA generates an NRDY interrupt request at the reception of the OUT token and sets the NRDYSTS.PIPENRDY[9:0] flag to 1 and FRMNUM.OVRN flag to 1. For the pipe for transfers other than isochronous transfers in which an interrupt is generated, the USBA generates an NRDY interrupt request when a NAK handshake is transferred after the data following the OUT token is received, and sets the NRDYSTS.PIPENRDY[9:0] flag to 1. However, during re-transmission (due to data PID mismatch), the NRDY interrupt request is not generated. In addition, if an error occurs in the data packet, the NRDY interrupt request is not generated.
- For the pipe for isochronous transfers, when a token is not received successfully within an interval frame.
  In this case, the USBA generates an NRDY interrupt request when SOF is received, and sets the NRDYSTS.PIPENRDY[9:0] flags to 1.

Figure 39.7 shows the NRDY Interrupt Generation Timing (In Function Controller Operation).

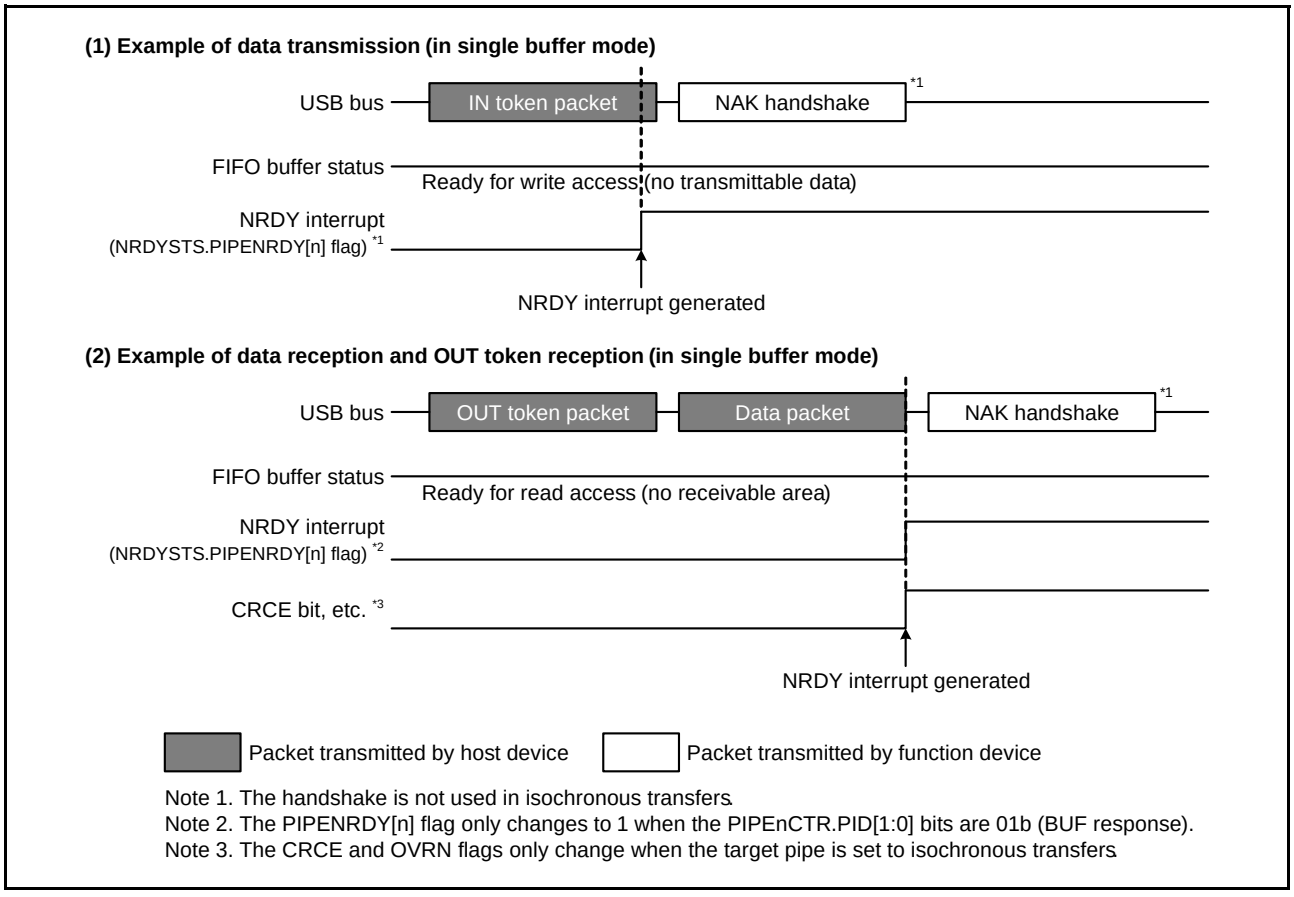

Figure 39.7 NRDY Interrupt Generation Timing (In Function Controller Operation)

39.3.6.3 BEMP Interrupt

On detecting a BEMP interrupt for the pipe whose PID[1:0] bits in the pipe control register are set to 01b (BUF response), the USBA sets the bit corresponding to the BEMPSTS.PIPEBEMP[9:0] flag to 1. If the corresponding bit in the BEMPENB register is set to 1, the USBA sets the INTSTS0.BEMP flag to 1 and generates a USBAR interrupt request.
The following describes the conditions in which the USBA generates an internal BEMP interrupt request.

(1) For the pipe in the transmitting direction:

When the FIFO buffer of the corresponding pipe is empty on completion of transmission (including zero-length packet transmission), and during single buffer mode, an internal BEMP interrupt request is generated simultaneously with the BRDY interrupt for the pipe other than default control pipe. However, the internal BEMP interrupt request is not generated on any of the following conditions.

- In double buffer mode, data starts to be written to the FIFO buffer on the CPU side when data transfer from one plane is complete.
- When the buffer is cleared by setting the PIPEnCTR.ACLRM or the BCLR bit in a FIFO port control register to 1.
- When IN transfer (zero-length packet transmission) is performed during the control transfer status stage during function controller operation.

(2) For the pipe in the receiving direction:

When the successfully-received data packet size exceeds the specified maximum packet size. In this case, the USBA generates a BEMP interrupt request, sets the corresponding BEMPSTS.PIPEBEMP[9:0] flag to 1, discards the received data, and modifies the setting of the PID[1:0] bits of the corresponding pipe to 11b (STALL response). Here, the USBA returns no response in host controller operation, and returns a STALL response in function controller operation. However, the internal BEMP interrupt request is not generated on any of the following conditions.

- When a CRC error or a bit stuffing error is detected in the received data.
- When a setup transaction is being performed

Figure 39.8 shows the BEMP Interrupt Generation Timing (In Function Controller Operation).

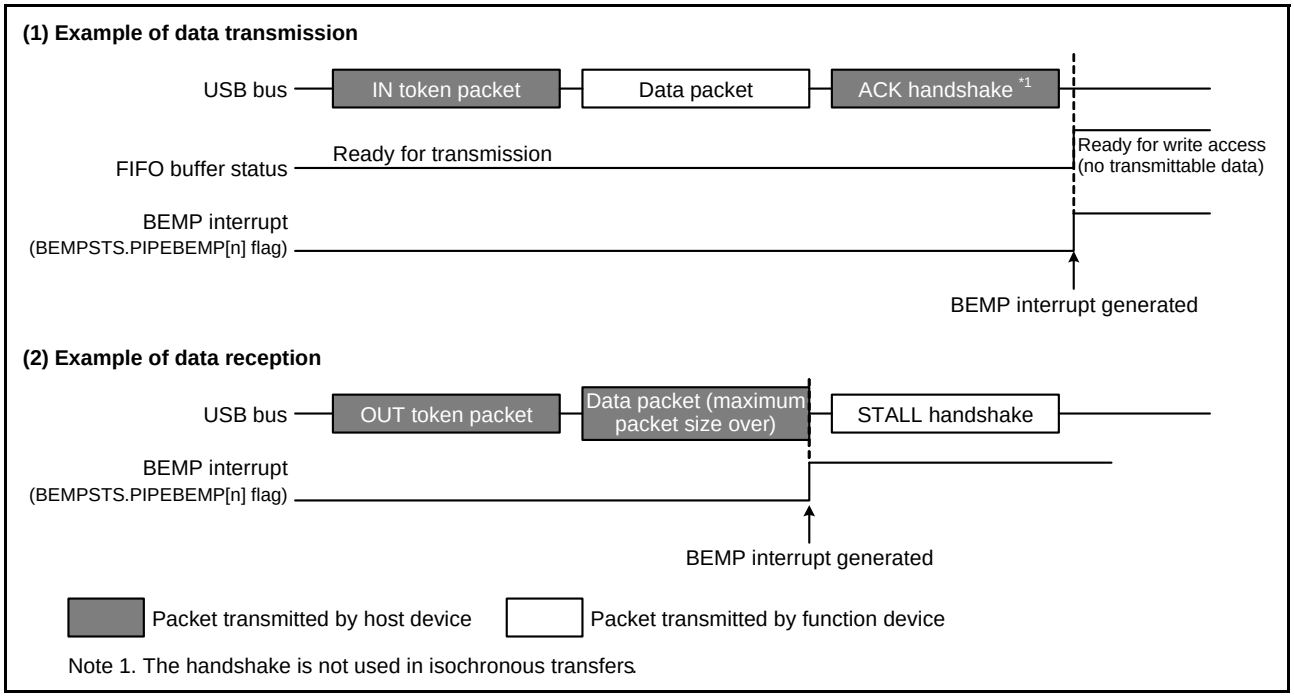

Figure 39.8 BEMP Interrupt Generation Timing (In Function Controller Operation)

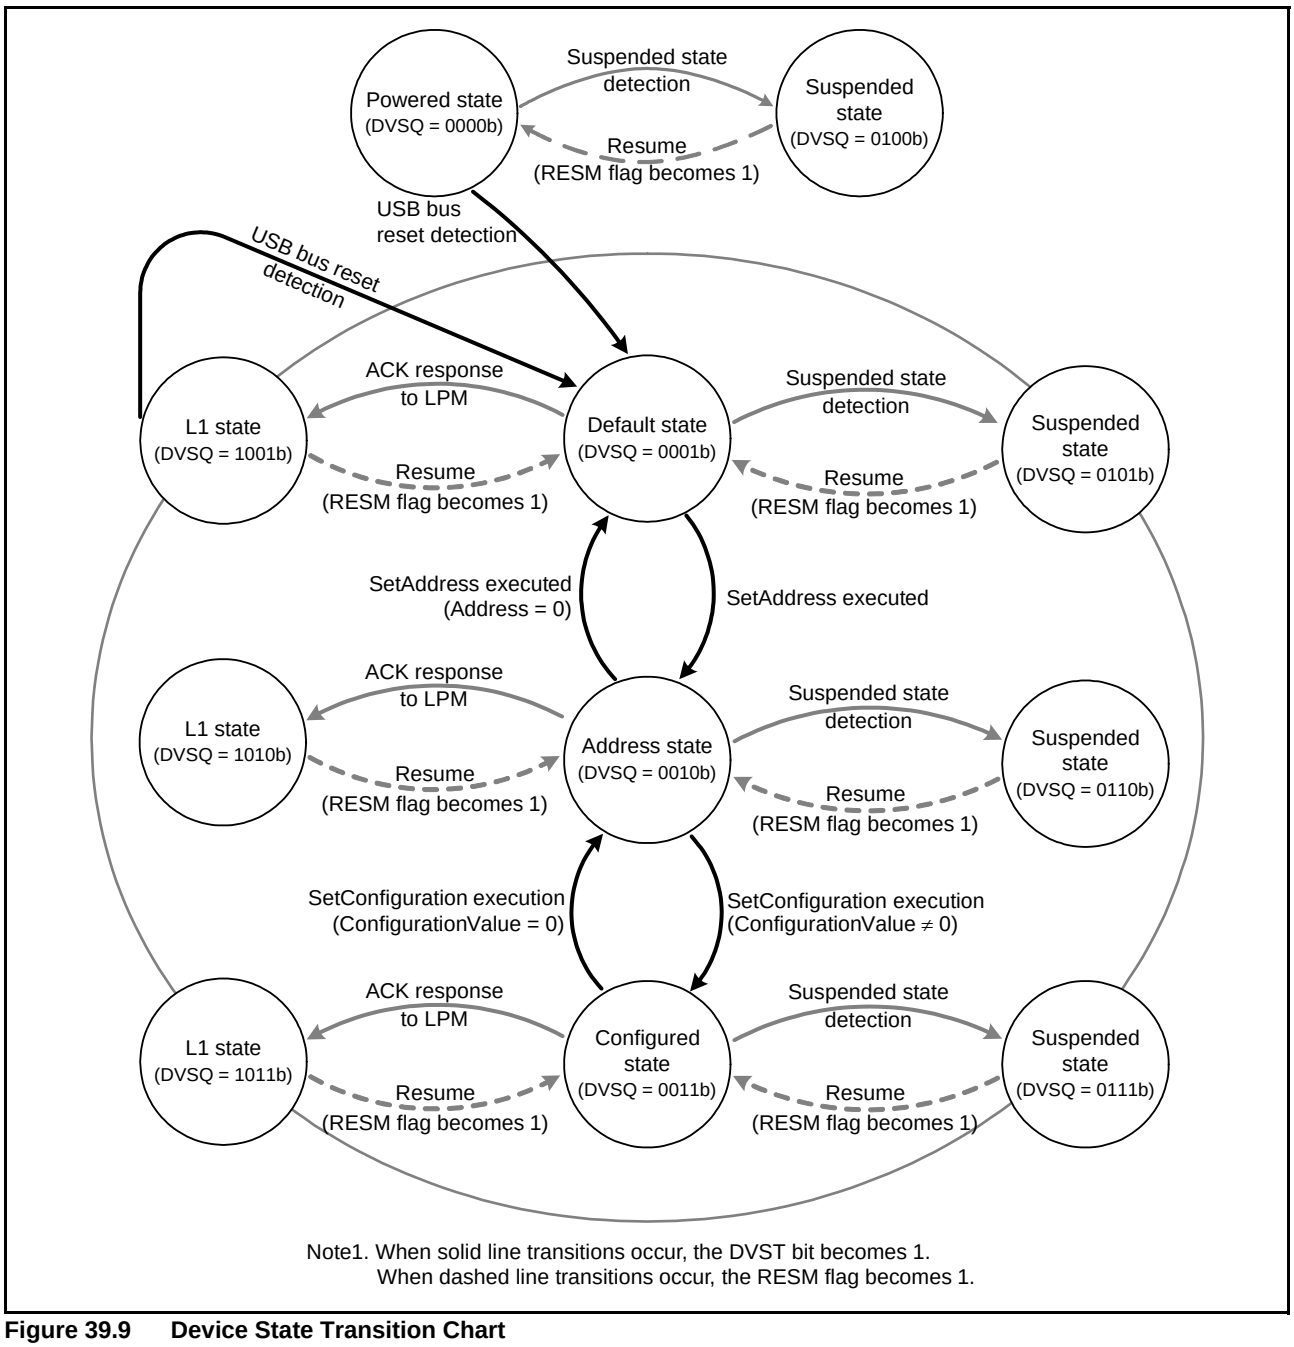
39.3.6.4 Device State Transition Interrupt in Function Controller Operation

Figure 39.9 shows the Device State Transition Chart for the USBA. The USBA controls the device states and generates device state transition interrupts. However, the USBA detects a return from the suspended state (by detecting the resume signal) by the resume interrupt. Device state transition interrupts can be enabled or disabled by the INTENB0 register. The transitioned device state can be checked by the INTSTS0.DVSQ[2:0] flags. To make a transition to the default state, a device state transition interrupt is generated after a USB bus reset is detected. The USBA controls device states only in function controller operation. Device state transition interrupts are also generated only in function controller operation.



Note1. When solid line transitions occur, the DVST bit becomes 1.
When dashed line transitions occur, the RESM flag becomes 1.

Figure 39.9 Device State Transition Chart

39.3.6.5 Control Transfer Stage Transition Interrupt in Function Controller Operation

Control transfer stage transitions of the USBA are illustrated in Figure 39.10. The USBA controls the control transfer sequence and generates control transfer stage transition interrupts. Control transfer stage transition interrupts can be enabled or disabled by the INTENB0 register. The transitioned transfer stage can be checked by the INTSTS0.CTSQ[2:0] flags. Control transfer stage transition interrupts are generated only in function controller operation. Control transfer sequence errors are shown below. When an error occurs, the DCPCTR.PID[1:0] bits are set to 10b or 11b (STALL response).

(1) Control read transfer
  (a) The OUT token is received with no data transferred in response to the IN token in the data stage.
  (b) The IN token is received in the status stage.
  (c) A data packet of data PID = DATA0 is received in the status stage.
(2) Control write transfer
  (a) The IN token is received with no ACK response returned in response to the OUT token in the data stage.
  (b) The first data packet of data PID = DATA0 is received in the data stage.
  (c) The OUT token is received in the status stage.
(3) Control write no data transfer
  (a) The OUT token is received in the status stage.

If the number of pieces of receive data has exceeded the *wLength* value in the USB request in the control write transfer data stage, it is not recognized as a control transfer sequence error. When the USBA receives a packet other than the zero-length packet in the control read transfer status stage, the USBA returns an ACK response and completes the processing successfully.
When a control transfer stage transition interrupt is generated (INTSTS0.CTRT flag is 1) due to a sequence error, the value of CTSQ[2:0] flags are 110b is retained until the CTRT flag is set to 0 (interrupt status clear). Therefore, while CTSQ[2:0] bits are 110b is retained, the control transfer stage transition interrupt of setup stage completion is not generated even if a new USB request is received. (Completion of setup stage is retained by the USBA, and a control transfer stage transition interrupt is generated after the interrupt status is cleared by software.)

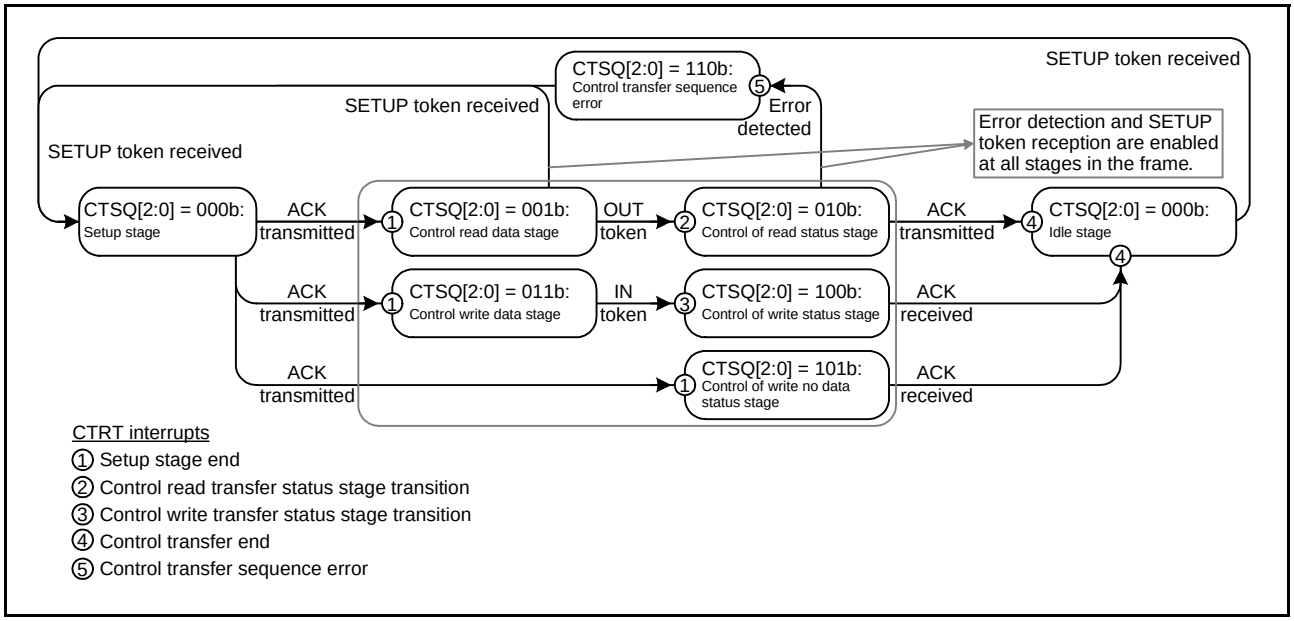


Figure 39.10 Control Transfer Stage Transition Chart

39.3.6.6 Frame Number Refresh Interrupt

In host controller operation, an interrupt is generated at the timing when the frame number is updated.
In function controller operation, a frame number refresh interrupt is generated when the frame number is updated. If the SOF cannot be received due to something like packet corruption, the frame number refresh interrupt is generated by the SOF recovery function. However, in this case the FRMNUM.FRNM[10:0] flags will not be updated.

39.3.6.7 VBUS Interrupt

When the USBA_VBUS pin level changes, a VBUS interrupt is generated. The level of the USBA_VBUS pin can be checked with the INTSTS0.VBSTS flag. Whether the host controller is connected or disconnected can be confirmed using the VBUS interrupt. However, if the system is activated with the host controller connected, the first VBUS interrupt is not generated because there is no change in the USBA_VBUS pin level.

39.3.6.8 Resume Interrupt

In function controller operation, a resume interrupt is generated when the device state is the suspended state and the USB bus state has changed (from J state to K state, or from J state to SE0). Recovery from the suspended state is detected by means of the resume interrupt. When the host controller is selected, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

39.3.6.9 OVRCR Interrupt

An OVRCR interrupt is generated when the USBA_OVRCURA or USBA_OVRCURB pin level has changed. The levels of the USBA_OVRCURA and USBA_OVRCURB pins can be checked with the SYSSTS0.OVCMON[1:0] flags. The external power supply IC can check whether overcurrent has been detected using the OVRCR interrupt.
For OTG connection, whether a change has been detected in the external power supply IC VBUS comparator can be checked using the OVRCR interrupt.

39.3.6.10 BCHG Interrupt

A BCHG interrupt is generated when the USB bus state has changed. The BCHG interrupt can be used to detect whether the peripheral device is connected and can also be used to detect a remote wakeup in host controller operation. The BCHG interrupt is generated regardless during host controller operation or function controller operation.

39.3.6.11 DTCH Interrupt

A DTCH interrupt is generated when disconnection of the USB bus is detected in host controller operation. The USBA detects bus disconnection based on USB 2.0.
After detecting a DTCH interrupt, the USBA controls hardware as described below (irrespective of the value set in the corresponding interrupt enable bit). All pipes in which communications are currently carried out for the pertinent port should be terminated by software and make a transition to the wait state for bus connection to the pertinent port (wait state for ATTCH interrupt generation).

- Modifies and indicates the DVSTCTR0.UACT bit for the port in which a DTCH interrupt has been detected to 0.
- Puts the port in which a DTCH interrupt has been generated into the Idle state.

39.3.6.12 SACK Interrupt

A SACK interrupt is generated when an ACK response for the transmitted setup packet has been received from the peripheral device in host controller operation. The SACK interrupt can be used to confirm that the setup transaction has been completed successfully.

39.3.6.13 SIGN Interrupt

A SIGN interrupt is generated when an ACK response for the transmitted setup packet has not been correctly received from the peripheral device three consecutive times in host controller operation. The SIGN interrupt can be used to detect no ACK response transmitted from the peripheral device or corruption of an ACK packet.

39.3.6.14 ATTCH Interrupt

An ATTCH interrupt is generated when J state or K state of the full-speed signal level is detected on the USB port for 2.5 µs in host controller operation. To be more specific, an ATTCH interrupt is detected on any of the following conditions.

- When K state, SE0, or SE1 changes to J state, and J state continues 2.5 µs.
- When J state, SE0, or SE1 changes to K state, and K state continues 2.5 µs.

39.3.6.15 EOFERR Interrupt

An EOFERR interrupt is generated when it is detected that communication is not completed at the EOF2 timing defined in USB 2.0.
After detecting an EOFERR interrupt, the USBA controls hardware as described below (irrespective of the value set in the corresponding interrupt enable bit). All pipes in which communications are currently carried out for the pertinent port should be terminated by software and perform re-enumeration of the pertinent port.

- Modifies and indicates the DVSTCTR0.UACT bit for the port in which an EOFERR interrupt has been detected to 0.
- Puts the port in which an EOFERR interrupt has been generated into the Idle state.

39.3.6.16 Portable Device Detection Interrupt

The USBA sets the INTSTS1.PDDETINT flag to 1 on detecting a portable device and generates the portable device detection interrupt. When the portable device detection interrupt is generated, use software to repeat reading the BCCTRL.PDDETSTS flag until the same value is read three or more times, and perform debounce processing.

39.3.6.17 LPMEND Interrupt

When the LPM transaction is ended because a response from the peripheral device or a timeout is detected, the INTSTS1.LPMEND flag is set to 1 and the LPMEND interrupt is generated.

39.3.6.18 L1RSMEND Interrupt

When performing processing to exit the L1 state, when the exit processing is complete, the INTSTS1.L1RSMEND flag becomes 1, and the L1RSMEND interrupt is generated.

39.3.7 Pipe Control

Pipe setting items of the USBA are listed in Table 39.18. USB data transfer is performed through logical pipes called endpoints. The USBA is provided with 10 pipes for data transfer. Set each pipe according to the user system specifications.

Table 39.18 Pipe Setting Items

Register Symbol	Bit Name	Setting	Note
DCPCFG PIPECFG	TYPE[1:0]	Transfer type	Pipes 1 to 9: Settable
	BFRE	BRDY interrupt mode	Pipes 1 to 5: Settable
	DBLB	Selection of double buffer	Pipes 1 to 5: Settable
	CNTMD	Select continuous transfer mode or discontinuous transfer mode	Pipes 1, 2: Settable only when bulk transfer is selected Pipes 3 to 5: Settable
	DIR	Selection of transfer direction	IN or OUT settable
	EPNUM[3:0]	Endpoint number	Pipes 1 to 9: Settable Set this number to a value other than 0000b when one or more pipes are used.
	SHTNAK	Selection of pipe disable at the end of transfer	Pipes 1, 2: Settable only when bulk transfer is selected Pipes 3 to 5: Settable
PIPEBUF	BUFSIZE[4:0]	FIFO buffer size	Default control pipe: Setting disabled (fixed to 64 bytes) Pipes 1 to 5: Settable (up to 2 Kbytes specifiable) Pipes 6 to 9: Setting disabled (fixed to 64 bytes)
	BUFNMB[7:0]	FIFO buffer number	default control pipe: Setting disabled (fixed to area 00h) Pipes 1 to 5: Setting disabled (area 08h to 87h specifiable) Pipes 6 to 9: Setting disabled (fixed to area 04h to 07h respectively)
DCPMAXP PIPEMAXP	DEVSEL[3:0]	Selection of device	Viewable only in host controller operation
	MXPS	Maximum packet size	Setting compliant with USB 2.0
PIPEPERI	IFIS	Buffer flush	Pipes 1, 2: Settable only when isochronous transfer is selected Pipes 3 to 5: Setting disabled Pipes 6 to 9: Setting disabled
	IITV[2:0]	Interval counter	Pipes 1, 2: Settable only when isochronous transfer is selected Pipes 3 to 5: Setting disabled Pipes 6 to 9: Settable only in host controller operation
DCPCTR, PIPEnCTR	BSTS	Buffer status	States of receive/transmit buffers of default control pipe are switched by the ISEL bit
	INBUFM	IN buffer monitor	Provided only for pipes 1 to 5
	SUREQ	SETUP request	Settable only for the default control pipe Controllable only in host controller operation
	SUREQCLR	SUREQ bit clear	Settable only for the default control pipe Controllable only in host controller operation
	ATREPM	Auto response mode	Pipes 1 to 5: Settable only in function controller operation
	ACLRM	Auto buffer clear	Pipes 1 to 9: Settable
	SQCLR	Sequence clear	Clearing the data toggle bit
	SQSET	Sequence set	Setting the data toggle bit
	SQMON	Sequence check	Checking the data toggle bit
	PBUSY	PIPE busy check	
	PID[1:0]	Response PID	
PIPEnTRE	TRENB	Transaction count enable	Pipes 1 to 5: Settable
	TRCLR	Current transaction counter clear	Pipes 1 to 5: Settable
PIPEnTRN	TRNCNT[15:0]	Transaction counter	Pipes 1 to 5: Settable

39.3.7.1 Pipe Control Register Switching Procedures

The following bits in the pipe control registers can be modified only when USB communication is prohibited (PID[1:0] bits are 00b (NAK response)). Figure 39.11 shows pipe control register switching procedures when USB communication is enabled (PID[1:0] bits are 01b (BUF response)).

The following shows the registers and bits that should not be modified when USB communication is enabled (PID[1:0] bits are 01b (BUF response)).

- Bits in registers DCPCFG and DCPMAXP
- DCPCTR.SQCLR and SQSET bits
- Bits in the PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI registers
- PIPEnCTR.ATREPM, ACLRM, SQCLR, and SQSET bits
- Bits in registers PIPEnTRE and PIPEnTRN
- Bits in the DEVADDm register (m = 0 to A)

For details on setting the bits in the DEVADDm register, follow the procedures of each bit described in section 39.2, Register Descriptions.

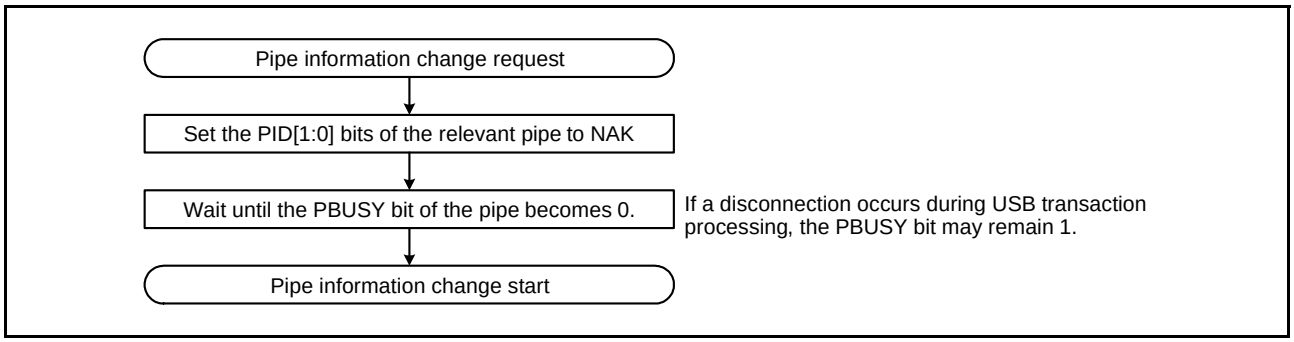

Figure 39.11 Procedure for Changing Pipe Information from the USB Communication Enabled State (PID[1:0] Bits are 01b (BUF Response))

The following bits in the pipe control registers can be modified only when the pertinent pipe information has not been set by the CURPIPE[3:0] bits in registers CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Registers that should not be set while the CURPIPE[3:0] bits are set:

- Bits in registers DCPCFG and DCPMAXP
- Bits in registers PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI
- PIPEnCTR.ACLRM bit

In order to modify pipe information, CURPIPE[3:0] bits should be set to a pipe other than the pipe to be modified. For the default control pipe, the buffer should be cleared using the BCLR bit after the pipe information is modified.

39.3.7.2 Transfer Types

The PIPECFG.TYPE[1:0] bits are used to specify the transfer type for each pipe. The transfer types that can be set for the pipes are as follows.

- Pipe 0 (default control pipe): No setting is necessary (fixed at control transfer).
- Pipes 1 and 2: These should be set to bulk transfer or isochronous transfer.
- Pipes 3 to 5: These should be set to bulk transfer.
- Pipes 6 to 9: These should be set to interrupt transfer.

39.3.7.3 Endpoint Number

The PIPECFG.EPNUM[3:0] bits are used to set the endpoint number for each pipe. The default control pipe is fixed at endpoint 0. The other pipes can be set from endpoint 1 to endpoint 15.

- Pipe 0 (default control pipe): No setting is necessary (fixed at endpoint 0).
- Pipes 1 to 9: The endpoint numbers from 1 to 15 should be selected and set.
  These should be set so that the combination of the PIPECFG.DIR bit and EPNUM[3:0] bits do not overlap.

39.3.7.4 Setting the Maximum Packet Size

Set the maximum packet size of each pipe with the DCPMAXP.MXPS[6:0] and PIPEMAXP.MXPS[10:0] bits. For the default control pipe and pipes 1 to 5, all maximum packet sizes defined in USB 2.0 can be set. For pipes 6 to 9, the maximum packet size is 64 bytes. Set the maximum packet size before starting a transfer (PID[1:0] bits are set to 01b (BUF response)).

- Default control pipe: Select 8, 16, 32, or 64.
- Pipes 1 to 5: Select 8, 16, 32, or 64 for bulk transfer.
- Pipes 1, 2: Set a value from 1 to 1023 for isochronous transfer.
- Pipes 6 to 9: Set a value of 1 to 64.

39.3.7.5 Transaction Counter (For Pipes 1 to 5 in the Reading Direction)

When the specified number of transactions has been completed in the data packet receiving direction, the USBA recognizes that the transfer has ended. Two transaction counters are provided: one is the PIPEnTRN register that specifies the number of transactions to be executed and the other is the current counter that internally counts the number of executed transactions. With the PIPECFG.SHTNAK bit set to 1, when the current counter value matches the specified number of transactions, the corresponding PIPEnCTR.PID[1:0] bits are set to 00b (NAK response) and the subsequent transfer is disabled. The transactions can be counted again from the beginning by initializing the current counter of the transaction counter function through the PIPEnTRE.TRCLR bit. The information read from the PIPEnTRN register differs depending on the setting of the PIPEnTRE.TRENB bit.

- TRENB bit is 0: The specified transaction counter value can be read.
- TRENB bit is 1: The current counter value indicating the internally counted number of executed transactions can be read.

When operating the TRCLR bit, the following should be noted.

- If the transactions are being counted and the PIPEnCTR.PID[1:0] bits are set to 01b (BUF response), the current counter cannot be cleared.
- If there is any data left in the buffer, the current counter cannot be cleared.

39.3.7.6 Response PID

Set the response PID of each pipe by the PIPEnCTR.PID[1:0] bits DCPCTR.PID[1:0]. The following shows the USB operation with various response PID settings:

(1) Setting the response PID in host controller operation

Specify the execution of transaction for the response PID.

(a) NAK setting: Pipe prohibited state where no transaction is made.

(b) BUF setting: Transaction is made according to the FIFO buffer state.
OUT direction: The OUT token is issued when the FIFO buffer contains transmit data.
IN direction: The IN token is issued when the FIFO buffer is not full and can receive data.

(c) STALL setting: Pipe prohibited state where no transaction is made

Note: Make the default control pipe's setup transaction using the DCPCTR.SUREQ bit.

(2) Setting the response PID in function controller operation

For the response PID, specify the response to transactions from the host.

(a) NAK setting: A NAK response is always returned to generated transactions.

(b) BUF setting: A response is returned to transactions according to the FIFO buffer.

(c) STALL setting: A STALL response is always returned to generated transactions.

Note: An ACK response is always returned to the setup transaction regardless of the value of the PID[1:0] bits and the USB request is stored in the register.

The USBA may write to the PID[1:0] bits, depending on the results of the transaction as described below.

(1) USBA sets the response PID in host controller operation

(a) NAK setting: The PID[1:0] bits are set to 00b (NAK response) in the following cases, stopping issuance of tokens automatically.

- In the response to the transmitted token during a transfer other than the isochronous transfer, an NRDY interrupt occurs (refer to section 39.3.6.2 for details).
- A short packet was received during bulk transfer with the PIPECFG.SHTNAK bit set to 1.
- The transaction counter ended during bulk transfer with the PIPECFG.SHTNAK bit set to 1.

(b) BUF setting: BUF is not written by the USBA.

(c) STALL setting: The PID[1:0] bits are set to STALL in the following cases, stopping issuance of tokens automatically.

- A STALL response was received in response to the transmitted token.
- A data packet exceeding the maximum packet size was received.

(2) USBA sets the response PID in function controller operation

(a) NAK setting:

- The SETUP token was successfully received (only default control pipe).
- The PIPECFG.SHTNAK bit was set to 1 during the bulk transfer and the transaction counter ended, or a short packet was received.

(b) BUF setting: BUF is not written by the USBA.

(c) STALL setting:

- A maximum packet size over error was detected in the receive data packet.
- A control transfer sequence error was detected.

39.3.7.7 Data PID Sequence Bit

When data is successfully transferred in the data stage, bulk transfer, or interrupt transfer of the control transfer, the sequence bit of the data PID is automatically toggled by the USBA. The sequence bit of the data PID transmitted next can be checked by the SQMON flag in DCPCTR and PIPEnCTR. The sequence bit changes upon receiving the ACK handshake during data transmission, or upon transmitting the ACK handshake during data reception. Furthermore, the data PID sequence bit can be modified by the SQCLR and SQSET bits in DCPCTR and PIPEnCTR.
In the control transfer during function controller operation, the USBA automatically sets the sequence bit at the stage transition. The data PID becomes DATA1 at the end of the setup stage. The sequence bit is not accessed in the status stage, and a response is returned with PID = DATA1. Therefore, sequence bit setting by software is not necessary. In the control transfer during host controller operation, the sequence bit must be set by software at the stage transition.
Note that the data PID sequence bit must be set by software when transmitting or receiving the ClearFeature() request regardless during the host or function controller operation.

39.3.7.8 Response PID = NAK Function

The USB has a function that disables pipe operation (PID[1:0] bits are set to 00b (NAK response)) at the timing at which the final data packet of a transaction is received (the USB automatically distinguishes this based on reception of a short packet or the transaction counter) by setting the PIPECFG.SHTNAK bit to 1. When the double buffer mode is being used for the FIFO buffer, using this function enables reception of data packets in transfer units. If pipe operation has been disabled, the pipe should be set to the enabled state again (PID[1:0] bits are set to 01b (BUF response)) by software. The response PID = NAK function can be used only when bulk transfers are used.

39.3.7.9 Auto Response Mode

With the pipes for bulk transfer (pipe 1 to pipe 5), when the PIPEnCTR.ATREPM bit is set to 1, a transition is made to auto response mode. During an OUT transfer (PIPECFG.DIR bit is 0), OUT-NAK mode is entered, and during an IN transfer (DIR bit is 1), null auto response mode is entered.

39.3.7.10 OUT-NAK Mode

With the pipes for bulk OUT transfer, NAK is returned in response to an OUT token and an NRDY interrupt is output when the PIPEnCTR.ATREPM bit is set to 1. To make a transition from normal mode to OUT-NAK mode, OUT-NAK mode should be specified in the pipe operation disabled state (PID[1:0] bits are set to 00b (NAK response)) before enabling pipe operation (PID[1:0] bits are set 01b (BUF response)). After pipe operation has been enabled, OUT-NAK mode becomes valid. However, if an OUT token is received immediately before pipe operation is disabled, the token data is normally received, and an ACK is retuned to the host. To transition from OUT-NAK mode to normal mode, OUT-NAK mode should be canceled in the pipe operation disabled state (PID[1:0] bits are set to 00b (NAK response)) before enabling pipe operation (PID[1:0] bits are set to 01b (BUF response)). In normal mode, reception of OUT data is enabled.

39.3.7.11 Null Auto Response Mode

With the pipes for bulk IN transfer, zero-length packets are continuously transmitted when the PIPEnCTR.ATREPM bit is set to 1. To make a transition from normal mode to null auto response mode, null auto response mode should be set in the pipe operation disabled state (PID[1:0] bits are set to 00b (NAK response)) before enabling pipe operation (PID[1:0] bits are set to 01b (BUF response)). After pipe operation has been enabled, null auto response mode becomes valid. Before setting null auto response mode, confirm that the PIPEnCTR.INBUFM flag is 0 because the mode can be set only when the buffer is empty. If the INBUFM flag is 1, the buffer should be emptied with the PIPEnCTR.ACLRM bit. While a transition to null auto response mode is being made, data should not be written from the FIFO port. To make a transition from null auto response mode to normal mode, pipe operation disabled state (PID[1:0] bits are set to 00b (NAK response)) should be retained for the period of zero-length packet transmission (about 10 µs) before canceling null auto response mode. In normal mode, data can be written from the FIFO port; therefore, packet transmission to the host is enabled by enabling pipe operation (PID[1:0] bits are set to 01b (BUF response)).

39.3.8 FIFO Buffers

39.3.8.1 FIFO Buffers

The USBA incorporates FIFO buffers for data transfer. The area used for each pipe is managed by the USBA. Access rights to FIFO buffers can be assigned to the system (CPU side) or the USBA (SIE side).

(1) Status of the FIFO Buffers

Table 39.19 and Table 39.20 list the states of the FIFO buffers in the USBA. The state of the FIFO buffers can be confirmed by reading the DCPCTR.BSTS flag and PIPEnCTR.INBUFM flag. The transfer direction for the FIFO buffers can be specified using either the PIPECFG.DIR bit or the CFIFOSEL.ISEL bit (when default control pipe is selected). The INBUFM flag is valid for pipe 1 to pipe 5 when transmitting. When a transfer pipe on the transmitting side is set to double buffer mode, the BSTS flag is used to monitor the buffer status on the CPU side, and the INBUFM flag is used to monitor the buffer status on the SIE side. When the CPU or DMAC/DTC write access to the FIFO port is slow, and the buffer empty status cannot be determined by the BEMP interrupt, the end of transmission can be confirmed by the INBUFM flag.

Table 39.19 FIFO Buffer Status Indicated by the BSTS Flag

ISEL or DIR Bit	BSTS Flag	FIFO Buffer Status
0 (data reception)	0	There is no received data, or data is being received. Data cannot be read from the FIFO port.
0 (data reception)	1	There is received data, or a zero-length packet has been received. Data can be reading from the FIFO port. Note that when a zero-length packet is received, data cannot be read and the FIFO buffer must be cleared.
1 (data transmission)	0	Data transmission is not complete. Data cannot be written to the FIFO port.
1 (data transmission)	1	Data transmission has been completed. Data can be written to the FIFO buffer.

Table 39.20 Buffer Status Indicated by the INBUFM Flag

DIR Bit	INBUFM Flag	FIFO Buffer Status
0 (data reception)	Invalid	Invalid
1 (data transmission)	0	Data transmission has been completed. There is no data to be transmitted, or transmit data is being written to the FIFO port.
1 (data transmission)	1	Transmittable data is present.

39.3.8.2 Clearing the FIFO Buffers

Table 39.21 lists information pertaining to clearing FIFO buffers by the USBA. FIFO buffers can be cleared using the BCLR bit in a FIFO port control register, DCLRM bit in the D0FIFOSEL/D1FIFOSEL register, and PIPEnCTR.ACLRM bit. Pipes 1 to 5 can be set to single buffer mode or double buffer mode using the PIPECFG.DBLB bit.

Table 39.21 Methods of Clearing the FIFO Buffers

Cleared	FIFO Buffers on the CPU Side	FIFO Buffer That Has Had All Transmit Data Read	All Data in the FIFO Buffer Allocated to Pipe n
Bit used	CFIFOCTR.BCLR bit D0FIFOCTR.BCLR bit D1FIFOCTR.BCLR bit	D0FIFOSEL.DCLRM bit D1FIFOSEL.DCLRM bit	PIPEnCTR.ACLRM bit
Operation	When the BCLR bit is set to 1, the FIFO buffers on the CPU side of the pipes specified by the CFIFOSEL.CURPIPE[3:0] bits and CURPIPE[3:0] bits in the D0FIFOSEL/D1FIFOSEL register are cleared.	If the DCLRM bit is set to 1, after reading the received data for the pipe specified by the CURPIPE[3:0] bits in the D0FIFOSEL/D1FIFOSEL register, the FIFO buffer is automatically cleared.	If the ACLRM bit is set to 1 and then set to 0, all data in the FIFO buffer (both planes in double buffer mode) allocated to pipe n is cleared. Also, If the PID[1:0] bits are set to 01b (BUF response) while the ACLRM bit is still set to 1, all packets received are discarded.

(1) Received Packet Read-and-Discard Function in Auto Buffer Clear Mode

If the PIPEnCTR.ACLRM bit is set to 1 and the PID[1:0] bits are set to 01b (BUF response), the USBA discards all received data packets. However, if a normal data packet is received, the ACK response is returned to the host controller. The received packet read-and-discard function can only be set to FIFO buffers that are reading data. In addition, do not use pipes that are specified as isochronous transfer or interrupt transfer.

39.3.8.3 FIFO Port Functions

Table 39.22 shows the settings for the functions of the FIFO ports in the USBA. When writing data to a FIFO buffer, data is written until the maximum packet size is reached, and the FIFO buffer automatically becomes enabled to transmit data. To enable transmission before the maximum packet size is reached, set the BVAL bit in a FIFO port control register to end the write access. To transmit a zero-length packet, after using the BCLR bit to clear the FIFO buffer, the BVAL bit must be set to end the write access.
When reading data from a FIFO buffer, after all data has been read from the FIFO buffer, it automatically becomes ready to receive new packets. However, when a zero-length packet is received (DTLN[11:0] flags are 000h), data cannot be read from the FIFO buffer, and the BCLR bit must be used to clear the buffer. The length of the receive data can be confirmed using the DTLN[11:0] flags in a FIFO port control register.

Table 39.22 FIFO Port Function Settings

Register Name	Bit Name	Description
CFIFOSEL, D0FIFOSEL, D1FIFOSEL	RCNT	Selects DTLN[11:0] read mode.
	REW	FIFO buffer rewind (reread, rewrite).
	DCLRM	Automatically clears receive data for a current pipe after the data has been read (only for D0FIFO and D1FIFO).
	DREQE	Enables DMA/DTC transfers (only for D0FIFO and D1FIFO).
	MBW[1:0]	FIFO port access bit width.
	BIGEND	Selects FIFO port endian.
	ISEL	FIFO port access direction (only for the default control pipe).
	CURPIPE[3:0]	Selects the current pipe.
CFIFOCTR, D0FIFOCTR, D1FIFOCTR	BVAL	Ends writing to the FIFO buffer.
	BCLR	Clears FIFO buffers on the CPU side.
	DTLN[11:0]	Checks the length of the receive data.

(1) FIFO Port Selection

Table 39.23 shows the pipes that can be selected with the various FIFO ports. Use the CURPIPE[3:0] bits in a FIFO port select register to select the pipe to be accessed. After the pipe is selected, check to see that the value written to the CURPIPE[3:0] bits can be read correctly, (if the previous pipe number is read, it indicates the USBA is modifying the pipe). Then, check to see if the FRDY flag in a FIFO port control register is 1, and access the FIFO buffers. In addition, use the MBW[1:0] bits in a FIFO port select register to select the bus width to be accessed. The PIPECFG.DIR bit is used to select the FIFO buffer access direction, and the ISEL bit in a FIFO port select register determines the direction of the default control pipe.

Table 39.23 FIFO Port Access by Pipe

Pipe	Access Method	Port that can be Used
default control pipe	CPU access	CFIFO port register
Pipe 1 to pipe 9	CPU access	CFIFO port register D0FIFO/D1FIFO port register
	DMAC/DTC access	D0FIFO/D1FIFO port register

(2) REW Bit

The pipe currently being accessed can be halted, another pipe can be accessed, and then it is possible to continue processing on the current pipe. Set the REW bit in a FIFO port select register to perform this. If a pipe is selected by setting the CURPIPE[3:0] bits in a FIFO port select register and the REW bit to 1 simultaneously, the pointer used to read from and write to the FIFO buffer is reset, and the read or write access can be carried out from the first byte. If a pipe is selected by setting the REW bit to 0, the pointer used to read from and write to the FIFO buffer is not reset, and the data access previously selected can be continued. To access a FIFO port, after selecting a pipe, check to see if an FRDY flag in a FIFO port control register is 1.

39.3.8.4 DMA/DTC Transfers (D0FIFO and D1FIFO Ports)

(1) Overview of DMA/DTC Transfers

The FIFO port can be accessed using the DMAC/DTC for pipes 1 to 9. When access to the buffer for the pipe targeted for DMA/DTC transfer is enabled, a DMA/DTC transfer request is issued.
Set the MBW[1:0] bits in the D0FIFOSEL/D1FIFOSEL register to select the transfer width to the FIFO port, set the CURPIPE[3:0] bits to select the pipe targeted for DMA/DTC transfer. Do not change the selected pipe during DMA/DTC transfer.

(2) D0FIFO/D1FIFO Auto Clear Mode (Reading Ports D0FIFO and D1FIFO)

When the DCLRM bit in the D0FIFOSEL/D1FIFOSEL register is set to 1, if the FIFO buffer read access is completed, the USBA automatically clears the FIFO buffer of the selected pipe.
In Table 39.24, the relationship between packet reception and FIFO buffer clearing processing by software is shown for various bit settings. As shown in Table 39.24, the conditions for clearing a FIFO buffer depends on the PIPECFG.BFRE bit setting. Using the DCLRM bit eliminates the need for a FIFO buffer to be cleared by software in any situation that requires FIFO buffer clearing. This enables DMA/DTC transfers without involving software.
D0FIFO/D1FIFO auto clear mode can be used when reading a FIFO buffer.

Table 39.24 Relationship Between Packet Reception and FIFO Buffer Clearing Processing by Software

Buffer Status When a Packet is Received	Bit Setting			
	DCLRM bit is 0		DCLRM bit is 1	
	BFRE bit is 0	BFRE bit is 1	BFRE bit is 0	BFRE bit is 1
Buffer full	Clearing not necessary	Clearing not necessary	Clearing not necessary	Clearing not necessary
Zero-length packet reception	Clearing necessary	Clearing necessary	Clearing not necessary	Clearing not necessary
Normal short packet reception	Clearing not necessary	Clearing necessary	Clearing not necessary	Clearing not necessary
Transaction count end	Clearing not necessary	Clearing necessary	Clearing not necessary	Clearing not necessary

39.3.8.5 Allocating the FIFO Buffers

Figure 39.12 is an example of the memory map for a USBA FIFO buffer. The FIFO buffer is an area shared by the CPU and the USBA. Access rights to the FIFO buffers can be given to the CPU side or USBA side (SIE side).

An independent area is set for the FIFO buffer of each pipe. A memory area is set by the first block number and the number of blocks (specified by the PIPEBUF.BUFSIZE[4:0] and BUFNMB[7:0] bits), regarding 64 bytes as one block. When the PIPECFG.CNTMD bit is 1 (continuous transfer mode), set the BUFSIZE[4:0] bits to an integral multiple of the maximum packet size. In addition, when the PIPECFG.DBLB bit is set to 1 (double buffer mode), twice the memory area specified by the PIPEBUF.BUFSIZE[4:0] bits is allocated to the same pipe.

Three FIFO ports are used to access (read data from and write data to) a FIFO buffer. Set the CFIFOSEL/D0FIFOSEL/D1FIFOSEL.CURPIPE[3:0] bits to specify the pipe the FIFO port is allocated to.

The BSTS flags in registers DCPCTR and PIPEnCTR, and the PIPEnCTR.INBUFM flag can be used to check the status of a FIFO buffer for each pipe. Use the CFIFOCTR/D0FIFOCTR/D1FIFOCTR.FRDY flag to check access rights for a FIFO port.

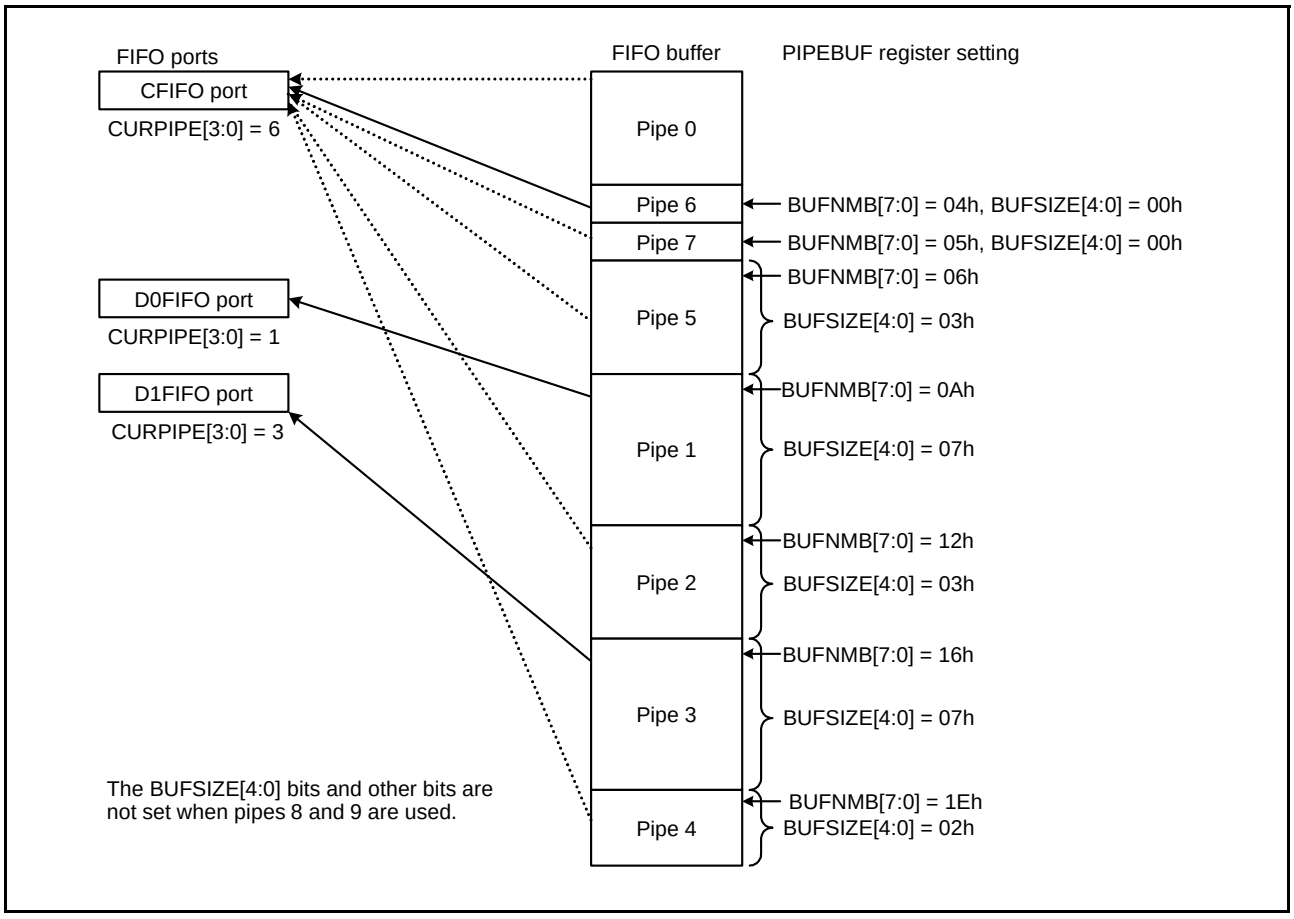

Figure 39.12 Example of a FIFO Buffer Memory Map

39.3.9 Control Transfer Using the Default Control Pipe

The default control pipe is used for data transfer in the control transfer data stage. The default control pipe's FIFO buffer is a 64-byte single buffer of the fixed area for both control read and control write. This FIFO buffer can only be accessed through the CFIFO port.

39.3.9.1 Control Transfer in Host Controller Operation

(1) Setup Stage

Registers USBREQ, USBVAL, USBINDX, and USBLENG are used to transmit the USB request of the SETUP transaction. Writing the setup packet data to the register and then setting the DCPCTR.SUREQ bit to 1 transmits the set data as the SETUP transaction. The SUREQ bit becomes 0 when the transaction is completed. Do not modify the above USB request registers while the SUREQ bit is 1. After the USBA detects that the peripheral device is connected, issue the first SETUP transaction for the device using the sequence described above by setting the DCPMAXP.DEVSEL[3:0] bits to 0 and setting the DEVADD0.USBSPD[1:0] bits. After the connected peripheral device enters the Address state, issue SETUP transactions using the sequence described above with the assigned USBAddress set in the DEVSEL[3:0] bits and the bits in the DEVADDm register corresponding to the specified USBAddress set appropriately (m = 0 to A). For example, set the DEVADD2 register when the PIPEMAXP.DEVSEL[3:0] bits are 0010b, and set the DEVADD5 register when the PIPEMAXP.DEVSEL[3:0] bits are 0101b. When a transaction is transmitted, an interrupt request is generated by the response from the peripheral device (INTSTS1.SIGN and SACK flags). This interrupt request allows the USBA to check the SETUP transaction result. The DATA0 data packet (USB request) of the SETUP transaction is transmitted regardless of the DCPCTR.SQMON flag setting.

(2) Data Stage

The data stage is used to transfer data using the default control pipe's FIFO buffer.
Before accessing the default control pipe's FIFO buffer, set the CFIFOSEL.ISEL bit to specify the access direction. In addition, set the DCPCFG.DIR bit to specify the transfer direction. The first data packet in the data stage must be transferred with the data PID set to DATA1. Transactions can be executed by setting the data PID to DATA1 using the DCPCTR.SQSET bit and setting the PID[1:0] bits to 01b (BUF response). Completion of data transfer is detected by the BRDY interrupt or the BEMP interrupt. Data transfer of multiple packets is enabled in continuos transfer mode. If the transmit data size is an integral multiple of the maximum packet size, control the control write transfer by software to transmit a zero-length packet last.

(3) Status Stage

The status stage is used for zero-length packet data transfer in the reverse direction of the data stage. As in the data stage, data transfer using the default control pipe's FIFO buffer is performed in the status stage. Transactions are executed using the same procedure as the data stage. Data packets in the status stage must be transmitted and received with the data PID set to DATA1. Set the data PID to DATA1 by the DCPCTR.SQSET bit. When a zero-length packet is received, check the receive-data length by the CFIFOCTR.DTLN[11:0] flags after the BRDY interrupt is generated, and then clear the FIFO buffer by using the BCLR bit.

39.3.9.2 Control Transfer in function controller operation

(1) Setup Stage

The USBA returns an ACK response in response to a normal setup packet for the USBA. The following describes the USBA operation in the setup stage.
The USBA sets the following bits upon receiving a new setup packet.

- Sets the INTSTS0.VALID flag to 1.
- Sets the DCPCTR.PID[1:0] bits to 00b (NAK response).
- Sets the DCPCTR.CCPL bit to 0.

When the USBA receives a data packet following a setup packet, the USBA stores the USB request parameters in registers USBREQ, USBVAL, USBINDX, and USBLENG.

Before performing the response processing for the control transfer, be sure to set VALID flag to 0. While VALID flag is 1, the PID[1:0] bits cannot be set to 01b (BUF response) and the data stage cannot be finished. With the VALID flag function, the USBA can suspend the ongoing request processing upon receiving a new USB request during the control transfer and return a response to the latest request.

Furthermore, the USBA automatically checks the direction bit (bit 8 of *bmRequestType*), and the request data length (*wLength*) in the received USB request, and recognizes the control read transfer, control write transfer, and control write no data transfer to control stage transitions. In the case of an incorrect sequence, a sequence error of the control transfer stage transition interrupt occurs, and interrupt is reported to software. For details on stage control by the USBA, see Figure 39.10, Control Transfer Stage Transition Chart.

(2) Data Stage

Perform data transfer by the default control pipe in response to the received USB request. Before accessing the default control pipe's FIFO buffer, set the CFIFOSEL.ISEL bit to specify the access direction. A transaction is executed when the DCPCTR.PID[1:0] bits are set to 10b (BUF response). Completion of data transfer is detected by the BRDY interrupt or BEMP interrupt. Use the BRDY interrupt for control write transfers, and use the BEMP interrupt for control read transfers.

(3) Status Stage

While the DCPCTR.PID[1:0] bits are set to 01b (BUF response), control transfer can be finished by setting the DCPCTR.CCPL bit to 1.
After the DCPCTR.CCPL bit is set to 1, the USBA automatically executes the status stage according to the data transfer direction determined in the setup stage. The status stage is executed specifically as follows.

- For control read transfer:

The USBA receives a zero-length packet from the USB host and transmits an ACK response.

- For control write transfer and no data control transfer:

The USBA transmits a zero-length packet and receives an ACK response from the USB host.

(4) Control Transfer Auto Response Function

The USBA automatically responds to a normal SetAddress() request. If the SetAddress() request contains any of the following errors, a response must be returned by software.

- When *bmRequestType* is not 00h: Except control write transfer
- When the *wIndex* value is not 00h: Request error
- When the *wLength* value is not 00h: Except no data control transfer
- When the *wValue* value is larger than 7Fh: Request error
- When INTSTS0.DVSQ[2:0] flags are 011b (configured state): control transfer of device state error

To all requests other than SetAddress(), a response by the corresponding software is required.

39.3.10 Bulk Transfer for Pipes 1 to 5

The FIFO buffer usage (setting of single buffer/double buffer or continuous transfer mode/discontinuous transfer mode) is selectable for the bulk transfer. Up to 2 Kbytes of the FIFO buffer size can be set.

39.3.11 Interrupt Transfer for Pipes 6 to 9

In function controller operation, the USBA performs the interrupt transfer according to the cycle managed by the USB host.
In host controller operation, the token issuing timing can be set by the interval counter.

39.3.11.1 Interval Counter for Interrupt Transfer in Host Controller Operation

To perform the interrupt transfer, specify the transaction interval for the PIPEPERI.IITV[2:0] bits. The USBA issues interrupt transfer tokens according to the set interval.

(1) Initializing the Counter

When the MCU is reset, or when the PIPEnCTR.ACLRM bit is set to 1, the interval counter is initialized. Note that the PIPEPERI.IITV[2:0] bits are not initialized when the ACLRM bit is initialized.

Note that the interval counter is not initialized in the following case.

- USB bus reset, USB suspend
  The IITV[2:0] bits are not initialized. When the DVSTCTR0.UACT bit is set to 1, the count continues from the value before entering the USB bus reset state or the USB suspend state.

(2) Operation when Tokens Cannot Be Transmitted or Received at the Token Generation Timing

No token is generated in the following cases even at the token generation timing. In this case, try to execute a transaction in the next interval.

- The PID[1:0] bits are set to NAK response or STALL response.
- No available area is left in the FIFO buffer at the token transmit timing during transfer in the IN (receiving) direction.
- The FIFO buffer contains no transmit data at the token transmit timing during transfer in the OUT (transmitting) direction.

39.3.12 Isochronous Transfer for Pipes 1 and 2

The USBA has the following functions for isochronous transfers.

- Notification of isochronous transfer error
- Interval counter (specified by the PIPEPERI.IITV[2:0] bits)
- Isochronous IN transfer data setup control (IDLE function)
- Isochronous IN transfer buffer flush function (specified by the PIPEPERI.IFIS bit)

39.3.12.1 Error Detection in Isochronous Transfers

The USBA has a function for detecting the following error information for software to manage isochronous transfer errors. Table 39.25 and Table 39.26 show the priority in which errors are detected by the USBA and the interrupts generated corresponding to errors.

(1) PID errors
- The PID value of the received packet is invalid.

(2) CRC errors and bit stuffing errors
- A CRC error was found in the received packet or the bit stuffing is incorrect.

(3) Maximum packet size over
- The data size of the received packet exceeded the maximum packet size.

(4) Overrun and underrun errors
- In host controller operation:
  No available area is left in the FIFO buffer at the token transmit timing during transfer in the IN (receiving) direction.
  The FIFO buffer contains no transmit data at the token transmit timing during transfer in the OUT (transmitting) direction.
- In function controller operation:
  The FIFO buffer contains no data when an IN token is received during transfer in the IN (transmitting) direction.
  No available area is left in the FIFO buffer when an OUT token is received during transfer in the OUT (receiving) direction.

(5) Interval error
In function controller operation, the following cases are treated as an interval error.
- Failed to receive an IN token in the interval frame during the isochronous IN transfer.
- Failed to receive an OUT token in the interval frame during the isochronous OUT transfer.

Table 39.25 Detecting an Error When a Token is Issued or Received

Detection Priority	Error Type	Interrupt Generated at Error Detection and Status
1	PID error	No interrupt is generated regardless of the selected controller function. (Ignored as a corrupted packet.)
2	CRC error, bit stuffing error	No interrupt is generated regardless of the selected controller function. (Ignored as a corrupted packet.)
3	Overrun error, underrun error	An NRDY interrupt is generated and the OVRN flag is set to 1 regardless of the selected controller function. In function controller operation, a zero-length packet is transmitted in response to the IN token. No data packet is received in response to the OUT token.
4	Interval error	An NRDY interrupt is generated in function controller operation, but no interrupt is generated in host controller operation.

Table 39.26 Detecting an Error When Receiving a Data Packet

Detection Priority	Error Type	Interrupt Generated at Error Detection and Status
1	PID error	No interrupt is generated (ignored as a corrupted packet.)
2	CRC error, bit stuffing error	An NRDY interrupt is generated and the CRCE flag is set to 1 regardless of the selected controller function.
3	Maximum packet size over error	A BEMP interrupt is generated and the PID[1:0] bits are set to STALL response regardless of the selected controller function.

39.3.12.2 Data PID

The following describes actions to be taken for the received token in function controller operation.

(1) IN token:
- DATA0: Transmitted as PID of the data packet.
- DATA1: Not transmitted.

(2) OUT token:
- DATA0: Successfully received as PID of the data packet.
- DATA1: Successfully received as PID of the data packet.

39.3.12.3 Interval Counter

The isochronous transfer interval can be set by the PIPEPERI.IITV[2:0] bits. In function controller operation, the interval counter enables functions shown in Table 39.27 below. In host controller operation, the token issuing timing is generated. In host controller operation, the interval counter operates in the same manner as in the interrupt transfer.

Table 39.27 Interval Counter Functions Provided in Function Controller Operation

Transfer Direction	Function	Detecting Condition
IN	Transmit buffer flush function	Failed to receive an IN token successfully in the interval frame during the isochronous IN transfer.
OUT	Notification of reception of no token	Failed to receive an OUT token successfully in the interval frame during the isochronous OUT transfer.

Since the interval counting is performed upon reception of SOF or by the recovered SOF, the isochronism can be maintained even if the SOF packet is corrupted. The settable frame interval is $2^{IITV[2:0]}$ frame.

(1) Initializing the Interval Counter in Function Controller Operation

When the MCU is reset, a USB bus reset is detected, or when the PIPEnCTR.ACLRM bit is set to 1, the interval counter is initialized. Note that the PIPEPERI.IITV[2:0] bits are initialized when the MCU is reset.

After the interval counter is initialized, the interval count starts under the following conditions after a packet is successfully transferred.
1. SOF is received after data is transmitted in response to the IN token with PID[1:0] bits set to 01b (BUF response).
2. SOF is received after data is received in response to the OUT token with PID[1:0] bits set to 01b (BUF response).

The interval counter is not initialized under the following conditions.
- When PID[1:0] bits are set to NAK response or STALL response
  The interval timer does not stop. Try to execute a transaction in the next interval.
- USB suspend
  The IITV[2:0] bits are not initialized. When SOF is received, the interval counter starts counting from the value before entering the suspended state.

(2) Interval Counting and Transfer Control in Host Controller Operation

The USBA controls the interval between token issuance operations based on the PIPEPERI.IITV[2:0] bit settings. Specifically, the USBA issues a token for a selected pipe once every $2^{IITV[2:0]}$ frames.
The USBA starts counting the token issuance interval at the frame following the frame in which the PID[1:0] bits have been set to 01b (BUF response).

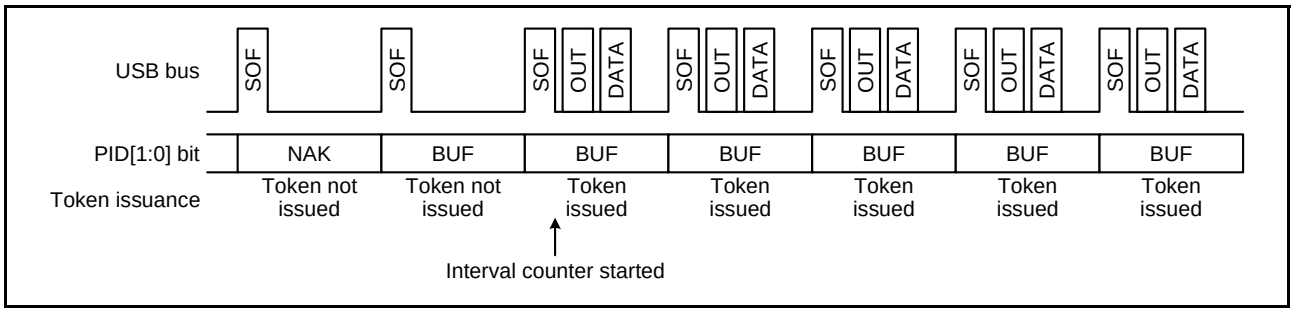

Figure 39.13 Token Issuance When IITV[2:0] Bits are 000b

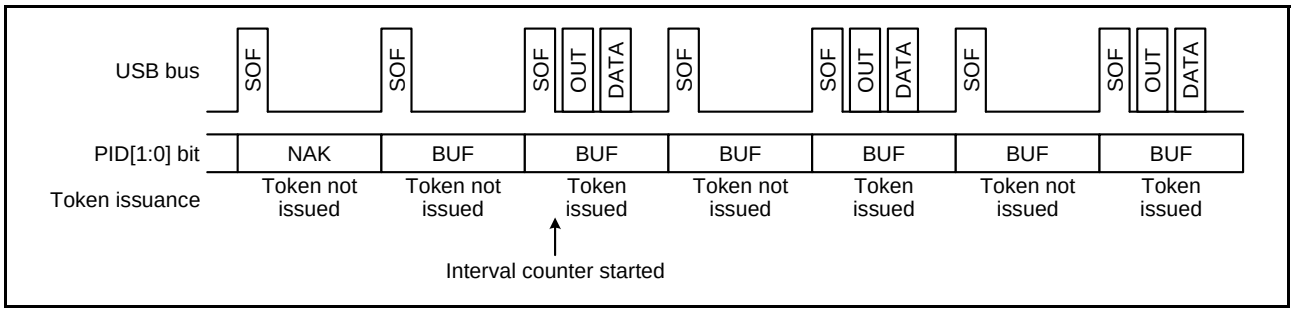

Figure 39.14 Token Issuance When IITV[2:0] Bits are 001b

When the selected pipe is set for isochronous transfers, the USBA carries out the following operation in addition to controlling the token issuance interval. The USBA issues a token even when the NRDY interrupt generation condition is satisfied.

(a) When the selected pipe is for isochronous IN transfers

The USBA generates an NRDY interrupt when the USBA issues an IN token but does not receive a packet successfully from a peripheral device (no response or packet error).
The USBA sets the FRMNUM.OVRN flag to 1 generating an NRDY interrupt when the time to issue an IN token comes while the USBA cannot receive data because the FIFO buffer is full (due to the fact that the CPU or DMAC/DTC is too slow to read data from the FIFO buffer).

(b) When the selected pipe is for isochronous OUT transfers

The USBA sets the OVRN flag to 1 generating an NRDY interrupt and transmitting a zero-length packet when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer (because the CPU or DMAC/DTC is too slow to write data to the FIFO buffer).
The token issuance interval is reset on any of the following conditions.

- When the MCU is reset
  (The IITV[2:0] bits are also set to 000b).
- When the PIPEnCTR.ACLRM bit has been set to 1.

(3) Interval Counting and Transfer Control in Function Controller Operation

(a) When the selected pipe is for isochronous OUT transfers

The USBA generates an NRDY interrupt when the USBA fails to receive a data packet during the frame over the interval set by the PIPEPERI.IITV[2:0] bits.
The USBA also generates an NRDY interrupt when the USBA fails to receive data because of a CRC error or other errors contained in the data packet or because of the FIFO buffer being full.
The NRDY interrupt is generated at the timing of SOF packet reception. Even if the SOF packet is corrupted, the internal recovery function allows the interrupt to be generated at the timing to receive the SOF packet.
However, when the IITV[2:0] bits are set to a value other than 000b, the USBA generates an NRDY interrupt on receiving an SOF packet for every interval after starting interval counting operation.
When the PID[1:0] bits are set to 00b (NAK response) after starting the interval timer, the USBA does not generate an NRDY interrupt on receiving an SOF packet.
The condition to start interval counting depends on the setting of IITV[2:0] bits as shown below.

- When the IITV[2:0] bits are 000b:
  The interval counting starts when the PID[1:0] bits of the selected pipe are modified to BUF.

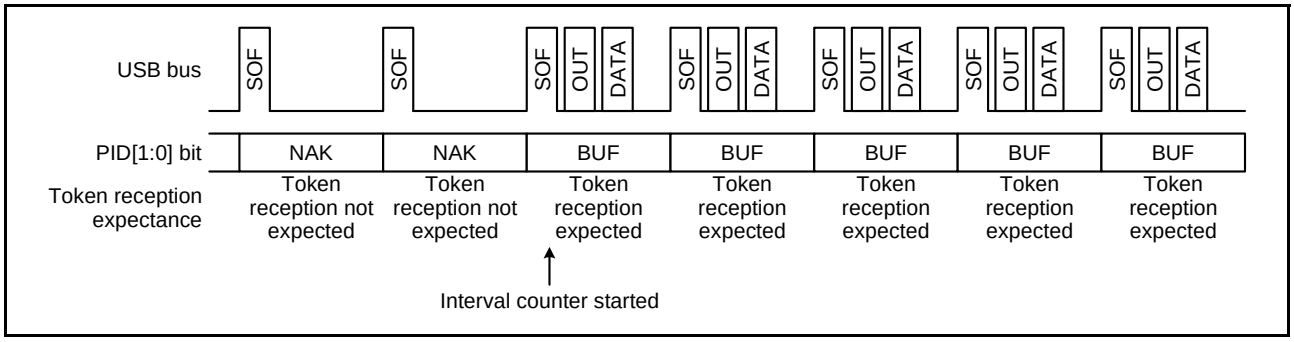

Figure 39.15 Relationship between Frames and Token Reception Expectance When the IITV[2:0] Bits are 000b

- When the IITV[2:0] bits are a value other than 000b:
  The interval counter starts on completion of successful reception of the first data packet after the PID[1:0] bits for the selected pipe have been modified to 01b (BUF response).

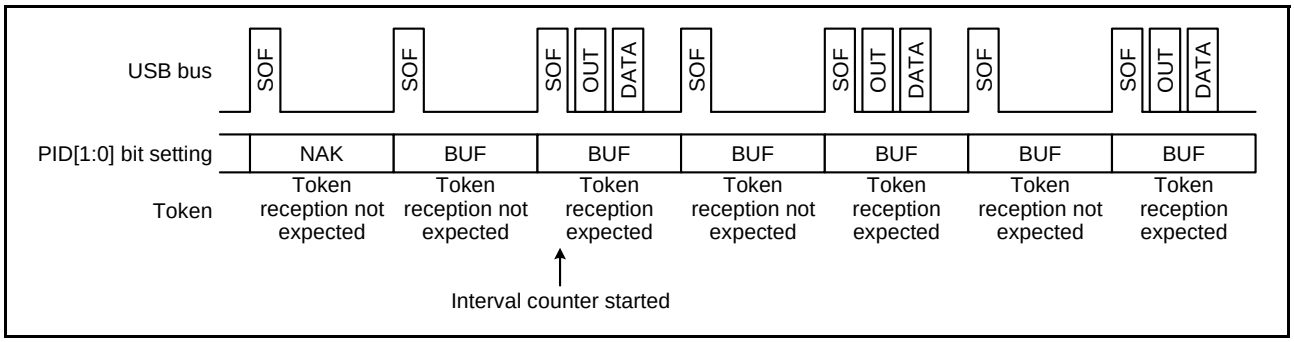

Figure 39.16 Relationship between Frames and Token Reception Expectance When the IITV[2:0] Bits are 001b

(b) When the selected pipe is for isochronous IN transfers

When the PIPEPERI.IFIS bit is cleared to 0, the USBA transmits a data packet in response to a received IN token irrespective of the setting of the PIPEPERI.IITV[2:0] bits.
When the IFIS bit is set to 1, since the FIFO buffer contains data that can be transmitted, the USBA clears the FIFO buffer if it fails to receive an IN token during the frame over the interval set by the IITV[2:0] bits.
The USBA also clears the FIFO buffer when the USBA fails to receive an IN token successfully because of a bus error such as a CRC error contained in the IN token.
The FIFO buffer is cleared at the timing of SOF packet reception. Even if the SOF packet is corrupted, the recovery function allows the FIFO buffer to be cleared at the timing to receive the SOF packet.

The timing to start interval counting depends on the setting of the IITV[2:0] bits (similar to the timing during OUT transfers).
The interval counter is cleared when any of the following conditions is fulfilled in function controller operation.

- When the MCU is reset (here, the IITV[2:0] bits are also set to 000b).
- When the PIPEnCTR.ACLRM bit is set to 1.
- When a USB bus reset is detected.

(4) Isochronous Transfer Transmit Data Setup in Function Controller Operation

In function controller operation, in the isochronous data transmission of the USBA, after data is written to the FIFO buffer, a data packet can be transmitted in the first frame after the SOF packet is detected. This function is called the isochronous transfer transmit data setup function. When double FIFO mode is used, only the one buffer that finished writing earlier can enter the transmittable state even when writing to both buffers has been completed. For this reason, even if two or more IN tokens are received in the same frame, only one packet of FIFO buffer data is transmitted.

When the FIFO buffer is ready to transmit data when an IN token is received, the data is transmitted and a normal response is returned. However, if the FIFO buffer cannot transmit data, a zero-length packet is transmitted and an underrun error occurs.

Figure 39.17 shows an example of transmission using the isochronous transfer transmit data setup function when the IITV[2:0] bits are set to 000b (each frame) by the USBA.

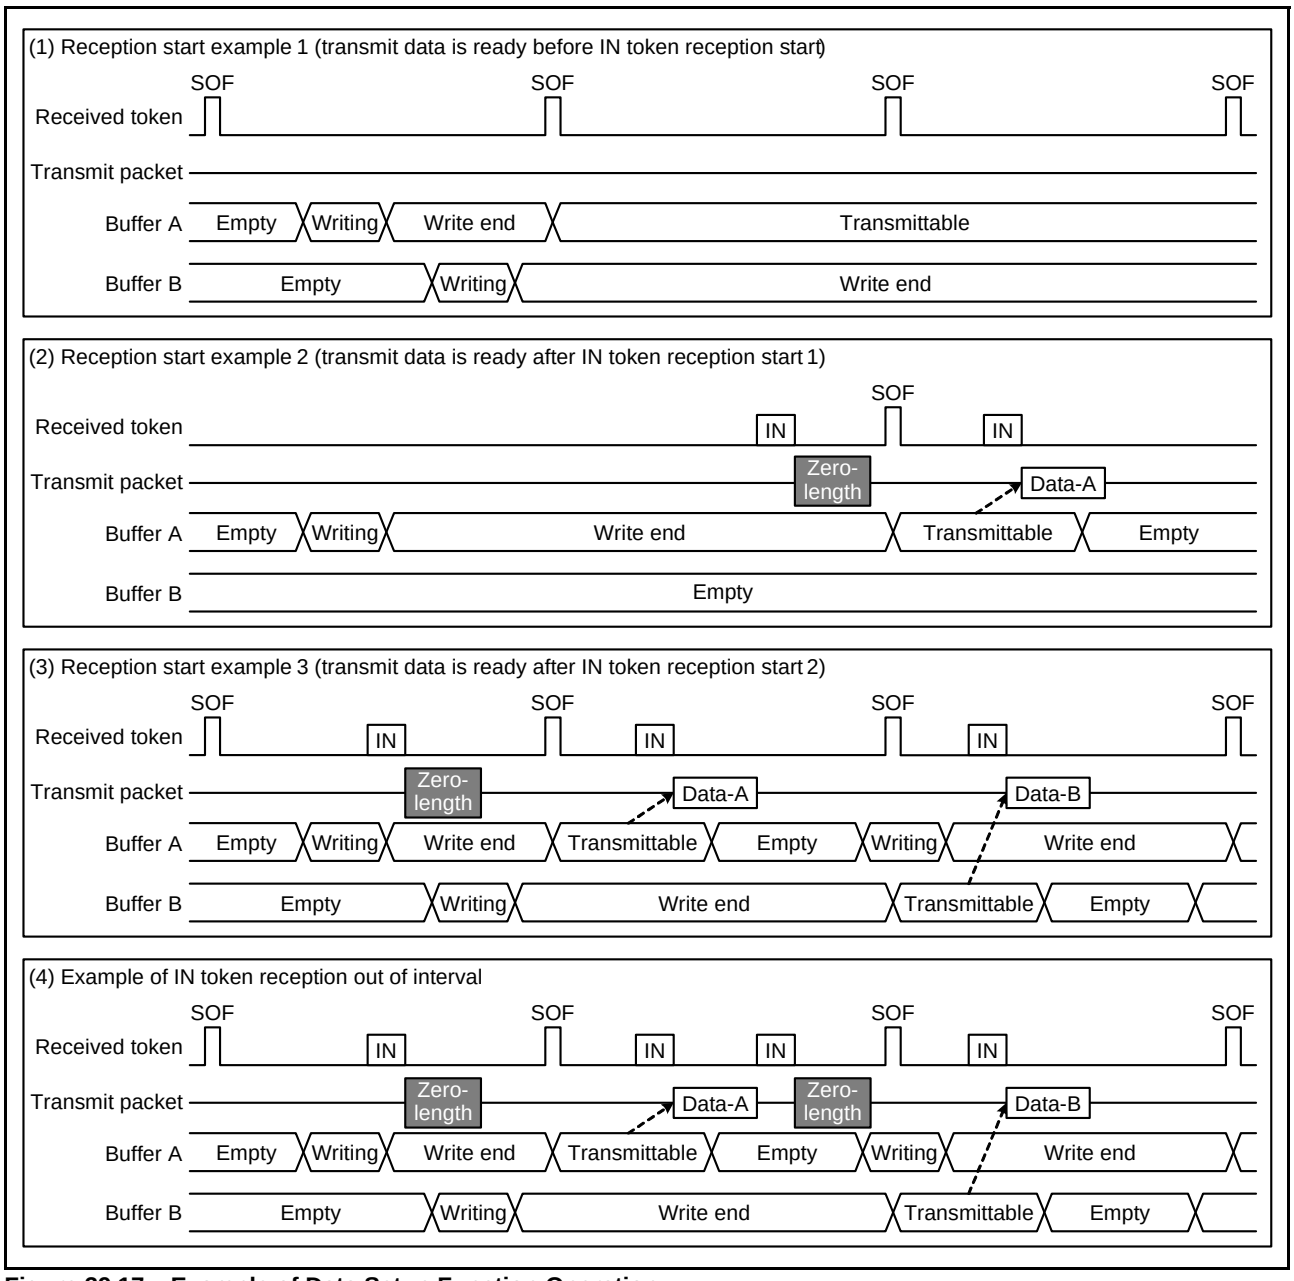

Figure 39.17 Example of Data Setup Function Operation

(5) Isochronous Transfer Transmit Buffer Flush in Function Controller Operation

In function controller operation, the USBA does not receive an IN token in the interval frame during the isochronous data transmission. When the USBA receives the SOF packet of the next frame, the USBA treats it as a corrupted IN token and clears the buffer that is ready to transmit data to make it writable.
When the double-buffer is used and data has already been written to both of the buffers, the USBA regards that the discarded FIFO buffer was transmitted in the same interval frame and makes the FIFO buffer (that is not discarded after the next SOF packet was received) transmittable.
The operation start timing of the buffer flush function varies depending on the value of the PIPEPERI.IITV[2:0] bits.

(1) When the PIPEPERI.IITV[2:0] bits are 000b, the buffer flush operation starts from the first frame after the pipe is enabled.
(2) When the PIPEPERI.IITV[2:0] bits are not 000b, the buffer flush operation starts after the first normal transaction.

Figure 39.18 shows an example of operation of the buffer flush function of the USBA. However, for tokens prior to the interval frame (out of interval), the written data or a zero-length packet as an underrun error is transmitted according to the data setup status.

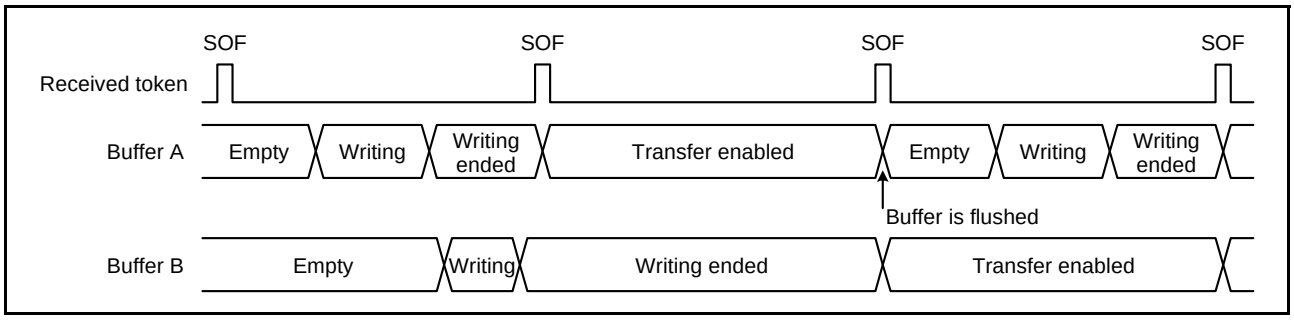

Figure 39.18 Example of Buffer Flush Operation

Figure 39.19 shows an example of occurrence of interval errors of the USBA. There are five types of interval errors ((2) to (6)) shown in the figure below. An interval error occurs at timing ① and the buffer flush function works.
Occurrence of an interval error during the IN transfer activates the buffer flush function, and occurrence of an interval error during the OUT transfer generates an NRDY interrupt.
Distinguish NRDY interrupt (such as receive packet error) from overrun error by the FRMNUM.OVRN flag.
A response according to the FIFO buffer status is returned to shaded tokens.

(1) IN token:

- When the FIFO buffer is ready to transmit data, the data is transmitted and a normal response is returned.
- When the FIFO buffer is not ready to transmit data, a zero-length packet is transmitted and an underrun error occurs.

(2) OUT token:

- When the FIFO buffer is ready to receive data, the data is received and a normal response is returned.
- When the FIFO buffer is not ready to receive data, the received data is discarded and an overrun error occurs.

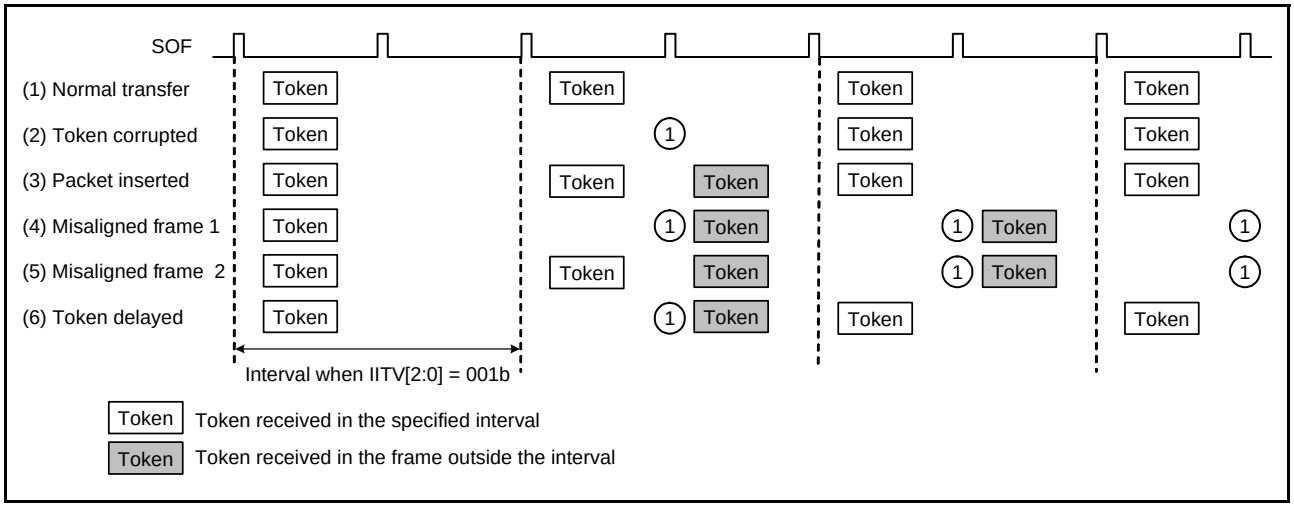

Figure 39.19 Example of Interval Error Occurrence When the PIPEPERI.IITV[2:0] Bits are 001b

39.3.13 SOF Recovery Function

In function controller operation, if an SOF packet is not received at intervals of 1 ms (full-speed operation) due to a corrupted or lost SOF packet, SOF recovery is made in the controller. The SOF recovery starts working when an SOF packet is received while the SYSCFG.USBE bit is set to 1 and the LPSTS.SUSPENDM bit is set to 1. The recovery function is initialized under the following conditions.

- MCU reset
- USB bus reset
- Detection of suspension

The SOF recovery function works with the following specifications.

(1) The frame interval (1 ms) follows the reset handshake result.
(2) The recovery function does not work until an SOF packet is received.
(3) After the first SOF packet is received, 1 ms is counted by the internal 60-MHz clock to recover SOF packets.
(4) After the second (or subsequent) SOF packet is received, SOF packets are recovered using the previous reception interval.
(5) Recovery is not made during suspension or reception of a USB bus reset.

The USBA carries out the following operations when receiving the SOF packet reception. These operations also operate normally with SOF recovery, if the SOF packet was missing.

(1) Updating frame number
(2) Frame number refresh interrupt
(3) Isochronous transfer interval count

If an SOF packet is lost during full-speed operation, the FRMNUM.FRNM[10:0] flags are not updated.

39.3.14 Pipe Schedule

39.3.14.1 Conditions for Generating a Transaction

In host controller operation, after the DVSTCTR0.UACT bit has been set to 1, the USBA generates a transaction under the conditions shown in Table 39.28.

Table 39.28 Conditions for Generating a Transaction

Transaction	Conditions for Generation				
	DIR	PID[1:0]	IITV[2:0]	Buffer State	SUREQ
Setup	— *1	— *1	— *1	— *1	Set 1
Control transfer data stage, status stage, bulk transfer	IN	BUF	— *1	Receive area exists	— *1
	OUT	BUF	— *1	Transmit data exists	— *1
Interrupt transfer	IN	BUF	Valid *2	Receive area exists	— *1
	OUT	BUF	Valid *2	Transmit data exists	— *1
Isochronous transfer	IN	BUF	Valid *2	See note 3	— *1
	OUT	BUF	Valid *2	See note 4	— *1

Note 1. The hyphen (—) in the table indicates that the condition is unrelated to the generating of tokens.
Note 2. "Valid" indicates that, for interrupt transfers and isochronous transfers, a transaction is generated only in transfer frames that are based on the interval counter.
Note 3. A transaction is generated regardless of whether there is a receive area. If there is no receive area, however, the received data is discarded.
Note 4. A transaction is generated regardless of whether there is any data to be transmitted. If there is no data to be transmitted, however, a zero-length packet is transmitted.

39.3.14.2 Transfer Schedule

This section describes the transfer scheduling within a frame of the USBA. After the USBA transmits an SOF packet, the transfer is carried out in the sequence described below.

1. Execution of interrupt transfers and isochronous transfers
   A pipe is searched in the order of Pipe 1 → Pipe 2 → Pipe 6 → Pipe 7 → Pipe 8 → Pipe 9, and then, if there is a pipe for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.
2. Setup transactions for control transfers
   If a setup transaction is possible, it is transmitted.
3. Execution of bulk transfers, control transfer data stages, and control transfer status stages
   A pipe is searched in the order of default control pipe → Pipe 1 → Pipe 2 → Pipe 3 → Pipe 4 → Pipe 5, and then, if there is a pipe for which a transaction for a bulk transfer, a control transfer data stage, or a control transfer status stage can be generated, the transaction is generated.
   When a transaction is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral device is ACK or NAK. If there is time for transfer within the frame, step 3 is repeated.

39.3.14.3 Enabling USB Communication

Setting the DVSTCTR0.UACT bit to 1 initiates SOF packet transmission and transaction generation is enabled. Setting the UACT bit to 0 stops SOF packet transmission and the USBA enters the suspend state. If the setting of the UACT bit is changed from 1 to 0, processing stops after the next SOF packet is transmitted.

39.3.15 Battery Charging Detection Processing

Data Contact Detect processing (checking D+ line contact), Primary Detection processing (charger detection processing), and Secondary Detection processing (charger determination processing) defined by Battery Charging Specification Revision 1.2 can be controlled.
Sections 39.3.15.1 and 39.3.15.2 describe operations in host controller operation and function controller operation.

39.3.15.1 Processing in Function Controller Operation

To operate a USBA as a battery charging Portable Device, the following processing is required. Figure 39.20 shows the processing flowchart.

(1) VBUS supply is detected by the VBUS interrupt and VBSTS flag.

(2) Start Primary Detection processing after detecting contact with the D+ and D– lines. Battery Charging Specification Revision 1.2 describes two processing methods for Data Contact Detect. The USBA supports both methods in the ways described below.

- Software wait
  Perform a 300 to 900 ms software wait
- Detecting contact by hardware
  Apply 7 to 13 µA of current to the D+ line to hold the D+ line at the logical high level. This is done to detect the D+ and D– lines going to the logical low level due to pull-down resistors in the host when the D+ and D– lines come in contact with those of the host. The USBA sets the BCCTRL.IDPSRCE bit to 1 and sets the D+ line high. When the D+ line is detected as becoming low by the SYSSTS0.LNST[1:0] bits, the BCCTRL.IDPSRCE bit is set to 0.

(3) Set the BCCTRL.VDPSRCE bit and BCCTRL.IDPSRCE bit to 1 simultaneously to start the Primary Detection processing. Then, perform a 40 ms software wait, and check the BCCTRL.CHGDETSTS flag. If the CHGDETSTS flag is 1, it is determined that a charger is detected, and the BCCTRL.VDPSRCE and BCCTRL.IDPSRCE bits are set to 0.

(4) Set the BCCTRL.VDPSRCE bit and BCCTRL.IDPSRCE bit to 1 simultaneously to start the Secondary Detection processing. Then, perform a 40 ms software wait, check the BCCTRL.PDDETSTS flag, and determine the result of the Secondary Detection processing.

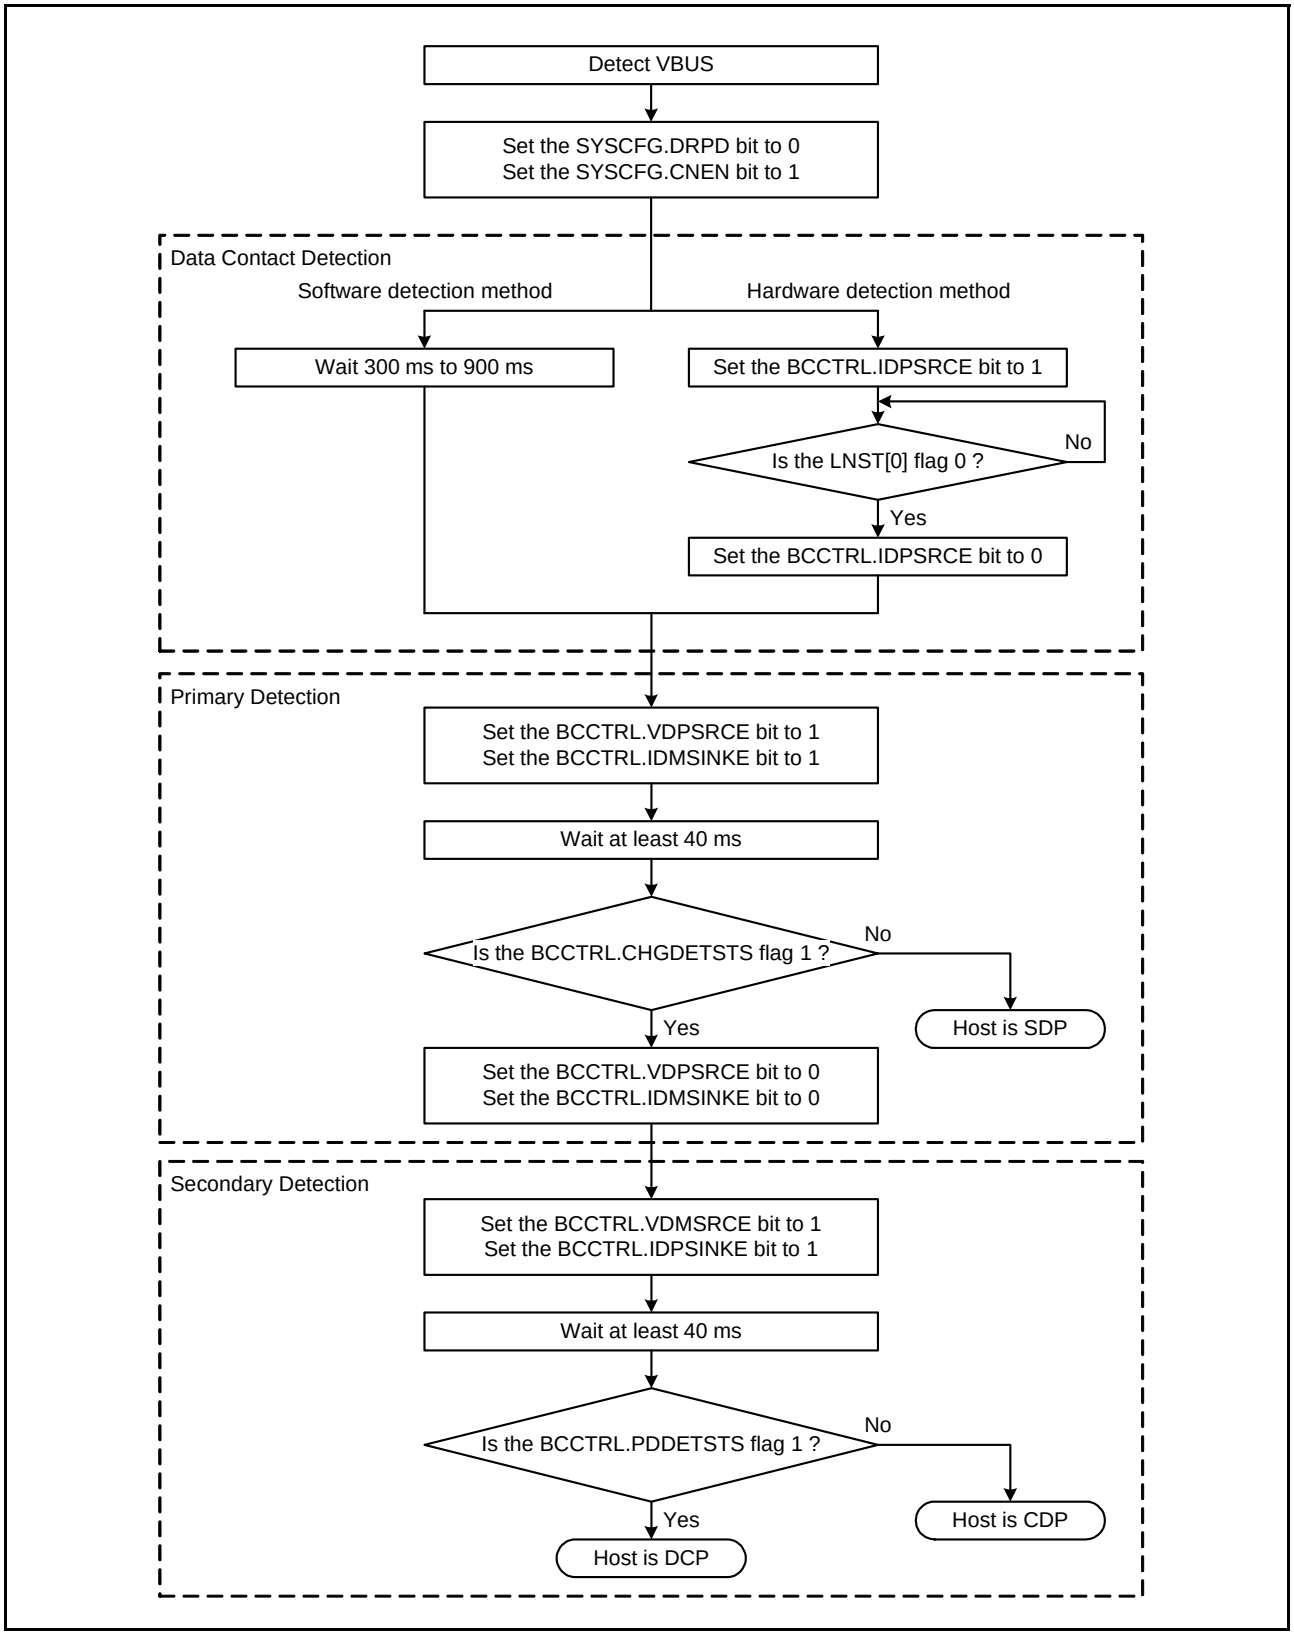

Figure 39.20 Processing as a Portable Device

39.3.15.2 Processing in Host Controller Operation

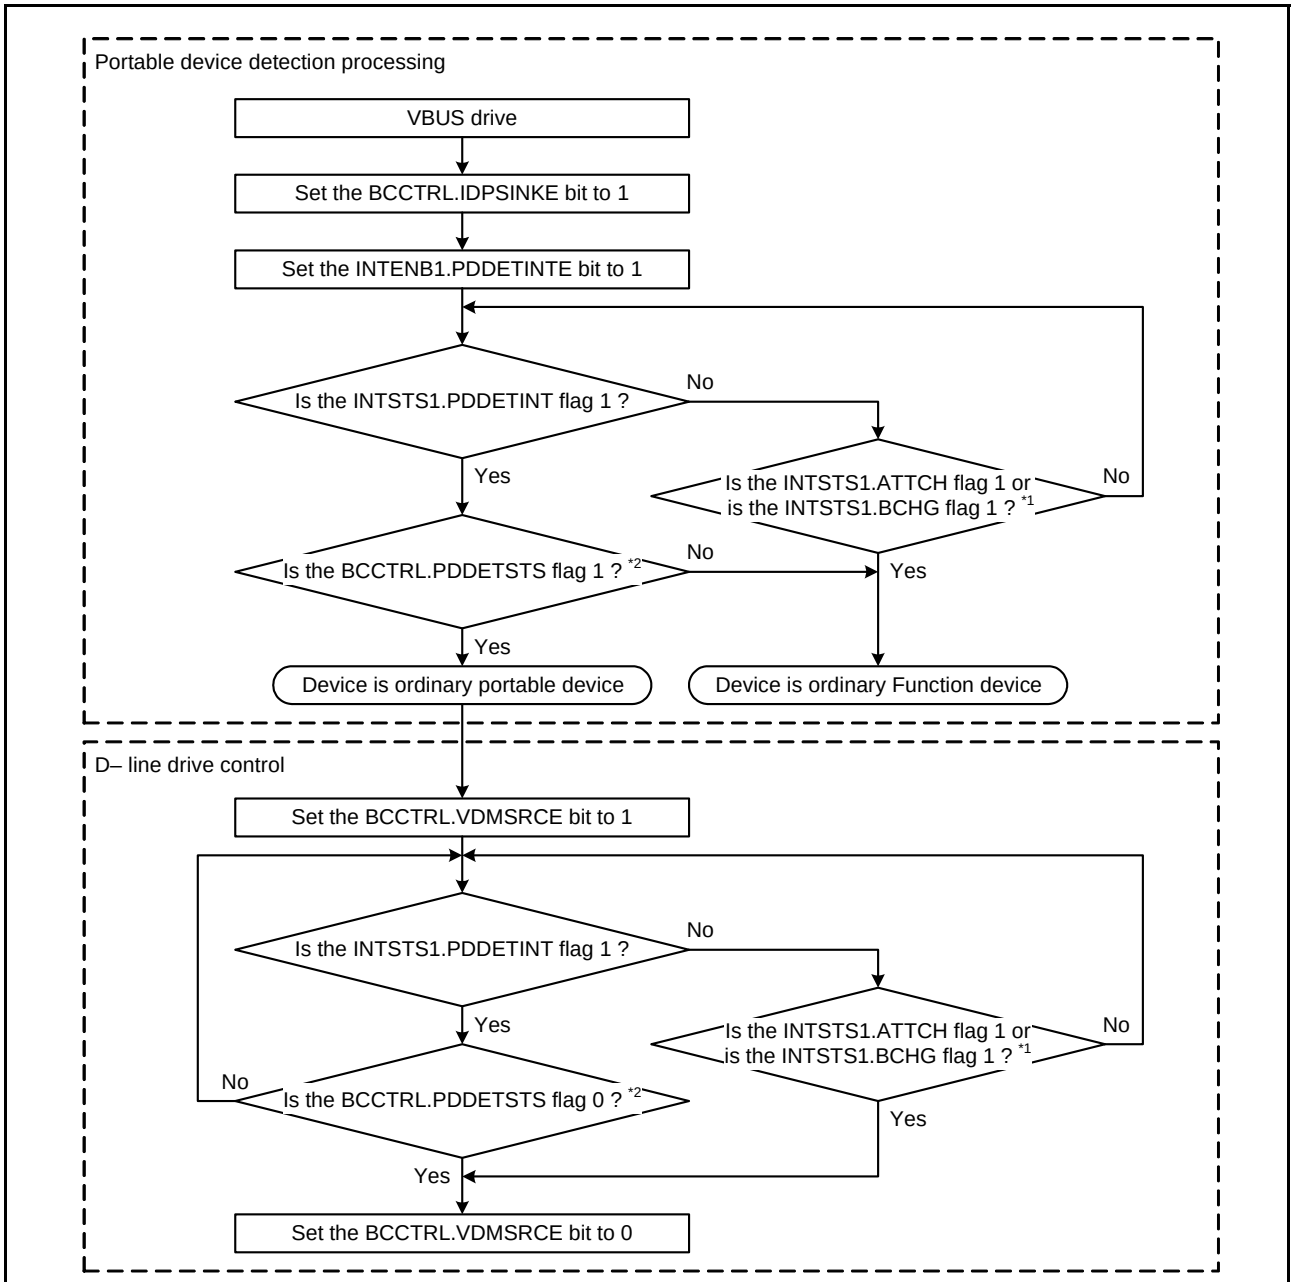
In host controller operation, driving the D– line is required for a Portable Device to implement Primary Detection. Two Primary Detection methods are provided: one for when the hardware has a Portable Device detection function and the other for when the hardware does not have the function or the function is not used even though the hardware has it. Figure 39.21 and Figure 39.22 show processing for the respective methods.

- When using the Portable Device detection function
  The D– line is driven when a Portable Device is detected.

(1) Start driving the VBUS.
(2) Set the BCCTRL.IDMSINKE bit to 1 to enable the Portable Device detection circuit.
(3) Read the BCCTRL.PDDETSTS flag in the Portable Device detection interrupt processing. If the PDDETSTS flag is 1, set the BCCTRL.VDMSRCE bit to 1.
(4) When the BCCTRL.PDDETSTS flag is read in the Portable Device detection interrupt processing after driving the D– line, if the PDDETSTS flag is 0, set the BCCTRL.VDMSRCE bit to 0.

- When not using the Portable Device detection function
  Regardless of whether or not a Portable Device was detected, drive the D– line after device disconnection is detected, and leave the D– line open after connection is detected. Software handles the timing of (1) and (2).

(1) After device disconnection is detected, start driving the D– line within 200 ms.
(2) After device connection is detected, stop driving the D– line within 10 ms.



Note 1. If the PHY clock is being supplied (LPSTS.SUSPENDM bit is 1), the determination is made by the device connection detection interrupt; if the clock is stopped (SUSPENDM bit is 0), the determination is made by the bus change interrupt and the SYSSTS0.LNST[1:0] flags.
Note 2. Read the flag several times to eliminate chattering.

Figure 39.21 Processing Flow When Using the Portable Device Detection Function

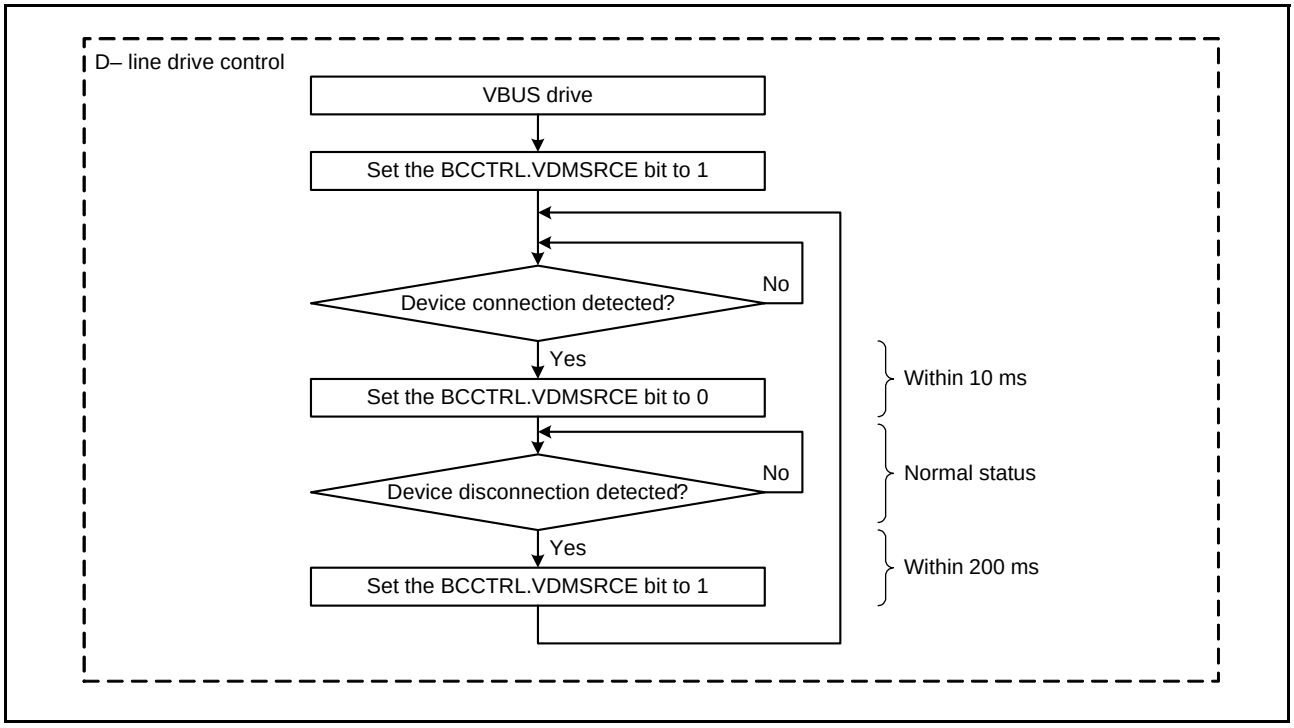


Figure 39.22 Processing Flow When Not Using Portable Device Detection Function

39.3.16 Link Power Management Processing

The Link Power Management standard defines the existing suspended state as the L2 state, and newly defines the L1 state as a state that can be entered into and exited from faster than the L2 state. Table 39.29 is a Comparison of the L1 State and L2 State.

Table 39.29 Comparison of the L1 State and L2 State

Item	L1 State	L2 State
Transition	LPM transaction	Idle for 3 ms
Exit caused by host	(1) Host Drive the K state for a period specified by the HIRD[3:0] bits. Drive period can be specified from 75 µs to 9.96 ms. (2) Function Exits within 10 µs	(1) Host Drive the K state for at least 20 ms (2) Function Exits within 10 ms
Exit caused by function	(1) Function Drive the K state for 50 µs (2) Host Drive the K state for 60 to 990 µs	(1) Function Drive the K state for 1 to 15 ms (2) Host Drive the K state for at least 20 ms
Signaling	Low- and full-speed idle	Low- and full-speed idle
Enabling remote wakeup	Specified by the LPM token	Specified by the SetFeature() request

39.3.16.1 Processing in Function Controller Operation

(1) Contents of the Descriptor

In function controller operation, the USBA must return its Descriptor when a GetDescriptor() request is received. The content of the Descriptor to be returned must be modified depending on whether the USBA accepts or denies transition to or exit from the L1 state according to the LPM transaction. Table 39.30 shows the Relationship Between LPM Support and the Descriptor.

Table 39.30 Relationship Between LPM Support and the Descriptor

LPM Support	*bcdUSB* Field	USB 2.0 Extension Descriptor		Response to Received LPM Request	Note
		Provided/ Not provided	LPM bit		
No	0200h	Not provided	—	No response	Normal operation when the LPM is not supported
	0201h	Provided	0	STALL	Setting when it is obvious that LPM is not supported. In this case, a STALL response must be returned.
Yes	0201h	Provided	1	ACK or NYET	Normal operation when the LPM is supported

The LPM bit in USB 2.0 Extension Descriptor declares whether the USBA accepts or denies transition to or exit from the L1 state. To provide USB 2.0 Extension Descriptor, the *bcdUSB* field of the Standard Device Descriptor must be set to a value of 0201h or larger.

When the LPM is not supported, the USB 2.0 Extension Descriptor is not provided and the *bcdUSB* field value must be 0200h. Even if an LPM token is received in this case, it must be ignored.

When the LPM is not clearly supported, it is also possible to set *bcdUSB* field value to 0201h and the LPM bit in USB 2.0 Extension Descriptor to 0 (no support for the LPM token). In this case, however, the LPM token cannot be ignored and a STALL response must be returned.

When the LPM token is supported, set *bcdUSB* field value to 0201h and set the LPM bit in USB 2.0 Extension Descriptor to 1 (supports the LPM token). This allows acknowledgment of returning a NYET or ACK response to the LPM token.

(2) Processing When Receiving an LPM Token

The following describes the procedure to enter and exit the L1 state in function controller operation.

(1) When the USBA receives an LPM token from the host, the settings of the PL1CTRL1.L1RESPEN, L1RESPMD[1:0], and L1NEGOMD bits determines whether to return an ACK, NYET, or STALL response, or ignore.

(2) When an LPM token is received and an ACK response is returned, if the LPM token is not retransmitted within 8 µs, the USBA enters the L1 state. The USBA processes retransmission of the LPM token and transition to the L1 state. The device state transition interrupt can be used to detect the transition to the L1 state.

(3) There are two types of processing for exiting the L1 state:

- When the host starts the resume:
  When the resume signal is detected, the resume interrupt is generated and the function starts processing to exit the L1 state.
- When the function outputs a remote wakeup signal:
  If the DVSTCTR0.WKUP bit is set to 1, a remote wakeup signal is output to the host. When exiting the L2 state, the DVSTCTR0.WKUP bit must be set to 0 by software, but the USBA sets the DVSTCTR0.WKUP bit to 0 when exiting from the L1 state.

(3) BESL Field Value Negotiation Function

The BESL field value included in the LPM token is the period that the outputs the resume signal when returning from the L1 state. The BESL field value can be adjusted to accommodate the target system. For example, a low HIRD threshold value must be set for a system that focuses on improving transfer efficiency, while a high HIRD threshold value must be set for a system that focuses on low power consumption.

As per the PL1CTRL1.L1NEGOMD and HIRDTHR[3:0] bit settings, an ACK response or NYET response is returned when the received BESL field value is compared to the HIRD threshold value, and a request can be made to the host to modify the BESL field value.

39.3.16.2 Processing in Host Controller Operation

(1) Processing When Transmitting an LPM Token

The following describes the procedure to enter and exit the L1 state in host controller operation.

(1) When the HL1CTRL1.L1REQ bit is set to 1, an LPM token is transmitted from the host to the function.

(2) If an ACK response is received from the function, a transition to the L1 state starts within 10 µs and is completed within 50 µs. In this case, if a transaction error is detected, the LPM token starts retransmitting within 8 µs. Retransmission can be performed up to two times. The USBA controls all of this processing.

(3) There are two types of processing for returning from the L1 state.

- When the host starts the resume:
  When the DVSTCTR0.RESUME bit is set to 1, the USBA starts outputting the resume signal and starts the processing to exit the L1 state.
- When the function outputs a remote wakeup signal:
  When the USBA detects a remote wakeup signal being output from the function, the USBA sets the DVSTCTR0.RESUME bit *1 to 1 and starts outputting the resume signal.

Note 1. Unlike exiting from the L2 state, the USBA sets the DVSTCTR0.RESUME bit to 0. When the RESUME bit becomes 0, the DVSTCTR0.UACT bit becomes 1, and the L1RSMEND interrupt request is generated.

39.3.17 USB External Connection Circuit

Figure 39.23 shows an example of the USB Connector's OTG Connection in Self Powered Mode.
The USBA controls the pull-up resistor of the D+ line, and the pull-down resistor of the D+ and D– lines. Set the SYSCFG.DPRPU bit and DRPD bit to specify pull-up or pull-down for each line.
In addition, in function control operation, if the DPRPU bit is set to 0 while communicating with the USB host, the pull-up resistor for the USB data line becomes invalid, and the USB host can be notified of a device disconnection.

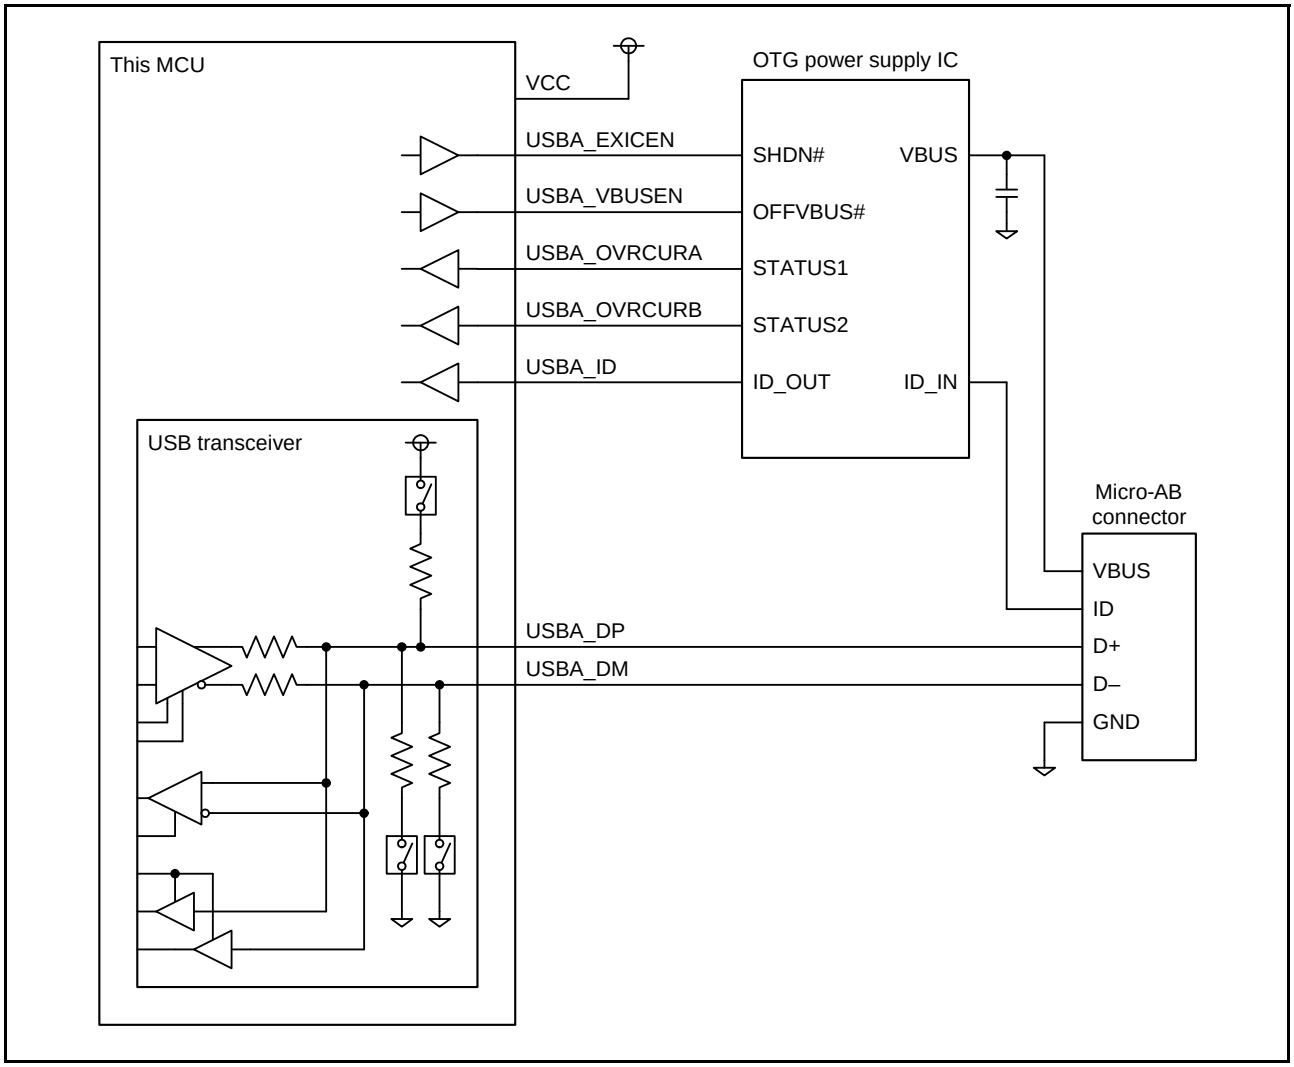

Figure 39.23 USB Connector's OTG Connection in Self Powered Mode

39.4 Notes on Using the USBA

39.4.1 Setting the USBA Module Stop Function

Set the MSTPCRB.MSTPB12 bit to start or stop USBA operation. The USBA is stopped after a reset. Registers in the USBA can be accessed by setting the MSTPCRB.MSTPB12 bit to 1 (module-stop state is canceled). After enabling access to USBA registers, when operating the PHY circuit, configure settings for items such as the input system clock frequency, and then set the PHYSET.DIRPD bit to 0. Refer to section 11, Low Power Consumption for details.

39.4.2 Setting to Transition to Deep Software Standby Mode

Before transitioning to deep software standby mode, clear the DVSTCTR0.VBUSEN bit to 0.

40. Serial Communications Interface (SCIg, SCIh)

This MCU has nine independent serial communications interface (SCI) channels. The SCI consists of the SCIg module (SCI0 to SCI7) and the SCIh module (SCI12).
The SCIg module (SCI0 to SCI7) can handle both asynchronous and clock synchronous serial communications. Asynchronous serial data communications can be carried out with standard asynchronous communications chips such as a Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communications Interface Adapter (ACIA). As an extended function in asynchronous communications mode, the SCI also supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards). The SCI is also supports simple SPI interfaces, and simple I^2C-bus interfaces when configured for single-master systems.
The SCIh module includes the functions of the SCIg module, and supports an extended serial communication protocol formed of Start Frames and Information Frames.
In this section, “PCLK” is used to refer to PCLKB.

40.1 Overview

Table 40.1 lists the specifications of the SCIg module, Table 40.2 lists the specifications of the SCIh module, and Table 40.3 lists the specifications of the individual SCI channels.
Figure 40.1 and Figure 40.2 show the block diagrams of the SCIg module, and Figure 40.3 shows the block diagram of the SCIh module.

Table 40.1 SCIg Specifications (1/2)

Item		Description
Serial communication modes		• Asynchronous • Clock synchronous • Smart card interface • Simple I^2C-bus • Simple SPI bus
Transfer speed		Bit rate specifiable with the on-chip baud rate generator.
Full-duplex communications		Transmitter: Continuous transmission possible using double-buffer structure. Receiver: Continuous reception possible using double-buffer structure.
I/O pins		Refer to Table 40.4 to Table 40.6.
Data transfer		Selectable as LSB first or MSB first transfer*1
Interrupt sources		Transmit end, transmit data empty, receive data full, and receive error Completion of generation of a start condition, restart condition, or stop condition (for simple I^2C mode)
Low power consumption function		Module stop state can be set for each channel.
Asynchronous mode	Data length	7, 8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Parity	Even parity, odd parity, or no parity
	Receive error detection	Parity, overrun, and framing errors
	Hardware flow control	CTSn# and RTSn# pins can be used in controlling transmission/reception.
	Start-bit detection	Low level or falling edge is selectable.
	Break detection	When a framing error occurs, a break can be detected by reading the RXDn pin level directly.
	Clock source	An internal or external clock can be selected. Transfer rate clock input from the TMR can be used. (SCI5, SCI6)
	Double-speed mode	Baud rate generator double-speed mode is selectable.
	Multi-processor communications function	Serial communication among multiple processors
	Noise cancellation	The signal paths from input on the RXDn pins incorporate digital noise filters.

Table 40.1 SCIg Specifications (2/2)

Item		Description
Clock synchronous mode	Data length	8 bits
	Receive error detection	Overrun error
	Hardware flow control	CTSn# and RTSn# pins can be used in controlling transmission/reception.
Smart card interface mode	Error processing	An error signal can be automatically transmitted when detecting a parity error during reception
		Data can be automatically retransmitted when receiving an error signal during transmission
	Data type	Both direct convention and inverse convention are supported.
Simple I2C mode	Transfer format	I2C-bus format
	Operating mode	Master (single-master operation only)
	Transfer rate	Fast mode is supported (refer to section 40.2.11, Bit Rate Register (BRR) to set the transfer rate).
	Noise cancellation	The signal paths from input on the SSCLn and SSDAn pins incorporate digital noise filters, and the interval for noise cancellation is adjustable.
Simple SPI bus	Data length	8 bits
	Detection of errors	Overrun error
	SS input pin function	Applying the high level to the SSn# pin can cause the output pins to enter the high-impedance state.
	Clock settings	Four kinds of settings for clock phase and clock polarity are selectable.
Bit rate modulation function		Correction of outputs from the on-chip baud rate generator can reduce errors.
Event link function (supported by SCI5 only)		Error (receive error or error signal detection) event output
		Receive data full event output
		Transmit data empty event output
		Transmit end event output

Note 1. In simple I2C mode, only MSB first is available.

Table 40.2 SCIh Specifications (1/2)

Item	Description
Serial communication modes	• Asynchronous • Clock synchronous • Smart card interface • Simple I2C-bus • Simple SPI bus
Transfer speed	Bit rate specifiable with the on-chip baud rate generator.
Full-duplex communications	Transmitter: Continuous transmission possible using double-buffer structure. Receiver: Continuous reception possible using double-buffer structure.
I/O pins	Refer to Table 40.4 to Table 40.7.
Data transfer	Selectable as LSB first or MSB first transfer*1
Interrupt sources	Transmit end, transmit data empty, receive data full, and receive error Completion of generation of a start condition, restart condition, or stop condition (for simple I2C mode)
Low power consumption function	Module stop state can be set.

Table 40.2 SCIh Specifications (2/2)

Item		Description
Asynchronous mode	Data length	7, 8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Parity	Even parity, odd parity, or no parity
	Receive error detection	Parity, overrun, and framing errors
	Hardware flow control	CTSn# and RTSn# pins can be used in controlling transmission/reception.
	Start-bit detection	Low level or falling edge is selectable.
	Break detection	When a framing error occurs, a break can be detected by reading the RXDn pin level directly.
	Clock source	An internal or external clock can be selected. Transfer rate clock input from the TMR can be used. (SCI12)
	Double-speed mode	Baud rate generator double-speed mode is selectable.
	Multi-processor communications function	Serial communication among multiple processors
	Noise cancellation	The signal paths from input on the RXDn pins incorporate digital noise filters.
Clock synchronous mode	Data length	8 bits
	Receive error detection	Overrun error
	Hardware flow control	CTSn# and RTSn# pins can be used in controlling transmission/reception.
Smart card interface mode	Error processing	An error signal can be automatically transmitted when detecting a parity error during reception
		Data can be automatically retransmitted when receiving an error signal during transmission
	Data type	Both direct convention and inverse convention are supported.
Simple I^2C mode	Transfer format	I^2C-bus format
	Operating mode	Master (single-master operation only)
	Transfer rate	Fast mode is supported (refer to section 40.2.11, Bit Rate Register (BRR) to set the transfer rate).
	Noise cancellation	The signal paths from input on the SSCLn and SSDAn pins incorporate digital noise filters, and the interval for noise cancellation is adjustable.
Simple SPI bus	Data length	8 bits
	Detection of errors	Overrun error
	SS input pin function	Applying the high level to the SSn# pin can cause the output pins to enter the high-impedance state.
	Clock settings	Four kinds of settings for clock phase and clock polarity are selectable.
Extended serial mode	Start Frame transmission	• Output of a low level as the Break Field over a specified width and generation of interrupts on completion • Detection of bus collisions and the generation of interrupts on detection
	Start Frame reception	• Detection of the Break Field low width and generation of an interrupt on detection • Comparison of Control Fields 0 and 1 and generation of an interrupt when the two match • Two kinds of data for comparison (primary and secondary) can be set in Control Field 1. • A priority interrupt bit can be set in Control Field 1. • Handling of Start Frames that do not include a Break Field • Handling of Start Frames that do not include a Control Field • Function for measuring bit rates
	I/O control function	• Selectable polarity for TXDX12 and RXDX12 signals • Selection of a digital filter for the RXDX12 signal • Half-duplex operation employing RXDX12 and TXDX12 signals multiplexed on the same pin • Selectable timing for the sampling of data received through RXDX12 • Signals received on RXDX12 can be passed though to SCIg when the extended serial mode control section is off.
	Timer function	• Usable as a reloading timer
Bit rate modulation function		Correction of outputs from the on-chip baud rate generator can reduce errors.

Note 1. In simple I^2C mode, only MSB first is available.

	SIOX12	I/O	SCI12 transfer data input/output

40.2 Register Descriptions

40.2.1 Receive Shift Register (RSR)

RSR is a shift register which is used to receive serial data input from the RXDn pin and converts it into parallel data.
When one frame of data has been received, it is automatically transferred to the RDR register.
The RSR register cannot be directly accessed by the CPU.

40.2.2 Receive Data Register (RDR)

Address(es): SCI0.RDR 0008 A005h, SCI1.RDR 0008 A025h, SCI2.RDR 0008 A045h, SCI3.RDR 0008 A065h, SCI4.RDR 0008 A085h, SCI5.RDR 0008 A0A5h, SCI6.RDR 0008 A0C5h, SCI7.RDR 0008 A0E5h, SCI12.RDR 0008 B305h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

RDR is an 8-bit register that stores receive data.
When one frame of serial data has been received, the received serial data is transferred from RSR to RDR. Then the RSR register can receive the next data.
Since RSR and RDR function as a double buffer in this way, continuous receive operations can be performed.
Read RDR only once after a receive data full interrupt (RXI) has occurred. Note that if next one frame of data is received before reading receive data from RDR, an overrun error occurs.
RDR cannot be written to by the CPU.

40.2.3 Receive Data Register H, L, HL (RDRH, RDRL, RDRHL)

- Receive Data Register H (RDRH)

Address(es): SCI0.RDRH 0008 A010h, SCI1.RDRH 0008 A030h, SCI2.RDRH 0008 A050h, SCI3.RDRH 0008 A070h, SCI4.RDRH 0008 A090h, SCI5.RDRH 0008 A0B0h, SCI6.RDRH 0008 A0D0h, SCI7.RDRH 0008 A0F0h, SCI12.RDRH 0008 B310h

- Receive Data Register L (RDRL)

Address(es): SCI0.RDRL 0008 A011h, SCI1.RDRL 0008 A031h, SCI2.RDRL 0008 A051h, SCI3.RDRL 0008 A071h, SCI4.RDRL 0008 A091h, SCI5.RDRL 0008 A0B1h, SCI6.RDRL 0008 A0D1h, SCI7.RDRL 0008 A0F1h, SCI12.RDRL 0008 B311h

- Receive Data Register HL (RDRHL)

Address(es): SCI0.RDRHL 0008 A010h, SCI1.RDRHL 0008 A030h, SCI2.RDRHL 0008 A050h, SCI3.RDRHL 0008 A070h, SCI4.RDRHL 0008 A090h, SCI5.RDRHL 0008 A0B0h, SCI6.RDRHL 0008 A0D0h, SCI7.RDRHL 0008 A0F0h, SCI12.RDRHL 0008 B310h

	RDRHL															
	RDRH								RDRL							
	b7	b6	b5	b4	b3	b2	b1	b0	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RDRH and RDRL are 8-bit registers that store receive data. Use these registers when asynchronous mode and 9-bit data length are selected.

RDRL is the shadow register of RDR; i.e. access to RDRL is equivalent to access to RDR.

After one frame of data is received, the received data is transferred from the RSR register to these registers, thus allowing the RSR register to receive the next data.

The RSR, RDRH and RDRL registers have a double-buffered construction to enable continuous reception.

Read RDRH and RDRL should be performed only once in the order from RDRH to RDRL when a receive data full interrupt (RXI) request is issued. Note that an overrun error occurs when the next frame of data is received before the received data has been read from RDRL.

The CPU cannot write to the RDRH and RDRL registers. Bits 0 to 7 in RDRH are fixed to 0. These bits are read as 0.

The RDRHL register can be accessed in 16-bit units.

40.2.4 Transmit Data Register (TDR)

Address(es): SCI0.TDR 0008 A003h, SCI1.TDR 0008 A023h, SCI2.TDR 0008 A043h, SCI3.TDR 0008 A063h, SCI4.TDR 0008 A083h, SCI5.TDR 0008 A0A3h, SCI6.TDR 0008 A0C3h, SCI7.TDR 0008 A0E3h, SCI12.TDR 0008 B303h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

TDR is an 8-bit register that stores transmit data.

When the SCI detects that the TSR register is empty, it transfers the transmit data written in the TDR register to the TSR register and starts transmission.

The double-buffered structures of the TDR register and the TSR register enable continuous serial transmission. If the next transmit data has already been written to the TDR register when one frame of data is transmitted, the SCI transfers the written data to the TSR register to continue transmission.

The CPU is able to read from or write to the TDR register at any time. Only write transmit data to the TDR register once after each instance of the transmit data empty interrupt (TXI).

40.2.5 Transmit Data Register H, L, HL (TDRH, TDRL, TDRHL)

- Transmit Data Register H (TDRH)

Address(es): SCI0.TDRH 0008 A00Eh, SCI1.TDRH 0008 A02Eh, SCI2.TDRH 0008 A04Eh, SCI3.TDRH 0008 A06Eh, SCI4.TDRH 0008 A08Eh, SCI5.TDRH 0008 A0AEh, SCI6.TDRH 0008 A0CEh, SCI7.TDRH 0008 A0EEh, SCI12.TDRH 0008 B30Eh

- Transmit Data Register L (TDRL)

Address(es): SCI0.TDRL 0008 A00Fh, SCI1.TDRL 0008 A02Fh, SCI2.TDRL 0008 A04Fh, SCI3.TDRL 0008 A06Fh, SCI4.TDRL 0008 A08Fh, SCI5.TDRL 0008 A0AFh, SCI6.TDRL 0008 A0CFh, SCI7.TDRL 0008 A0EFh, SCI12.TDRL 0008 B30Fh

- Transmit Data Register HL (TDRHL)

Address(es): SCI0.TDRHL 0008 A00Eh, SCI1.TDRHL 0008 A02Eh, SCI2.TDRHL 0008 A04Eh, SCI3.TDRHL 0008 A06Eh, SCI4.TDRHL 0008 A08Eh, SCI5.TDRHL 0008 A0AEh, SCI6.TDRHL 0008 A0CEh, SCI7.TDRHL 0008 A0EEh, SCI12.TDRHL 0008 B30Eh

	TDRHL															
	TDRH								TDRL							
	b7	b6	b5	b4	b3	b2	b1	b0	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

TDRH and TDRL are 8-bit registers that store transmit data. Use these registers when asynchronous mode and 9-bit data length are selected.

TDRL is the shadow register of TDR; i.e. access to TDRL is equivalent to access to TDR.

When empty space is detected in the TSR register, the transmit data stored in the TDRH and TDRL registers is transferred to TSR; i.e., transmitting is started.

The TSR, TDRH and TDRL registers have a double-buffered construction to realize continuous reception. When the next data to be transmitted is stored in the TDRL register after one frame of data has been transmitted, the transmitting operation is continued by transfer to the TSR register.

The CPU can read and write to the TDRH and TDRL registers. Bits 0 to 7 in RDRH are fixed to 1. These bits are read as 1. The write value should be 1.

Writing transmit data to the TDRH and TDRL registers should be performed only once in the order from TDRH to TDRL when a transmit data empty interrupt (TXI) request is issued.

The TDRHL register can be accessed in 16-bit units.

40.2.6 Transmit Shift Register (TSR)

TSR is a shift register that transmits serial data.

To perform serial data transmission, the SCI first automatically transfers transmit data from TDR to TSR, and then sends the data to the TXDn pin.

TSR cannot be directly accessed by the CPU.

40.2.7 Serial Mode Register (SMR)

Note: Some bits in SMR have different functions in smart card interface mode and non-smart card interface mode.

(1) Non-Smart Card Interface Mode (SCMR.SMIF = 0)

Address(es): SCI0.SMR 0008 A000h, SCI1.SMR 0008 A020h, SCI2.SMR 0008 A040h, SCI3.SMR 0008 A060h, SCI4.SMR 0008 A080h, SCI5.SMR 0008 A0A0h, SCI6.SMR 0008 A0C0h, SCI7.SMR 0008 A0E0h, SCI12.SMR 0008 B300h

	b7	b6	b5	b4	b3	b2	b1	b0
	CM	CHR	PE	PM	STOP	MP	CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKS[1:0]	Clock Select	b1 b0 0 0: PCLK (n = 0)*1 0 1: PCLK/4 (n = 1)*1 1 0: PCLK/16 (n = 2)*1 1 1: PCLK/64 (n = 3)*1	R/W*4
b2	MP	Multi-Processor Mode	(Valid only in asynchronous mode) 0: Multi-processor communications function is disabled 1: Multi-processor communications function is enabled	R/W*4
b3	STOP	Stop Bit Length	(Valid only in asynchronous mode) 0: 1 stop bit 1: 2 stop bits	R/W*4
b4	PM	Parity Mode	(Valid only when the PE bit is 1) 0: Selects even parity 1: Selects odd parity	R/W*4
b5	PE	Parity Enable	(Valid only in asynchronous mode) • When transmitting 0: Parity bit addition is not performed 1: The parity bit is added • When receiving 0: Parity bit checking is not performed 1: The parity bit is checked	R/W*4
b6	CHR	Character Length	(Valid only in asynchronous mode*2) Selects in combination with the SCMR.CHR1 bit. CHR1 CHR 0 0: Transmit/receive in 9-bit data length 0 1: Transmit/receive in 9-bit data length 1 0: Transmit/receive in 8-bit data length (initial value) 1 1: Transmit/receive in 7-bit data length*3	R/W*4
b7	CM	Communications Mode	0: Asynchronous mode or simple I2C mode 1: Clock synchronous mode or simple SPI mode	R/W*4

Note 1. n is the decimal notation of the value of n in the BRR register (refer to section 40.2.11, Bit Rate Register (BRR)).
Note 2. In other than asynchronous mode, this bit setting is invalid and a fixed data length of 8 bits is used.
Note 3. LSB first is fixed and the MSB (bit 7) in the TDR register is not transmitted in transmission.
Note 4. Writable only when TE in SCR = 0 and RE in SCR = 0 (both serial transmission and reception are disabled).

CKS[1:0] Bits (Clock Select)

These bits select the clock source for the on-chip baud rate generator.

For the relation between the settings of these bits and the baud rate, refer to section 40.2.11, Bit Rate Register (BRR).

MP Bit (Multi-Processor Mode)

Disables/enables the multi-processor communications function. The settings of the PE bit and PM bit are invalid in multi-processor mode.

STOP Bit (Stop Bit Length)

Selects the stop bit length in transmission.
In reception, only the first stop bit is checked regardless of this bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.

PM Bit (Parity Mode)

Selects the parity mode (even or odd) for transmission and reception.
The setting of the PM bit is invalid in multi-processor mode.

PE Bit (Parity Enable)

When this bit is set to 1, the parity bit is added to transmit data, and the parity bit is checked in reception.
Irrespective of the setting of the PE bit, the parity bit is not added or checked in multi-processor format.

CHR Bit (Character Length)

Selects the data length for transmission and reception.
Selects in combination with the CHR1 bit in SCMR.
In other than asynchronous mode, a fixed data length of 8 bits is used.

(2) Smart Card Interface Mode (SCMR.SMIF = 1)

Address(es): SMCI0.SMR 0008 A000h, SMCI1.SMR 0008 A020h, SMCI2.SMR 0008 A040h, SMCI3.SMR 0008 A060h, SMCI4.SMR 0008 A080h, SMCI5.SMR 0008 A0A0h, SMCI6.SMR 0008 A0C0h, SMCI7.SMR 0008 A0E0h, SMCI12.SMR 0008 B300h

	b7	b6	b5	b4	b3	b2	b1	b0
	GM	BLK	PE	PM	BCP[1:0]		CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKS[1:0]	Clock Select	b1 b0 0 0: PCLK (n = 0)*1 0 1: PCLK/4 (n = 1)*1 1 0: PCLK/16 (n = 2)*1 1 1: PCLK/64 (n = 3)*1	R/W*2
b3, b2	BCP[1:0]	Base Clock Pulse	Selects the number of base clock cycles in combination with the SCMR.BCP2 bit. Table 40.8 lists the combinations of the SCMR.BCP2 bit and SMR.BCP[1:0] bits.	R/W*2
b4	PM	Parity Mode	(Valid only when the PE bit is 1) 0: Selects even parity 1: Selects odd parity	R/W*2
b5	PE	Parity Enable	When this bit is set to 1, a parity bit is added to transmit data, and the parity of received data is checked. Set this bit to 1 in smart card interface mode.	R/W*2
b6	BLK	Block Transfer Mode	0: Normal mode operation 1: Block transfer mode operation	R/W*2
b7	GM	GSM Mode	0: Normal mode operation 1: GSM mode operation	R/W*2

Note 1. n is the decimal notation of the value of n in BRR (refer to section 40.2.11, Bit Rate Register (BRR)).
Note 2. Writable only when TE in SCR = 0 and RE in SCR = 0 (both serial transmission and reception are disabled).

CKS[1:0] Bits (Clock Select)

These bits select the clock source for the on-chip baud rate generator.

For the relationship between the settings of these bits and the baud rate, refer to section 40.2.11, Bit Rate Register (BRR).

BCP[1:0] Bits (Base Clock Pulse)

These bits select the number of base clock cycles in a 1-bit data transfer time in smart card interface mode.

Set these bits in combination with the SCMR.BCP2 bit.

For details, refer to section 40.6.4, Receive Data Sampling Timing and Reception Margin.

Table 40.8 Combinations of the SCMR.BCP2 Bit and SMR.BCP[1:0] Bits

SCMR.BCP2 Bit	SMR.BCP[1:0] Bits		Number of Base Clock Cycles for 1-Bit Transfer Period
0	0	0	93 clock cycles (S = 93)*1
0	0	1	128 clock cycles (S = 128)*1
0	1	0	186 clock cycles (S = 186)*1
0	1	1	512 clock cycles (S = 512)*1
1	0	0	32 clock cycles (S = 32)*1 (Initial Value)
1	0	1	64 clock cycles (S = 64)*1
1	1	0	372 clock cycles (S = 372)*1
1	1	1	256 clock cycles (S = 256)*1

Note 1. S is the value of S in BRR (refer to section 40.2.11, Bit Rate Register (BRR)).

PM Bit (Parity Mode)

Selects the parity mode for transmission and reception (even or odd).
For details on the usage of this bit in smart card interface mode, refer to section 40.6.2, Data Format (Except in Block Transfer Mode).

PE Bit (Parity Enable)

Set the PE bit to 1.
The parity bit is added to transmit data before transmission, and the parity bit is checked in reception.

BLK Bit (Block Transfer Mode)

Setting this bit to 1 allows block transfer mode operation.
For details, refer to section 40.6.3, Block Transfer Mode.

GM Bit (GSM Mode)

Setting this bit to 1 allows GSM mode operation.
In GSM mode, the SSR.TEND flag set timing is put forward to 11.0 etu (elementary time unit = 1-bit transfer time) from the start and the clock output control function is appended. For details, refer to section 40.6.6, Serial Data Transmission (Except in Block Transfer Mode) and section 40.6.8, Clock Output Control.

40.2.8 Serial Control Register (SCR)

Note: Some bits in the SCR register have different functions in smart card interface mode and non-smart card interface mode.

(1) Non-Smart Card Interface Mode (SCMR.SMIF = 0)

Address(es): SCI0.SCR 0008 A002h, SCI1.SCR 0008 A022h, SCI2.SCR 0008 A042h, SCI3.SCR 0008 A062h, SCI4.SCR 0008 A082h, SCI5.SCR 0008 A0A2h, SCI6.SCR 0008 A0C2h, SCI7.SCR 0008 A0E2h, SCI12.SCR 0008 B302h

	b7	b6	b5	b4	b3	b2	b1	b0
	TIE	RIE	TE	RE	MPIE	TEIE	CKE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKE[1:0]	Clock Enable	• For SCI0 to SCI4 and SCI7 (Asynchronous mode) b1 b0 0 0: On-chip baud rate generator The SCKn pin functions as I/O port. 0 1: On-chip baud rate generator The clock with the same frequency as the bit rate is output from the SCKn pin. 1 x: External clock The clock with a frequency 16 times the bit rate should be input from the SCKn pin. Input a clock signal with a frequency eight times the bit rate when the SEMR.ABCS bit is 1. (Clock synchronous mode) b1 b0 0 x: Internal clock The SCKn pin functions as the clock output pin. 1 x: External clock The SCKn pin functions as the clock input pin.	R/W*1
b1, b0	CKE[1:0]	Clock Enable	• For SCI5, SCI6, and SCI12 (Asynchronous mode) b1 b0 0 0: On-chip baud rate generator The SCKn pin is available for use as an I/O port according to the I/O port settings. 0 1: On-chip baud rate generator The clock with the same frequency as the bit rate is output from the SCKn pin. 1 x: External clock or TMR clock • The clock with a frequency 16 times the bit rate should be input from the SCKn pin. Input a clock signal with a frequency eight times the bit rate when the SEMR.ABCS bit is 1. • The TMR clock can be used. The SCKn pin is available for use as an I/O port according to the I/O port settings when the TMR clock is used. (Clock synchronous mode) b1 b0 0 x: Internal clock The SCKn pin functions as the clock output pin. 1 x: External clock The SCKn pin functions as the clock input pin.	R/W*1
b2	TEIE	Transmit End Interrupt Enable	0: A TEI interrupt request is disabled 1: A TEI interrupt request is enabled	R/W

Bit	Symbol	Bit Name	Description	R/W
b3	MPIE	Multi-Processor Interrupt Enable	(Valid in asynchronous mode when SMR.MP = 1) 0: Normal reception 1: When the data with the multi-processor bit set to 0 is received, the data is not read, and setting the status flags ORER and FER in SSR to 1 is disabled. When the data with the multi-processor bit set to 1 is received, the MPIE bit is automatically cleared to 0, and normal reception is resumed.	R/W
b4	RE	Receive Enable	0: Serial reception is disabled 1: Serial reception is enabled	R/W*2
b5	TE	Transmit Enable	0: Serial transmission is disabled 1: Serial transmission is enabled	R/W*2
b6	RIE	Receive Interrupt Enable	0: RXI and ERI interrupt requests are disabled 1: RXI and ERI interrupt requests are enabled	R/W
b7	TIE	Transmit Interrupt Enable	0: A TXI interrupt request is disabled 1: A TXI interrupt request is enabled	R/W

x: Don't care

Note 1. Writable only when TE = 0 and RE = 0.

Note 2. 1 can be written only when TE = 0 and RE = 0, while the SMR.CM bit is 1. After setting TE or RE to 1, only 0 can be written to TE and RE. While the SMR.CM bit is 0 and the SIMR1.IICM bit is 0, writing is enabled under any condition.

CKE[1:0] Bits (Clock Enable)

These bits select the clock source and SCKn pin function.

The combination of the settings of these bits and of the SEMR.ACS0 bit sets the internal TMR clock.

TEIE Bit (Transmit End Interrupt Enable)

Enables or disables a TEI interrupt request.

A TEI interrupt request is disabled by setting the TEIE bit to 0.

In simple I^2C mode, the TEI is allocated to the interrupt on completion of issuing a start, restart, or stop condition (STI). In this case, the TEIE bit can be used to enable or disable the STI.

MPIE Bit (Multi-Processor Interrupt Enable)

When this bit is set to 1 and the data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags ORER and FER in the SSR register to 1 is disabled. When the data with the multi-processor bit set to 1 is received, the MPIE bit is automatically cleared to 0, and normal reception is resumed. For details, refer to section 40.4, Multi-Processor Communications Function.

When the data with the multi-processor bit set to 0 is received, the receive data is not transferred from the RSR to the RDR, a receive error is not detected, and setting the flags ORER and FER to 1 is disabled.

When the data with the multi-processor bit set to 1 is received, the MPB bit is set to 1, the MPIE bit is automatically cleared to 0, the RXI and ERI interrupt requests are enabled (if the SCR.RIE bit is set to 1), and setting the flags ORER and FER to 1 is enabled.

Set the MPIE bit to 0 if multi-processor communications function is not to be used.

RE Bit (Receive Enable)

Enables or disables serial reception.

When this bit is set to 1, serial reception is started by detecting the start bit in asynchronous mode or the synchronous clock input in clock synchronous mode. Note that the SMR register should be set prior to setting the RE bit to 1 in order to designate the reception format.

Even if reception is halted by setting the RE bit to 0, the ORER, FER, PER, and RDRF flags in the SSR register are not affected and the previous value is retained.

TE Bit (Transmit Enable)

Enables or disables serial transmission.

When this bit is set to 1, serial transmission is started by writing transmit data to TDR. Note that SMR should be set prior to setting the TE bit to 1 in order to designate the transmission format.

RIE Bit (Receive Interrupt Enable)

Enables or disables RXI and ERI interrupt requests.

An RXI interrupt request is disabled by setting the RIE bit to 0.

An ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in the SSR register and then setting the flag to 0, or setting the RIE bit to 0.

TIE Bit (Transmit Interrupt Enable)

Enables or disables TXI interrupt request.

A TXI interrupt request is disabled by setting the TIE bit to 0.

(2) Smart Card Interface Mode (SCMR.SMIF = 1)

Address(es): SMCI0.SCR 0008 A002h, SMCI1.SCR 0008 A022h, SMCI2.SCR 0008 A042h, SMCI3.SCR 0008 A062h, SMCI4.SCR 0008 A082h, SMCI5.SCR 0008 A0A2h, SMCI6.SCR 0008 A0C2h, SMCI7.SCR 0008 A0E2h, SMCI12.SCR 0008 B302h

	b7	b6	b5	b4	b3	b2	b1	b0
	TIE	RIE	TE	RE	MPIE	TEIE	CKE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKE[1:0]	Clock Enable	• When SMR.GM = 0 b1 b0 0 0: Output disabled (The SCKn pin is available for use as an I/O port according to the I/O port settings.) 0 1: Clock output 1 x: (Setting prohibited) • When SMR.GM = 1 b1 b0 0 0: Output fixed low x 1: Clock output 1 0: Output fixed high	R/W*1
b2	TEIE	Transmit End Interrupt Enable	This bit should be 0 in smart card interface mode.	R/W
b3	MPIE	Multi-Processor Interrupt Enable	This bit should be 0 in smart card interface mode.	R/W
b4	RE	Receive Enable	0: Serial reception is disabled 1: Serial reception is enabled	R/W*2
b5	TE	Transmit Enable	0: Serial transmission is disabled 1: Serial transmission is enabled	R/W*2
b6	RIE	Receive Interrupt Enable	0: RXI and ERI interrupt requests are disabled 1: RXI and ERI interrupt requests are enabled	R/W
b7	TIE	Transmit Interrupt Enable	0: A TXI interrupt request is disabled 1: A TXI interrupt request is enabled	R/W

x: Don't care

Note 1. Writable only when TE = 0 and RE = 0.

Note 2. 1 can be written only when TE = 0 and RE = 0. After setting TE or RE to 1, only 0 can be written in TE and RE.

For details on interrupt requests, refer to section 40.12, Interrupt Sources.

CKE[1:0] Bits (Clock Enable)

These bits control the clock output from the SCKn pin.

In GSM mode, clock output can be dynamically switched. For details, refer to section 40.6.8, Clock Output Control.

TEIE Bit (Transmit End Interrupt Enable)

This bit should be 0 in smart card interface mode.

MPIE Bit (Multi-Processor Interrupt Enable)

This bit should be 0 in smart card interface mode.

RE Bit (Receive Enable)

Enables or disables serial reception.

When this bit is set to 1, serial reception is started by detecting the start bit. Note that the SMR register should be set prior to setting the RE bit to 1 in order to designate the reception format.

Even if reception is halted by setting the RE bit to 0, the ORER, FER, and PER flags in the SSR register are not affected and the previous value is retained.

TE Bit (Transmit Enable)

Enables or disables serial transmission.

When this bit is set to 1, serial transmission is started by writing transmit data to the TDR register. Note that the SMR register should be set prior to setting the TE bit to 1 in order to designate the transmission format.

RIE Bit (Receive Interrupt Enable)

Enables or disables RXI and ERI interrupt requests.

An RXI interrupt request is disabled by setting the RIE bit to 0.

An ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in the SSR register and then setting the flag to 0, or setting the RIE bit to 0.

TIE Bit (Transmit Interrupt Enable)

Enables or disables TXI interrupt request.

A TXI interrupt request is disabled by setting the TIE bit to 0.

40.2.9 Serial Status Register (SSR)

Some bits in the SSR register have different functions in smart card interface mode and non-smart card interface mode.

(1) Non-Smart Card Interface Mode (SCMR.SMIF = 0)

Address(es): SCI0.SSR 0008 A004h, SCI1.SSR 0008 A024h, SCI2.SSR 0008 A044h, SCI3.SSR 0008 A064h, SCI4.SSR 0008 A084h, SCI5.SSR 0008 A0A4h, SCI6.SSR 0008 A0C4h, SCI7.SSR 0008 A0E4h, SCI12.SSR 0008 B304h

	b7	b6	b5	b4	b3	b2	b1	b0
	TDRE	RDRF	ORER	FER	PER	TEND	MPB	MPBT
Value after reset:	1	0	0	0	0	1	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MPBT	Multi-Processor Bit Transfer	Sets the multi-processor bit for adding to the transmission frame 0: Data transmission cycles 1: ID transmission cycles	R/W
b1	MPB	Multi-Processor	Value of the multi-processor bit in the reception frame 0: Data transmission cycles 1: ID transmission cycles	R
b2	TEND	Transmit End Flag	0: A character is being transmitted. 1: Character transfer has been completed.	R
b3	PER	Parity Error Flag	0: No parity error occurred 1: A parity error has occurred	R/(W) *1
b4	FER	Framing Error Flag	0: No framing error occurred 1: A framing error has occurred	R/(W) *1
b5	ORER	Overrun Error Flag	0: No overrun error occurred 1: An overrun error has occurred	R/(W) *1
b6	RDRF	Receive Data Full Flag	0: No valid data is held in the RDR register 1: Received data is held in the RDR register	R/(W) *2
b7	TDRE	Transmit Data Empty Flag	0: Data to be transmitted is held in the TDR register 1: No data is held in the TDR register	R/(W) *2

Note 1. Only 0 can be written to this bit, to clear the flag. To clear this flag, confirm that the flag is 1 and then set it to 0.
Note 2. Write 1 when writing is necessary.

MPB Bit (Multi-Processor)

Holds the value of the multi-processor bit in the reception frame. This bit does not change when the SCR.RE bit is 0.

TEND Flag (Transmit End Flag)

Indicates completion of transmission.

[Setting conditions]

- When the SCR.TE bit is set to 0 (serial transmission is disabled)
  When the SCR.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated at the time of transmission of the tail-end bit of a character being transmitted

[Clearing condition]

- When transmit data are written to the TDR register while the SCR.TE bit is 1
  When setting the TEND flag to 0 to complete the interrupt handling, refer to section 15.5.2, Level Detection.

PER Flag (Parity Error Flag)

Indicates that a parity error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When a parity error is detected during reception
  Although receive data when the parity error occurs is transferred to RDR, no RXI interrupt request occurs. Note that when the PER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to PER after reading PER = 1
  When setting the PER flag to 0 to complete the interrupt handling, refer to section 15.5.2, Level Detection.
  Even when the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

FER Flag (Framing Error Flag)

Indicates that a framing error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When the stop bit is 0
  In 2-stop-bit mode, only the first stop bit is checked whether it is 1 but the second stop bit is not checked. Note that although receive data when the framing error occurs is transferred to RDR, no RXI interrupt request occurs. In addition, when the FER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to FER after reading FER = 1
  When setting the FER flag to 0 to complete the interrupt handling, refer to section 15.5.2, Level Detection.
  Even when the SCR.RE bit is set to 0, the FER flag is not affected and retains its previous value.

ORER Flag (Overrun Error Flag)

Indicates that an overrun error has occurred during reception and the reception ends abnormally.

[Setting condition]

- When the next data is received before receive data is read from RDR
  In RDR, receive data prior to an overrun error occurrence is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, subsequent serial reception cannot be performed. Note that, in clock synchronous mode, serial transmission also cannot continue.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1
  When setting the ORER flag to 0 to complete the interrupt handling, refer to section 15.5.2, Level Detection.
  Even when the SCR.RE bit is set to 0, the ORER flag is not affected and retains its previous value.

RDRF Flag (Receive Data Full Flag)

Indicates whether the RDR register has received data.

[Setting condition]

- When data has been received normally, and transferred from RSR to RDR

[Clearing condition]

- When data is read from RDR

TDRE Flag (Transmit Data Empty Flag)

Indicates whether the TDR register has data to be transmitted.

[Setting condition]

- When data is transferred from TDR to TSR

[Clearing condition]

- When data is written to TDR

(2) Smart Card Interface Mode (SCMR.SMIF = 1)

Address(es): SMCI0.SSR 0008 A004h, SMCI1.SSR 0008 A024h, SMCI2.SSR 0008 A044h, SMCI3.SSR 0008 A064h, SMCI4.SSR 0008 A084h, SMCI5.SSR 0008 A0A4h, SMCI6.SSR 0008 A0C4h, SMCI7.SSR 0008 A0E4h, SMCI12.SSR 0008 B304h

	b7	b6	b5	b4	b3	b2	b1	b0
	TDRE	RDRF	ORER	ERS	PER	TEND	MPB	MPBT
Value after reset:	1	0	0	0	0	1	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MPBT	Multi-Processor Bit Transfer	This bit should be set to 0 in smart card interface mode.	R/W
b1	MPB	Multi-Processor	This bit is not used in smart card interface mode. It should be set to 0.	R
b2	TEND	Transmit End Flag	0: A character is being transmitted. 1: Character transfer has been completed.	R
b3	PER	Parity Error Flag	0: No parity error occurred 1: A parity error has occurred	R/(W) *1
b4	ERS	Error Signal Status Flag	0: Low error signal not responded 1: Low error signal responded	R/(W) *1
b5	ORER	Overrun Error Flag	0: No overrun error occurred 1: An overrun error has occurred	R/(W) *1
b6	RDRF	Receive Data Full Flag	0: No valid data is held in the RDR register 1: Received data is held in the RDR register	R/(W) *2
b7	TDRE	Transmit Data Empty Flag	0: Data to be transmitted is held in the TDR register 1: No data is held in the TDR register	R/(W) *2

Note 1. Only 0 can be written to this bit, to clear the flag. To clear this flag, confirm that the flag is 1 and then set it to 0.
Note 2. Write 1 when writing is necessary.

TEND Flag (Transmit End Flag)

With no error signal from the receiving side, this bit is set to 1 when further data for transfer is ready to be transferred to the TDR register.

[Setting conditions]

- When the SCR.TE bit = 0 (serial transmission is disabled)
  When the SCR.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When a specified period has elapsed after the latest transmission of 1 byte, the ERS flag is 0, and the TDR register is not updated
  The set timing is determined by register settings as listed below.
  When SMR.GM = 0 and SMR.BLK = 0, 12.5 etu after the start of transmission
  When SMR.GM = 0 and SMR.BLK = 1, 11.5 etu after the start of transmission
  When SMR.GM = 1 and SMR.BLK = 0, 11.0 etu after the start of transmission
  When SMR.GM = 1 and SMR.BLK = 1, 11.0 etu after the start of transmission

[Clearing condition]

- When transmit data are written to the TDR register while the SCR.TE bit is 1
  When setting the TEND flag to 0 to complete the interrupt handling, refer to section 15.5.2, Level Detection.

PER Flag (Parity Error Flag)

Indicates that a parity error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When a parity error is detected during reception
  Although receive data when the parity error occurs is transferred to RDR, no RXI interrupt request occurs. Note that when the PER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to PER after reading PER = 1
  When setting the PER flag to 0 to complete the interrupt handling, refer to section 15.5.2, Level Detection.
  Even when the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

ERS Flag (Error Signal Status Flag)

[Setting condition]

- When a low error signal is sampled

[Clearing condition]

- When 0 is written to ERS after reading ERS = 1
  When setting the ERS flag to 0 to complete the interrupt handling, refer to section 15.5.2, Level Detection.
  Even when the SCR.RE bit is set to 0, the ERS flag is not affected and retains its previous value.

ORER Flag (Overrun Error Flag)

Indicates that an overrun error has occurred during reception and the reception ends abnormally.

[Setting condition]

- When the next data is received before receive data is read from RDR
  In RDR, the receive data prior to an overrun error occurrence is retained, but data received following the overrun error occurrence is lost. When the ORER flag is set to 1, subsequent serial reception cannot be performed.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1
  When setting the ORER flag to 0 to complete the interrupt handling, refer to section 15.5.2, Level Detection.
  Even when the SCR.RE bit is set to 0, the ORER flag is not affected and retains its previous value.

RDRF Flag (Receive Data Full Flag)

Indicates whether the RDR register has received data.

[Setting condition]

- When data has been received normally, and transferred from RSR to RDR

[Clearing condition]

- When data is read from RDR

TDRE Flag (Transmit Data Empty Flag)

Indicates whether the TDR register has data to be transmitted.

[Setting condition]

- When data is transferred from TDR to TSR

[Clearing condition]

- When data is written to TDR

40.2.10 Smart Card Mode Register (SCMR)

Address(es): SMCI0.SCMR 0008 A006h, SMCI1.SCMR 0008 A026h, SMCI2.SCMR 0008 A046h, SMCI3.SCMR 0008 A066h, SMCI4.SCMR 0008 A086h, SMCI5.SCMR 0008 A0A6h, SMCI6.SCMR 0008 A0C6h, SMCI7.SCMR 0008 A0E6h, SMCI12.SCMR 0008 B306h

	b7	b6	b5	b4	b3	b2	b1	b0
	BCP2	—	—	CHR1	SDIR	SINV	—	SMIF
Value after reset:	1	1	1	1	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	SMIF	Smart Card Interface Mode Select	0: Non-smart card interface mode (Asynchronous mode, clock synchronous mode, simple SPI mode, or simple I2C mode) 1: Smart card interface mode	R/W*1
b1	—	Reserved	This bit is read as 1. The write value should be 1.	R/W
b2	SINV	Transmitted/Received Data Invert	0: TDR contents are transmitted as they are. Receive data is stored as it is in RDR. 1: TDR contents are inverted before being transmitted. Receive data is stored in inverted form in RDR.	R/W*1
b3	SDIR	Transmitted/Received Data Transfer Direction	This bit can be used in the following modes. • Smart card interface mode • Asynchronous mode (multi-processor mode) • Clock synchronous mode • Simple SPI mode Set this bit to 1 if operation is to be in simple I2C mode. 0: Transfer with LSB first 1: Transfer with MSB first	R/W*1
b4	CHR1	Character Length 1	(Only valid in asynchronous mode)*2 Selects in combination with the SMR.CHR bit. CHR1 CHR 0 0: Transmit/receive in 9-bit data length 0 1: Transmit/receive in 9-bit data length 1 0: Transmit/receive in 8-bit data length (initial value) 1 1: Transmit/receive in 7-bit data length*3	R/W*1
b6, b5	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b7	BCP2	Base Clock Pulse 2	Selects the number of base clock cycles in combination with the SMR.BCP[1:0] bits. Table 40.9 lists the combinations of the SCMR.BCP2 bit and SMR.BCP[1:0] bits.	R/W*1

Note 1. Writable only when TE in SCR = 0 and RE in SCR = 0 (both serial transmission and reception are disabled).
Note 2. The setting is invalid and a fixed data length of 8 bits is used in modes other than asynchronous mode.
Note 3. LSB first should be selected and the value of MSB (b7) in the TDR register cannot be transmitted.

SMIF Bit (Smart Card Interface Mode Select)

When this bit is set to 1, smart card interface mode is selected.

When this bit is set to 0, non-smart card interface mode, i.e., asynchronous mode (including multi-processor mode), clock synchronous mode, simple SPI mode, or simple I2C mode is selected.

SINV Bit (Transmitted/Received Data Invert)

Inverts the transmit/receive data logic level. This bit does not affect the logic level of the parity bit. To invert the parity bit, invert the PM bit in the SMR register.

CHR1 bit (Character Length 1)

Selects the data length of transmit/receive data.

Selects in combination with the CHR bit in SMR.

A fixed data length of 8 bits is used in modes other than asynchronous mode.

BCP2 Bit (Base Clock Pulse 2)

Selects the number of base clock cycles in a 1-bit data transfer time in smart card interface mode. Set this bit in combination with the SMR.BCP[1:0] bits.

Table 40.9 Combinations of the SCMR.BCP2 Bit and SMR.BCP[1:0] Bits

SCMR.BCP2 Bit	SMR.BCP[1:0] Bits		Number of Base Clock Cycles for 1-Bit Transfer Period
0	0	0	93 clock cycles (S = 93)*1
0	0	1	128 clock cycles (S = 128)*1
0	1	0	186 clock cycles (S = 186)*1
0	1	1	512 clock cycles (S = 512)*1
1	0	0	32 clock cycles (S = 32)*1 (Initial Value)
1	0	1	64 clock cycles (S = 64)*1
1	1	0	372 clock cycles (S = 372)*1
1	1	1	256 clock cycles (S = 256)*1

Note 1. S is the value of S in BRR (refer to section 40.2.11, Bit Rate Register (BRR)).

40.2.11 Bit Rate Register (BRR)

Address(es): SCI0.BRR 0008 A001h, SCI1.BRR 0008 A021h, SCI2.BRR 0008 A041h, SCI3.BRR 0008 A061h, SCI4.BRR 0008 A081h, SCI5.BRR 0008 A0A1h, SCI6.BRR 0008 A0C1h, SCI7.BRR 0008 A0E1h, SCI12.BRR 0008 B301h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

The BRR register is an 8-bit register that adjusts the bit rate.
As each SCI channel has independent baud rate generator control, different bit rates can be set for each. Table 40.10 shows the relationship between the setting (N) in the BRR register and the bit rate (B) for normal asynchronous mode, multi-processor transfer, clock synchronous mode, smart card interface mode, simple SPI mode, and simple I²C mode. The BRR register is writable only when the TE and RE bits in the SCR register are 0.

Table 40.10 Relationship between N Setting in BRR and Bit Rate B

Mode	SEMR Settings		BRR Setting	Error
	BGDM Bit	ABCS Bit		
Asynchronous, multi-processor transfer	0	0	$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	$Error\ (\%) = \{\frac{PCLK \times 10^6}{B \times 64 \times 2^{2n-1} \times (N+1)} - 1\} \times 100$
	0	1	$N = \frac{PCLK \times 10^6}{32 \times 2^{2n-1} \times B} - 1$	$Error\ (\%) = \{\frac{PCLK \times 10^6}{B \times 32 \times 2^{2n-1} \times (N+1)} - 1\} \times 100$
	1	0		
	1	1	$N = \frac{PCLK \times 10^6}{16 \times 2^{2n-1} \times B} - 1$	$Error\ (\%) = \{\frac{PCLK \times 10^6}{B \times 16 \times 2^{2n-1} \times (N+1)} - 1\} \times 100$
Clock synchronous, simple SPI			$N = \frac{PCLK \times 10^6}{8 \times 2^{2n-1} \times B} - 1$	
Smart card interface			$N = \frac{PCLK \times 10^6}{S \times 2^{2n+1} \times B} - 1$	$Error\ (\%) = \{\frac{PCLK \times 10^6}{B \times S \times 2^{2n+1} \times (N+1)} - 1\} \times 100$
Simple I²C*1			$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	

B: Bit rate (bps)
N: BRR setting for on-chip baud rate generator ($0 \le N \le 255$)
PCLK: Operating frequency (MHz)
n and S: Determined by the settings of the SMR and SCMR registers as listed in the table below.
Note 1. Adjust the bit rate so that the widths at high and low level of the SCL output in simple I²C mode satisfy the I²C standard.

Table 40.11 Calculating Widths at High and Low Level for SCL

Mode	SCL	Formula (Result in Seconds)
I²C	Width at high level (minimum value)	$(N+1) \times 4 \times 2^{2n-1} \times 7 \times \frac{1}{PCLK \times 10^6}$
	Width at low level (minimum value)	$(N+1) \times 4 \times 2^{2n-1} \times 8 \times \frac{1}{PCLK \times 10^6}$

Table 40.12 Clock Source Settings

SMR.CKS[1:0] Bit Setting	Clock Source	n
0 0	PCLK	0
0 1	PCLK/4	1
1 0	PCLK/16	2
1 1	PCLK/64	3

Table 40.13 Base Clock Settings in Smart Card Interface Mode

SCMR.BCP2 Bit Setting	SMR.BCP[1:0] Bit Setting	Base Clock Cycles for 1-bit Period	S
0	0 0	93 clock cycles	93
0	0 1	128 clock cycles	128
0	1 0	186 clock cycles	186
0	1 1	512 clock cycles	512
1	0 0	32 clock cycles	32
1	0 1	64 clock cycles	64
1	1 0	372 clock cycles	372
1	1 1	256 clock cycles	256

Table 40.14 lists examples of N settings in BRR in normal asynchronous mode. Table 40.15 lists the maximum bit rate settable for each operating frequency. Examples of BRR (N) settings in clock synchronous mode and simple SPI mode are listed in Table 40.18. Examples of BRR (N) settings in smart card interface mode are listed in Table 40.20. Examples of BRR (N) settings in simple I^2C mode are listed in Table 40.22. In smart card interface mode, the number of base clock cycles S in a 1-bit data transfer time can be selected. For details, refer to section 40.6.4, Receive Data Sampling Timing and Reception Margin. Table 40.16 and Table 40.19 list the maximum bit rates with external clock input.

When either the asynchronous mode base clock select bit (ABCS) or the baud rate generator double-speed mode select bit (BGDM) in the serial extended mode register (SEMR) is set to 1 in asynchronous mode, the bit rate becomes twice that listed in Table 40.14. When both of those registers are set to 1, the bit rate becomes four times the listed value.

Table 40.14 Examples of BRR Settings for Various Bit Rates (Asynchronous Mode)

Note: This is an example when the ABCS and BGDM bits in SEMR are 0.
When either the ABCS bit or BGDM bit is set to 1, the bit rate doubles.
When both ABCS and BGDM bits in SEMR are set to 1, the bit rate increases four times.

7.5 M											0	0*1							0	1

Space: Setting prohibited.

—: Can be set, but an error will occur.

Note 1. Continuous transmission or reception is not possible. After transmitting/receiving one frame of data, there is an interval of a 1-bit period before starting transmitting/receiving the next frame of data. The output of the synchronization clock is stopped for a 1-bit period. For this reason, it takes 9 bits worth of time to transfer one frame (8 bits) of data, and the average transfer rate is 8/9 times the bit rate.

Table 40.19 Maximum Bit Rate with External Clock Input (Clock Synchronous Mode, Simple SPI Mode)

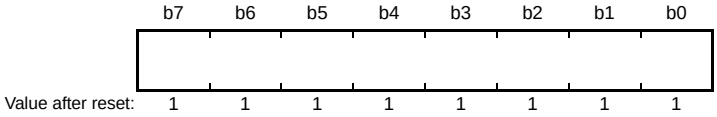
40.2.12 Modulation Duty Register (MDDR)

Address(es): SCI0.MDDR 0008 A012h, SCI1.MDDR 0008 A032h, SCI2.MDDR 0008 A052h, SCI3.MDDR 0008 A072h, SCI4.MDDR 0008 A092h, SCI5.MDDR 0008 A0B2h, SCI6.MDDR 0008 A0D2h, SCI7.MDDR 0008 A0F2h, SCI12.MDDR 0008 B312h



The MDDR register corrects the bit rate adjusted by the BRR register.
When the SEMR.BRME bit is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected according to the settings of the MDDR register (M/256). The relationship between the MDDR register setting (M) and the bit rate (B) is given in Table 40.24.
The range of the value that can be set in the MDDR register is from 80h to FFh. A value other than these cannot be set.
The MDDR register is writable only when the TE and RE bits in the SCR register are 0.

Table 40.24 Relationship between MDDR Setting (M) and Bit Rate (B) When Bit Rate Modulation Function is Used

Mode	SEMR Settings		BRR Setting	Error
	BGDM Bit	ABCS Bit		
Asynchronous multi-processor communication	0	0	$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times (256/M) \times B} - 1$	$Error\ (\%) = \{\frac{PCLK \times 10^6}{B \times 64 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\} \times 100$
	0	1	$N = \frac{PCLK \times 10^6}{32 \times 2^{2n-1} \times (256/M) \times B} - 1$	$Error\ (\%) = \{\frac{PCLK \times 10^6}{B \times 32 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\} \times 100$
	1	0		
	1	1	$N = \frac{PCLK \times 10^6}{16 \times 2^{2n-1} \times (256/M) \times B} - 1$	$Error\ (\%) = \{\frac{PCLK \times 10^6}{B \times 16 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\} \times 100$
Clock synchronous mode, simple SPI mode*1			$N = \frac{PCLK \times 10^6}{8 \times 2^{2n-1} \times (256/M) \times B} - 1$	
Smart card interface mode			$N = \frac{PCLK \times 10^6}{S \times 2^{2n+1} \times (256/M) \times B} - 1$	$Error\ (\%) = \{\frac{PCLK \times 10^6}{B \times S \times 2^{2n+1} \times (256/M) \times (N+1)} - 1\} \times 100$
Simple I^2C*2			$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times (256/M) \times B} - 1$	

B: Bit rate (bps)
M: MDDR setting (128 ≤ MDDR ≤ 256)
N: BRR setting for baud rate generator (0 ≤ N ≤ 255)
PCLK: Operating frequency (MHz)
n and S: Determined by the settings of the SMR and SCMR registers as listed in Table 40.12 and Table 40.13, section 40.2.11, Bit Rate Register (BRR).

Note 1. Do not use this function in clock synchronous mode and in the highest speed settings in simple SPI mode (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).
Note 2. Adjust the bit rate so that the widths at high and low level of the SCL output in simple I^2C mode satisfy the I^2C standard.

40.2.13 Serial Extended Mode Register (SEMR)

Address(es): SCI0.SEMR 0008 A007h, SCI1.SEMR 0008 A027h, SCI2.SEMR 0008 A047h, SCI3.SEMR 0008 A067h, SCI4.SEMR 0008 A087h, SCI5.SEMR 0008 A0A7h, SCI6.SEMR 0008 A0C7h, SCI7.SEMR 0008 A0E7h, SCI12.SEMR 0008 B307h

	b7	b6	b5	b4	b3	b2	b1	b0
	RXDESEL	BGDM	NFEN	ABCS	—	BRME	—	ACS0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ACS0	Asynchronous Mode Clock Source Select	(Valid only in asynchronous mode) 0: External clock input 1: Logical AND of two compare matches output from TMR (valid for SCI5, SCI6, and SCI12 only) Available compare match output varies per SCI channel.	R/W*1
b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b2	BRME	Bit Rate Modulation Enable	0: Bit rate modulation function is disabled. 1: Bit rate modulation function is enabled.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	ABCS	Asynchronous Mode Base Clock Select	(Valid only in asynchronous mode) 0: Selects 16 base clock cycles for 1-bit period. 1: Selects 8 base clock cycles for 1-bit period.	R/W*1
b5	NFEN	Digital Noise Filter Function Enable	(In asynchronous mode) 0: Noise cancellation function for the RXDn input signal is disabled. 1: Noise cancellation function for the RXDn input signal is enabled. (in simple I^2C mode) 0: Noise cancellation function for the SSCLn and SSDAn input signals is disabled. 1: Noise cancellation function for the SSCLn and SSDAn input signals is enabled. The NFEN bit should be 0 in any mode other than above.	R/W*1
b6	BGDM	Baud Rate Generator Double-Speed Mode Select	(Only valid the CKE[1] bit in SCR is 0 in asynchronous mode). 0: Baud rate generator outputs the clock with normal frequency. 1: Baud rate generator outputs the clock with doubled frequency.	R/W
b7	RXDESEL	Asynchronous Start Bit Edge Detection Select	(Valid only in asynchronous mode) 0: The low level on the RXDn pin is detected as the start bit. 1: A falling edge on the RXDn pin is detected as the start bit.	R/W*1

Note 1. Writable only when TE in SCR = 0 and RE in SCR = 0 (both serial transmission and reception are disabled).

The SEMR register is used to select a clock source for 1-bit period in asynchronous mode or a detection method of the start bit.

ACS0 Bit (Asynchronous Mode Clock Source Select)

Selects the clock source in the asynchronous mode.

The ACS0 bit is valid in asynchronous mode (SMR.CM bit = 0) and when an external clock input is selected (SCR.CKE[1:0] bits = 10b or 11b). This bit is used to select an external clock input or the logical AND of compare matches output from the internal TMR.

Set the ACS0 bit to 0 in other than asynchronous mode.

For SCI5, SCI6, and SCI12, the TMOn output (n = 0 to 3) of TMR units 0 and 1 can be set as the serial transfer base clock. Refer to Table 40.25 for details.

These bits for the other SCI channels than SCI5, SCI6, and SCI12 are reserved. The write values to these bits for other than SCI5, SCI6, and SCI12 should be 0.

Table 40.25 Correspondence between SCI Channels and Compare Match Outputs

SCI	TMR	Compare Match Output
SCI5	Unit 0	TMO0, TMO1
SCI6	Unit 1	TMO2, TMO3
SCI12	Unit 0	TMO0, TMO1

Figure 40.4 shows a setting example of when TMO0 and TMO1 in the TMR unit 0 are selected for output.

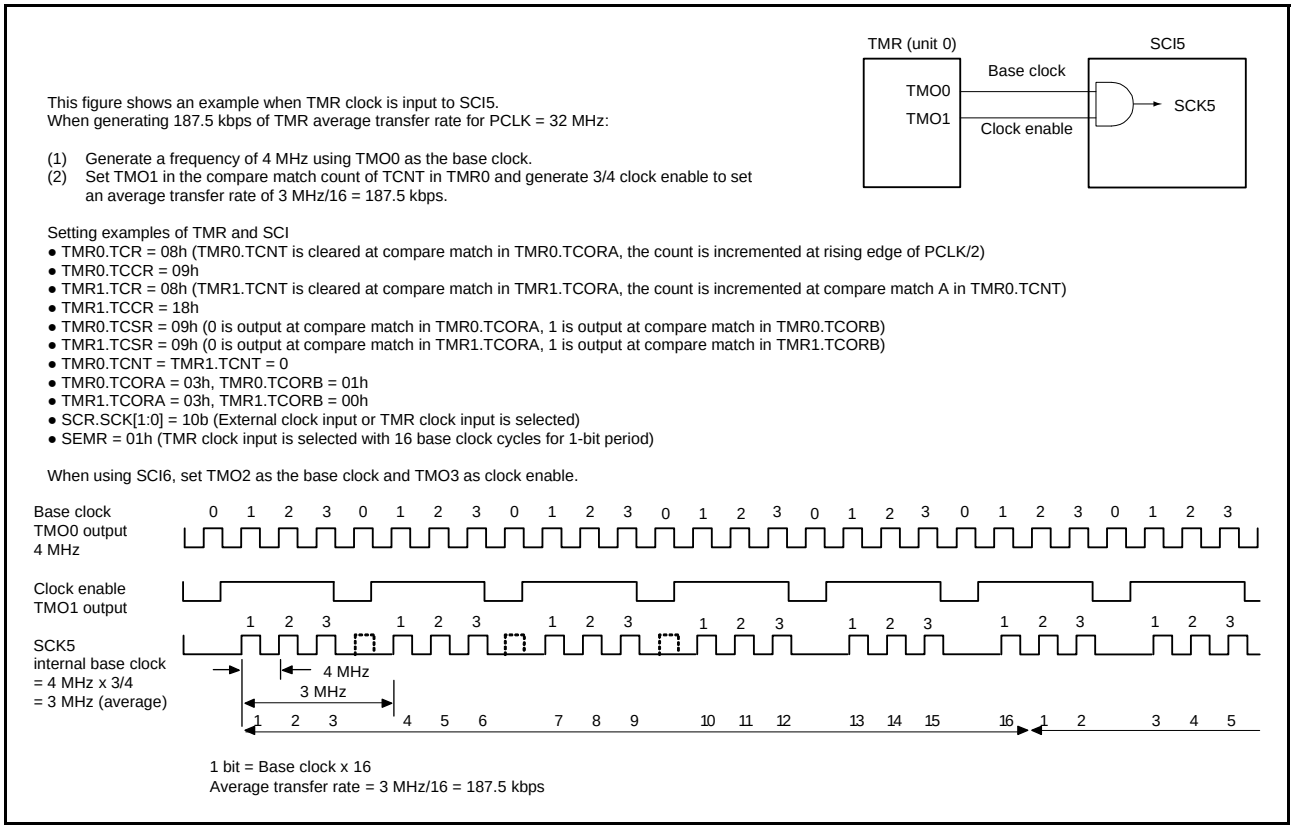


Figure 40.4 Example of Average Transfer Rate Setting When TMR Clock is Input

BRME bit (Bit Rate Modulation Enable)

Enables and disables the bit rate modulation function. The bit rate generated by on-chip baud rate generator is evenly corrected when this function is enabled.

NFEN Bit (Digital Noise Filter Function Enable)

This bit enables or disables the digital noise filter function.
When the function is enabled, noise cancellation is applied to the RXDn input signal in asynchronous mode, and noise cancellation is applied to the SSDAn and SSCLn input signals in simple I^2C mode.
In any mode other than above, set the NFEN bit to 0 to disable the digital noise filter function.
When the function is disabled, input signals are transferred as is, as internal signals.

BGDM bit (Baud Rate Generator Double-Speed Mode Select)

Selects the cycle of output clock for the baud rate generator.
This bit is valid when the on-chip baud rate generator is selected as the clock source (SCR.CKE[1] = 0) in asynchronous mode (SMR.CM = 0). For the clock output from the baud rate generator, either normal or doubled frequency can be selected. The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1, the base clock cycle is halved and the bit rate is doubled.
Set this bit to 0 in modes other than asynchronous mode.

RXDESEL Bit (Asynchronous Start Bit Edge Detection Select)

Selects the detection method of the start bit for reception in asynchronous mode. When a break occurs, data receiving operation depends on the settings of this bit. Set this bit to 1 when reception should be stopped while a break occurs or when reception should be started without retaining the RXDn pin input at high level for the period of one data frame or longer after completion of the break.
Set this bit to 0 in modes other than asynchronous mode.

40.2.14 Noise Filter Setting Register (SNFR)

Address(es): SCI0.SNFR 0008 A008h, SCI1.SNFR 0008 A028h, SCI2.SNFR 0008 A048h, SCI3.SNFR 0008 A068h, SCI4.SNFR 0008 A088h, SCI5.SNFR 0008 A0A8h, SCI6.SNFR 0008 A0C8h, SCI7.SNFR 0008 A0E8h, SCI12.SNFR 0008 B308h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	NFCS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	NFCS[2:0]	Noise Filter Clock Select	In asynchronous mode, the standard setting for the base clock is as follows. b2 b0 0 0 0: The clock signal divided by 1 is used with the noise filter. In simple I2C mode, the standard settings for the clock source of the on-chip baud rate generator selected by the SMR.CKS[1:0] bits are given below. b2 b0 0 0 1: The clock signal divided by 1 is used with the noise filter. 0 1 0: The clock signal divided by 2 is used with the noise filter. 0 1 1: The clock signal divided by 4 is used with the noise filter. 1 0 0: The clock signal divided by 8 is used with the noise filter. Settings other than above are prohibited.	R/W*1
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR are 0 (serial reception and transmission disabled).

NFCS[2:0] Bits (Noise Filter Clock Select)

These bits select the sampling clock for the digital noise filter. To use the noise filter in asynchronous mode, set these bits to 000b. In simple I2C mode, set the bits to a value in the range from 001b to 100b.

40.2.15 I²C Mode Register 1 (SIMR1)

Address(es): SCI0.SIMR1 0008 A009h, SCI1.SIMR1 0008 A029h, SCI2.SIMR1 0008 A049h, SCI3.SIMR1 0008 A069h, SCI4.SIMR1 0008 A089h, SCI5.SIMR1 0008 A0A9h, SCI6.SIMR1 0008 A0C9h, SCI7.SIMR1 0008 A0E9h, SCI12.SIMR1 0008 B309h

	b7	b6	b5	b4	b3	b2	b1	b0
	IICDL[4:0]					—	—	IICM
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IICM	Simple I²C Mode Select	SMIF IICM 0 0: Asynchronous mode, Multi-processor mode, Clock synchronous mode (in asynchronous mode, synchronous, or simple SPI mode) 0 1: Simple I²C mode 1 0: Smart card interface mode 1 1: Setting prohibited.	R/W*1
b2, b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7 to b3	IICDL[4:0]	SSDA Output Delay Select	(Cycles below are of the clock signal from the on-chip baud rate generator.) b7 b3 0 0 0 0 0: No output delay 0 0 0 0 1: 0 to 1 cycle 0 0 0 1 0: 1 to 2 cycles 0 0 0 1 1: 2 to 3 cycles 0 0 1 0 0: 3 to 4 cycles 0 0 1 0 1: 4 to 5 cycles : : 1 1 1 1 0: 29 to 30 cycles 1 1 1 1 1: 30 to 31 cycles	R/W*1

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR are 0 (both serial transmission and reception are disabled).

SIMR1 is used to select simple I²C mode and the number of delay stages for the SSDA output.

IICM Bit (Simple I²C Mode Select)

In conjunction with the SMIF bit in the SCMR register, this bit selects the operating mode.

IICDL[4:0] Bits (SSDA Output Delay Select)

These bits are used to set a delay for output on the SSDAn pin relative to the falling edge of the output on the SSCLn pin. The available delay settings range from no delay to 31 cycles, with the clock signal from the on-chip baud rate generator as the base. The signal obtained by frequency-dividing PCLK by the divisor set in the SMR.CKS[1:0] bits is supplied as the clock signal from the on-chip baud rate generator. Set these bits to 00000b unless operation is in simple I²C mode. In simple I²C mode, set the bits to a value in the range from 00001b to 11111b.

40.2.16 I²C Mode Register 2 (SIMR2)

Address(es): SCI0.SIMR2 0008 A00Ah, SCI1.SIMR2 0008 A02Ah, SCI2.SIMR2 0008 A04Ah, SCI3.SIMR2 0008 A06Ah, SCI4.SIMR2 0008 A08Ah, SCI5.SIMR2 0008 A0AAh, SCI6.SIMR2 0008 A0CAh, SCI7.SIMR2 0008 A0EAh, SCI12.SIMR2 0008 B30Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	IICACKT	—	—	—	IICCSC	IICINTM
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IICINTM	I²C Interrupt Mode Select	0: Use ACK/NACK interrupts. 1: Use reception and transmission interrupts.	R/W*1
b1	IICCSC	Clock Synchronization	0: No synchronization with the clock signal 1: Synchronization with the clock signal	R/W*1
b4 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	IICACKT	ACK Transmission Data	0: ACK transmission 1: NACK transmission and reception of ACK/NACK	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR are 0 (serial reception and transmission disabled).

SIMR2 is used to select how reception and transmission are controlled in simple I²C mode.

IICINTM Bit (I²C Interrupt Mode Select)

This bit selects the sources of interrupt requests in simple I²C mode.

IICCSC Bit (Clock Synchronization)

Set the IICCSC bit to 1 if the internally generated SSCLn clock signal is to be synchronized when the SSCLn pin has been placed at the low level in the case of a wait inserted by the other device, etc.

The SSCLn clock signal is not synchronized if the IICCSC bit is 0. The SSCLn clock signal is generated in accord with the rate selected in the BRR regardless of the level being input on the SSCLn pin.

Set the IICCSC bit to 1 except during debugging.

IICACKT Bit (ACK Transmission Data)

Transmitted data contains ACK bits. Set this bit to 1 when ACK and NACK bits are received.

40.2.17 I²C Mode Register 3 (SIMR3)

Address(es): SCI0.SIMR3 0008 A00Bh, SCI1.SIMR3 0008 A02Bh, SCI2.SIMR3 0008 A04Bh, SCI3.SIMR3 0008 A06Bh, SCI4.SIMR3 0008 A08Bh, SCI5.SIMR3 0008 A0ABh, SCI6.SIMR3 0008 A0CBh, SCI7.SIMR3 0008 A0EBh, SCI12.SIMR3 0008 B30Bh

	b7	b6	b5	b4	b3	b2	b1	b0
	IICSCLS[1:0]		IICSDAS[1:0]		IICSTIF	IICSTPREQ	IICRSTAREQ	IICSTAREQ
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IICSTAREQ	Start Condition Generation	0: A start condition is not generated. 1: A start condition is generated.*1, *3, *4, *5	R/W
b1	IICRSTAREQ	Restart Condition Generation	0: A restart condition is not generated. 1: A restart condition is generated.*2, *3, *4, *5	R/W
b2	IICSTPREQ	Stop Condition Generation	0: A stop condition is not generated. 1: A stop condition is generated.*2, *3, *4, *5	R/W
b3	IICSTIF	Issuing of Start, Restart, or Stop Condition Completed Flag	0: There are no requests for generating conditions or a condition is being generated. 1: A start, restart, or stop condition is completely generated.	R/W
b5, b4	IICSDAS[1:0]	SSDA Output Select	b5 b4 0 0: Serial data output 0 1: Generate a start, restart, or stop condition. 1 0: Output the low level on the SSDAn pin. 1 1: Place the SSDAn pin in the high-impedance state.	R/W
b7, b6	IICSCLS[1:0]	SSCL Output Select	b7 b6 0 0: Serial clock output 0 1: Generate a start, restart, or stop condition. 1 0: Output the low level on the SSCLn pin. 1 1: Place the SSCLn pin in the high-impedance state.	R/W

Note 1. Only generate a start condition after checking the bus state and confirming that it is free.
Note 2. Generate a restart or stop condition after checking the bus state and confirming that it is busy.
Note 3. Do not set more than one from among the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits to 1 at a given time.
Note 4. Execute the generation of a condition after the value of the IICSTIF flag is 0.
Note 5. Do not write 0 to this bit while it is 1. Generation of a condition is suspended by writing 0 to this bit while it is 1.

SIMR3 is used to control the simple I²C mode start and stop conditions, and to hold the SSDAn and SSCLn pins at fixed levels.

IICSTAREQ Bit (Start Condition Generation)

When a start condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTAREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the start condition

IICRSTAREQ Bit (Restart Condition Generation)

When a restart condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICRSTAREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the restart condition

IICSTPREQ Bit (Stop Condition Generation)

When a stop condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTPREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the stop condition

IICSTIF Flag (Issuing of Start, Restart, or Stop Condition Completed Flag)

After generating a condition, this bit indicates that the generation is completed. When using the IICSTAREQ, IICRSTAREQ, or IICSTPREQ bit to cause generation of a condition, do so after setting the IICSTIF flag to 0.

When the IICSTIF flag is 1 while an interrupt request is enabled by setting the SCR.TEIE bit, an STI request is output.

[Setting condition]

- Completion of the generation of a start, restart, or stop condition (however, in cases where this conflicts with any of the conditions for the flag becoming 0 listed below, the other condition takes precedence)

[Clearing conditions]

- Writing 0 to the bit (confirm that the IICSTIF flag is 0 before doing so)
- Writing 0 to the SIMR1.IICM bit (when operation is not in simple I^2C mode)
- Writing 0 to the SCR.TE bit

IICSDAS[1:0] Bits (SSDA Output Select)

These bits control output from the SSDAn pin.

Set the IICSDAS[1:0] and IICSCLS[1:0] bits to the same value during normal operations.

IICSCLS[1:0] Bits (SSCL Output Select)

These bits control output from the SSCLn pin.

Set the IICSCLS[1:0] and IICSDAS[1:0] bits to the same value during normal operations.

40.2.18 I²C Status Register (SISR)

Address(es): SCI0.SISR 0008 A00Ch, SCI1.SISR 0008 A02Ch, SCI2.SISR 0008 A04Ch, SCI3.SISR 0008 A06Ch, SCI4.SISR 0008 A08Ch, SCI5.SISR 0008 A0ACh, SCI6.SISR 0008 A0CCh, SCI7.SISR 0008 A0ECh, SCI12.SISR 0008 B30Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	IICACKR
Value after reset:	0	0	x	x	0	x	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	IICACKR	ACK Reception Data Flag	0: ACK received 1: NACK received	R/W*1
b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b2	—	Reserved	The read value is undefined.	R
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5, b4	—	Reserved	The read value is undefined.	R
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 0 can be written to this bit, to clear the flag.

SISR is used to monitor state in relation to simple I²C mode.

IICACKR Flag (ACK Reception Data Flag)

Received ACK and NACK bits can be read from this bit.

The IICACKR flag is updated at the rising of SSCLn clock for the ACK/NACK receiving bit.

40.2.19 SPI Mode Register (SPMR)

Address(es): SCI0.SPMR 0008 A00Dh, SCI1.SPMR 0008 A02Dh, SCI2.SPMR 0008 A04Dh, SCI3.SPMR 0008 A06Dh, SCI4.SPMR 0008 A08Dh, SCI5.SPMR 0008 A0ADh, SCI6.SPMR 0008 A0CDh, SCI7.SPMR 0008 A0EDh, SCI12.SPMR 0008 B30Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	CKPH	CKPOL	—	MFF	—	MSS	CTSE	SSE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SSE	SSn# Pin Function Enable	0: SSn# pin function is disabled. 1: SSn# pin function is enabled.	R/W*1
b1	CTSE	CTS Enable	0: CTS function is disabled (RTS output function is enabled). 1: CTS function is enabled.	R/W*1
b2	MSS	Master Slave Select	0: Transmission is through the TXDn pin and reception is through the RXDn pin (master mode). 1: Reception is through the TXDn pin and transmission is through the RXDn pin (slave mode).	R/W*1
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	MFF	Mode Fault Flag	0: No mode fault error 1: Mode fault error	R/W*2
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	CKPOL	Clock Polarity Select	0: Clock polarity is not inverted. 1: Clock polarity is inverted.	R/W*1
b7	CKPH	Clock Phase Select	0: Clock is not delayed. 1: Clock is delayed.	R/W*1

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR are 0 (both serial transmission and reception are disabled).
Note 2. Only 0 can be written to these bits, which clears the flag.

SPMR is used to select the extension settings in asynchronous and clock synchronous modes.

SSE Bit (SSn# Pin Function Enable)

Set this bit to 1 if the SSn# pin is to be used in control of transmission and reception (in simple SPI mode). Set this bit to 0 in any other mode. Furthermore, even for usage in simple SPI mode, the SSn# pin on the master side is not required to control reception and transmission when master mode (SCR.CKE[1:0] = 00b and MSS = 0) is selected and there is a single master, so the setting for the SSE bit is 0. Do not set both the SSE and CTSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).

CTSE Bit (CTS Enable)

Set this bit to 1 if the SSn# pin is to be used for inputting of the CTS control signal to control of transmission and reception. The RTS signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode, simple SPI mode, and simple I^2C mode. Do not set both the CTSE and SSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).

MSS Bit (Master Slave Select)

This bit selects between master and slave operation in simple SPI mode. The functions of the TXDn and RXDn pins are reversed when the MSS bit is set to 1, so that data is received through the TXDn pin and transmitted through the RXDn pin.
Set this bit to 0 in modes other than simple SPI mode.

MFF Flag (Mode Fault Flag)

This bit indicates mode fault errors.
In a multi-master configuration, determine the mode fault error occurrence by reading the MFF flag.
[Setting condition]

- Input on the SSn# pin being at the low level during master operation in simple SPI mode (SSE bit = 1 and MSS bit = 0)

[Clearing condition]

- Writing 0 to the bit after it was read as 1

CKPOL Bit (Clock Polarity Select)

This bit selects the polarity of the clock signal output through the SCKn pin. Refer to Figure 40.56 for details.
Set the bit to 0 in other than simple SPI mode and clock synchronous mode.

CKPH Bit (Clock Phase Select)

This bit selects the phase of the clock signal output through the SCKn pin. Refer to Figure 40.56 for details.
Set the bit to 0 in other than simple SPI mode and clock synchronous mode.

40.2.20 Extended Serial Module Enable Register (ESMER)

Address(es): SCI12.ESMER 0008 B320h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	ESME
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ESME	Extended Serial Mode Enable	0: The extended serial mode is disabled. 1: The extended serial mode is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ESME Bit (Extended Serial Mode Enable)

When the ESME bit is 1, the facilities of the extended serial mode control section are enabled.
When the ESME bit is 0, the extended serial mode control section is initialized.

Table 40.26 Settings of the ESME Bit and Timer Operation Mode

ESME Bit	Timer Mode	Break Field Low Width Determination Mode	Break Field Low Width Output Mode
0	Available*1	Not available	Not available
1	Available	Available	Available

Note 1. Operation is only possible with PCLK selected.

40.2.21 Control Register 0 (CR0)

Address(es): SCI12.CR0 0008 B321h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	BRME	RXDSF	SFSF	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	SFSF	Start Frame Status Flag	0: Start Frame detection function is disabled. 1: Start Frame detection function is enabled.	R
b2	RXDSF	RXDX12 Input Status Flag	0: RXDX12 input is enabled. 1: RXDX12 input is disabled.	R
b3	BRME	Bit Rate Measurement Enable	0: Measurement of bit rate is disabled. 1: Measurement of bit rate is enabled.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

40.2.22 Control Register 1 (CR1)

Address(es): SCI12.CR1 0008 B322h

	b7	b6	b5	b4	b3	b2	b1	b0
	PIBS[2:0]			PIBE	CF1DS[1:0]		CF0RE	BFE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BFE	Break Field Enable	0: Break Field detection is disabled. 1: Break Field detection is enabled.	R/W
b1	CF0RE	Control Field 0 Reception Enable	0: Reception of Control Field 0 is disabled. 1: Reception of Control Field 0 is enabled.	R/W
b3, b2	CF1DS[1:0]	Control Field 1 Data Register Select	b3 b2 0 0: Selects comparison with the value in PCF1DR. 0 1: Selects comparison with the value in SCF1DR. 1 0: Selects comparison with the values in PCF1DR and SCF1DR. 1 1: Setting prohibited.	R/W
b4	PIBE	Priority Interrupt Bit Enable	0: The priority interrupt bit is disabled. 1: The priority interrupt bit is enabled.	R/W
b7 to b5	PIBS[2:0]	Priority Interrupt Bit Select	b7 b5 0 0 0: 0th bit of Control Field 1 0 0 1: 1st bit of Control Field 1 0 1 0: 2nd bit of Control Field 1 0 1 1: 3rd bit of Control Field 1 1 0 0: 4th bit of Control Field 1 1 0 1: 5th bit of Control Field 1 1 1 0: 6th bit of Control Field 1 1 1 1: 7th bit of Control Field 1	R/W

40.2.23 Control Register 2 (CR2)

Address(es): SCI12.CR2 0008 B323h

	b7	b6	b5	b4	b3	b2	b1	b0
	RTS[1:0]		BCCS[1:0]		—	DFCS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	DFCS[2:0]	RXDX12 Signal Digital Filter Clock Select	b2 b0 0 0 0: Filter is disabled. 0 0 1: Filter clock is SCI base clock*1, *2 0 1 0: Filter clock is PCLK/8 0 1 1: Filter clock is PCLK/16 1 0 0: Filter clock is PCLK/32 1 0 1: Filter clock is PCLK/64 1 1 0: Filter clock is PCLK/128 1 1 1: Setting prohibited	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5, b4	BCCS[1:0]	Bus Collision Detection Clock Select	• When SEMR.BGDM = 0 or SEMR.BGDM = 1 and SMR.CKS[1:0] = a value other than 00b b5 b4 0 0: SCI base clock 0 1: SCI base clock frequency divided by 2 1 0: SCI base clock frequency divided by 4 1 1: Setting prohibited • When SEMR.BGDM = 1 and SMR.CKS[1:0] = 00b b5 b4 0 0: SCI base clock frequency divided by 2 0 1: SCI base clock frequency divided by 4 1 0: Setting prohibited 1 1: Setting prohibited	R/W
b7, b6	RTS[1:0]	RXDX12 Reception Sampling Timing Select	• When SCI12.SEMR.ABCS = 0 b7 b6 0 0: Rising edge of the 8th cycle of SCI base clock 0 1: Rising edge of the 10th cycle of SCI base clock 1 0: Rising edge of the 12th cycle of SCI base clock 1 1: Rising edge of the 14th cycle of SCI base clock • When SCI12.SEMR.ABCS = 1 b7 b6 0 0: Rising edge of the 4th cycle of SCI base clock 0 1: Rising edge of the 5th cycle of SCI base clock 1 0: Rising edge of the 6th cycle of SCI base clock 1 1: Rising edge of the 7th cycle of SCI base clock	R/W

Note: The period of the SCI base clock is 1/16 of a single bit period when the SCI12.SEMR.ABCS is 0, and 1/8 of a single bit period when the SCI12.SEMR.ABCS is 1.
Note 1. To use the SCI base clock, set the SCI12.SCR.TE bit to 1.
Note 2. The SCI base clock divided by 2 is the filter clock when the SEMR.BGDM bit is 1 and the SMR.CKS[1:0] bits are 00b.

40.2.24 Control Register 3 (CR3)

Address(es): SCI12.CR3 0008 B324h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SDST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SDST	Start Frame Detection Start	0: Detection of Start Frame is not performed. 1: Detection of Start Frame is performed.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SDST Bit (Start Frame Detection Start)

Detection of a Start Frame begins when this bit is set to 1. The bit is read as 0.

40.2.25 Port Control Register (PCR)

Address(es): SCI12.PCR 0008 B325h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	SHARPS	—	—	RXDXPS	TXDXPS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TXDXPS	TXDX12 Signal Polarity Select	0: The polarity of TXDX12 signal is not inverted for output. 1: The polarity of TXDX12 signal is inverted for output.	R/W
b1	RXDXPS	RXDX12 Signal Polarity Select	0: The polarity of RXDX12 signal is not inverted for input. 1: The polarity of RXDX12 signal is inverted for input.	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	SHARPS	TXDX12/RXDX12 Pin Multiplexing Select	0: The TXDX12 and RXDX12 pins are independent. 1: The TXDX12 and RXDX12 signals are multiplexed on the same pin.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SHARPS Bit (TXDX12/RXDX12 Pin Multiplexing Select)

When this bit is set to 1, the TXDX12 and RXDX12 signals are multiplexed on the same pin so that half-duplex communications become possible.

40.2.26 Interrupt Control Register (ICR)

Address(es): SCI12.ICR 0008 B326h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	AEDIE	BCDIE	PIBDIE	CF1MIE	CF0MIE	BFDIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BFDIE	Break Field Low Width Detected Interrupt Enable	0: Interrupts on detection of the low width for a Break Field are disabled. 1: Interrupts on detection of the low width for a Break Field are enabled.	R/W
b1	CF0MIE	Control Field 0 Match Detected Interrupt Enable	0: Interrupts on detection of a match with Control Field 0 are disabled. 1: Interrupts on detection of a match with Control Field 0 are enabled.	R/W
b2	CF1MIE	Control Field 1 Match Detected Interrupt Enable	0: Interrupts on detection of a match with Control Field 1 are disabled. 1: Interrupts on detection of a match with Control Field 1 are enabled.	R/W
b3	PIBDIE	Priority Interrupt Bit Detected Interrupt Enable	0: Interrupts on detection of the priority interrupt bit are disabled. 1: Interrupts on detection of the priority interrupt bit are enabled.	R/W
b4	BCDIE	Bus Collision Detected Interrupt Enable	0: Interrupts on detection of a bus collision are disabled. 1: Interrupts on detection of a bus collision are enabled.	R/W
b5	AEDIE	Valid Edge Detected Interrupt Enable	0: Interrupts on detection of a valid edge are disabled. 1: Interrupts on detection of a valid edge are enabled.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

40.2.27 Status Register (STR)

Address(es): SCI12.STR 0008 B327h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	AEDF	BCDF	PIBDF	CF1MF	CF0MF	BFDF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BFDF	Break Field Low Width Detection Flag	[Setting conditions] • Detection of the low width for a Break Field • Completion of the output of the low width for a Break Field • Underflow of the timer [Clearing condition] • Writing 1 to the BFDCL bit in STCR	R
b1	CF0MF	Control Field 0 Match Flag	[Setting condition] • A match between the value received in Control Field 0 and the set value. [Clearing condition] • Writing 1 to the CF0MCL bit in STCR	R
b2	CF1MF	Control Field 1 Match Flag	[Setting condition] • A match between the data received in Control Field 1 and the set values. [Clearing condition] • Writing 1 to the CF1MCL bit in STCR	R
b3	PIBDF	Priority Interrupt Bit Detection Flag	[Setting condition] • Detection of the priority interrupt bit [Clearing condition] • Writing 1 to the PIBDCL bit in STCR	R
b4	BCDF	Bus Collision Detected Flag	[Setting condition] • Detection of the bus collision [Clearing condition] • Writing 1 to the BCDCL bit in STCR	R
b5	AEDF	Valid Edge Detection Flag	[Setting condition] • Detection of a valid edge [Clearing condition] • Writing 1 to the AEDCL bit in STCR	R
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R

40.2.28 Status Clear Register (STCR)

Address(es): SCI12.STCR 0008 B328h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	AEDCL	BCDCL	PIBDCL	CF1MCL	CF0MCL	BFDCL
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BFDCL	BFDF Clear	Setting this bit to 1 clears the STR.BFDF flag. This bit is read as 0.	R/W
b1	CF0MCL	CF0MF Clear	Setting this bit to 1 clears the STR.CF0MF flag. This bit is read as 0.	R/W
b2	CF1MCL	CF1MF Clear	Setting this bit to 1 clears the STR.CF1MF flag. This bit is read as 0.	R/W
b3	PIBDCL	PIBDF Clear	Setting this bit to 1 clears the STR.PIBDF flag. This bit is read as 0.	R/W
b4	BCDCL	BCDF Clear	Setting this bit to 1 clears the STR.BCDF flag. This bit is read as 0.	R/W
b5	AEDCL	AEDF Clear	Setting this bit to 1 clears the STR.AEDF flag. This bit is read as 0.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

40.2.29 Control Field 0 Data Register (CF0DR)

Address(es): SCI12.CF0DR 0008 B329h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

The CF0DR register is an 8-bit readable and writable register that holds a value for comparison with Control Field 0.

40.2.30 Control Field 0 Compare Enable Register (CF0CR)

Address(es): SCI12.CF0CR 0008 B32Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	CF0CE7	CF0CE6	CF0CE5	CF0CE4	CF0CE3	CF0CE2	CF0CE1	CF0CE0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CF0CE0	Control Field 0 Bit 0 Compare Enable	0: Comparison with bit 0 of Control Field 0 is disabled. 1: Comparison with bit 0 of Control Field 0 is enabled.	R/W
b1	CF0CE1	Control Field 0 Bit 1 Compare Enable	0: Comparison with bit 1 of Control Field 0 is disabled. 1: Comparison with bit 1 of Control Field 0 is enabled.	R/W
b2	CF0CE2	Control Field 0 Bit 2 Compare Enable	0: Comparison with bit 2 of Control Field 0 is disabled. 1: Comparison with bit 2 of Control Field 0 is enabled.	R/W
b3	CF0CE3	Control Field 0 Bit 3 Compare Enable	0: Comparison with bit 3 of Control Field 0 is disabled. 1: Comparison with bit 3 of Control Field 0 is enabled.	R/W
b4	CF0CE4	Control Field 0 Bit 4 Compare Enable	0: Comparison with bit 4 of Control Field 0 is disabled. 1: Comparison with bit 4 of Control Field 0 is enabled.	R/W
b5	CF0CE5	Control Field 0 Bit 5 Compare Enable	0: Comparison with bit 5 of Control Field 0 is disabled. 1: Comparison with bit 5 of Control Field 0 is enabled.	R/W
b6	CF0CE6	Control Field 0 Bit 6 Compare Enable	0: Comparison with bit 6 of Control Field 0 is disabled. 1: Comparison with bit 6 of Control Field 0 is enabled.	R/W
b7	CF0CE7	Control Field 0 Bit 7 Compare Enable	0: Comparison with bit 7 of Control Field 0 is disabled. 1: Comparison with bit 7 of Control Field 0 is enabled.	R/W

40.2.31 Control Field 0 Receive Data Register (CF0RR)

Address(es): SCI12.CF0RR 0008 B32Bh

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

CF0RR is a readable register that holds the value received in Control Field 0. Writing to this register from the CPU or DTC is not possible.

40.2.32 Primary Control Field 1 Data Register (PCF1DR)

Address(es): SCI12.PCF1DR 0008 B32Ch

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

PCF1DR is an 8-bit readable and writable register that holds the 8-bit primary value for comparison with Control Field 1.

40.2.33 Secondary Control Field 1 Data Register (SCF1DR)

Address(es): SCI12.SCF1DR 0008 B32Dh

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

PCF1DR is an 8-bit readable and writable register that holds the 8-bit secondary value for comparison with Control Field 1.

40.2.34 Control Field 1 Compare Enable Register (CF1CR)

Address(es): SCI12.CF1CR 0008 B32Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	CF1CE7	CF1CE6	CF1CE5	CF1CE4	CF1CE3	CF1CE2	CF1CE1	CF1CE0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CF1CE0	Control Field 1 Bit 0 Compare Enable	0: Comparison with bit 0 of Control Field 1 is disabled. 1: Comparison with bit 0 of Control Field 1 is enabled.	R/W
b1	CF1CE1	Control Field 1 Bit 1 Compare Enable	0: Comparison with bit 1 of Control Field 1 is disabled. 1: Comparison with bit 1 of Control Field 1 is enabled.	R/W
b2	CF1CE2	Control Field 1 Bit 2 Compare Enable	0: Comparison with bit 2 of Control Field 1 is disabled. 1: Comparison with bit 2 of Control Field 1 is enabled.	R/W
b3	CF1CE3	Control Field 1 Bit 3 Compare Enable	0: Comparison with bit 3 of Control Field 1 is disabled. 1: Comparison with bit 3 of Control Field 1 is enabled.	R/W
b4	CF1CE4	Control Field 1 Bit 4 Compare Enable	0: Comparison with bit 4 of Control Field 1 is disabled. 1: Comparison with bit 4 of Control Field 1 is enabled.	R/W
b5	CF1CE5	Control Field 1 Bit 5 Compare Enable	0: Comparison with bit 5 of Control Field 1 is disabled. 1: Comparison with bit 5 of Control Field 1 is enabled.	R/W
b6	CF1CE6	Control Field 1 Bit 6 Compare Enable	0: Comparison with bit 6 of Control Field 1 is disabled. 1: Comparison with bit 6 of Control Field 1 is enabled.	R/W
b7	CF1CE7	Control Field 1 Bit 7 Compare Enable	0: Comparison with bit 7 of Control Field 1 is disabled. 1: Comparison with bit 7 of Control Field 1 is enabled.	R/W

40.2.35 Control Field 1 Receive Data Register (CF1RR)

Address(es): SCI12.CF1RR 0008 B32Fh

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

CF1RR is a readable register that holds the value received in Control Field 1. Writing to this register from the CPU or DTC is not possible.

40.2.36 Timer Control Register (TCR)

Address(es): SCI12.TCR 0008 B330h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	TCST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TCST	Timer Count Start	0: Stops the timer counting 1: Starts the timer counting	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

40.2.37 Timer Mode Register (TMR)

Address(es): SCI12.TMR 0008 B331h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	TCSS[2:0]			TWRC	—	TOMS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	TOMS[1:0]	Timer Operating Mode Select*1	b1 b0 0 0: Timer mode 0 1: Break Field low width determination mode 1 0: Break Field low width output mode 1 1: Setting prohibited	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	TWRC	Counter Write Control	0: Data is written to the reload register and counter 1: Data is written to the reload register only	R/W
b6 to b4	TCSS[2:0]	Timer Count Clock Source Select*1	b6 b4 0 0 0: PCLK 0 0 1: PCLK/2 0 1 0: PCLK/4 0 1 1: PCLK/8 1 0 0: PCLK/16 1 0 1: PCLK/32 1 1 0: PCLK/64 1 1 1: PCLK/128	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. Rewrite the TOMS[1:0] and TCSS[2:0] bits only when the timer is stopped (TCST = 0).

TWRC Bit (Counter Write Control)

This bit determines whether a value written to TPRE or TCNT is written to the reload register only or is written to both the reload register and the counter.

40.2.38 Timer Prescaler Register (TPRE)

Address(es): SCI12.TPRE 0008 B332h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

TPRE consists of an 8-bit reload register, a read buffer, and a counter, each of which has FFh as its initial value. The counter counts down in synchronization with the counter clock selected by the TMR.TCSS[2:0] bits, and is reloaded with the value in the reload register when it underflows. Underflows of this register provide the clock source to drive counting by the TCNT register. The reload register and read buffer are allocated to the same address. Data is written to the reload register in writing, and the counter value that has been transferred to the read buffer is returned in reading.
It takes one PCLK cycle to load a value from the reload register to the counter.

40.2.39 Timer Count Register (TCNT)

Address(es): SCI12.TCNT 0008 B333h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

TCNT consists of an 8-bit reload register, a read buffer, and a counter, each of which has FFh as its initial value. This down-counter counts underflows of the TPRE register until the TCNT register underflows, and is then reloaded with the value from the reload register. The reload register and read buffer are allocated to the same address. Data is written to the reload register in writing, and the counter value that has been transferred to the read buffer is returned in reading.
It takes one PCLK cycle to load a value from the reload register to the counter.

40.3 Operation in Asynchronous Mode

Figure 40.5 shows the general format for asynchronous serial communications.
One frame consists of a start bit (low level), transmit/receive data, a parity bit, and stop bits (high level).
In asynchronous serial communications, the communications line is usually held in the mark state (high level).
The SCI monitors the communications line. When the SCI detects a low, it regards that as a start bit and starts serial communication.
Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and the receiver also have a double-buffered structure, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

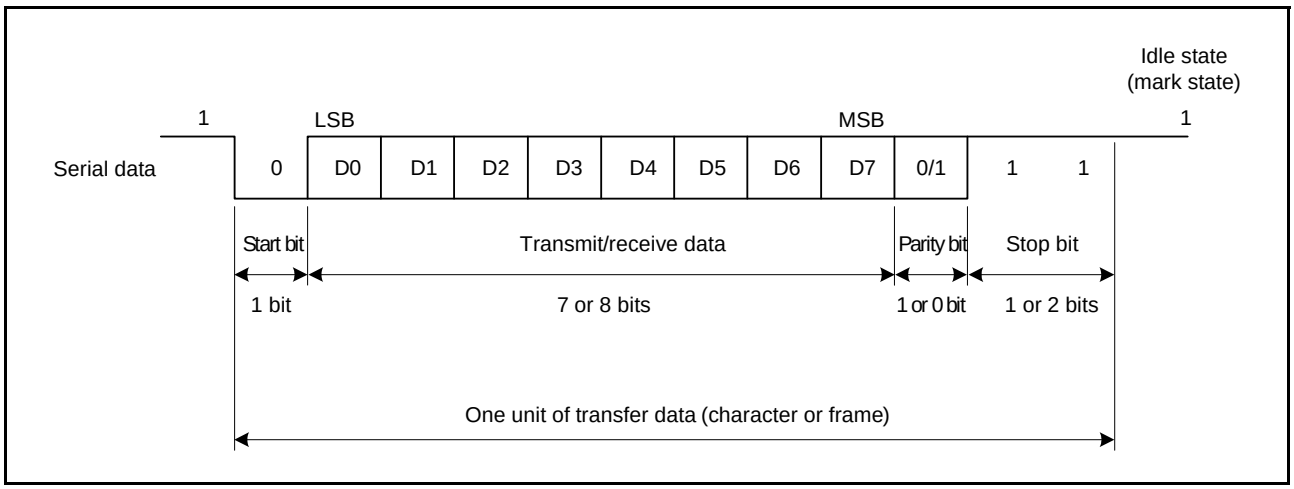

Figure 40.5 Data Format in Asynchronous Serial Communications (Example with 8-Bit Data, Parity, 2 Stop Bits)

40.3.1 Serial Data Transfer Format

Table 40.27 lists the serial data transfer formats that can be used in asynchronous mode.
Any of 18 transfer formats can be selected according to the SMR and SCMR setting. For details of multi-processor function, refer to section 40.4, Multi-Processor Communications Function.

Table 40.27 Serial Transfer Formats (Asynchronous Mode)

SCMR Setting	SMR Setting				Serial Transfer Format and Frame Length
CHR1	CHR	PE	MP	STOP	1 2 3 4 5 6 7 8 9 10 11 12 13
0	0	0	0	0	S 9-bit data STOP
0	0	0	0	1	S 9-bit data STOP STOP
0	0	1	0	0	S 9-bit data P STOP
0	0	1	0	1	S 9-bit data P STOP STOP
1	0	0	0	0	S 8-bit data STOP
1	0	0	0	1	S 8-bit data STOP STOP
1	0	1	0	0	S 8-bit data P STOP
1	0	1	0	1	S 8-bit data P STOP STOP
1	1	0	0	0	S 7-bit data STOP
1	1	0	0	1	S 7-bit data STOP STOP
1	1	1	0	0	S 7-bit data P STOP
1	1	1	0	1	S 7-bit data P STOP STOP
0	0	—	1	0	S 9-bit data MPB STOP
0	0	—	1	1	S 9-bit data MPB STOP STOP
1	0	—	1	0	S 8-bit data MPB STOP
1	0	—	1	1	S 8-bit data MPB STOP STOP
1	1	—	1	0	S 7-bit data MPB STOP
1	1	—	1	1	S 7-bit data MPB STOP STOP

S: Start bit
STOP: Stop bit
P: Parity bit
MPB: Multi-processor bit

40.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI operates on a base clock with a frequency of 16 times*1 the bit rate.
In reception, the SCI samples the falling edge of the start bit using the base clock, and performs internal synchronization. Since receive data is sampled at the rising edge of the 8th pulse*1 of the base clock, data is latched at the middle of each bit, as shown in Figure 40.6. Thus the reception margin in asynchronous mode is determined by formula (1) below.

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5)\ F - \frac{D - 0.5}{N}\ (1 + F) \right| \times 100\ [\%] \cdots \text{Formula (1)}$$

M: Reception margin
N: Ratio of bit rate to clock (N = 16 when ABCS in SEMR = 0, N = 8 when ABCS in SEMR = 1)
D: Duty cycle of clock (D = 0.5 to 1.0)
L: Frame length (L = 9 to 13)
F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined by the formula below.

M = {0.5 - 1/(2 × 16)} × 100 (%) = 46.875%

However, this is only the computed value, and a margin of 20% to 30% should be allowed in system design.

Note 1. This is an example when the ABCS bit in the SEMR register is 0. When the ABCS bit is 1, a frequency of 8 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 4th pulse of the base clock.

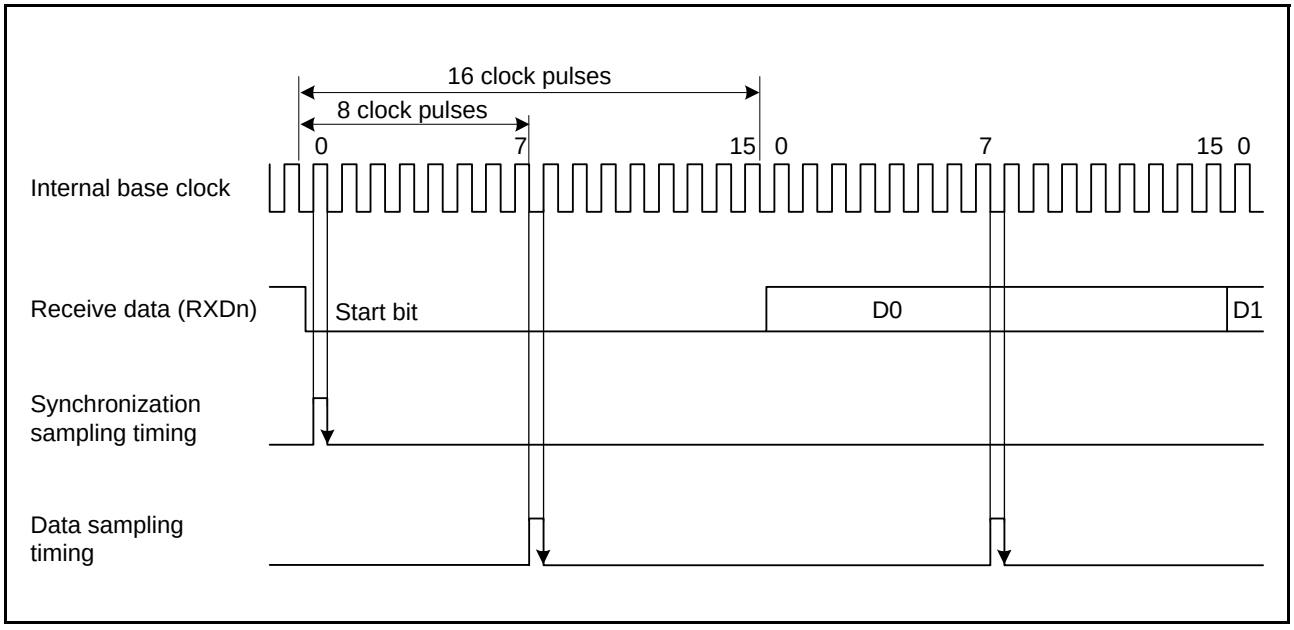

Figure 40.6 Receive Data Sampling Timing in Asynchronous Mode

40.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the SCI's transfer clock, according to the setting of the CM bit in the SMR register and the CKE[1:0] bits in the SCR register.

When an external clock is input to the SCKn pin, the clock frequency should be 16 times the bit rate (when SEMR.ABCS bit = 0) and 8 times the bit rate (when SEMR.ABCS bit = 1). In addition, when an external clock is specified, the base clock of TMR0 and TMR1 can be selected by the SCIn.SEMR.ACS0 bit (n = 5, 6, 12).

When the SCI is operated on an internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is such that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 40.7.

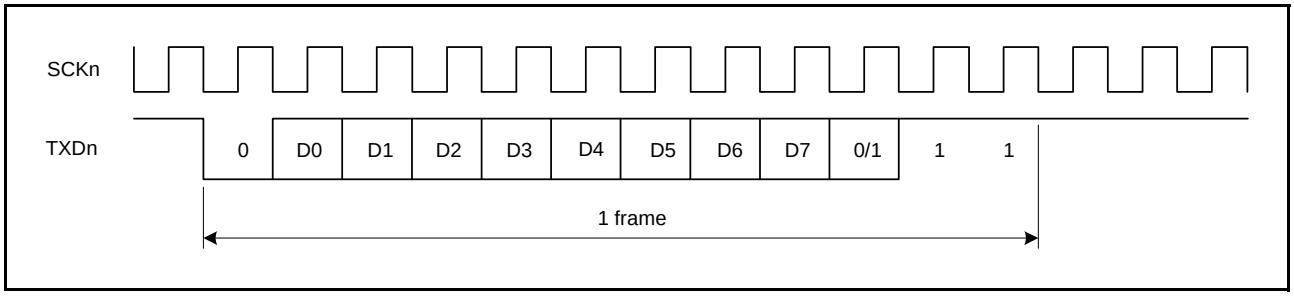

Figure 40.7 Phase Relationship between Output Clock and Transmit Data (Asynchronous Mode: SMR.CHR = 0, PE = 1, MP = 0, STOP = 1)

40.3.4 Double-Speed Mode

The output clock frequency of the on-chip baud rate generator is doubled by setting the SEMR.BGDM bit to 1, enabling high-speed communication at a doubled bit rate. If the SEMR.ABCS bit is set to 1 under the above condition, the number of base clock cycles changes from 16 to 8, so the bit rate becomes four times faster than the initial state.

As shown by Formula (1) in section 40.3.2, Receive Data Sampling Timing and Reception Margin in Asynchronous Mode, setting the SEMR.ABCS bit to 1 changes the number of cycles to 8, and the sampling interval becomes longer. This causes the reception margin to decrease. Therefore, setting the SEMR.BGDM bit to 1 and the SEMR.ABCS bit to 0 is recommended instead of setting the SEMR.BGDM bit to 0 and the SEMR.ABCS bit to 1 for high-speed operation at a doubled bit rate.

40.3.5 CTS and RTS Functions

The CTS function is the use of input on the CTSn# pin in transmission control. Setting the SPMR.CTSE bit to 1 enables the CTS function. When the CTS function is enabled, placing the low level on the CTSn# pin causes transmission to start.
Applying the high level to the CTS# pin while transmission is in progress does not affect transmission of the current frame, which continues.
In the RTS function, by using the function of output on the RTSn# pin, a low level is output when reception becomes possible. Conditions for output of the low and high level are shown below.

[Conditions for low-level output]
When the following conditions are all satisfied

- The SCR.RE bit is 1
- Reception is not in progress
- There are no received data yet to be read
- The ORER, FER, and PER flags in the SSR are all 0

[Condition for high-level output]
When the conditions for low-level output are not satisfied

Note that either one of CTS and RTS can be selected.

40.3.6 SCI Initialization (Asynchronous Mode)

Before transmitting and receiving data, start by writing the initial value 00h to the SCR register and then continue through the procedure for SCI given in Figure 40.8. Whenever the operating mode or transfer format is changed, the SCR register must be initialized before the change is made.

When the external clock is used in asynchronous mode, ensure that the clock signal is supplied even during initialization.

Note that setting the SCR.RE bit to 0 initializes neither the ORER, FER, PER, and RDRF flags in the SSR register nor registers RDR, RDRH, and RDRL.

Moreover, note that changing the value of the SCR.TE bit from 1 to 0 or 0 to 1 while the SCR.TIE bit is 1 leads to the generation of a transmit data empty interrupt (TXI) request.

In addition, note that setting bits TIE, TE, and TEIE in the SCR register to 1 simultaneously leads to the generation of a transmit end interrupt (TEI) request before the generation of a TXI interrupt request.

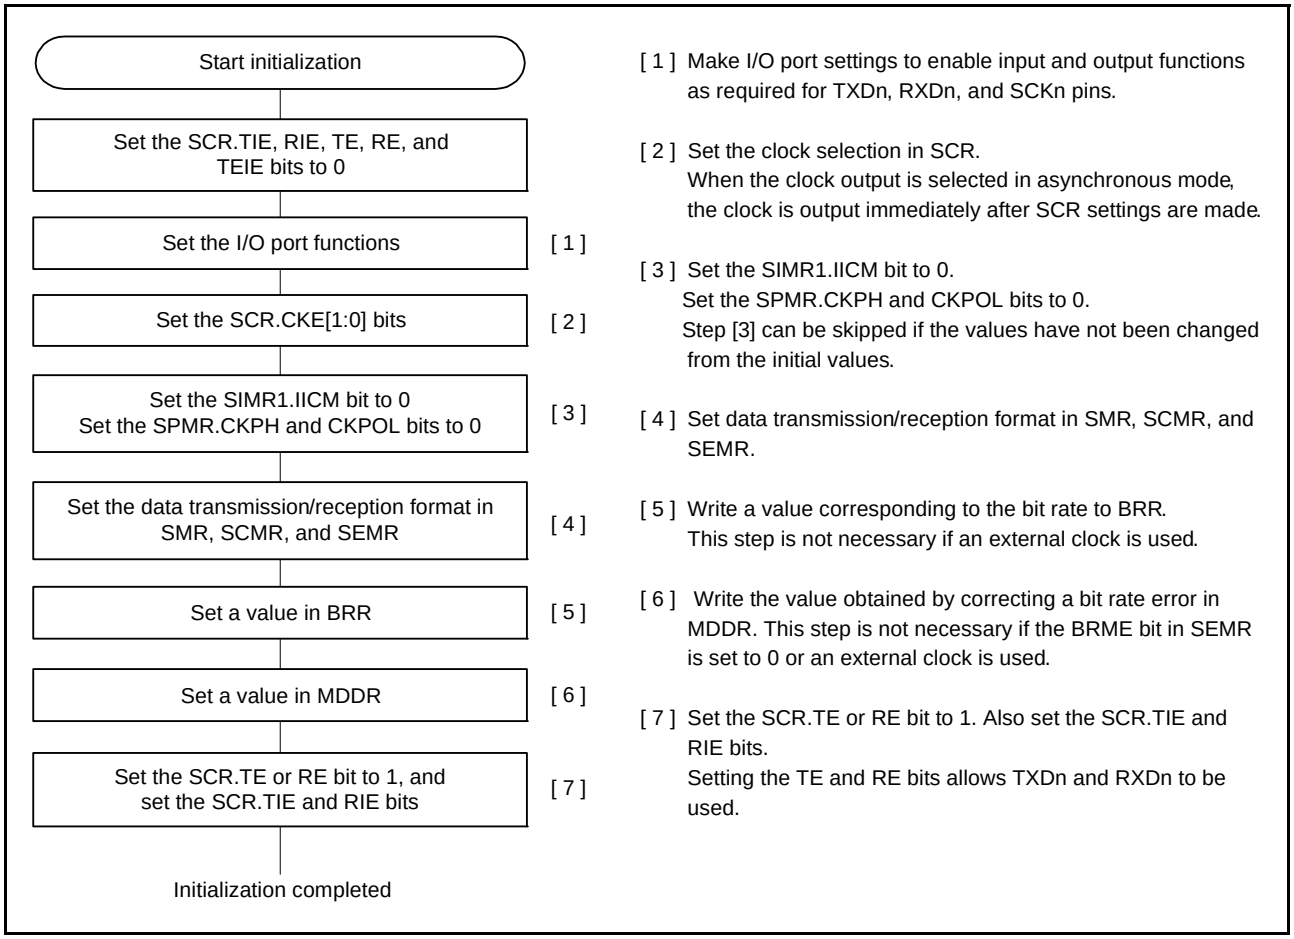

Figure 40.8 Sample SCI Initialization Flowchart (Asynchronous Mode)

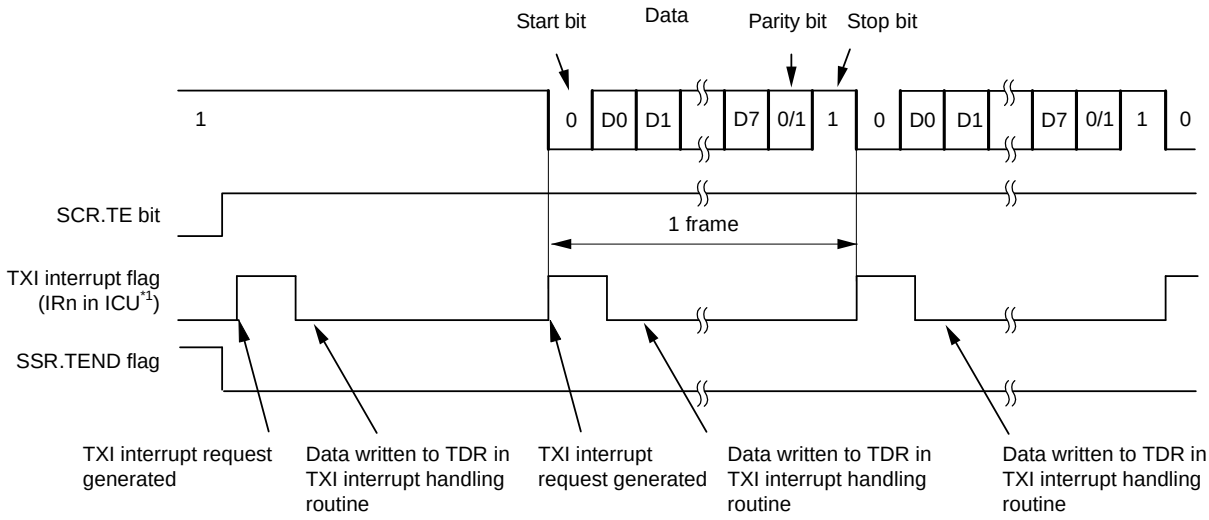
40.3.7 Serial Data Transmission (Asynchronous Mode)

Figure 40.9 to Figure 40.11 show an example of the operation for serial transmission in asynchronous mode.
In serial transmission, the SCI operates as described below.

1. The SCI transfers data from the TDR register*1 to the TSR register when data is written to the TDR register*1 in the TXI interrupt handling routine. The TXI interrupt request at the beginning of transmission is generated when the SCR.TE bit is set to 1 after the SCR.TIE bit is set to 1 or when these 2 bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) and a low level on the CTSn# pin causes data transfer from the TDR register*1 to the TSR register. If the SCR.TIE bit is 1 at this time, a TXI interrupt request is generated. Continuous transmission is obtainable by writing the next transmit data to the TDR register*1 in the TXI interrupt handling routine before transmission of the current transmit data is completed. When TEI interrupt requests are in use, set the SCR.TIE bit to 0 (a TXI interrupt request is disabled) and the SCR.TEIE bit to 1 (a TEI interrupt request is enabled) after the last of the data to be transmitted are written to the TDR register*1, *2 from the handling routine for TXI requests.
3. Data is sent from the TXDn pin in the following order: start bit, transmit data, parity bit or multi-processor bit (may be omitted depending on the format), and stop bit.
4. The SCI checks for updating of (writing to) the TDR register*3 at the time of stop bit output.
5. When the TDR register*3 is updated, setting of the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn# pin cause the next transfer of the next transmit data from the TDR register*1 to the TSR register and sending of the stop bit, after which serial transmission of the next frame starts.
6. If the TDR register*3 is not updated, the SSR.TEND flag is set to 1, the stop bit is sent, and then the mark state is entered in which 1 is output. If the SCR.TEIE bit is 1 at this time, the SSR.TEND flag is set to 1 and a TEI interrupt request is generated.

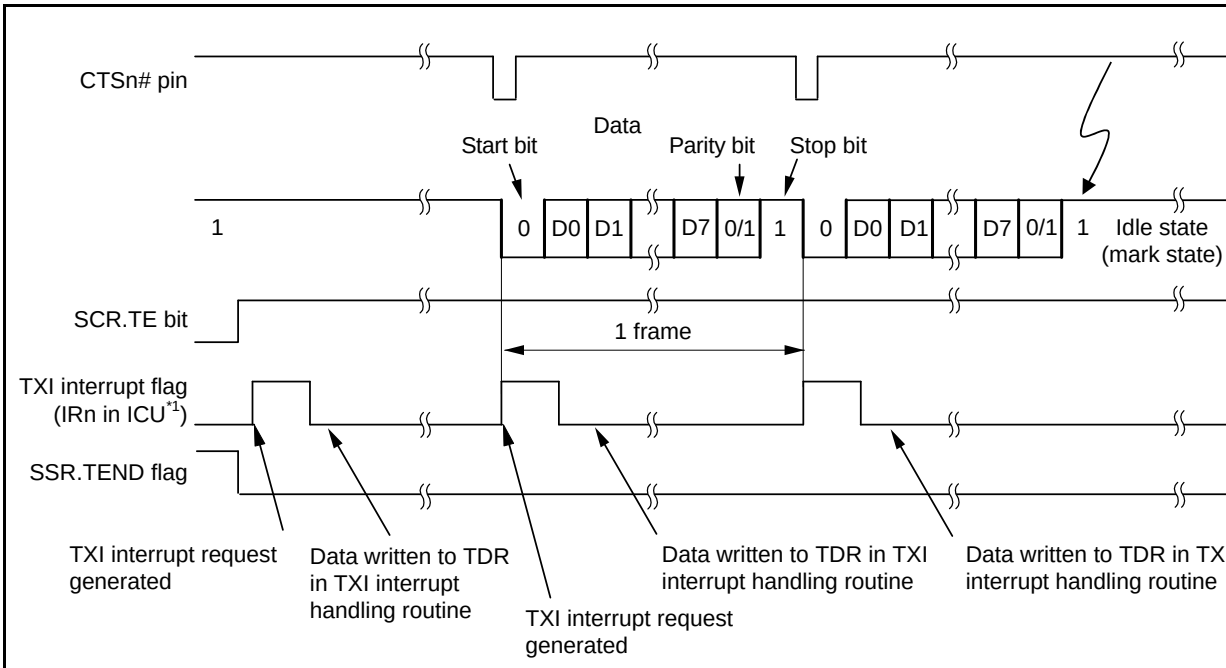
Note 1. Write data not to the TDR register but to the TDRH and TDRL registers when 9-bit data length is selected.
Note 2. Write data in the order from the TDRH register to the TDRL register when 9-bit data length is selected.
Note 3. The SCI checks for updating of the TDRL register only and does not check for updating of the TDRH register when 9-bit data length is selected.

Figure 40.12 shows a sample flowchart for serial transmission in asynchronous mode.



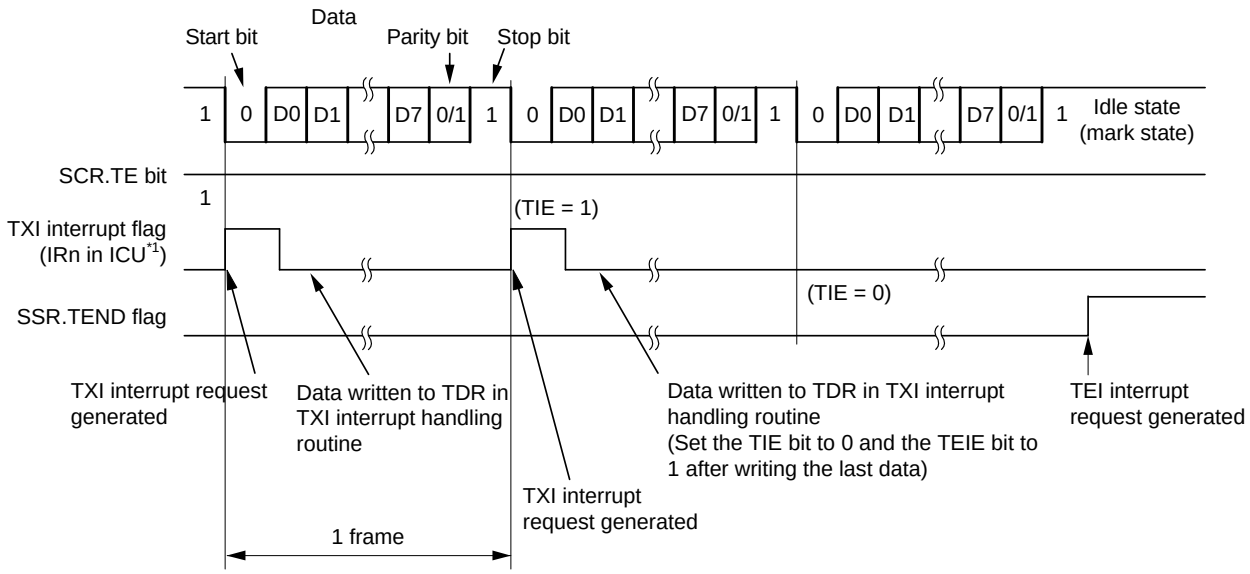
Note 1. Refer to the Interrupt Controller section for details on the corresponding interrupt vector number.

Figure 40.9 Example of Operation for Serial Transmission in Asynchronous Mode (1) (with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Not Used, at the Beginning of Transmission)



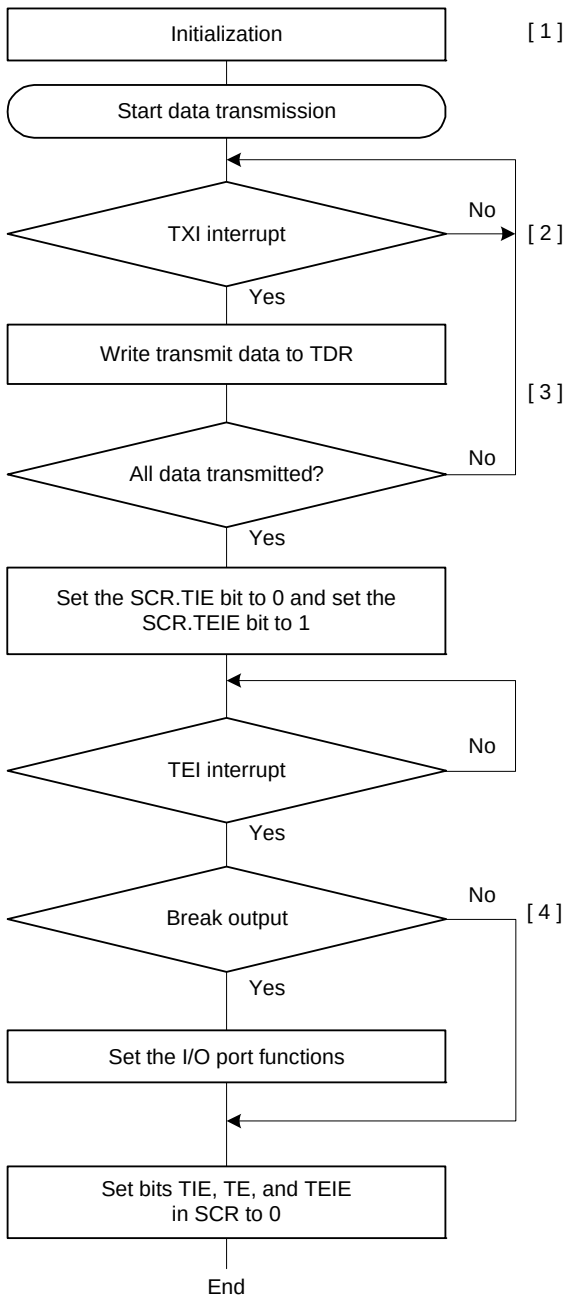
Note 1. Refer to the Interrupt Controller section for details on the corresponding interrupt vector number.

Figure 40.10 Example of Operation for Serial Transmission in Asynchronous Mode (2) (with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Used, at the Beginning of Transmission)



Note 1. Refer to the Interrupt Controller section for details on the corresponding interrupt vector number.

Figure 40.11 Example of Operation for Serial Transmission in Asynchronous Mode (3) (with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Not Used, from the Middle of Transmission until Transmission Completion)



[1] SCI initialization:
Set data transmission.
After the TE bit in SCR is set to 1, 1 is output for a frame, and transmission is enabled.

[2] Transmit data write to TDR by a TXI interrupt request:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (TXI) request is generated.
Write transmit data to TDR once in the TXI interrupt handling routine.

[3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR once using a TXI interrupt request.
Transmit data can also be written to TDR by activating the DMAC or DTC.
When TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted are written to the TDR

[4] Break output at the end of serial transmission:
To output a break in serial transmission, set the I/O port function corresponding to the TXDn pin (corresponding to output of the low level), and after switching the TXDn pin to the general I/O port function, set the TE bit in the SCR to 0.

Note: The TDR register becomes the TDRH and TDRL registers when 9-bit data length is selected. Write data in the order from TDRH to TDRL.

Figure 40.12 Example of Serial Transmission Flowchart in Asynchronous Mode

40.3.8 Serial Data Reception (Asynchronous Mode)

Figure 40.13 and Figure 40.14 show an example of the operation for serial data reception in asynchronous mode. In serial data reception, the SCI operates as described below.

1. When the value of the SCR.RE bit becomes 1, the output signal on the RTSn# pin goes to the low level.
2. When the SCI monitors the communications line and detects a start bit, it performs internal synchronization, stores receive data in the RSR register, and checks the parity bit and stop bit.
3. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to the RDR register*1.
4. If a parity error is detected, the SSR.PER flag is set to 1 and receive data is transferred to the RDR register*1. If the SCR.RIE bit is 1 at this time, an ERI interrupt request is generated.
5. If a framing error (when the stop bit is 0) is detected, the SSR.FER flag is set to 1 and receive data is transferred to the RDR register*1. If the SCR.RIE bit is 1 at this time, an ERI interrupt request is generated.
6. When reception finishes successfully, receive data is transferred to the RDR register*1. If the SCR.RIE bit is 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register*1 in this RXI interrupt handling routine before reception of the next receive data is completed. Reading the received data that have been transferred to the RDR register*1 causes the RTSn# pin to output the low level.

Note 1. Read data not in the RDR register but in the RDRH and RDRL registers when 9-bit data length is selected.
Note 2. The SCI checks for reading of the RDRL register only and does not check for reading of the RDRH register when 9-bit data length is selected.

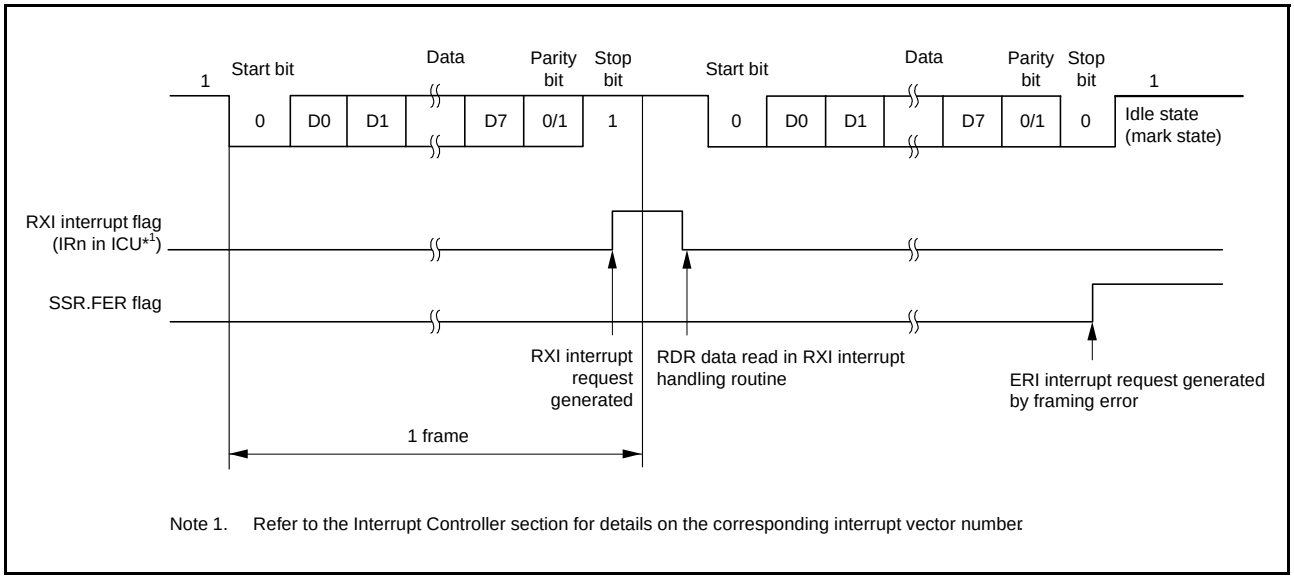


Figure 40.13 Example of SCI Operation for Serial Reception in Asynchronous Mode (1) (When RTS Function is Not Used) (Example with 8-Bit Data, Parity, 1 Stop Bit)

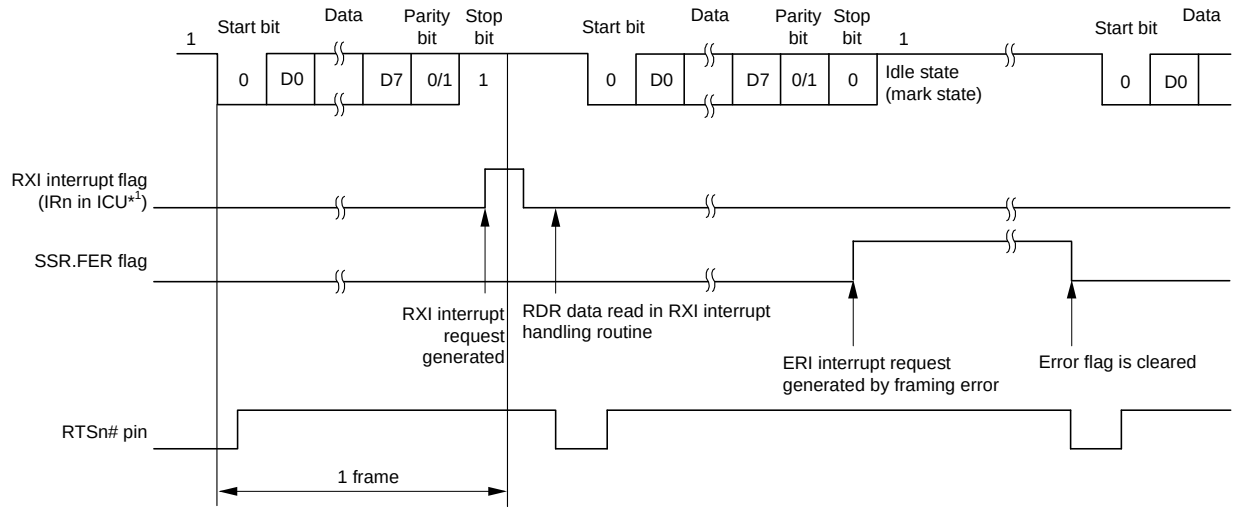

Note 1. Refer to the Interrupt Controller section for details on the corresponding interrupt vector number.

Figure 40.14 Example of SCI Operation for Serial Reception in Asynchronous Mode (2) (When RTS Function is Used) (Example with 8-Bit Data, Parity, 1 Stop Bit)

Table 40.28 lists the states of the flags in the SSR status register and receive data handling when a receive error is detected.

If a receive error is detected, an ERI interrupt request is generated but an RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, and PER flags to 0 before resuming reception. Moreover, be sure to read the RDR (or the RDRL) during overrun error processing. When a reception is forcibly terminated by setting the SCR.RE bit to 0 during operation, read the RDR (or the RDRL) register because received data which has not yet been read may be left in RDR (or the RDRL).

Figure 40.15 and Figure 40.16 show samples of flowcharts for serial data reception.

Table 40.28 Flags in the SSR Status Register and Receive Data Handling

Flags in the SSR Status Register				
ORER	**FER**	**PER**	**Receive Data**	**Receive Error Type**
1	0	0	Lost	Overrun error
0	1	0	Transferred to RDR*1	Framing error
0	0	1	Transferred to RDR*1	Parity error
1	1	0	Lost	Overrun error + framing error
1	0	1	Lost	Overrun error + parity error
0	1	1	Transferred to RDR*1	Framing error + parity error
1	1	1	Lost	Overrun error + framing error + parity error

Note 1. Read data not in RDR but in the RDRH and RDRL registers when 9-bit data length is selected.

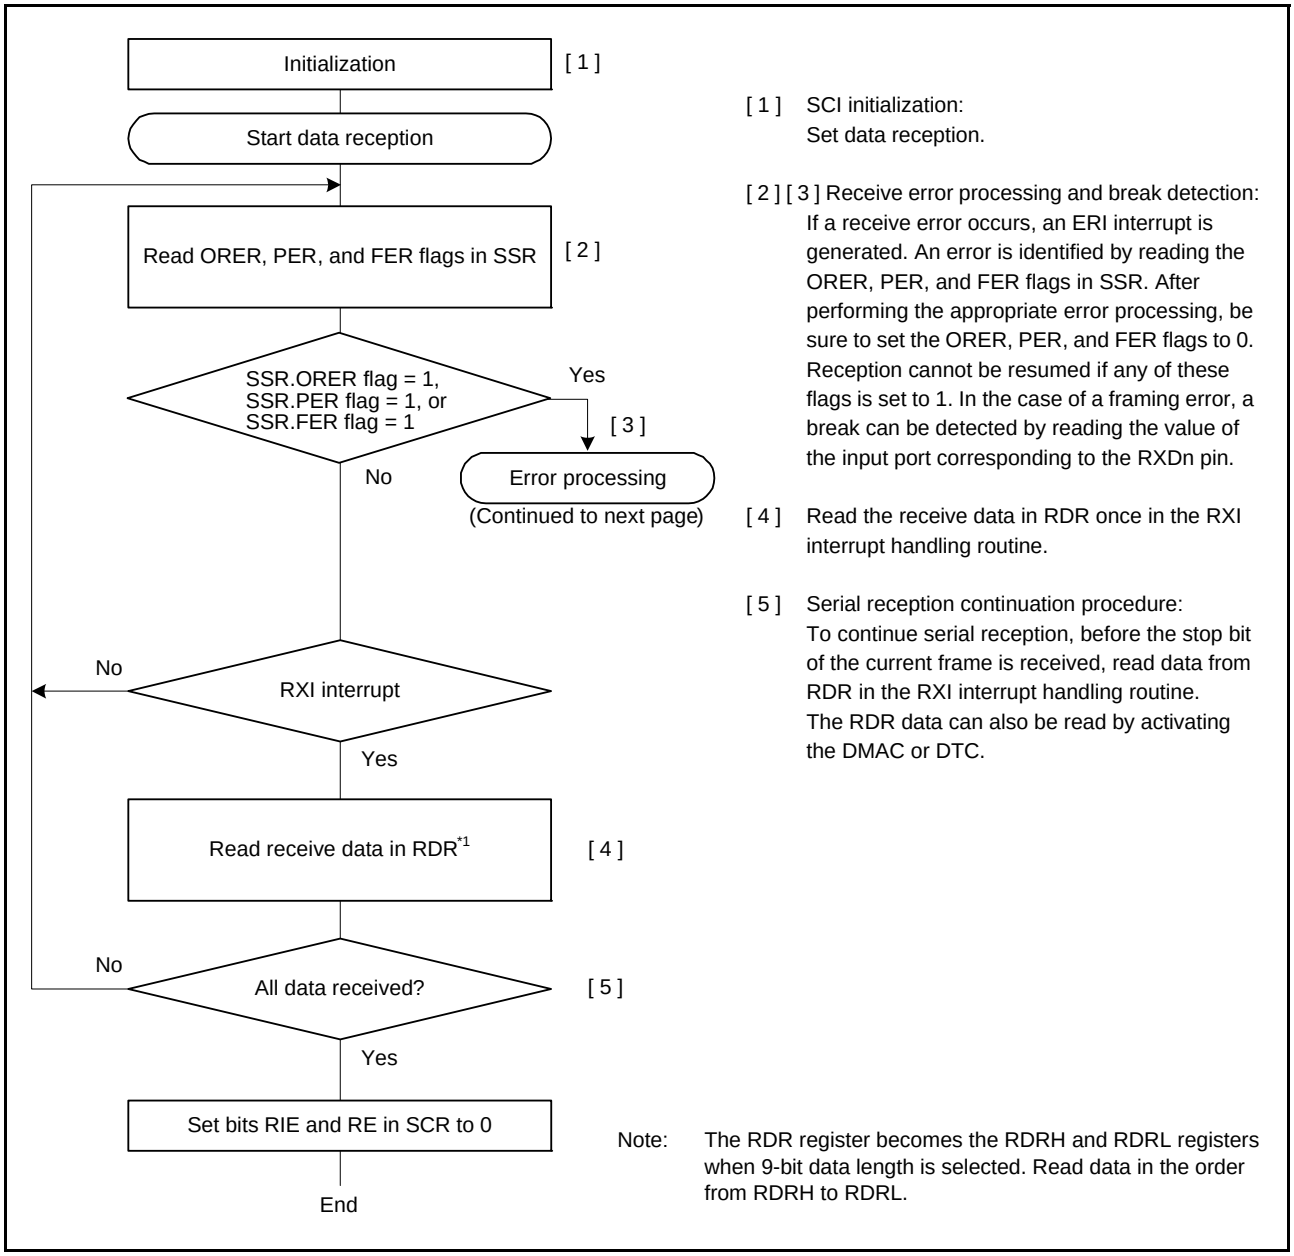

Figure 40.15 Example Flowchart of Serial Reception in Asynchronous Mode (1)

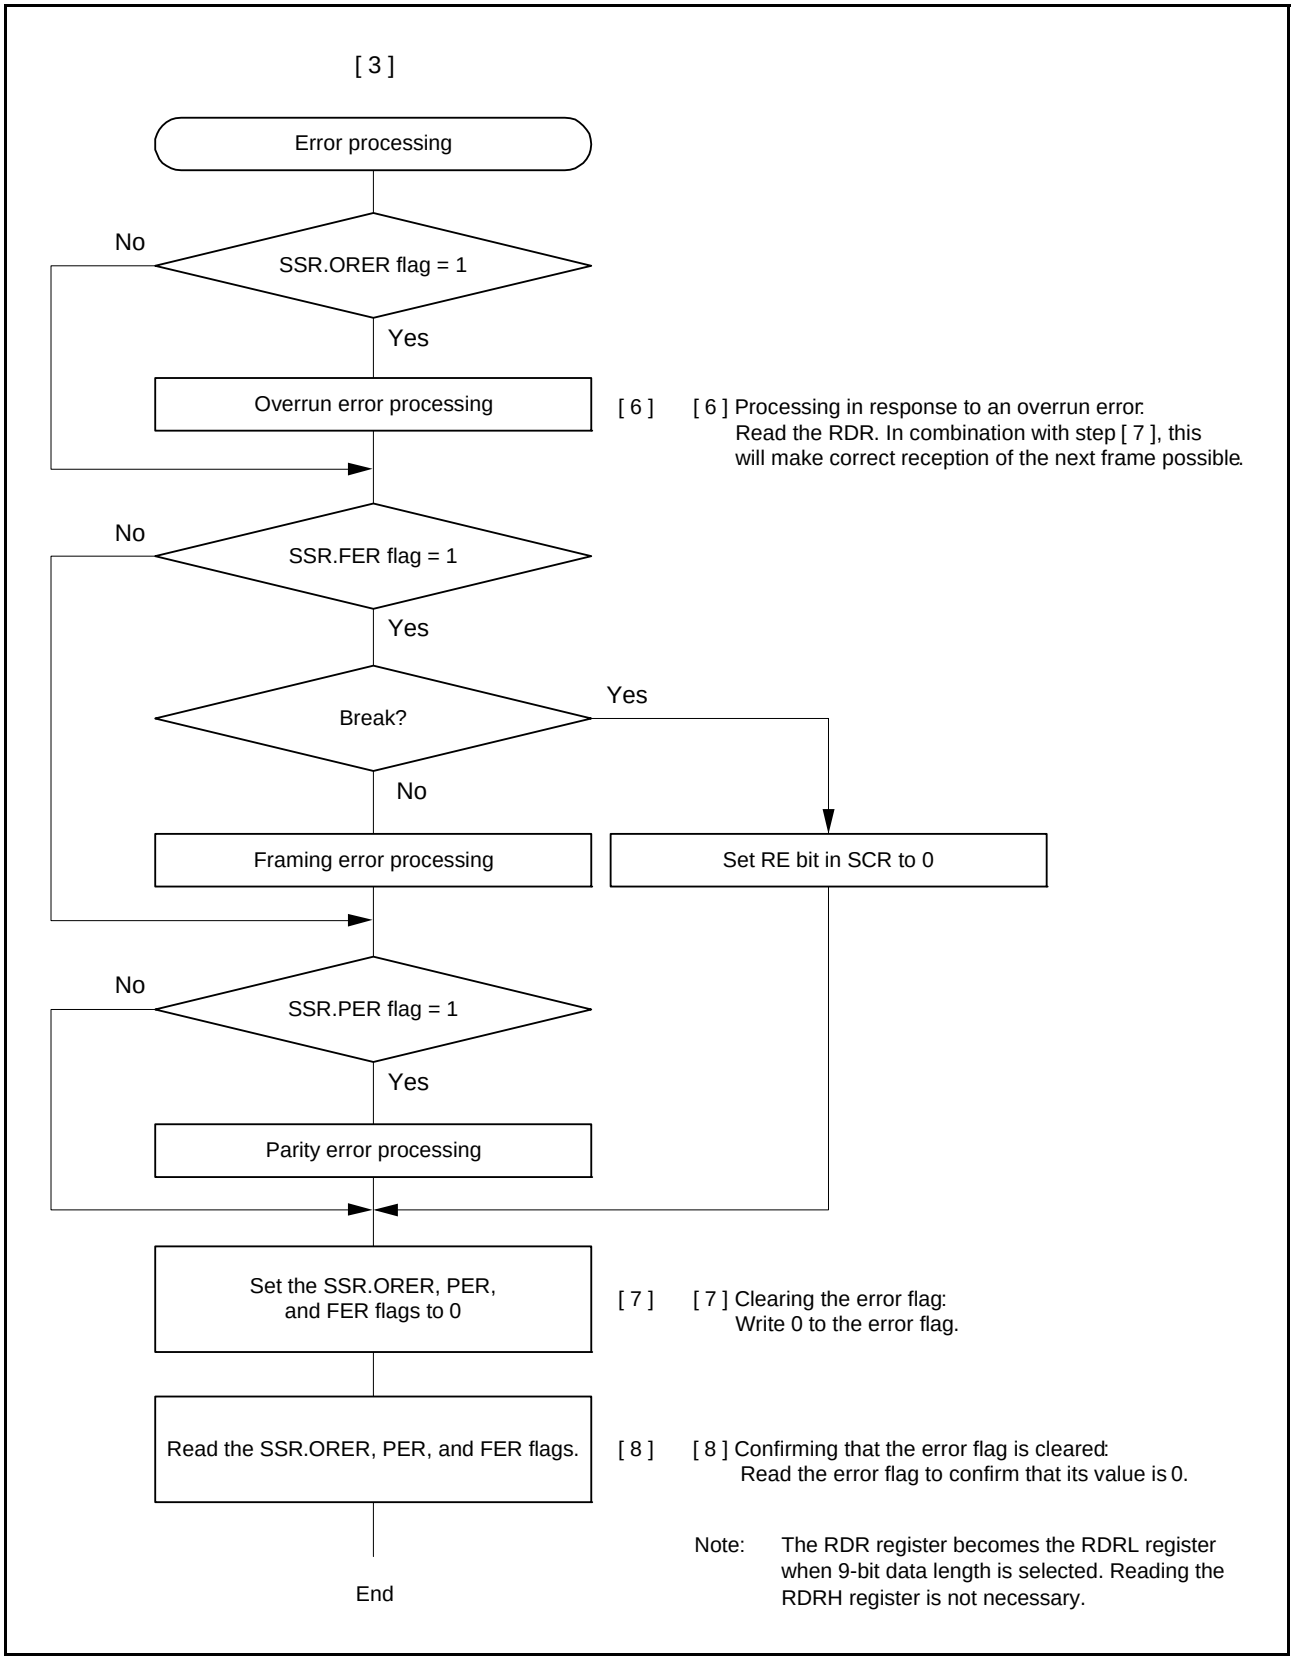

Figure 40.16 Example Flowchart of Serial Reception in Asynchronous Mode (2)

40.4 Multi-Processor Communications Function

Using the multi-processor communication functions enables to transmit and receive data by sharing a communication line between multiple processors by using asynchronous serial communication in which the multi-processor bit is added. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station. The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle. When the multi-processor bit is set to 1, it indicates the ID transmission cycle and when the multi-processor bit is set to 0, it indicates the data transmission cycle. Figure 40.17 shows an example of communication between processors by using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits the communication data in which the multi-processor bit set to 0 is added to the transmit data. Upon receiving the communication data in which the multi-processor bit is set to 1, the receiving station compares the received ID with the ID of the receiving station itself and if the two match, receives the communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until again receiving the communication data in which the multi-processor bit is set to 1.

For supporting this function, the SCI provides the SCR.MPIE bit. When the MPIE bit is set to 1, transfer of receive data from the RSR register to the RDR register (the RDRH and RDRL registers when 9-bit data length is selected), detection of a receive error, and setting the respective status flags ORER and FER in the SSR register are disabled until reception of data in which the multi-processor bit is set to 1. Upon receiving a reception character in which the multi-processor bit is set to 1, the SSR.MPB bit is set to 1 and the SCR.MPIE bit is automatically cleared, thus returning to a normal reception operation. During this time, an RXI interrupt is generated if the SCR.RIE bit is 1.

When the multi-processor format is specified, specification of the parity bit is disabled. Apart from this, there is no difference from the operation in the normal asynchronous mode. A clock which is used for the multi-processor communication is also the same as the clock used in the normal asynchronous mode.

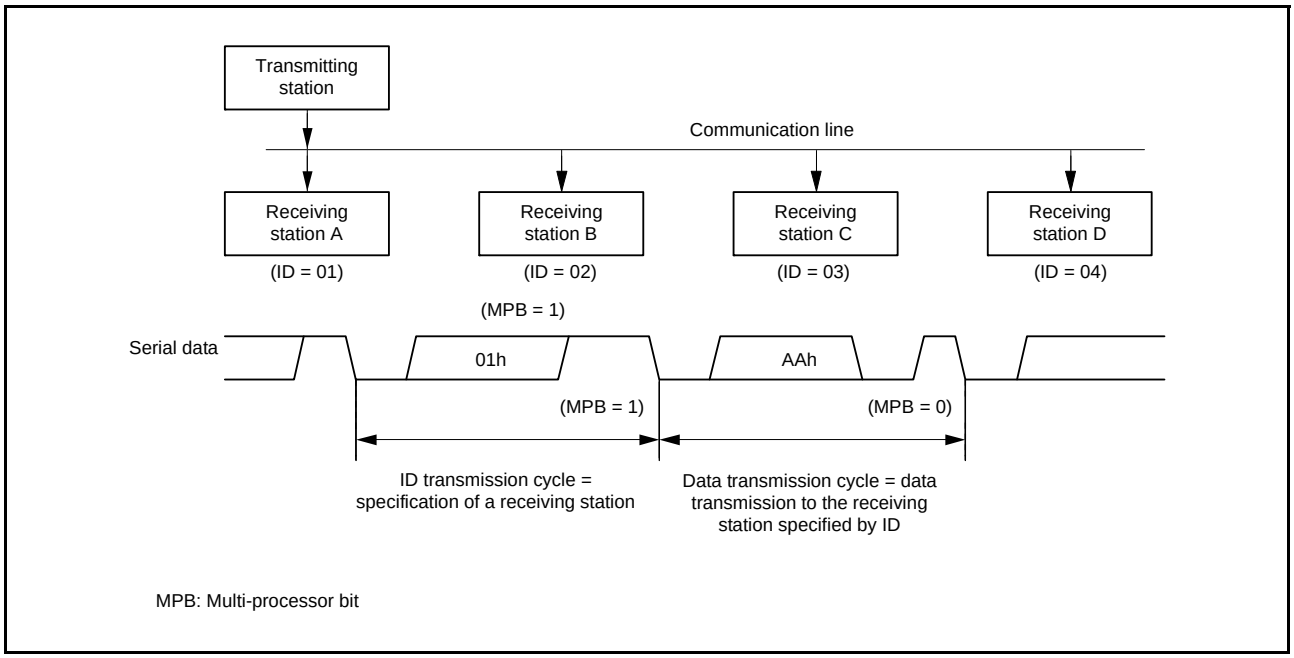

Figure 40.17 An Example of Communication using the Multi-Processor Format (Example of Transmission of Data AAh to Receiving Station A)

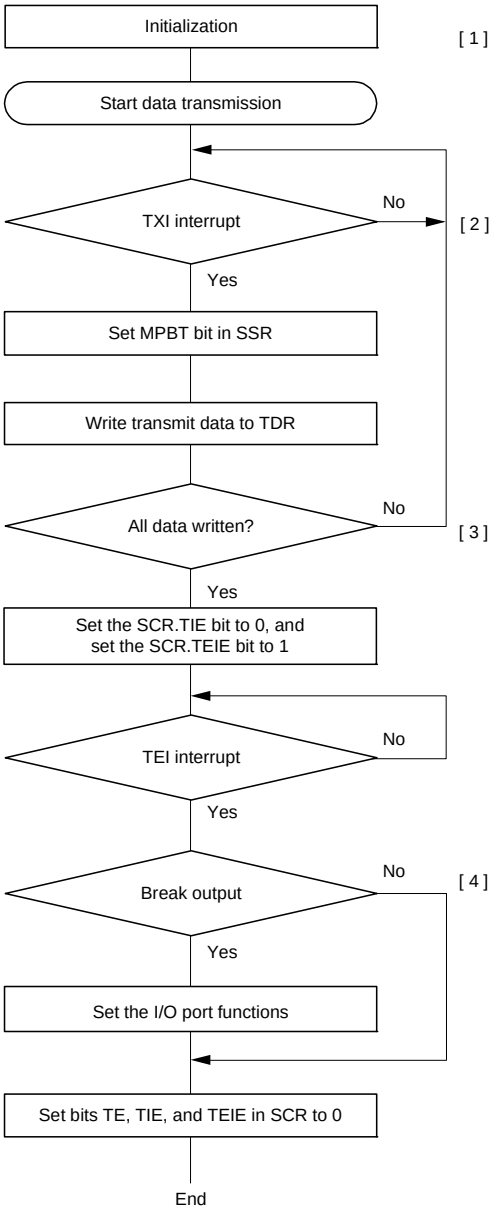
40.4.1 Multi-Processor Serial Data Transmission

Figure 40.18 is a sample flowchart of multi-processor data transmission. In the ID transmission cycle, the ID should be transmitted with the SSR.MPBT bit set to 1. In the data transmission cycle, the data should be transmitted with the MPBT bit set to 0. The other operations are the same as the operations in asynchronous mode.



[1] SCI initialization:
Set data transmission.
After the TE bit in SCR is set to 1, 1 is output for a frame, and transmission is enabled.

[2] TXI interrupt request:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (TXI) request is generated.
Set the MPBT bit in SSR to 0 or 1, and write transmit data to TDR once in the TXI interrupt handling routine.

[3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR once using a TXI interrupt request.
Transmit data can also be written to TDR by activating the DMAC or DTC.
When TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted are written to the TDR.

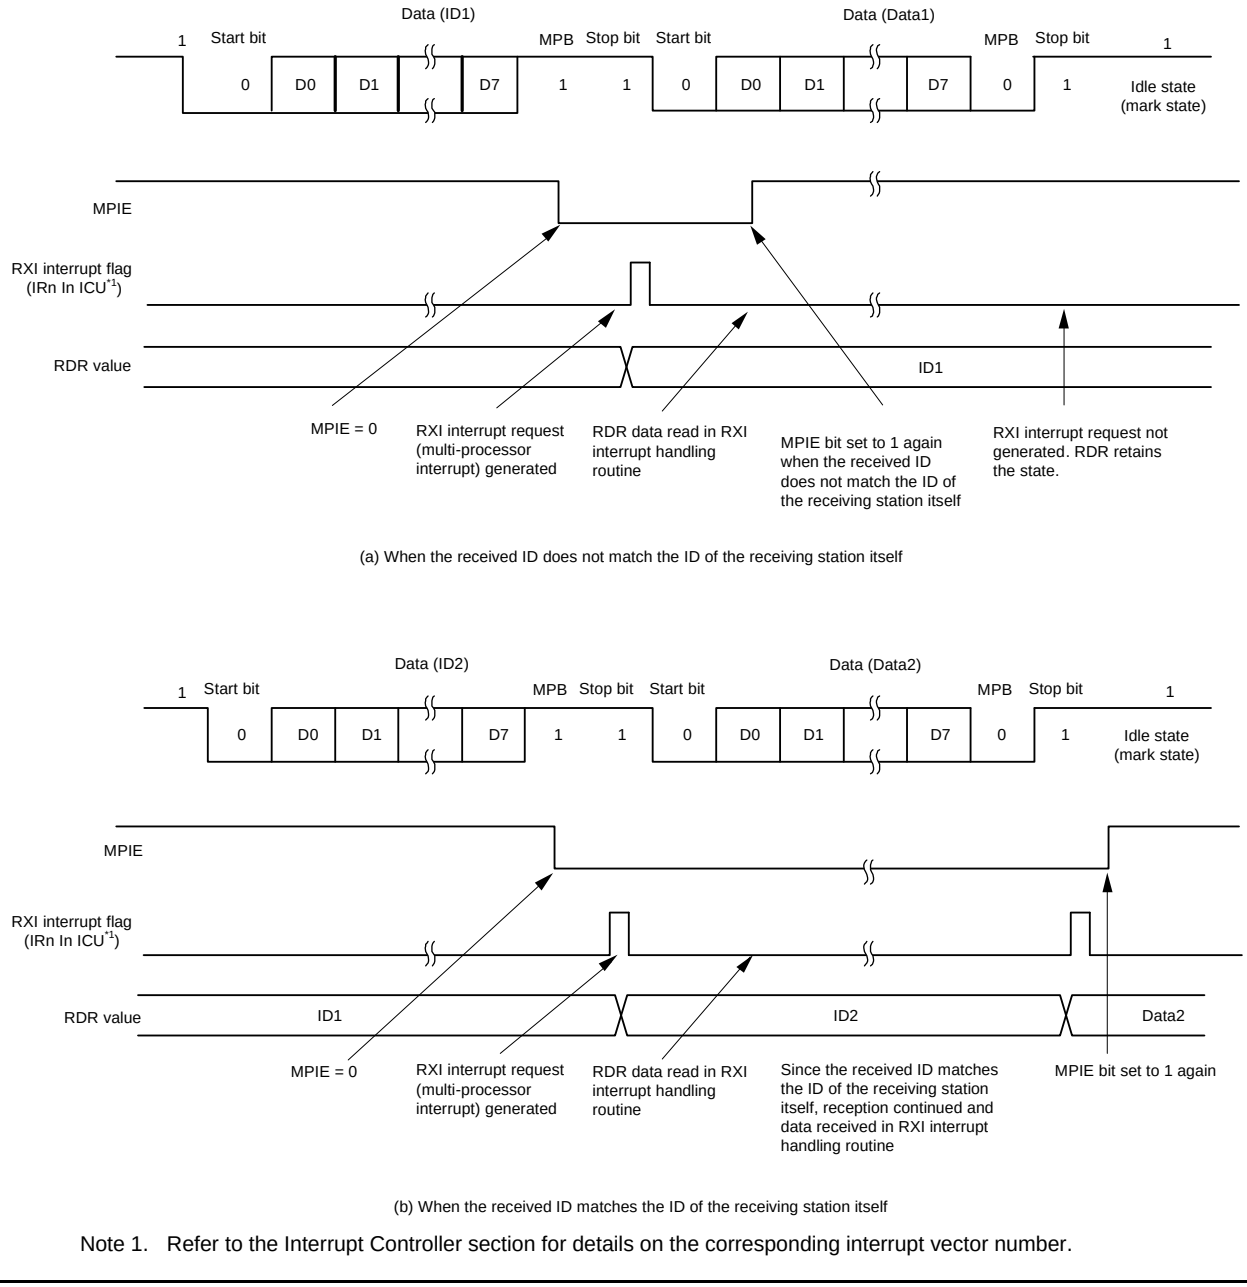
[4] Break output at the end of serial transmission:
To output a break in serial transmission, set the I/O port function corresponding to the TXDn pin (corresponding to output of the low level), and after switching the TXDn pin to the general I/O port function, set the TE bit in the SCR to 0.

Note: The TDR register becomes the TDRH and TDRL registers when 9-bit data length is selected. Write data in the order from TDRH to TDRL.

Figure 40.18 Example of Multi-Processor Serial Transmission Flowchart

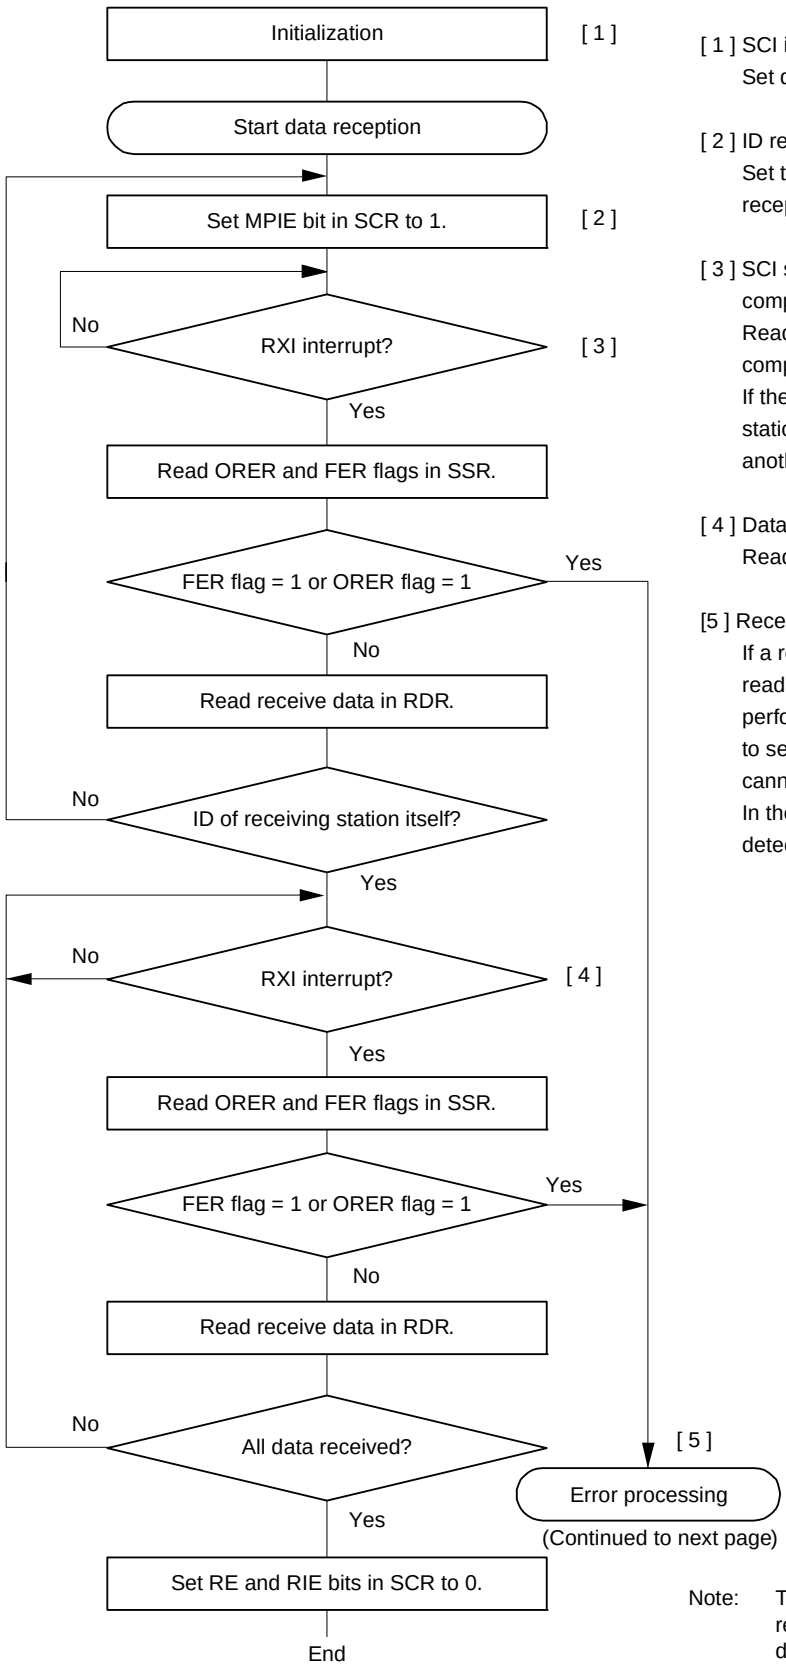
40.4.2 Multi-Processor Serial Data Reception

Figure 40.20 and Figure 40.21 are sample flowcharts of multi-processor data reception. When the SCR.MPIE bit is set to 1, reading the communication data is skipped until reception of the communication data in which the multi-processor bit is set to 1. When the communication data in which the multi-processor bit is set to 1 is received, the received data is transferred to RDR (the RDRH and RDRL registers when 9-bit data length is selected). During this time, the RXI interrupt request is generated. The other operations are the same as the operations in asynchronous mode.
Figure 40.19 is the example of operation for reception.



Note 1. Refer to the Interrupt Controller section for details on the corresponding interrupt vector number.

Figure 40.19 Example of SCI Reception (8-Bit Data/Multi-Processor Bit/1 Stop Bit)



[1] SCI initialization:
Set data reception.

[2] ID reception cycle:
Set the MPIE bit in SCR to 1 and wait for ID reception.

[3] SCI status confirmation and reception and comparison of ID:
Read data in RDR at the first RXI interrupt, and compare it with the ID of the receiving station itself. If the ID does not match the ID of the receiving station itself, set the MPIE bit to 1 again, and wait for another RXI interrupt RXI interrupt request.

[4] Data reception at an RXI interrupt:
Read data in RDR once in the RXI interrupt routine.

[5] Receive error processing and break detection:
If a receive error occurs, an error is identified by reading the ORER and FER flags in SSR. After performing the appropriate error processing, be sure to set the ORER and FER flags to 0. Reception cannot be resumed if any of these flags is set to 1. In the case of a framing error, a break can be detected by reading the value of the RXDn pin.

Note: The RDR register becomes the RDRH and RDRL registers when 9-bit data length is selected. Read data in the order from RDRH to RDRL.

Figure 40.20 Example of Multi-Processor Serial Reception Flowchart (1)

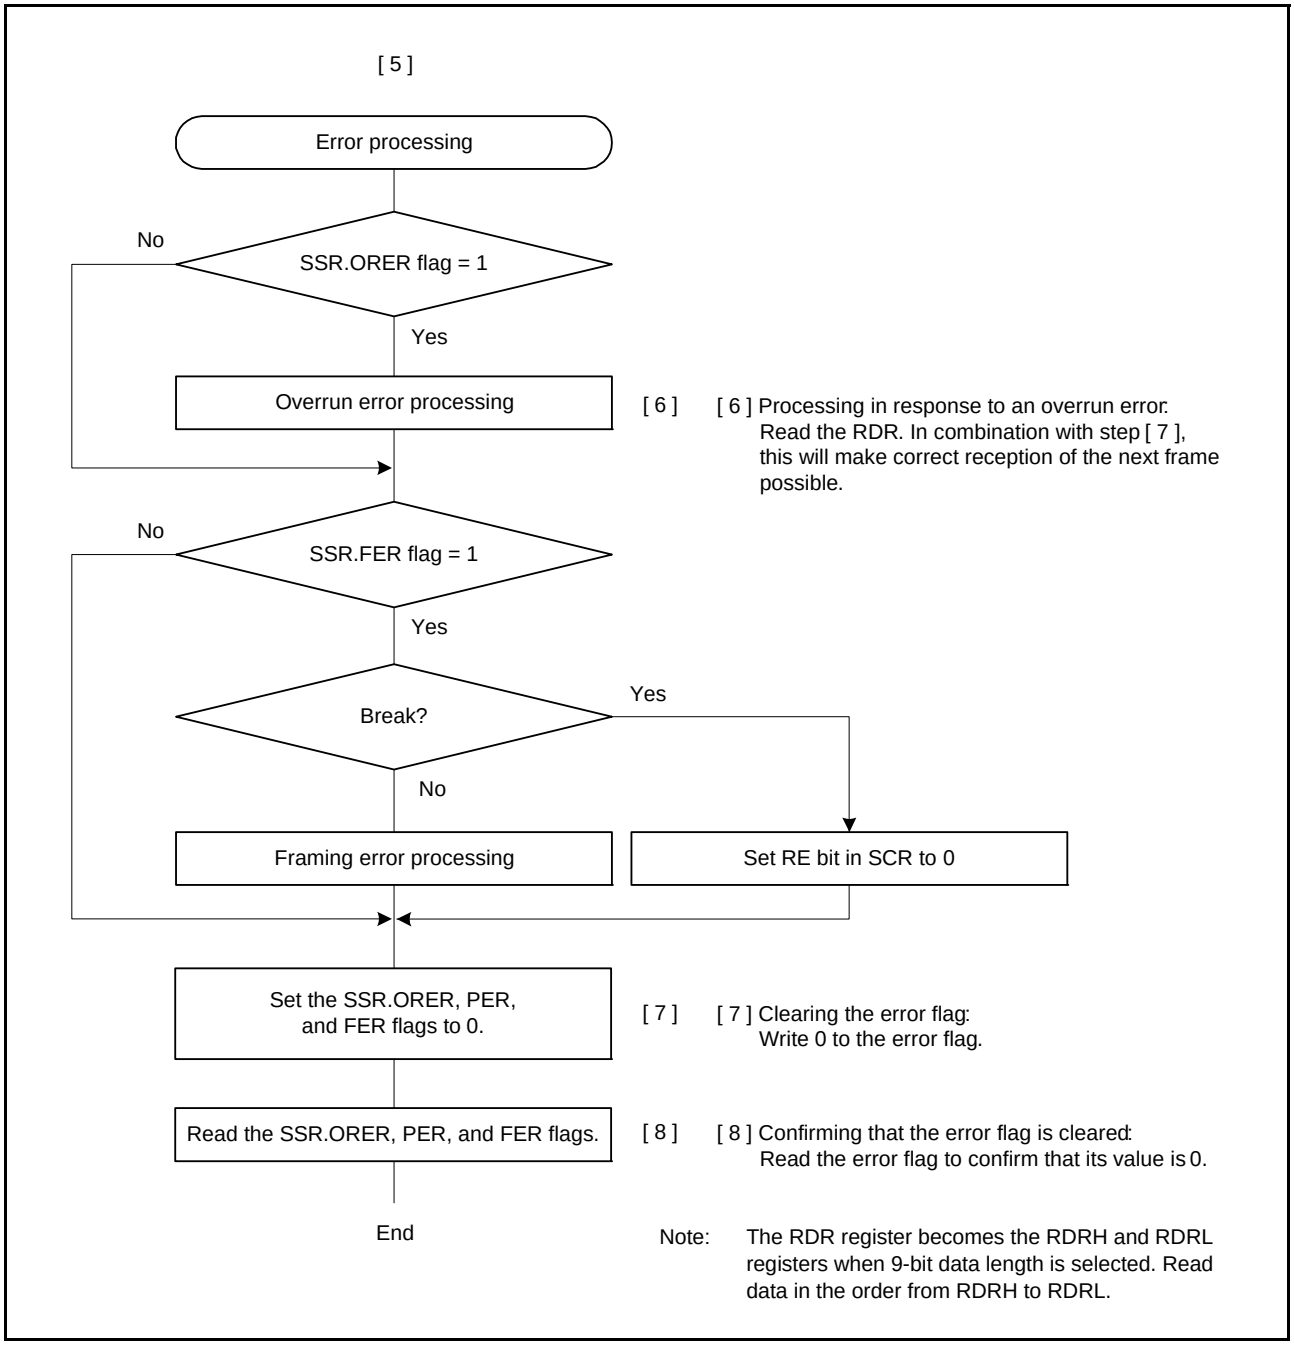


Figure 40.21 Example of Multi-Processor Serial Reception Flowchart (2)

40.5 Operation in Clock Synchronous Mode

Figure 40.22 shows the data format for clock synchronous serial data communications.
In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. One character in transfer data consists of 8-bit data. In clock synchronous mode, no parity bit can be added.
In data transmission, the SCI outputs data from one falling edge of the synchronization clock to the next. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the communication line holds the last bit output state.
Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications by use of a common clock. Both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

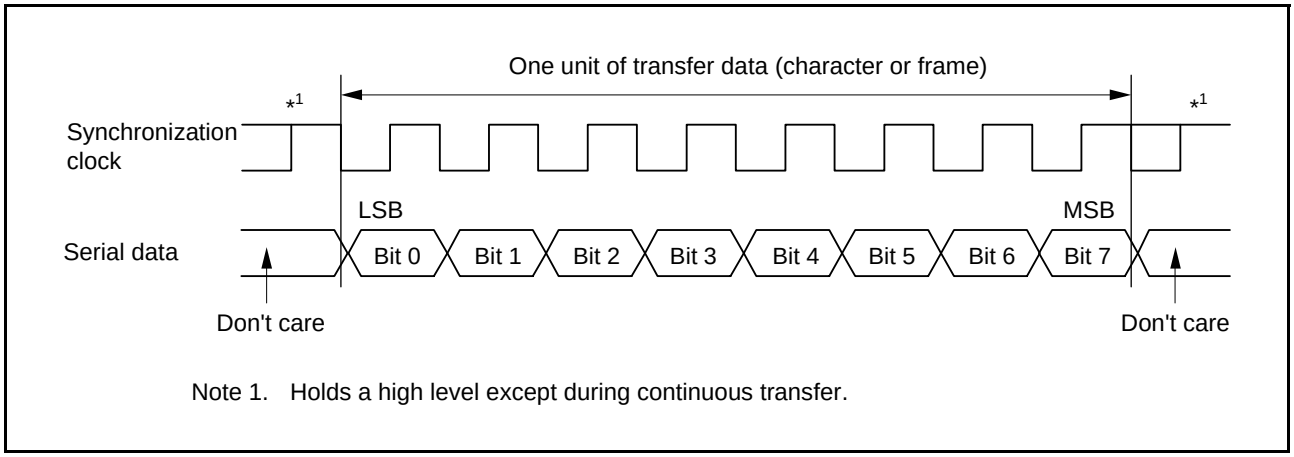

Figure 40.22 Data Format in Clock Synchronous Serial Communications (LSB First)

40.5.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCKn pin can be selected, according to the setting of the SCR.CKE[1:0] bits.
When the SCI is operated on an internal clock, the synchronization clock is output from the SCKn pin. Eight synchronization clock pulses are output in the transfer of one character, and when no transfer is performed the clock is held high. However, when only data reception is performed while the CTS function is disabled, the synchronization clock output is started at the same time when the SCR.RE bit set to 1. The synchronization clock is stopped at the high level when an overrun error occurs or the SCR.RE bit is set to 0.
When only data reception is performed and the CTS function is enabled, the clock output is not started even when the SCR.RE bit set to 1 if the CTSn# pin input is high when the SCR.RE bit is 0. The synchronization clock output is started when the SCR.RE bit is set to 1 and the CTSn# pin input is low. After that, if the CTSn# pin input is high on completion of the frame reception, the synchronization clock output is stopped at the high level. If the CTSn# pin input continues to be low, the synchronization clock is stopped at the high level when an overrun error occurs or the SCR.RE bit is set to 0.

40.5.2 CTS and RTS Functions

In the CTS function, CTSn# pin input is used to control reception/transmission start when the clock source is the internal clock. Setting the SPMR.CTSE bit to 1 enables the CTS function.
When the CTS function is enabled, placing the low level on the CTSn# pin causes reception/transmission to start. Applying the high level to the CTS# pin while reception/transmission are in progress does not affect reception/transmission of the current frame, which continues.
In the RTS function, RTSn# pin output is used to request reception/transmission start when the clock source is an external synchronizing clock. A low level is output when serial communications become possible. Conditions for output of the low and high level are shown below.

[Conditions for low-level output]
When the following conditions are all satisfied

- The SCR.RE or SCR.TE bit is 1
- Transmission or reception of data is not in progress
- There are no received data yet to be read (when the SCR.RE bit is 1)
- Transmit data has been written (when the SCR.TE bit is 1)
- The SSR.ORER flag is 0

[Condition for high-level output]
The conditions for low-level output have not been satisfied.

40.5.3 SCI Initialization (Clock Synchronous Mode)

Before transmitting and receiving data, start by writing the initial value 00h to the SCR register and then continue through the procedure for SCI given in Figure 40.23. Whenever the operating mode or transfer format is changed, the SCR register must be initialized before the change is made.

Note that setting the SCR.RE bit to 0 initializes neither the ORER, FER, and PER flags in the SSR register nor the RDR register.

Moreover, note that switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 while the SCR.TIE bit is 1 leads to the generation of a TXI interrupt request.

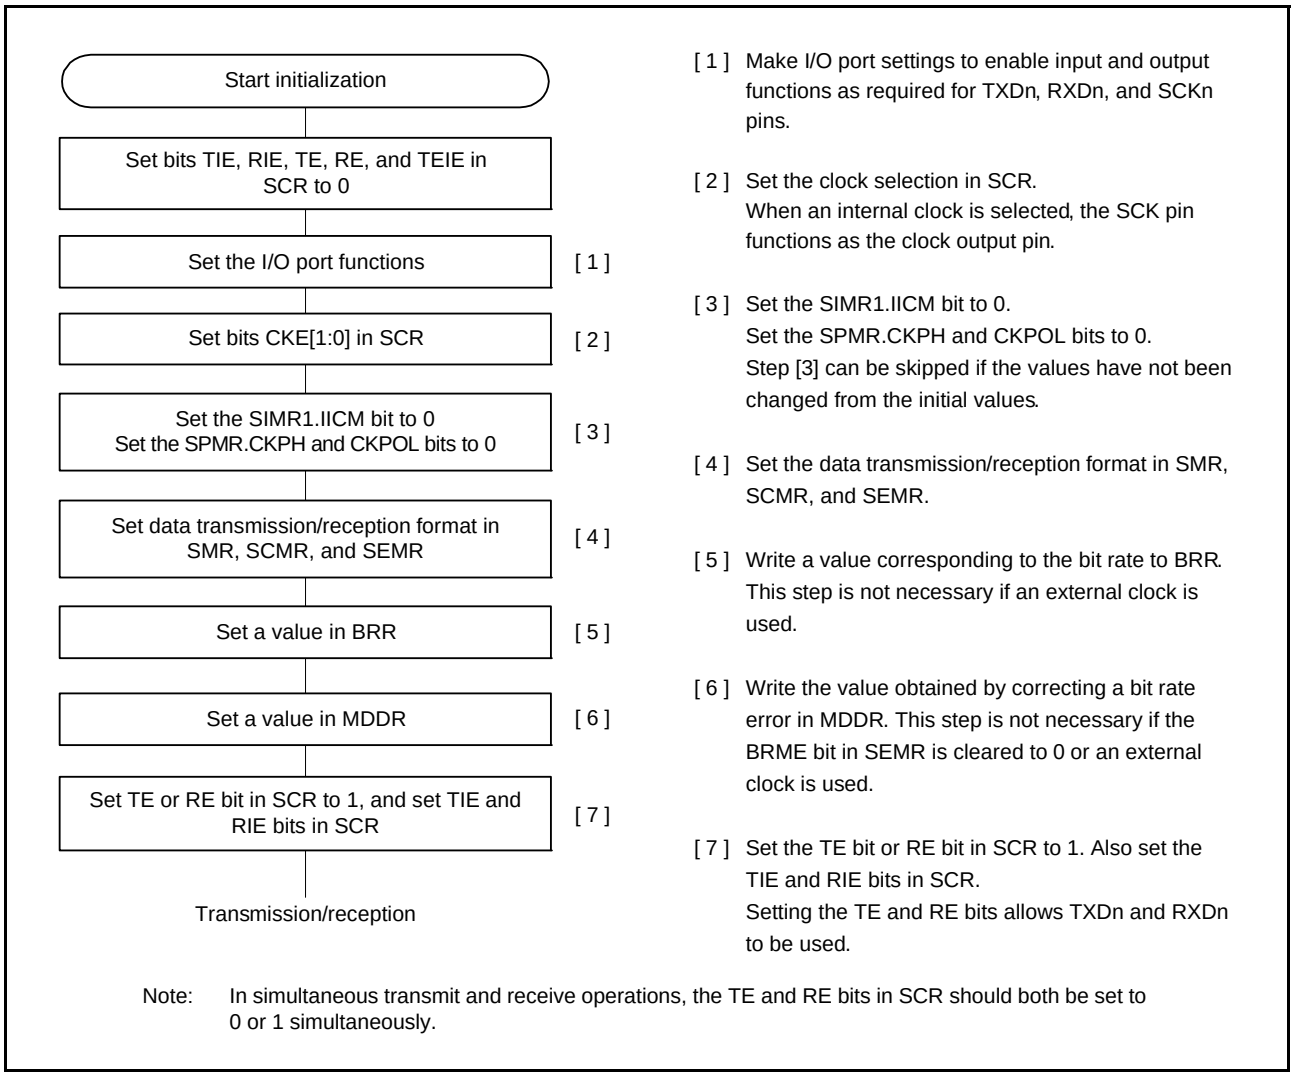

Figure 40.23 Example of SCI Initialization Flowchart (Clock Synchronous Mode)

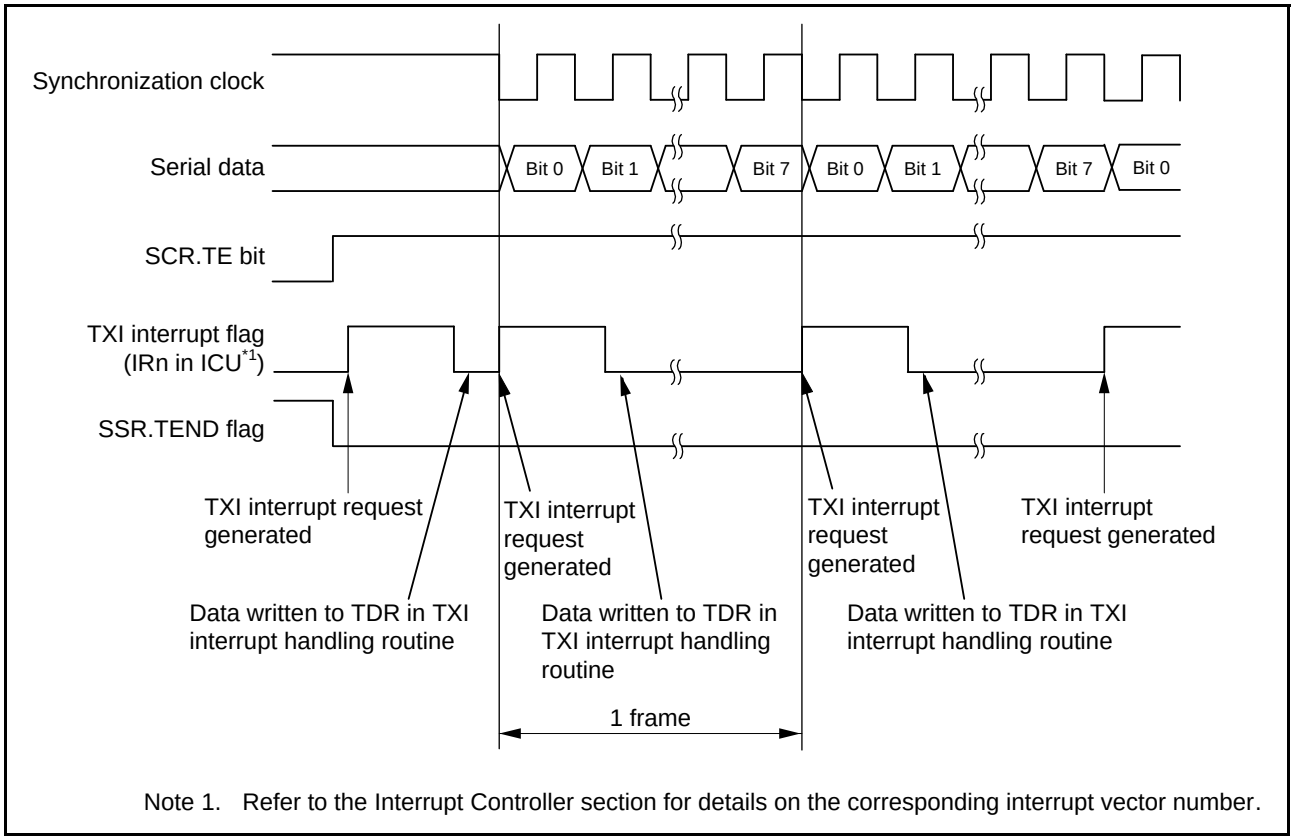
40.5.4 Serial Data Transmission (Clock Synchronous Mode)

Figure 40.23, Figure 40.24, and Figure 40.25 show an example of the operation for serial transmission in clock synchronous mode.
In serial data transmission, the SCI operates as described below.

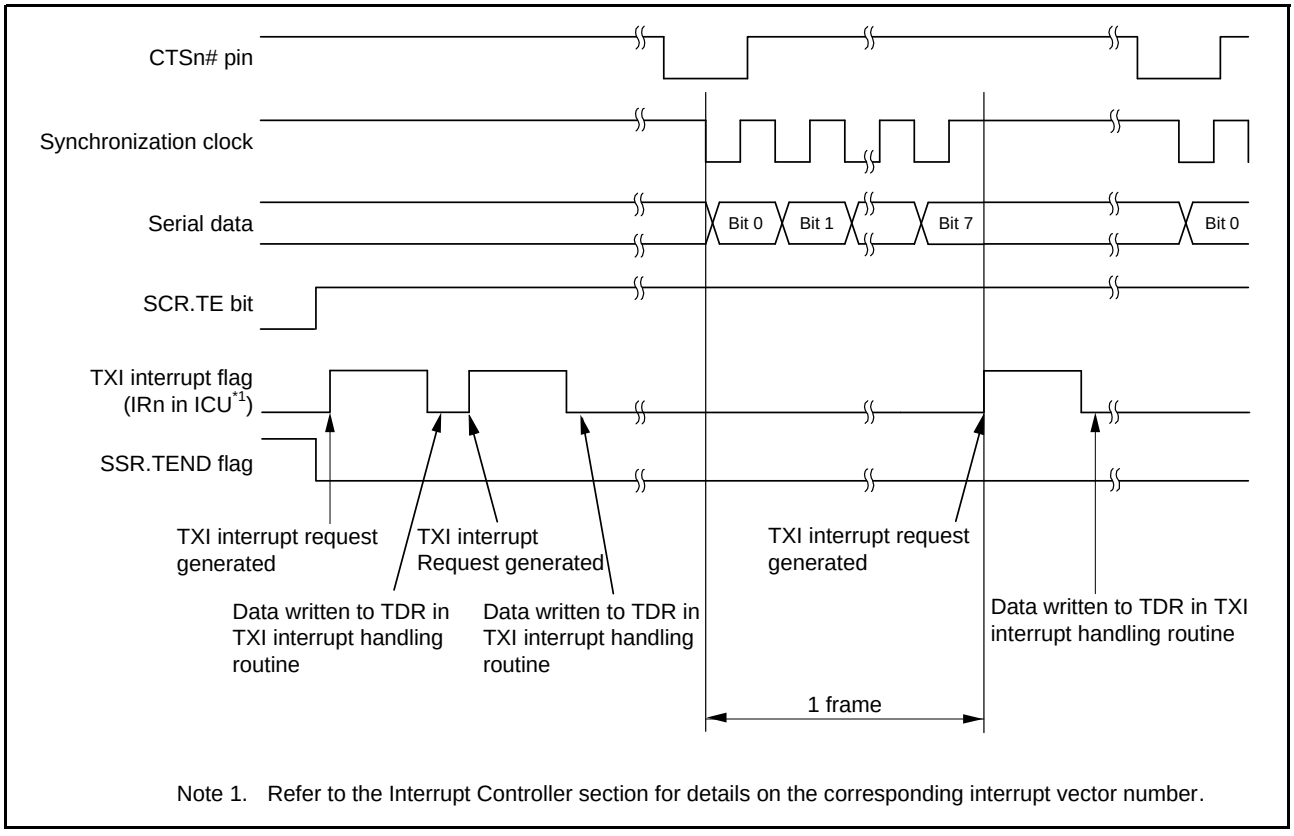
1. The SCI transfers data from TDR to TSR when data is written to TDR in the TXI interrupt handling routine. The TXI interrupt request at the beginning of transmission is generated when the TE bit in the SCR register is set to 1 after the TIE bit in the SCR register is set to 1 or when these 2 bits are set to 1 simultaneously by a single instruction.
2. After transferring data from the TDR register to the TSR register, the SCI starts transmission. When the SCR.TIE bit is set to 1 at this time, a TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to the TDR register in this TXI interrupt handling routine before transmission of the current transmit data has finished. When TEI interrupt requests are in use, set the SCR.TIE bit to 0 (a TXI interrupt request is disabled) and the SCR.TEIE bit to 1 (a TEI interrupt request is enabled) after the last of the data to be transmitted are written to the TDR register from the handling routine for TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when clock output mode has been specified and in synchronization with the input clock when use of an external clock has been specified. Output of the clock signal is suspended until the input CTS signal is at the low level while the CTSE bit in the SPMR register is 1 (CTS function is enabled).
4. The SCI checks for updating of (writing to) the TDR register at the time of the last bit output.
5. When TDR is updated, the next transmit data is transferred from the TDR register to the TSR register, and serial transmission of the next frame is started.
6. If the TDR register is not updated, set the SSR.TEND flag to 1 and the TXDn pin retains the output state of the last bit. If the TEIE bit in the SCR register is 1 at this time, a TEI interrupt request is generated. The SCKn pin is held high.

Figure 40.27 shows a sample flowchart of serial data transmission.
Transmission will not start while a receive error flag (ORER, FER, or PER in the SSR register) is set to 1. Be sure to set the receive error flags to 0 before starting transmission. Note that setting the RE bit in the SCR register to 0 does not clear the receive error flags.



Note 1. Refer to the Interrupt Controller section for details on the corresponding interrupt vector number.

Figure 40.24 Example of Serial Data Transmission in Clock Synchronous Mode When the CTS Function is Not Used at the Beginning of Transmission



Note 1. Refer to the Interrupt Controller section for details on the corresponding interrupt vector number.

Figure 40.25 Example of Serial Data Transmission in Clock Synchronous Mode When the CTS Function is Used at the Beginning of Transmission

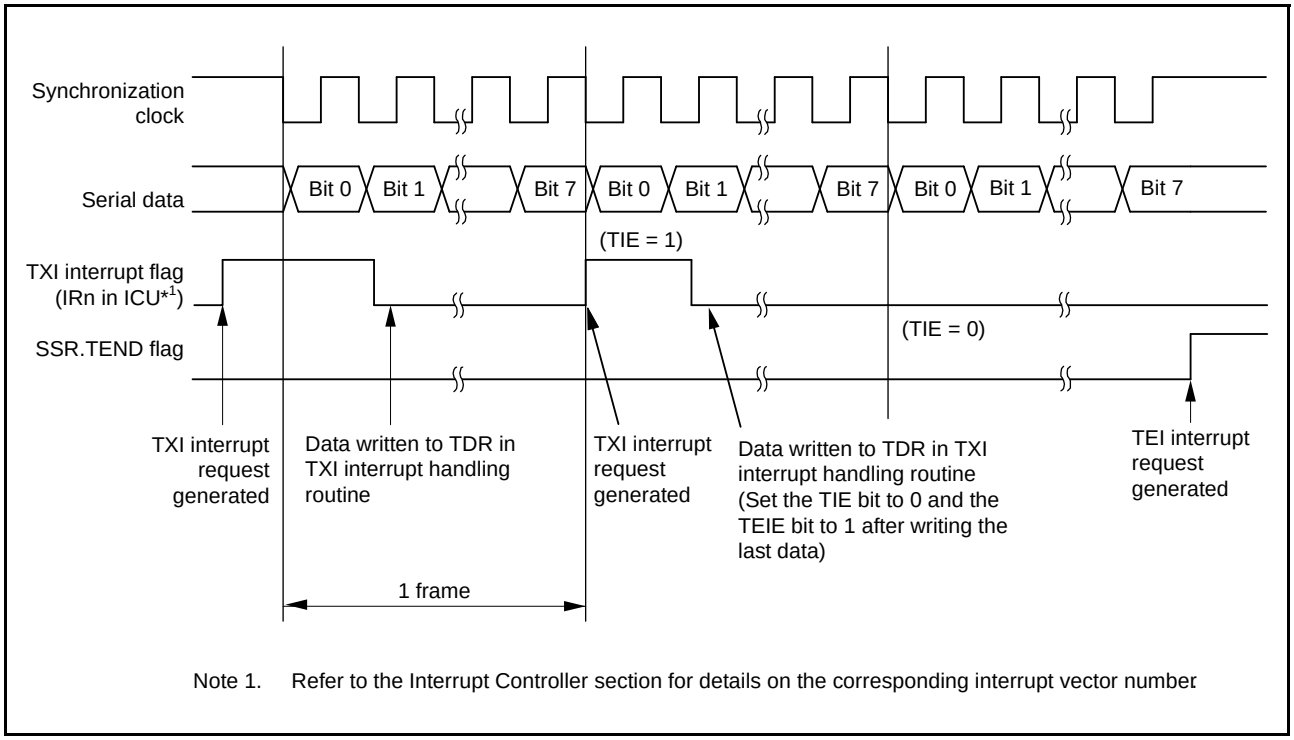


Figure 40.26 Example of Serial Data Transmission in Clock Synchronous Mode from the Middle of Transmission until Transmission Completion

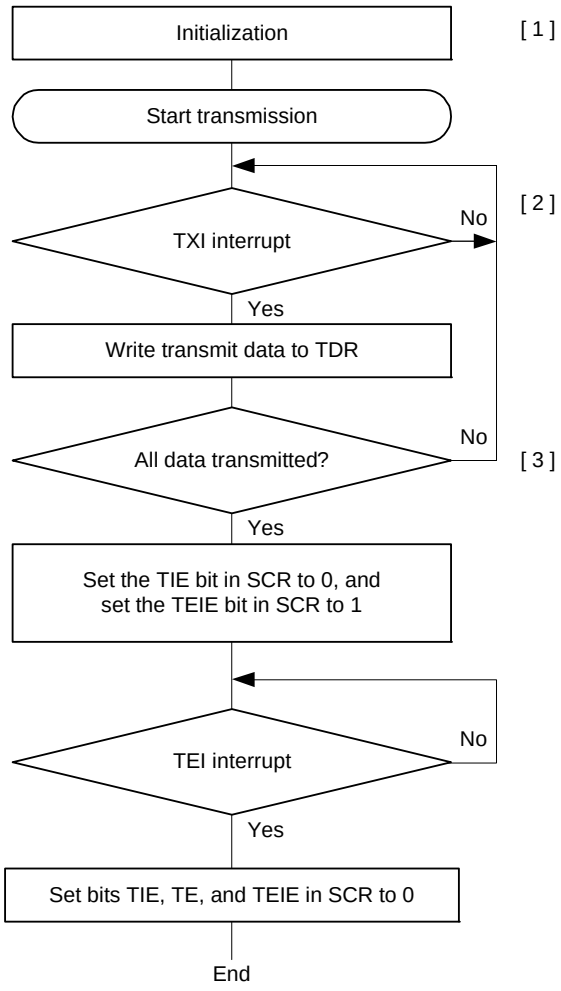


[1] SCI initialization:
Set data transmission.

[2] Writing transmit data write to TDR by a TXI interrupt request:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (TXI) request is generated.
Transmit data is written to TDR once from the handling routine for TXI requests.

[3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR upon accepting a transmit data empty interrupt (TXI) request. Transmit data can also be written to TDR by activating the DMAC or DTC by the TXI interrupt request.
When TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted are written to the TDR.

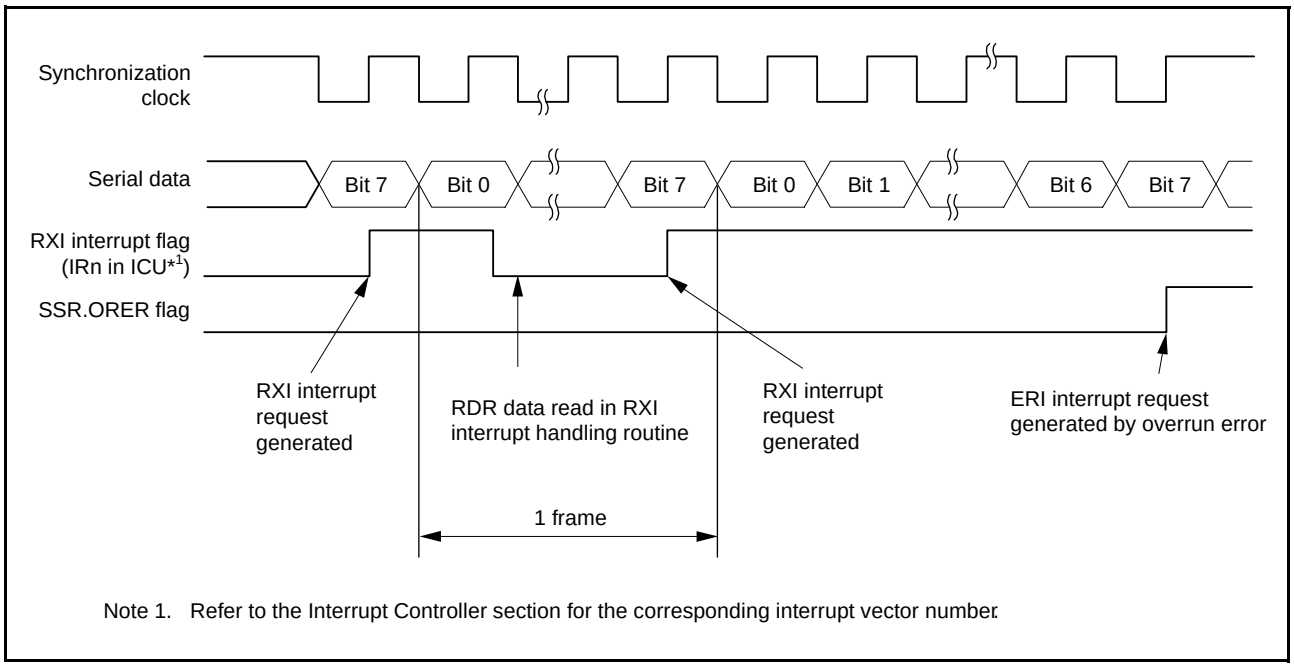
Note: When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCK pin for the last bit sets the SSR.TEND flag to 1. Setting the SCR.TE bit to 0 immediately after this may lead to insufficient received-data hold time on the receiver side.

Figure 40.27 Example Flowchart of Serial Transmission in Clock Synchronous Mode

40.5.5 Serial Data Reception (Clock Synchronous Mode)

Figure 40.28 and Figure 40.29 show an example of SCI operation for serial reception in clock synchronous mode. In serial data reception, the SCI operates as described below.

1. The value of the RE bit in the SCR register becoming 1 places the signal output on the RTSn# pin at the low level (when the RTS function is in use).
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.
3. If an overrun error occurs, the ORER flag in the SSR register is set to 1. If the RIE bit in the SCR register is 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to the RDR register.
4. When reception finishes successfully, receive data is transferred to the RDR register. If the RIE bit in the SCR register is 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in this RXI interrupt handling routine before reception of the next receive data is completed. Reading out the received data that have been transferred to the RDR register causes the RTSn# pin to output the low level (when the RTS function is in use).



Note 1. Refer to the Interrupt Controller section for the corresponding interrupt vector number.

Figure 40.28 Example of Operation for Serial Reception in Clock Synchronous Mode (1) (When RTS Function is Not Used)

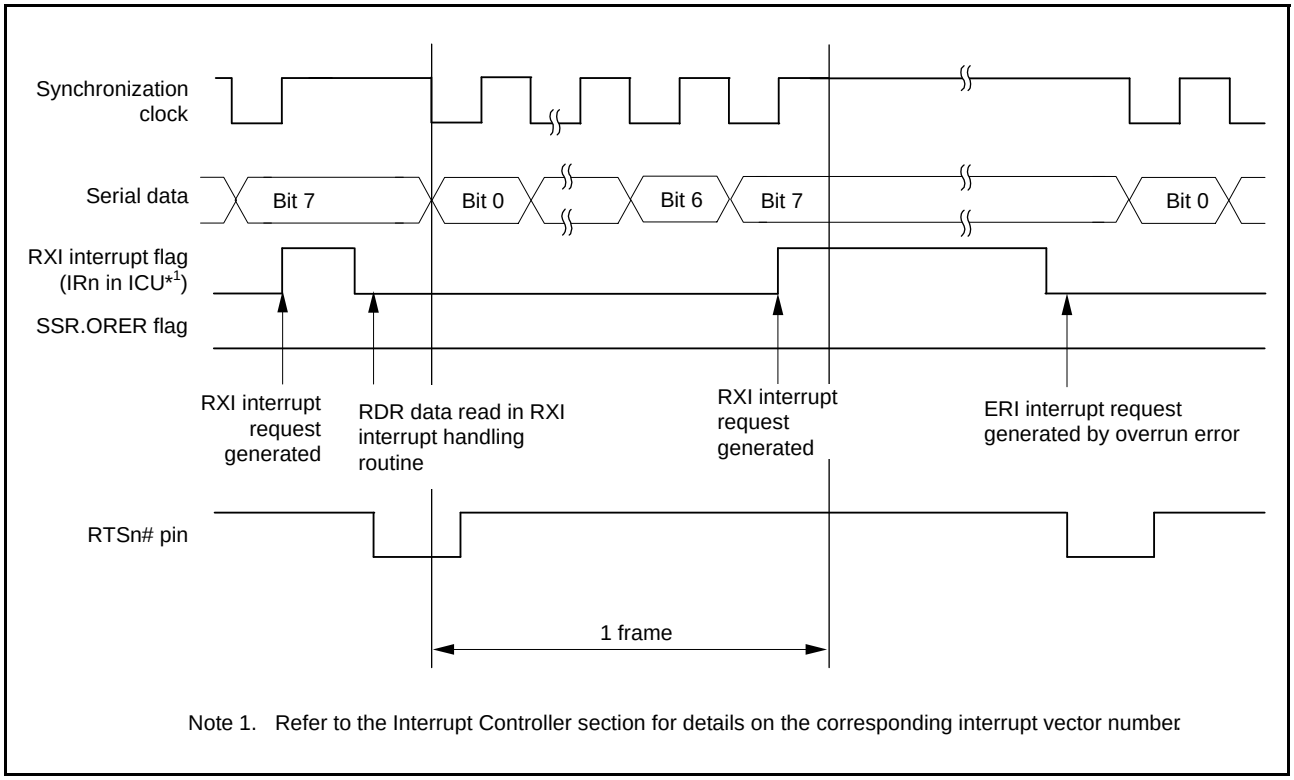


Figure 40.29 Example of Operation for Serial Reception in Clock Synchronous Mode (2) (When RTS Function is Used)

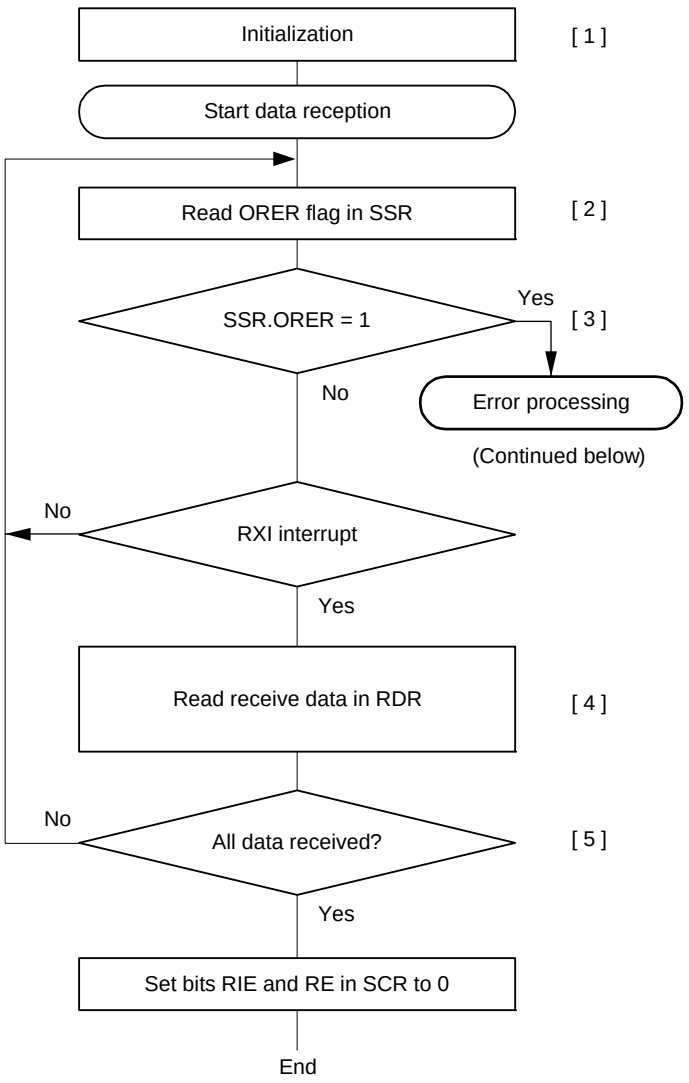
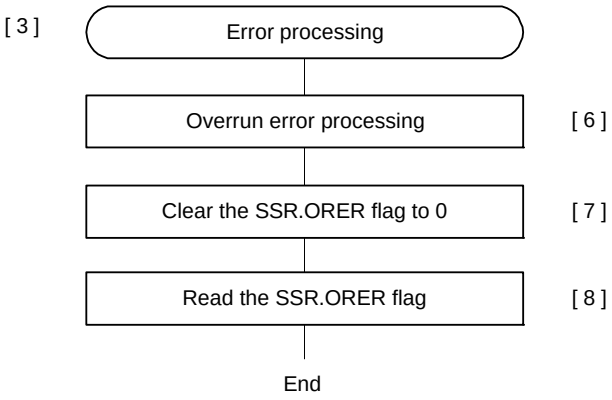
Data transfer cannot be resumed while a receive error flag is 1. Accordingly, clear the ORER, FER, and PER flags in the SSR register to 0 before resuming reception. Moreover, be sure to read the RDR register during overrun error processing. When a reception is forcibly terminated by setting the SCR.RE bit to 0 during operation, read the RDR register because received data which has not yet been read may be left in the RDR register.

Figure 40.30 shows a sample flowchart for serial data reception.





[1] SCI initialization:
Make input port-pin settings for pins to be used as RXDn pins.

[2] [3] Receive error processing:
If a receive error occurs, read the ORER flag in the SSR register, perform the relevant error processing, and then set the ORER flag to 0. Data reception cannot be resumed while the ORER flag is 1.

[4] Read the receive data in the RDR register once in the receive data full interrupt (RXI) request handling routine.

[5] Serial reception continuation procedure:
To continue serial reception, before the MSB (bit 7) of the current frame is received, finish reading the receive data in the RDR register. The RDR data can also be read by activating the DMAC or DTC by an RXI interrupt request.

[6] Processing in response to an overrun error:
Read the RDR register. In combination with step [7], this will make correct reception of the next frame possible.

[7] Clearing the error flag:
Write 0 to the error flag.

[8] Confirming that the error flag is cleared:
Read the error flag to confirm that its value is 0.

Figure 40.30 Example Flowchart of Serial Reception in Clock Synchronous Mode

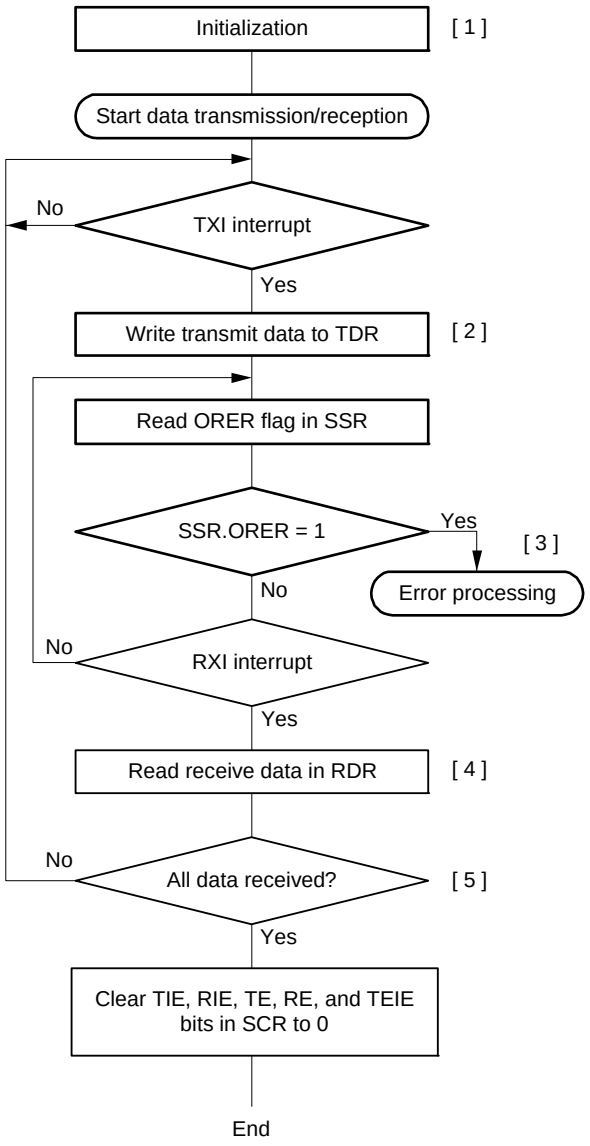
40.5.6 Simultaneous Serial Data Transmission and Reception (Clock Synchronous Mode)

Figure 40.31 shows a sample flowchart for simultaneous serial transmit and receive operations in clock synchronous mode.

After initializing the SCI, the following procedure should be used for simultaneous serial data transmit and receive operations.

To switch from transmit mode to simultaneous transmit and receive mode, check that the SCI has finished transmission by reading that the TEND flag in the SSR register is 1, and then initialize the SCR register. Then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode, check that the SCI has finished reception, and then set the RIE and RE bits to 0. Then check that the receive error flags (ORER, FER, and PER in the SSR register) are 0, and then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.



[1] SCI initialization:
The TXDn pin can act as the output pin for transmitted data and the RXDn pin can act as the input pin for received data at the same time.

[2] Transmit data write:
Write transmit data to TDR once in the TXI interrupt handling routine.

[3] Receive error processing:
If a receive error occurs, read the ORER flag in the SSR register, perform the relevant error processing, and then set the ORER flag to 0. Data reception cannot be resumed while the ORER flag is 1.

[4] Reading receive data:
Read the receive data in the RDR register once in the RXI interrupt request handling routine.

[5] Serial transmission/reception continuation procedure:
To continue serial transmission and reception, before the MSB (bit 7) of the current frame is received, finish reading the receive data in the RDR register by the RXI interrupt. Also, before the MSB (bit 7) of the current frame is transmitted, write data to the TDR register by the TXI interrupt. Transmit data can also be written to the TDR register by activating the DMAC or DTC by a transmit data empty interrupt (TXI) request. Similarly, the RDR data can also be read by activating the DMAC or DTC by a receive data full interrupt (RXI) request.

Note: When switching from transmit or receive operation to simultaneous transmit and receive operations first set the TIE, RIE, TE, RE, and TEIE bits in SCR to 0, and then set TIE, RIE, TE, and RE bits to 1 simultaneously.

Figure 40.31 Example Flowchart of Simultaneous Serial Transmission and Reception in Clock Synchronous Mode

40.6 Operation in Smart Card Interface Mode

The SCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function of the SCI.
Smart card interface mode can be selected using the appropriate register.

40.6.1 Sample Connection

Figure 40.32 shows a sample connection between a smart card (IC card) and this MCU.
As in the figure, since this MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.
Setting the TE and RE bits in the SCR register to 1 with an IC card disconnected enables closed transmission/reception allowing self-diagnosis.
To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card.
The output port of the this MCU can be used to output a reset signal.

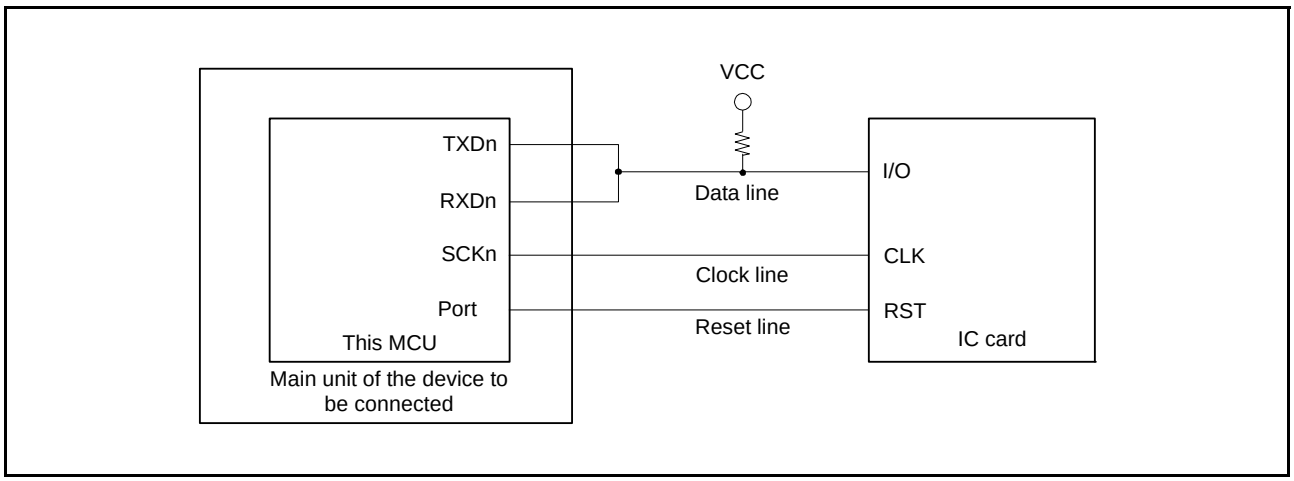


Figure 40.32 Sample Connection with a Smart Card (IC Card)

40.6.2 Data Format (Except in Block Transfer Mode)

Figure 40.33 shows the data transfer formats in smart card interface mode.

- One frame consists of 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 etu (elementary time unit: time required for transferring 1 bit) is secured as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low-level error signal is output for 1 etu after 10.5 etu has passed from the start bit.
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 etu.

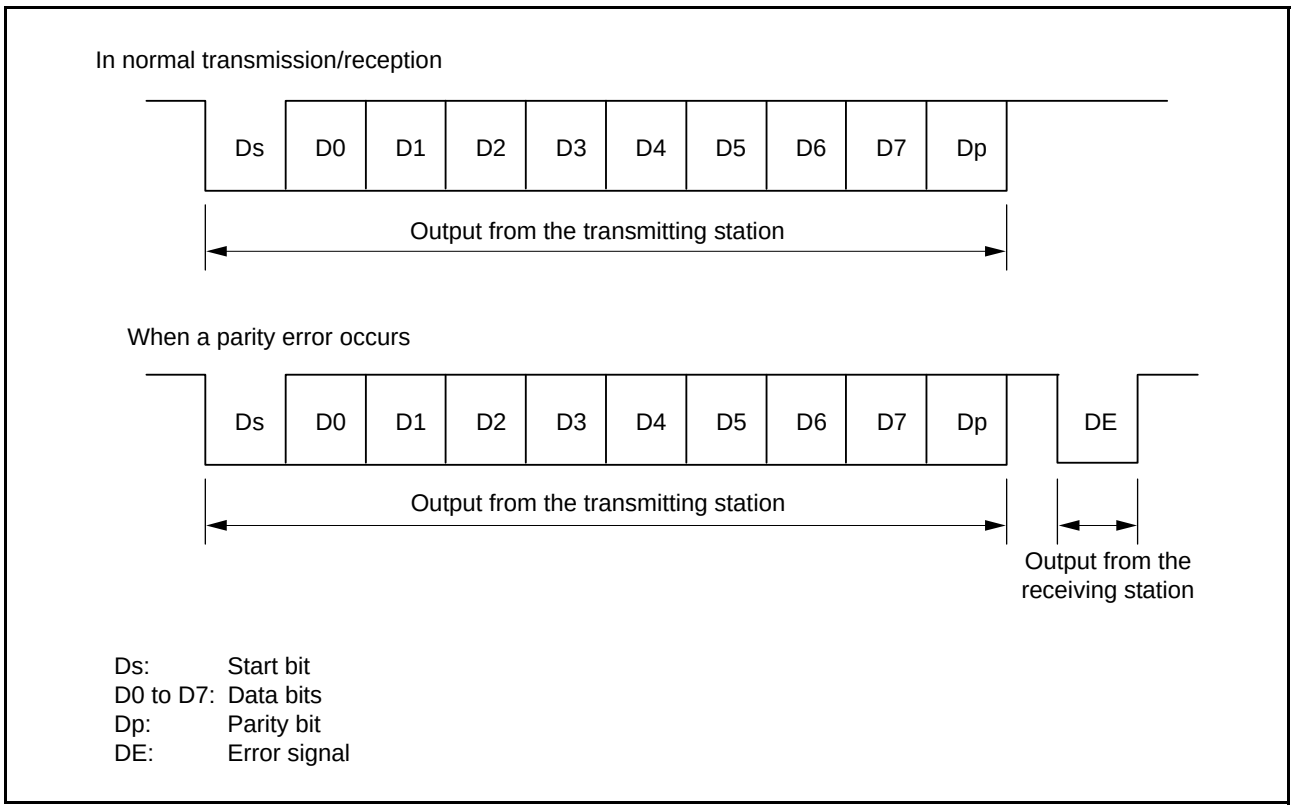

Figure 40.33 Data Formats in Smart Card Interface Mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedure below.

(1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 correspond to states Z and A, respectively, and data is transferred with LSB first as the start character, as shown in Figure 40.34. Therefore, data in the start character in the figure is 3Bh. When using the direct convention type, write 0 to both the SDIR and SINV bits in the SCMR register. Write 0 to the PM bit in the SMR register in order to use even parity, which is prescribed by the smart card standard.

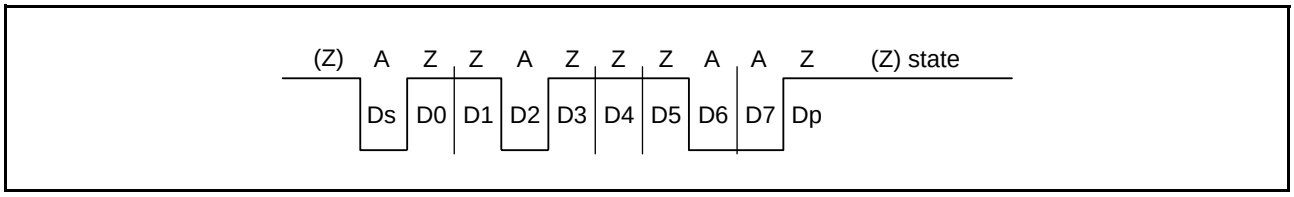

Figure 40.34 Direct Convention (SDIR in SCMR = 0, SINV in SCMR = 0, PM in SMR = 0)

(2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 correspond to states A and Z, respectively and data is transferred with MSB first as the start character, as shown in Figure 40.35. Therefore, data in the start character in the figure is 3Fh. When using the inverse convention type, write 1 to both the SDIR and SINV bits in the SCMR register. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to state Z. Since the SINV bit of the this MCU only inverts data bits D7 to D0, write 1 to the PM bit in the SMR register to invert the parity bit for both transmission and reception.

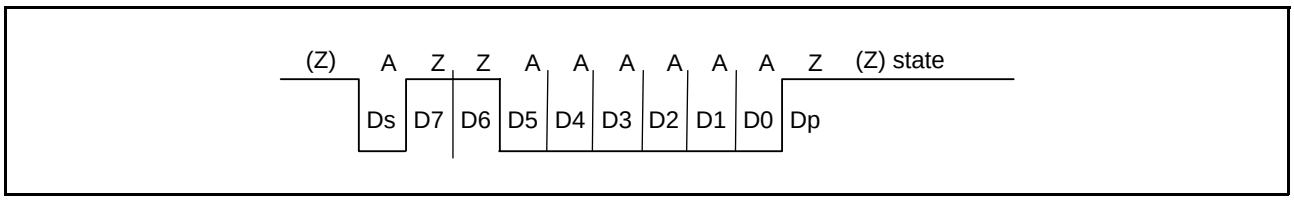

Figure 40.35 Inverse Convention (SDIR in SCMR = 1, SINV in SCMR = 1, PM in SMR = 1)

40.6.3 Block Transfer Mode

Block transfer mode is different from normal smart card interface mode in the following respects.

- Even if a parity error is detected during reception, no error signal is output. Since the PER bit in the SSR register is set by error detection, clear the PER bit before receiving the parity bit of the next frame.
- During transmission, at least 1 etu is secured as a guard time from the end of the parity bit until the start of the next frame.
- Since the same data is not retransmitted during transmission, the TEND flag in the SSR register is set 11.5 etu after transmission start.
- In block transfer mode, the ERS flag in the SSR register indicates the error signal status as in normal smart card interface mode, but the flag is read as 0 because no error signal is transferred.

40.6.4 Receive Data Sampling Timing and Reception Margin

Only the internal clock generated by the on-chip baud rate generator can be used as a transfer clock in smart card interface mode.

In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate according to the settings of the BCP2 bit in the SCMR register and the BCP[1:0] bits in the SMR register (the frequency is always 16 times the bit rate in normal asynchronous mode).

For data reception, the falling edge of the start bit is sampled with the base clock to perform internal synchronization. Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 40.36. The reception margin here is determined by the following formula.

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5)\ F - \frac{D - 0.5}{N}\ (1 + F) \right| \times 100\ [\%]$$

M: Reception margin (%)
N: Ratio of bit rate to clock (N = 32, 64, 372, 256)
D: Duty cycle of clock (D = 0 to 1.0)
L: Frame length (L = 10)
F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the above formula, the reception margin is determined by the formula below.

$$M = \{0.5 - 1/(2 \times 372)\} \times 100\ [\%] = 49.866\%$$

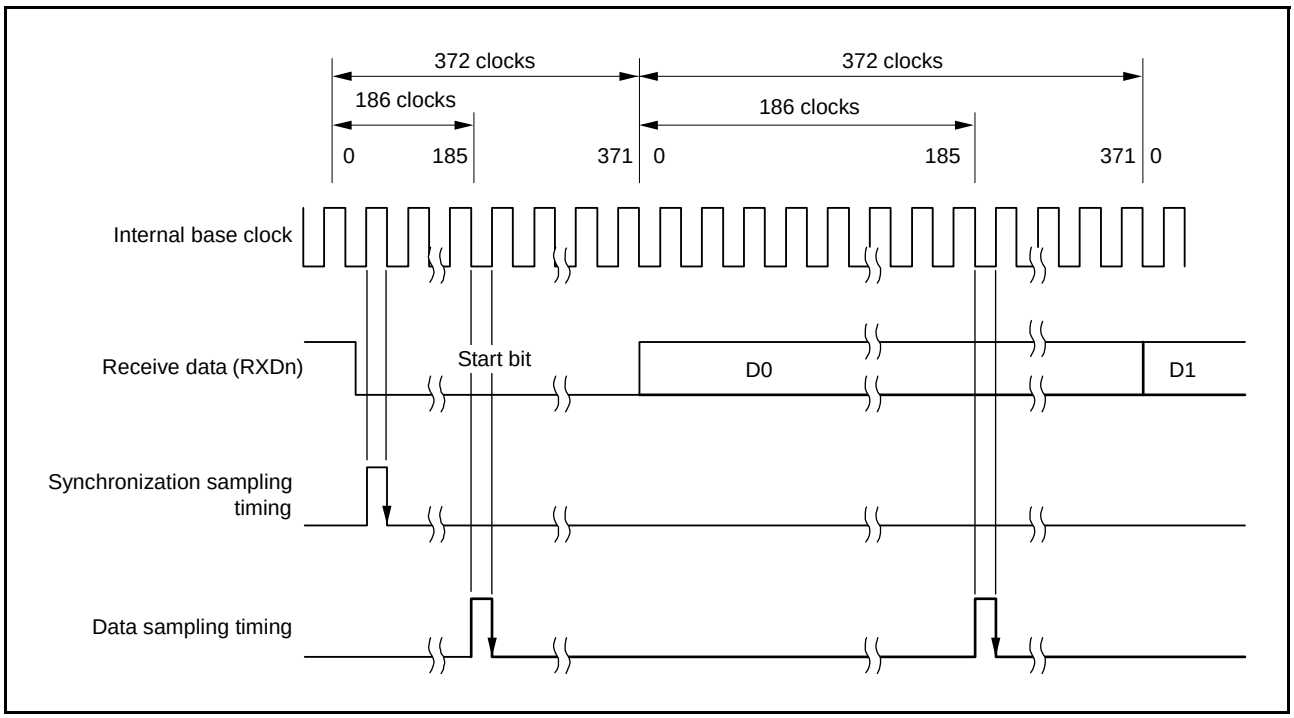

Figure 40.36 Receive Data Sampling Timing in Smart Card Interface Mode (When Clock Frequency is 372 Times the Bit Rate)

40.6.5 SCI Initialization (Smart Card Interface Mode)

Initialize the SCI following the example of flowchart shown in Figure 40.37.
Be sure to initialize the SCI before switching from transmission mode to reception mode and vice versa. Even if the RE bit is set to 0, the RDR register is not initialized.

To change reception mode to transmission mode, first check that reception has completed, and then initialize the SCI. At the end of initialization, set TE = 1 and RE = 0. Reception completion can be verified by reading the RXI request, ORER, or PER flag in the SSR register.
To change transmission mode to reception mode, first check that transmission has completed, and then initialize the SCI. At the end of initialization, set TE = 0 and RE = 1. Transmission completion can be verified by reading the TEND flag in the SSR register.

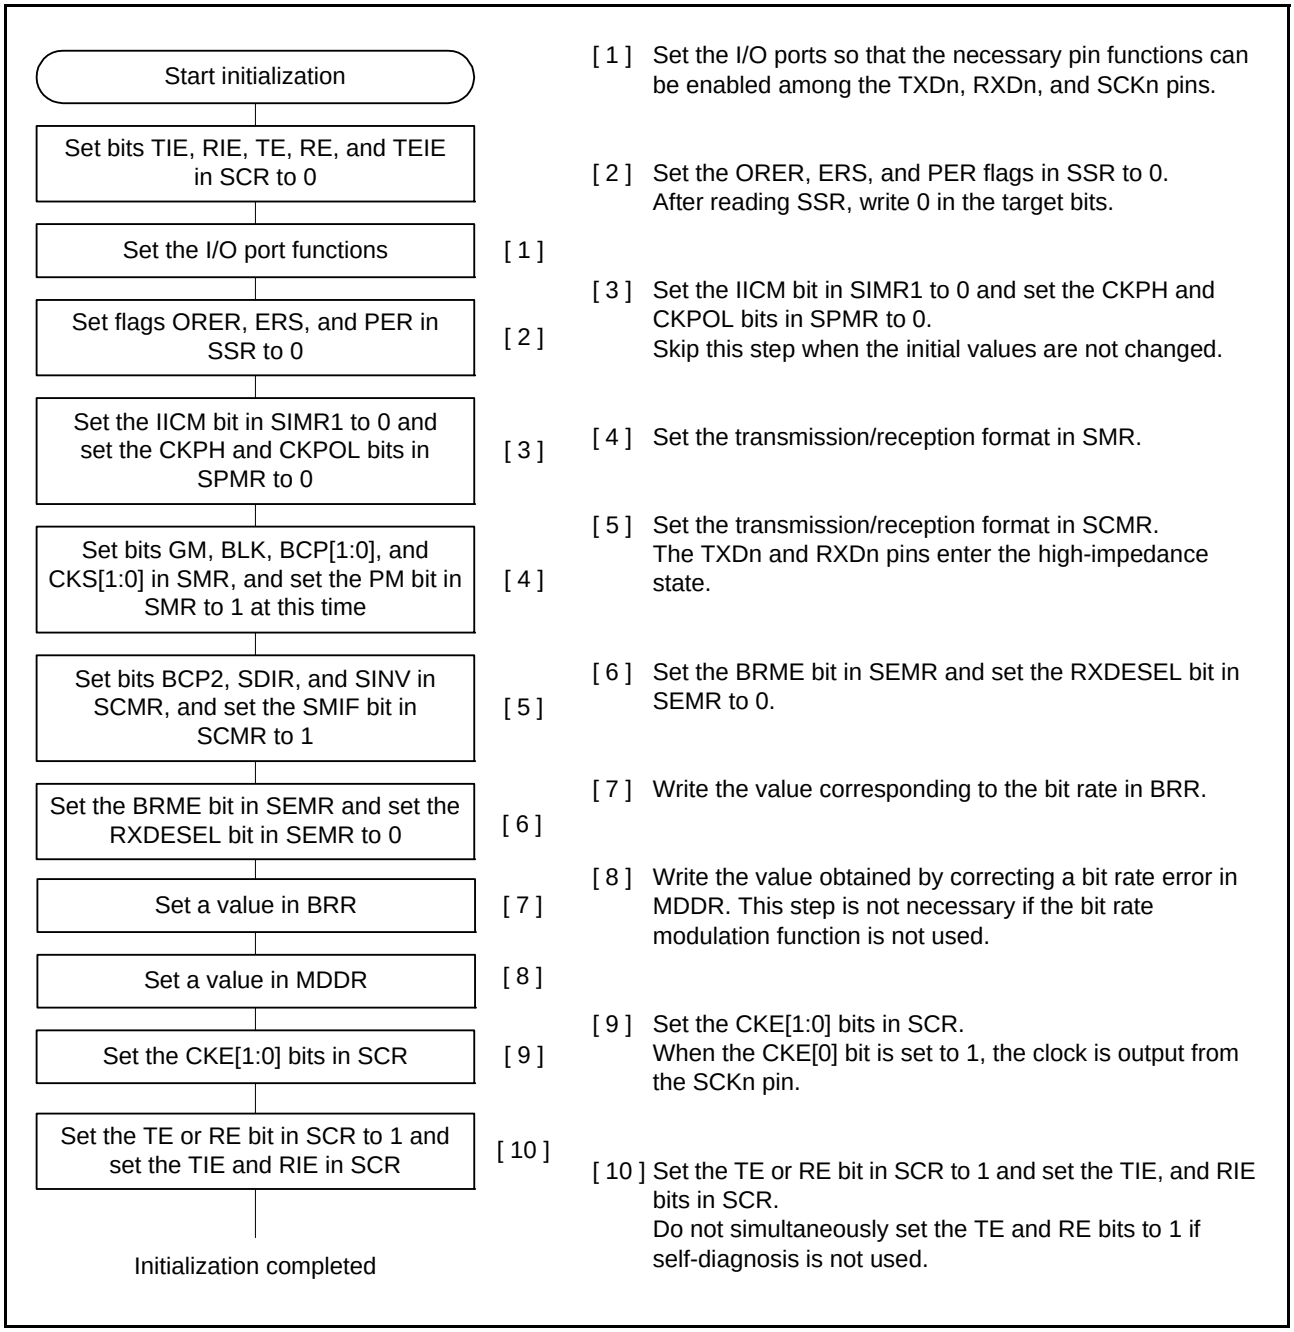

Figure 40.37 Example of SCI Initialization Flowchart (Smart Card Interface Mode)

40.6.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode), in that an error signal is sampled and data can be retransmitted, is different from that in non-smart card interface mode. Figure 40.38 shows the data retransfer operation during transmission.

1. When an error signal from the receiver end is sampled after one-frame data has been transmitted, the ERS flag in the SSR register is set to 1. If the RIE bit in the SCR register is 1 at this time, an ERI interrupt request is generated. Clear the ERS flag to 0 before the next parity bit is sampled.
2. For a frame in which an error signal is received, the TEND flag in the SSR register is not set. Data is retransferred from the TDR register to the TSR register allowing automatic data retransmission.
3. If no error signal is returned from the receiver, the ERS flag is not set to 1.
4. In this case, the SCI judges that transmission of one-frame data (including retransfer) has been completed, and the TEND flag is set. If the TIE bit in the SCR register is 1 at this time, a TXI interrupt request is generated. Writing transmit data to the TDR register starts transmission of the next data.

Figure 40.40 shows a sample flowchart of serial transmission. All the processing steps are automatically performed using a TXI interrupt request to activate the DTC or DMAC.
When the TEND flag in the SSR register is set to 1 in transmission, if the TIE bit in the SCR register is 1, a TXI interrupt request is generated. The DTC or DMAC is activated by a TXI interrupt request if the TXI interrupt request is specified as a source of DTC or DMAC activation beforehand, allowing transfer of transmit data. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.
If an error occurs, the SCI automatically retransmits the same data. During this retransmission, the TEND flag is kept to 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission in the case of error occurrence. However, since the ERS flag is not automatically cleared, set the RIE bit to 1 beforehand to enable an ERI interrupt request to be generated at error occurrence, and clear the ERS flag to 0.
When transmitting/receiving data using the DTC or DMAC, be sure to make settings to enable the DTC or DMAC before making SCI settings.
For DTC or DMAC settings, refer to section 18, DMA Controller (DMACAa), section 20, Data Transfer Controller (DTCa).

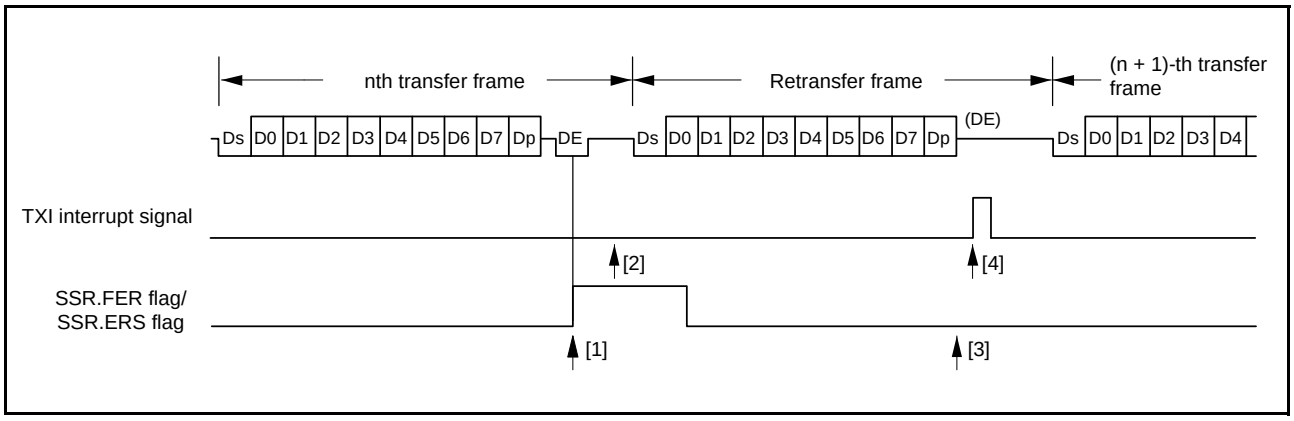

Figure 40.38 Data Retransfer Operation in SCI Transmission Mode

Note that the SSR.TEND flag is set in different timings depending on the GM bit setting in the SMR register. Figure 40.39 shows the TEND flag generation timing.

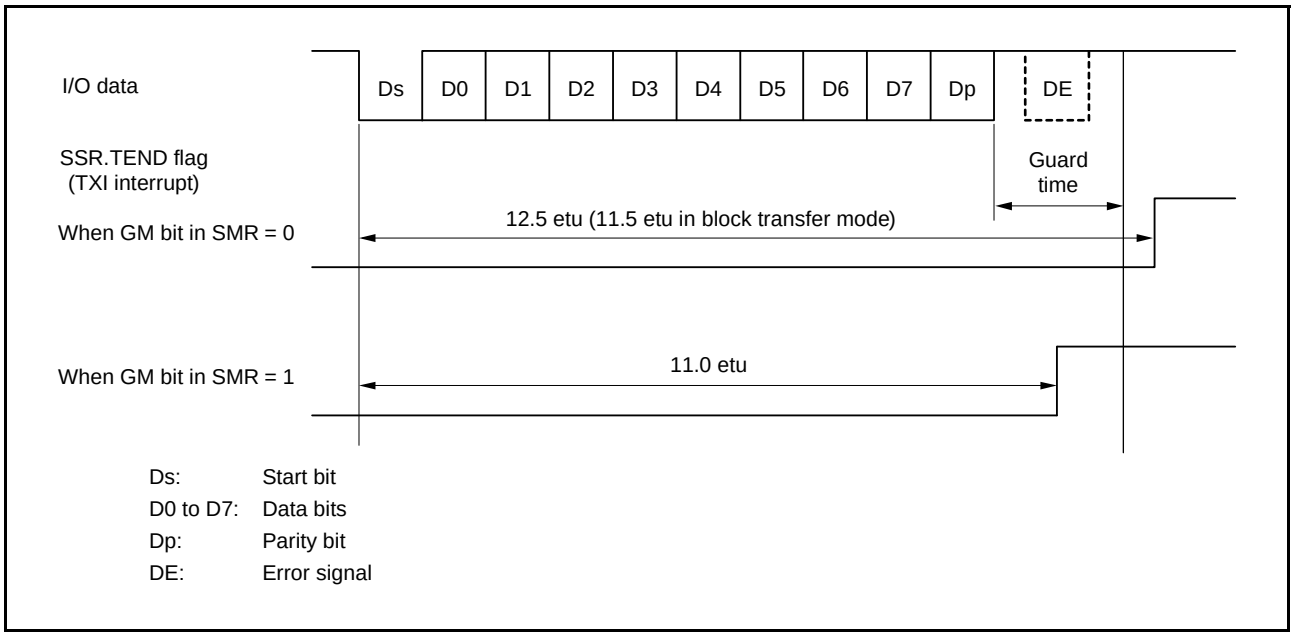

Figure 40.39 SSR.TEND Flag Generation Timing during Transmission

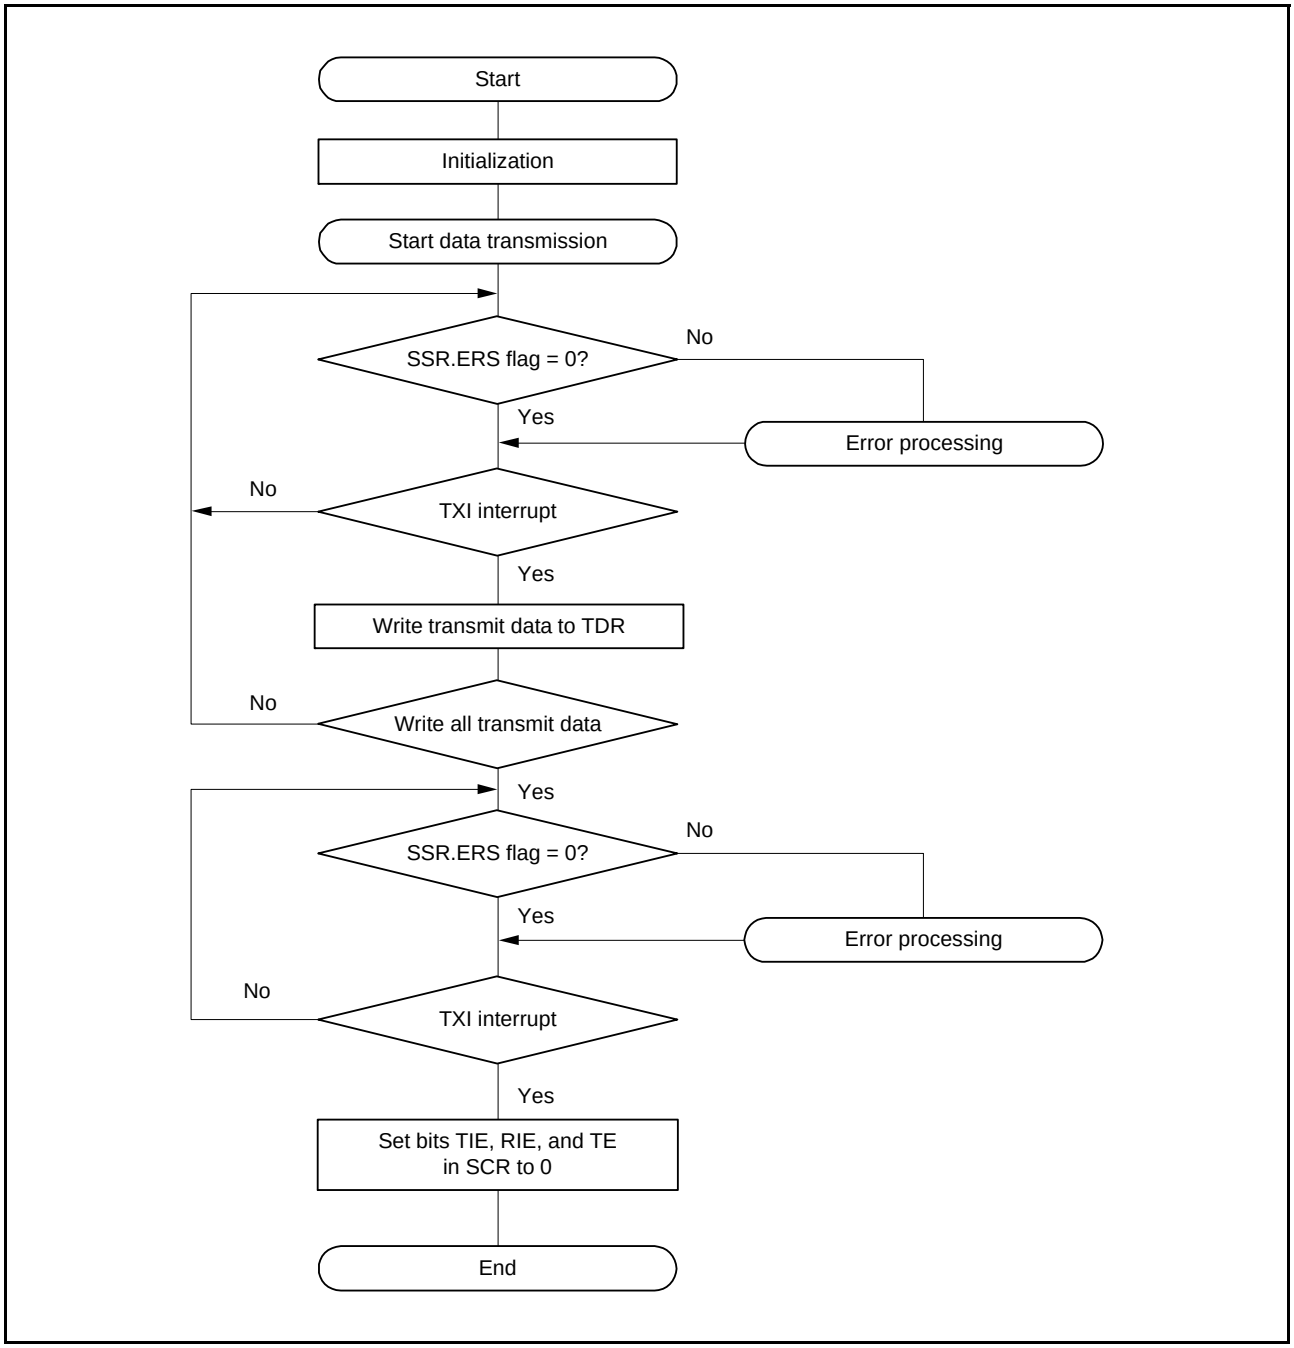

Figure 40.40 Sample Smart Card Interface Transmission Flowchart

40.6.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. Figure 40.41 shows the data retransfer operation in reception mode.

1. If a parity error is detected in receive data, the PER flag in the SSR register is set to 1. When the RIE bit in the SCR register is 1 at this time, an ERI interrupt request is generated. Clear the PER flag to 0 before the next parity bit is sampled.
2. For a frame in which a parity error is detected, no RXI interrupt is generated.
3. When no parity error is detected, the PER flag in the SSR register is not set to 1.
4. In this case, data is determined to have been received successfully. When the RIE bit in the SCR register is 1, an RXI interrupt request is generated.

Figure 40.42 shows a sample flowchart for serial data reception. All the processing steps are automatically performed using an RXI interrupt request to activate the DTC or DMAC.
In reception, setting the RIE bit to 1 allows an RXI interrupt request to be generated. The DTC or DMAC is activated by an RXI interrupt request if the RXI interrupt request is specified as a source of DTC or DMAC activation beforehand, allowing transfer of receive data.
If an error occurs during reception and either the ORER or PER flag in the SSR register is set to 1, a receive error interrupt (ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DTC or DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DTC or DMAC is transferred.
Even if a parity error occurs and the PER flag is set to 1 during reception, receive data is transferred to RDR, thus allowing the data to be read.
When a reception is forcibly terminated by setting the SCR.RE bit to 0 during operation, read the RDR register because the received data which has not yet been read may be left in RDR.

Note 1. For operations in block transfer mode, refer to section 40.3, Operation in Asynchronous Mode.

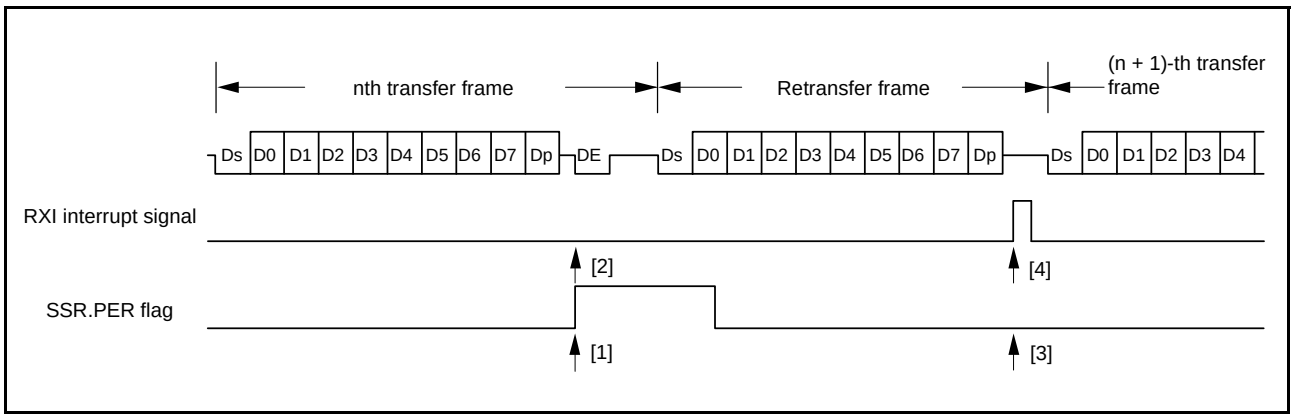

Figure 40.41 Data Retransfer Operation in SCI Reception Mode (Data Retransfer Operation during Reception)

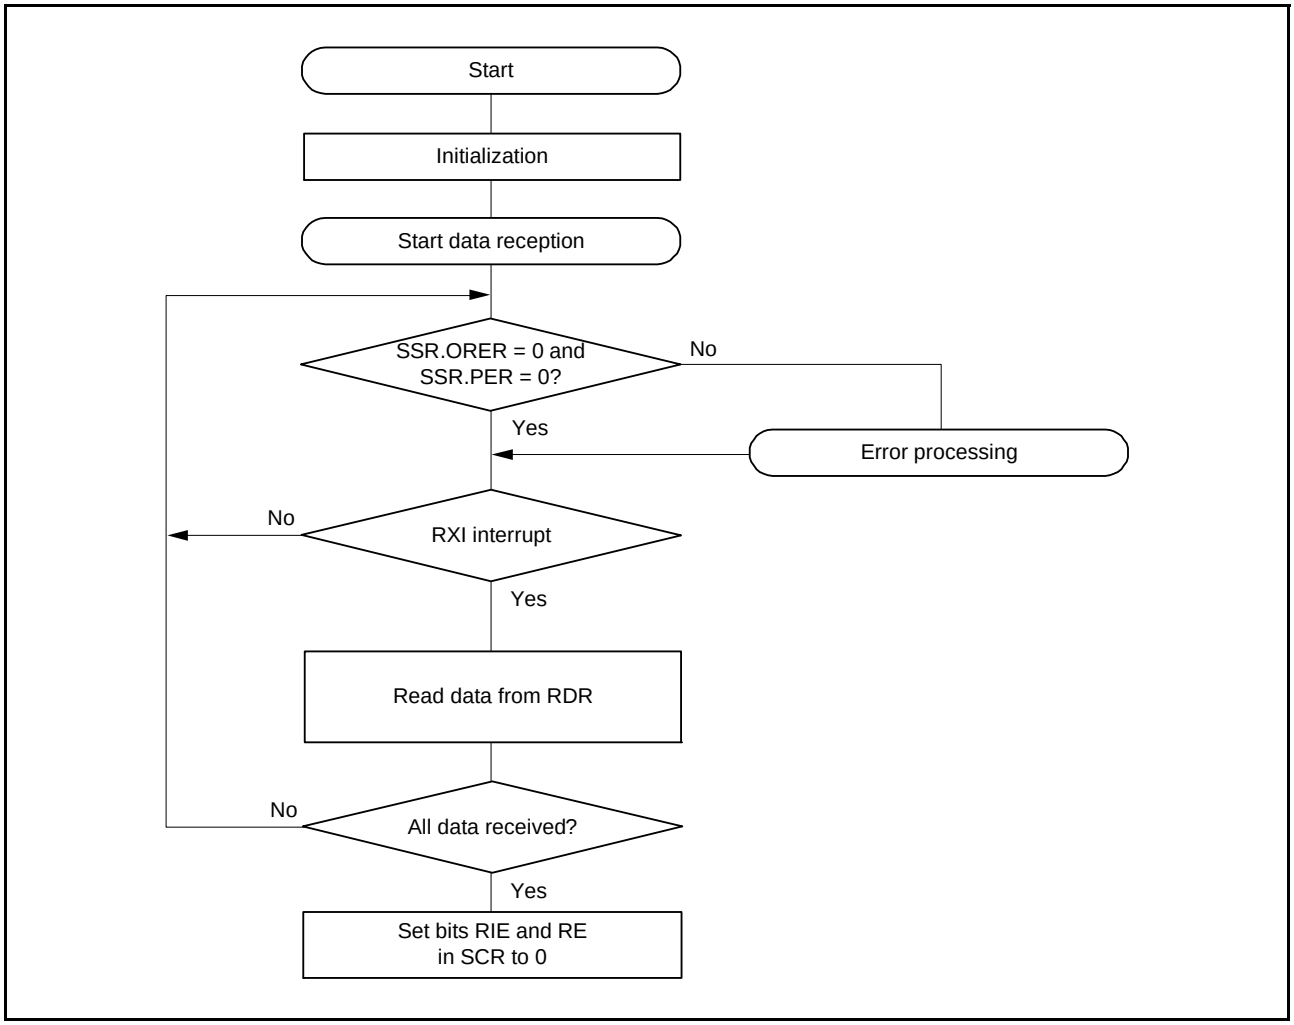

Figure 40.42 Sample Smart Card Interface Reception Flowchart

40.6.8 Clock Output Control

Clock output can be fixed using the CKE[1:0] bits in the SCR register when the GM bit in the SMR register is 1. Specifically, the minimum width of a clock pulse can be specified.

Figure 40.43 shows an example of clock output fixing timing when the CKE[0] bit is controlled with GM = 1 and CKE[1] = 0.

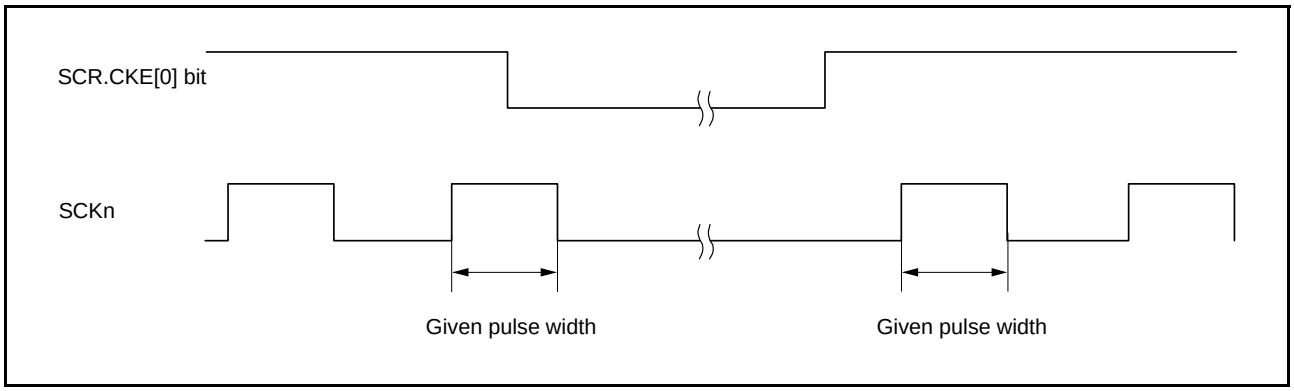

Figure 40.43 Clock Output Fixing Timing

To secure the appropriate clock duty cycle simultaneously with power-on, use the following procedure.

1. Initially, port input is enabled in the high-impedance state. To fix the potential level, use a pull-up or pull-down resistor.
2. Fix the SCKn pin to the specified output by setting the SCR.CKE[1] bit and I/O port functions.
3. Set SMR and SCMR to enable smart card interface mode.
4. Set the SCR.CKE[0] bit to 1 to start clock output.

40.7 Operation in Simple I²C Mode

Simple I²C-bus format is composed of 8 data bits and an acknowledge bit. By continuing into a slave-address frame after a start condition or restart condition, a master device is able to specify a slave device as the partner for communications. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied. The 8 data bits in all frames are transmitted in order from the MSB.

The I²C format and timing of the I²C-bus are shown in Figure 40.44 and Figure 40.45.

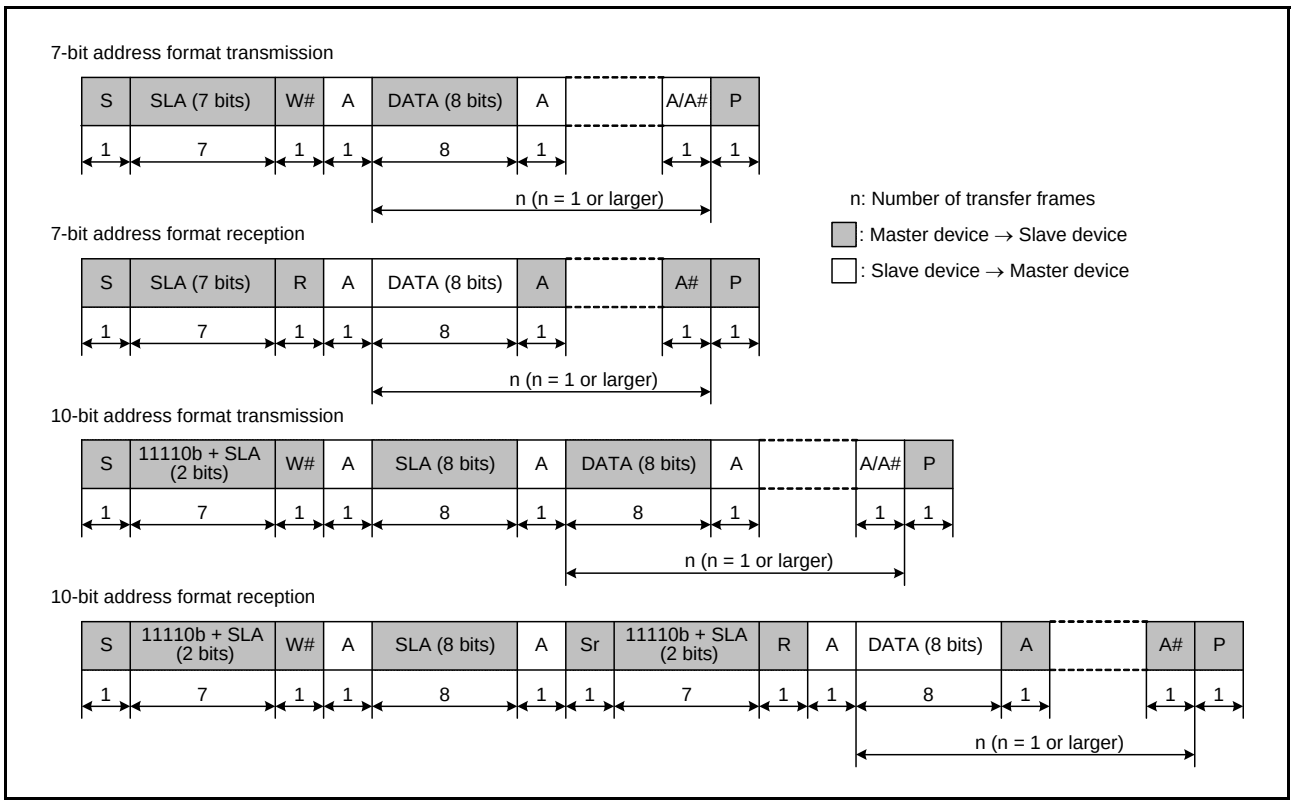

Figure 40.44 I²C-bus Format

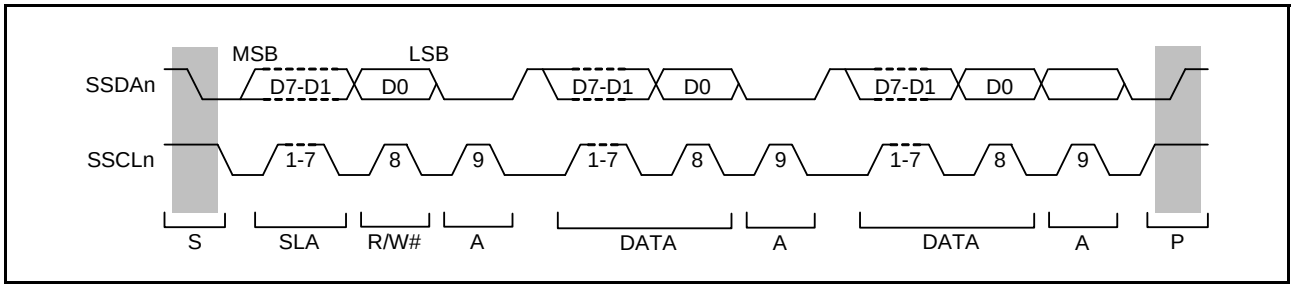

Figure 40.45 I²C-bus Timing (When SLA is 7 Bits)

S: Indicates a start condition, i.e. the master device changing the level on the SSDAn line from the high to the low level while the SSCLn line is at the high level.

SLA: Indicates a slave address, by which the master device selects a slave device.

R/W#: Indicates the direction of transfer (reception or transmission). The value 1 corresponds to transfer from the slave device to the master device and 0 corresponds to transfer from the master device to the slave device.

A/A#: Indicates an acknowledge bit. This is returned by the slave device for master transmission and by the master device for master reception. Return of the low level indicates ACK and return of the high level indicates NACK.

Sr: Indicates a restart condition, i.e. the master device changing the level on the SSDAn line from the high to the low level while the SSCLn line is at the high level and after the setup time has elapsed.

DATA: Indicates the data being received or transmitted.

P: Indicates a stop condition, i.e. the master device changing the level on the SSDAn line from the low to the high level while the SSCLn line is at the high level.

40.7.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to the IICSTAREQ bit in the SIMR3 register causes the generation of a start condition. The generation of a start condition proceeds through the following operations.

- The level on the SSDAn line falls (from the high level to the low level) and the SSCLn line is kept in the released state.
- The hold time for the start condition is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The level on the SSCLn line falls (from the high level to the low level), the IICSTAREQ bit in the SIMR3 register is set (to 0), and a start-condition generated interrupt is output.

Writing 1 to the IICRSTAREQ bit in the SIMR3 register causes the generation of a start condition. The generation of a start condition proceeds through the following operations.

- The SSDAn line is released and the SSCLn line is kept at the low level.
- The period at low level for the SSCLn line is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The SSCLn line is released (transition from the low to the high level).
- Once the high level on the SSCLn line is detected, the setup time for the restart condition is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The level on the SSDAn line falls (from the high level to the low level).
- The hold time for the restart condition is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The level on the SSCLn line falls (from the high level to the low level), the IICRSTAREQ bit in the SIMR3 register is set (to 0), and a restart-condition generated interrupt is output.

Writing 1 to the IICSTPREQ bit in the SIMR3 register causes the generation of a stop condition. The generation of a stop condition proceeds through the following operations.

- The level on the SSDAn line falls (from the high level to the low level) and the SSCLn line is kept at the low level.
- The period at low level for the SSCLn line is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The SSCLn line is released (transition from the low to the high level).
- Once the high level on the SSCLn line is detected, the setup time for the stop condition is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The SSDAn is released (transition from the low to the high level), the IICSTPREQ bit in the SIMR3 register is set (to 0), and a stop-condition generated interrupt is output.

Figure 40.46 shows the timing of operations in the generation of start, restart, and stop conditions.

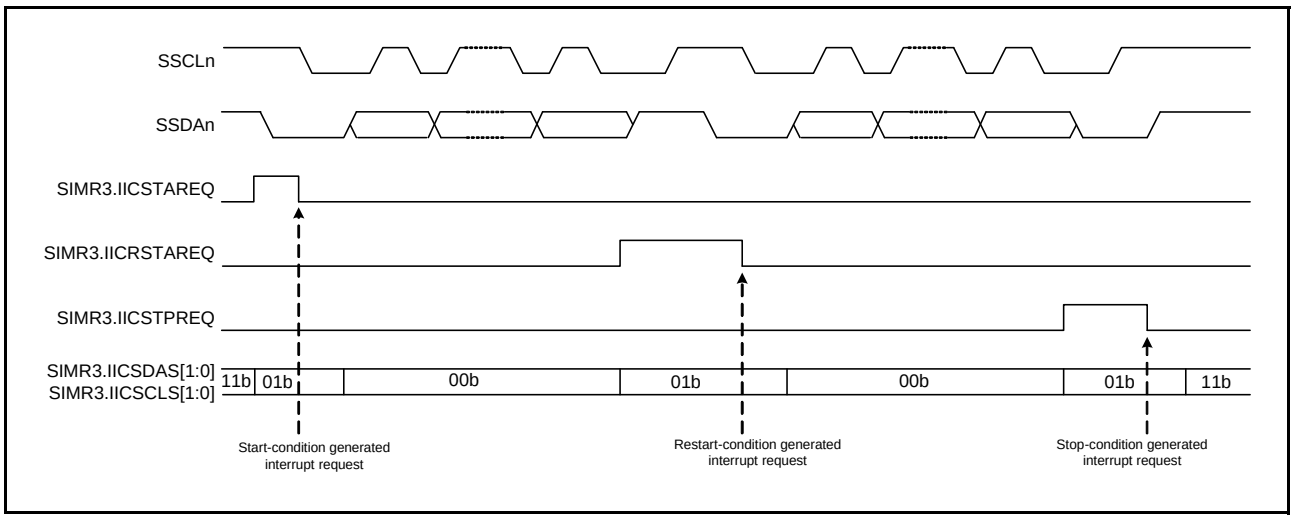

Figure 40.46 Timing of Operations in the Generation of Start, Restart, and Stop Conditions

40.7.2 Clock Synchronization

The SSCLn line may be placed at the low level in the case of a wait inserted by a slave device as the other side of transfer. Setting the IICCSC bit in the SIMR2 register to 1 applies control to obtain synchronization when the levels of the internal SSCLn clock signal and the level being input on the SSCLn pin differ.

When the IICCSC bit in the SIMR2 register is set to 1, the level of the internal SSCLn clock signal changes from low to high, counting to determine the period at high level is stopped while the low level is being input on the SSCLn pin, and counting to determine the period at high level starts after the transition of the input on the SSCLn pin to the high level. The interval from this time until counting to determine the period at high level starts on the transition of the SSCLn pin to the high level is the total of the delay of SSCLn output, delay for noise filtering of the input on the SSCLn pin (2 or 3 cycles of sampling clock for the noise filter), and delay for internal processing (1 or 2 cycles of PCLK). The period at high level of the internal SSCLn clock is extended even if other devices are not placing the low level on the SSCLn line.

If the IICCSC bit in the SIMR2 register is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SSCLn pin and the internal SSCLn clock. If the IICCSC bit in the SIMR2 register is 0, synchronization with the internal SSCLn clock is obtained for the transmission and reception of data.

If a slave device inserts a period of waiting into the interval until the transition of the internal SSCLn clock signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a period of waiting after the transition of the internal SSCLn clock signal from the low to the high level, although the generation-completed interrupt is issued without stopping the period of waiting, generation of the condition itself is not guaranteed. Figure 40.47 shows an example of operations to synchronize the clocks.

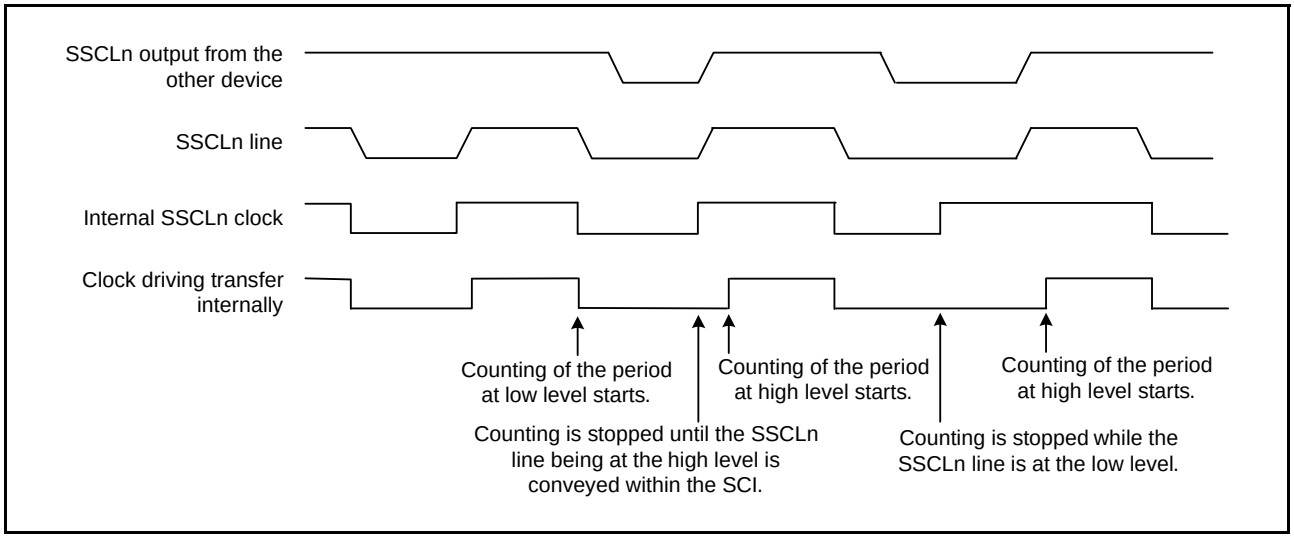

Figure 40.47 Example of Operations for Clock Synchronization

40.7.3 SSDA Output Delay

The IICDL[4:0] bits in the SIMR1 register can be used to set a delay for output on the SSDAn pin relative to falling edges of output on the SSCLn pin. Delay-time settings from 0 to 31 are selectable, representing periods of the corresponding numbers of cycles of the clock signal from the on-chip baud rate generator (derived by frequency-dividing the base clock, PCLK, by the divisor selected by the CKS[1:0] bits in the SMR register). A delay for output on the SSDAn pin is for the start condition/restart condition/stop condition signal, 8-bit transmit data, and an acknowledge bit. If the SSDA output delay is shorter than the time for the level on the SSCLn pin to fall, the change of the output on the SSDAn pin will start while the output level on the SSCLn pin is falling, creating a possibility of erroneous operation for slave devices. Ensure that settings for the delay of output on the SSDAn pin are for times greater than the time output on the SSCLn pin takes to fall (300 ns for I^2C in normal mode and fast mode).
Figure 40.48 shows the timing of delays in SSDA output.

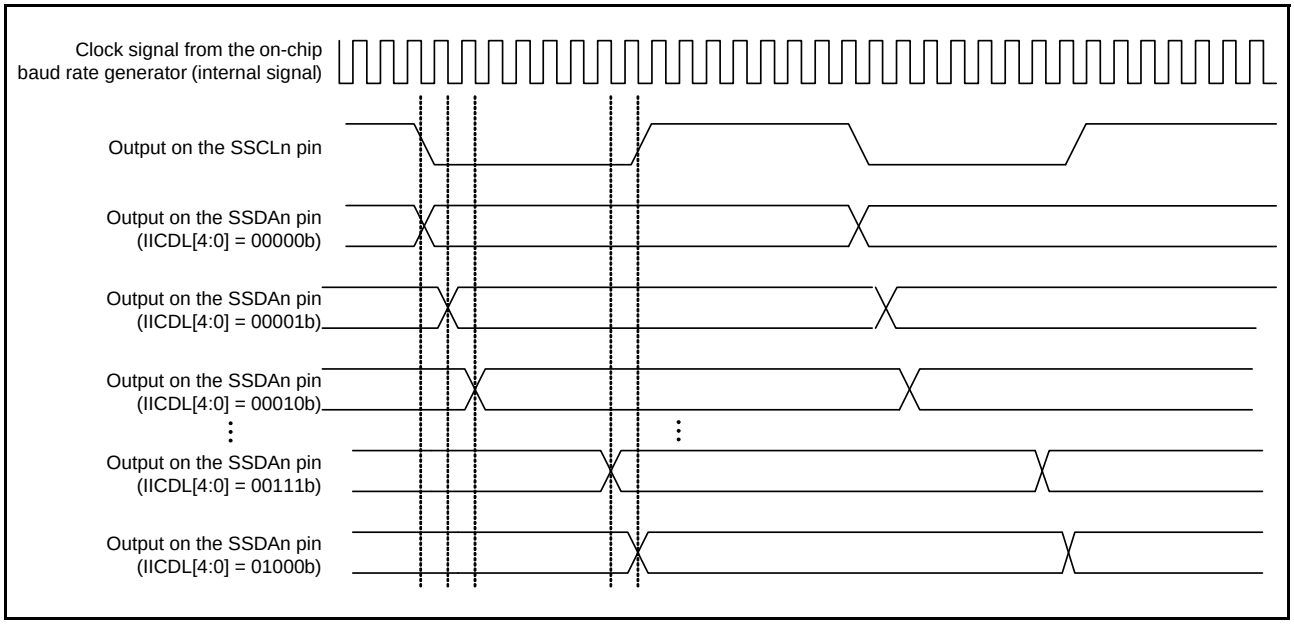

Figure 40.48 Timing of Delays in SSDA Output

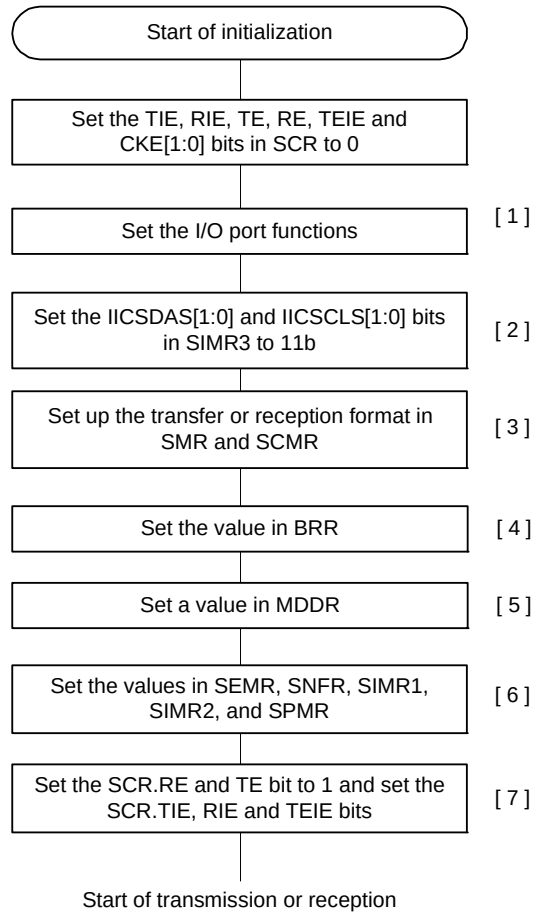
40.7.4 SCI Initialization (Simple I2C Mode)

Before transferring data, write the initial value (00h) to SCR and initialize the interface following the example shown in Figure 40.49.

When changing the operating mode, transfer format, and so on, be sure to set SCR to its initial value before proceeding with the changes.

In simple I2C mode, the open-drain setting for the communication ports should be made on the port side.



[1] Make I/O port settings that allow use (on N-channel open-drain output pins) of the SSCLn and SSDAn pin functions.

[2] Place the SSCLn and SSDAn pins in the high-impedance state until a start condition is to be generated.

[3] Set the format for transmission and reception in SMR and SCMR.
In SMR, set the CKS[1:0] bits to the desired value and set the other bits to 0.
In SCMR, set the SDIR bit to 1 and the SINV and SMIF bits to 0.

[4] Write the value for the desired bit rate to BRR.

[5] Write the value obtained by correcting a bit rate error in MDDR. This step is not necessary if the BRME bit in SEMR is cleared to 0.

[6] Set the values in SEMR, SNFR, SIMR1, SIMR2, and SPMR.
In SEMR, set the NFEN bit. Set the NFEN and BRME bits in SEMR.
In SNFR, set the NFCS[2:0] bits.
In SIMR1, set the IICM bit to 1 and the IICDL[4:0] bits as required.
In SIMR2, set the IICACKT and IICCSC bits to 1 and the IICINTM bits as required.
In SPMR, set all the bits to 0.

[7] Set the RE and TE bits in the SCR to 1. Then, set the SCR.TIE, RIE, and TEIE bits (for transmission and when the SIMR2.IICINTM bit is 1, set the RIE bit to 0). Setting the TE and RE bits to 1 makes the SSCLn and SSDAn pin functions available.

Note: Set the SCR.RE and TE bits to 0 or 1 at the same time.

Figure 40.49 Example of the Flowchart of SCI Initialization (for Simple I2C Mode)

40.7.5 Operation in Master Transmission (Simple I2C Mode)

Figure 40.50 and Figure 40.51 show examples of operations in master transmission and Figure 40.52 is a flowchart showing the procedure for data transmission. Refer to Table 40.33 for more information on the STI interrupt.
When 10-bit slave addresses are in use, steps [3] and [4] in Figure 40.52 are repeated twice.
In simple I2C mode, the transmit data empty interrupt (TXI) is generated when communication of one frame is completed, unlike the TXI interrupt request generation timing during clock synchronous transmission.

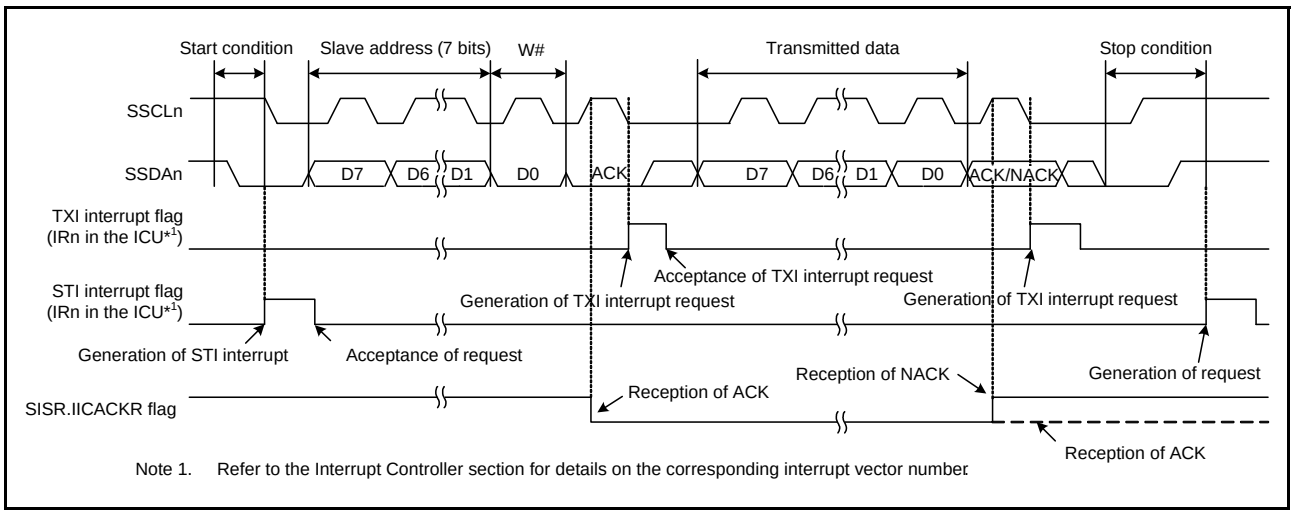


Figure 40.50 Example 1 of Operations for Master Transmission in Simple I2C-bus Mode (with 7-Bit Slave Addresses, Transmission Interrupts, and Reception Interrupts in Use)

When the SIMR2.IICINTM bit is set to 0 (use ACK/NACK interrupts) during master transmission, the DTC or DMAC is activated by the ACK interrupt as the trigger and necessary number of data bytes are transmitted. When the NACK is received, error processing, such as transmission stop and retransmission, is performed by the NACK interrupt as the trigger.

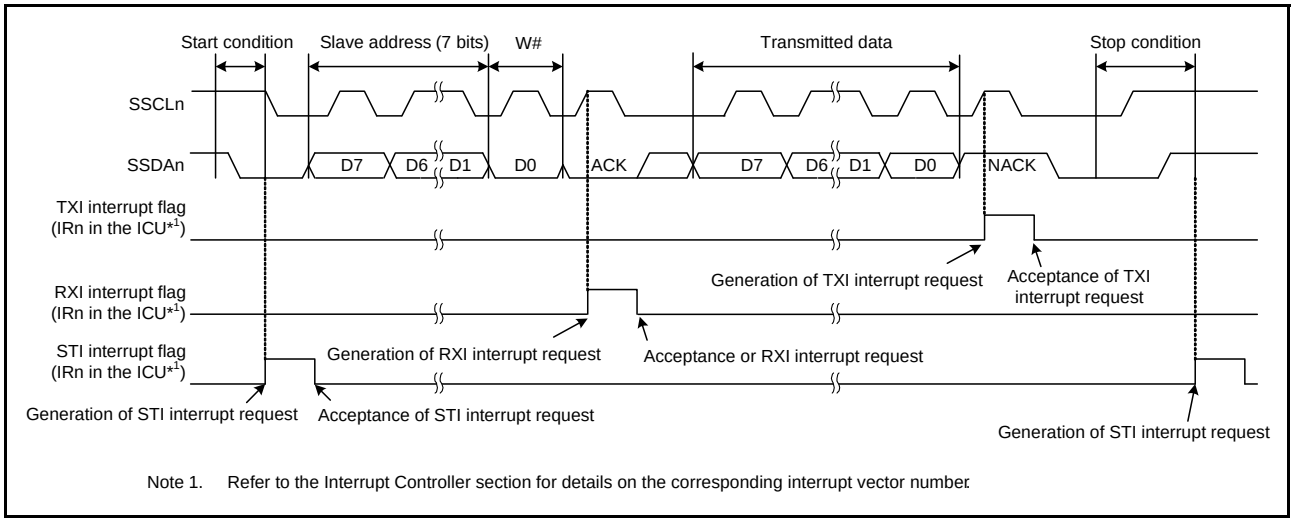

Figure 40.51 Example 2 of Operations for Master Transmission in Simple I2C-bus Mode (with 7-Bit Slave Addresses, ACK Interrupts, and NACK Interrupts in Use)

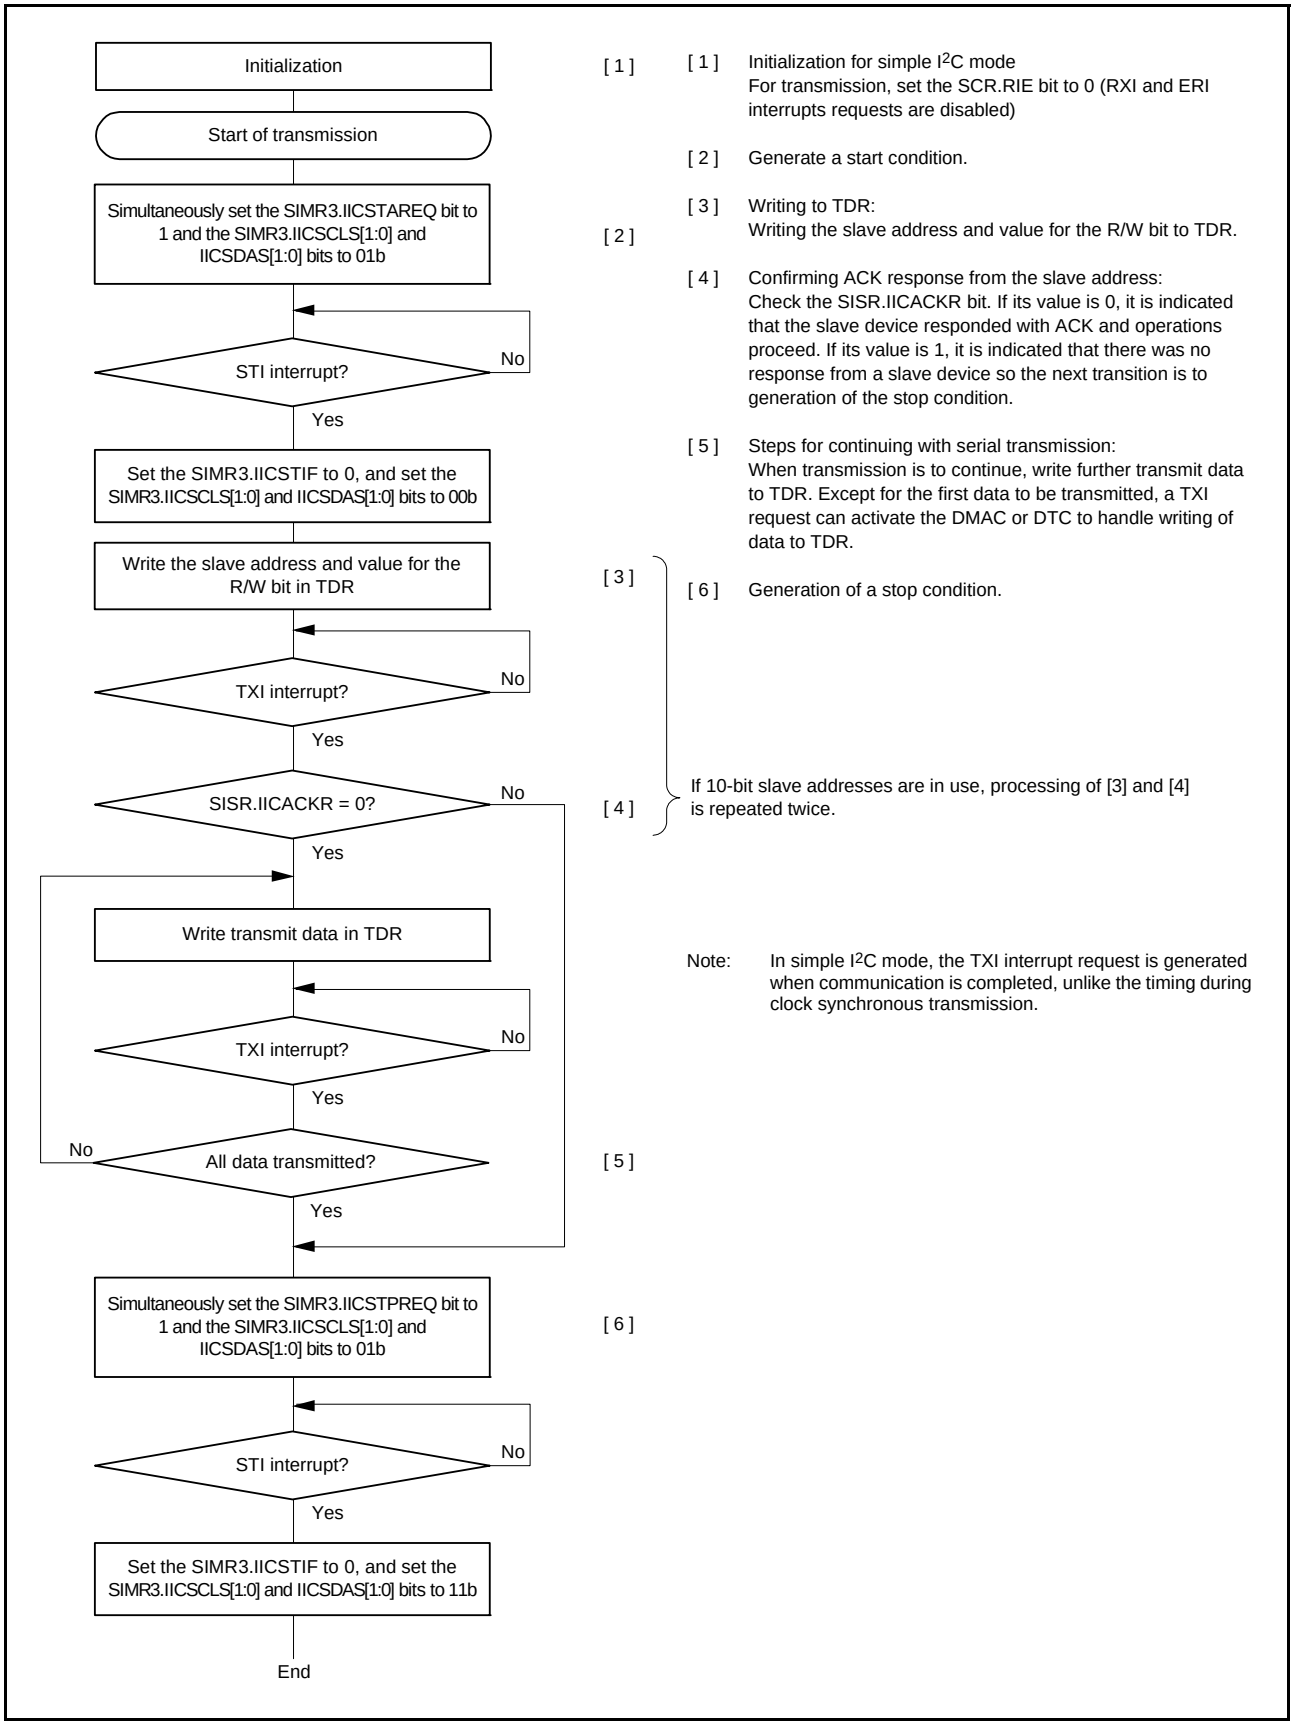

[1] [1] Initialization for simple I2C mode
For transmission, set the SCR.RIE bit to 0 (RXI and ERI interrupts requests are disabled)

[2] Generate a start condition.

[3] Writing to TDR:
[2] Writing the slave address and value for the R/W bit to TDR.

[4] Confirming ACK response from the slave address:
Check the SISR.IICACKR bit. If its value is 0, it is indicated that the slave device responded with ACK and operations proceed. If its value is 1, it is indicated that there was no response from a slave device so the next transition is to generation of the stop condition.

[5] Steps for continuing with serial transmission:
When transmission is to continue, write further transmit data to TDR. Except for the first data to be transmitted, a TXI request can activate the DMAC or DTC to handle writing of data to TDR.

[3] [6] Generation of a stop condition.

[4] If 10-bit slave addresses are in use, processing of [3] and [4] is repeated twice.

Note: In simple I2C mode, the TXI interrupt request is generated when communication is completed, unlike the timing during clock synchronous transmission.

Figure 40.52 Example of the Procedure for Master Transmission Operations in Simple I2C Mode (with Transmission Interrupts and Reception Interrupts in Use)

40.7.6 Master Reception (Simple I2C Mode)

Figure 40.53 shows an example of operations in simple I2C mode master reception and Figure 40.54 is a flowchart showing the procedure for master reception.

The value of the SIMR2.IICINTM bit is assumed to be 1 (use reception and transmission interrupts).

In simple I2C mode, the transmit data empty interrupt (TXI) is generated when communication of one frame is completed, unlike the TXI interrupt request generation timing during clock synchronous transmission.

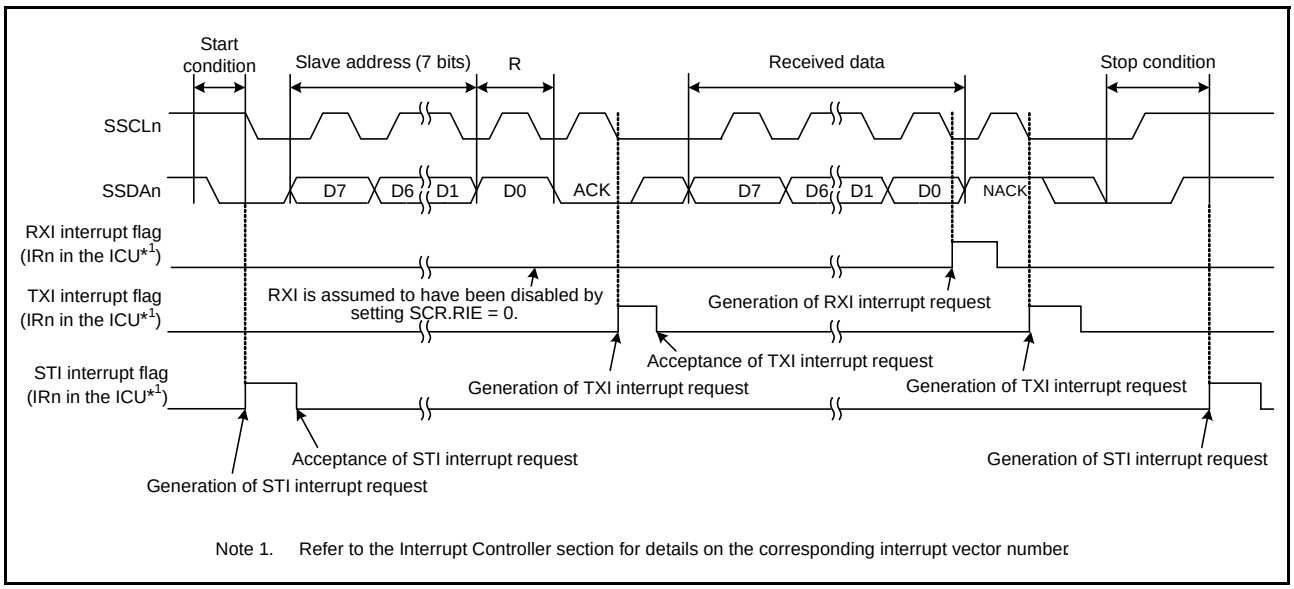

Figure 40.53 Example of Operations for Master Reception in Simple I2C-bus Mode (with 7-Bit Slave Addresses, Transmission Interrupts, and Reception Interrupts in Use)

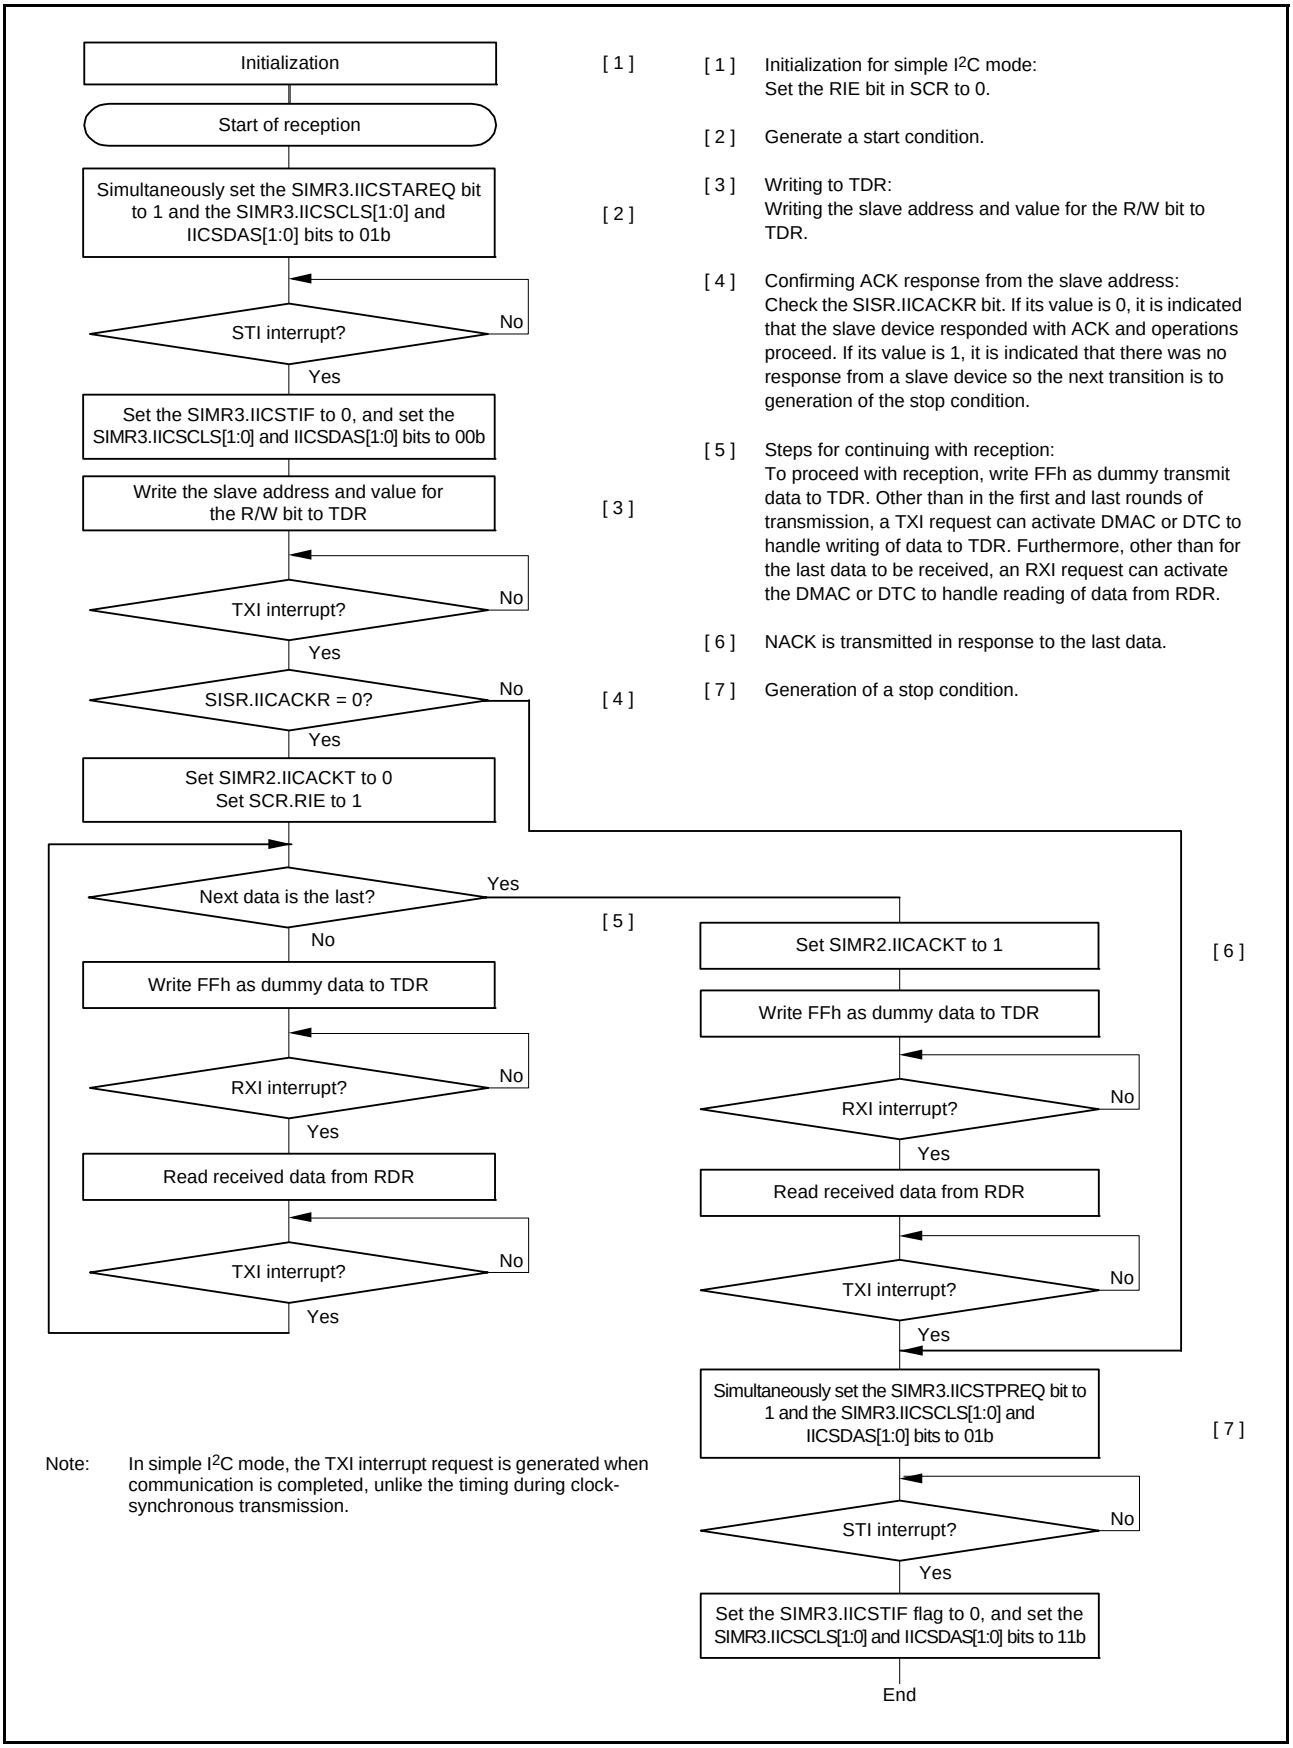


[1] Initialization for simple I²C mode:
Set the RIE bit in SCR to 0.

[2] Generate a start condition.

[3] Writing to TDR:
Writing the slave address and value for the R/W bit to TDR.

[4] Confirming ACK response from the slave address:
Check the SISR.IICACKR bit. If its value is 0, it is indicated that the slave device responded with ACK and operations proceed. If its value is 1, it is indicated that there was no response from a slave device so the next transition is to generation of the stop condition.

[5] Steps for continuing with reception:
To proceed with reception, write FFh as dummy transmit data to TDR. Other than in the first and last rounds of transmission, a TXI request can activate DMAC or DTC to handle writing of data to TDR. Furthermore, other than for the last data to be received, an RXI request can activate the DMAC or DTC to handle reading of data from RDR.

[6] NACK is transmitted in response to the last data.

[7] Generation of a stop condition.

Note: In simple I²C mode, the TXI interrupt request is generated when communication is completed, unlike the timing during clock-synchronous transmission.

Figure 40.54 Example of the Procedure for Master Reception Operations in Simple I²C Mode (with Transmission Interrupts and Reception Interrupts in Use)

40.8 Operation in Simple SPI Mode

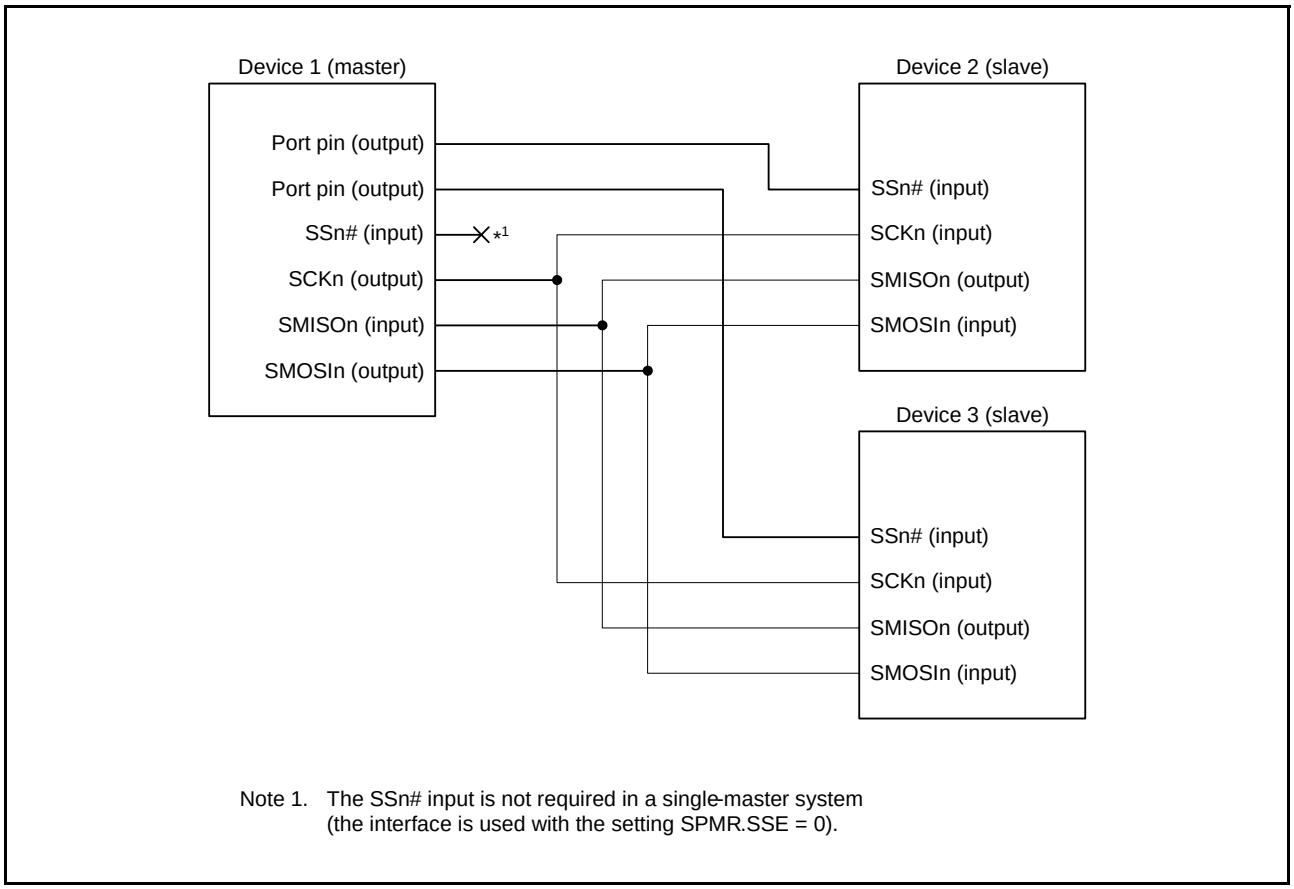
As an extended function, the SCI supports a simple SPI mode that handles transfer among one or multiple master devices and multiple slave devices.

Making the settings for clock synchronous mode (SCMR.SMIF = 0, SIMR1.IICM = 0, SMR.CM = 1) plus setting the SSE bit in the SPMR to 1 places the SCI in simple SPI mode. However, the SS pin function on the master side is unnecessary for connection of the device used as the master in simple SPI mode when the configuration only has a single master, so set the SSE bit in the SPMR to 0 in such cases.

Figure 40.55 shows an example of connections for simple SPI mode. Control a general port pin to produce the SS output signal from the master.

In simple SPI mode, data are transferred in synchronization with clock pulses in the same way as in clock synchronous mode. One character of data for transfer consists of 8 bits of data, and parity bits cannot be appended to this. The data can be inverted by setting the SCMR.SINV bit to 1.

Since the receiver and transmitter are independent of each other within the SCI module, full-duplex communications are possible, with a common clock signal. Furthermore, since both the transmitter and receiver have a double-buffered structure, writing of further transmit data while transmission is in progress and reading of previously received data while reception is in progress are both possible. Continuous transfer is thus possible.



Note 1. The SSn# input is not required in a single-master system (the interface is used with the setting SPMR.SSE = 0).

Figure 40.55 Example of Connections via a Simple SPI Mode (In Single Master Mode, SPMR.SSE Bit = 0)

40.8.1 States of Pins in Master and Slave Modes

The direction (input or output) of pins for the simple SPI mode interface differs according to whether the device is a master (SCR.CKE[1:0] = 00b or 01b and SPMR.MSS = 0) or slave (SCR.CKE[1:0] = 10b or 11b and SPMR.MSS = 1). Table 40.29 lists the states of pins according to the mode and the level on the SSn# pin.

Table 40.29 States of Pins by Mode and Input Level on the SSn# Pin

Mode	Input on SSn# Pin	State of SMOSIn Pin	State of SMISOn Pin	State of SCKn Pin
Master mode*1	High level (transfer can proceed)	Output for data transmission*2	Input for received data	Clock output*3
	Low level (transfer cannot proceed)	High-impedance	Input for received data (but disabled)	High-impedance
Slave mode	High level (transfer can proceed)	Input for received data (but disabled)	High-impedance	Clock input (but disabled)
	Low level (transfer cannot proceed)	Input for received data	Output for data transmission	Clock input

Note 1. When there is only a single master (SPMR.SSE = 0), transfer is possible regardless of the input level on the SSn# pin (this is equivalent to input of a high level on the SSn# pin). Since the SSn# pin function is not required, the pin is available for other purposes.
Note 2. The SMOSIn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE bit = 0).
Note 3. The SCKn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE and RE bits = 00b) in a multi-master configuration (SPMR.SSE = 1).

40.8.2 SS Function in Master Mode

Setting the CKE[1:0] bits in the SCR to 00b and the MSS bit in the SPMR to 0 selects master operation. The SSn# pin is not used in single-master configurations (SPMR.SSE = 0), so transmission or reception can proceed regardless of the value of the SSn# pin.

When the level on the SSn# pin is high in a multi-master configuration (SPMR.SSE = 1), a master device outputs clock signals from the SCKn pin before starting transmission or reception to indicate that there are no other masters or another master is performing reception or transmission. When the level on the SSn# pin is low in a multi-master configuration (SPMR.SSE = 1), there are other masters, and this indicates that transmission or reception is in progress. At this time the SMOSIn output and SCKn pins will be placed in the high-impedance state and starting transmission or reception will not be possible. Furthermore, the value of the SPMR.MFF bit will be 1, indicating a mode fault error. In a multi-master configuration, start error processing by reading SPMR.MFF flag. Also, even if a mode fault error occurs while transmission or reception is in progress, transmission or reception will not be stopped, but the SMOSIn and SCKn pin output will be placed in the high-impedance state after the completion of the transfer.

Control a general port pin to produce the SS output signal from the master.

40.8.3 SS Function in Slave Mode

Setting the CKE[1:0] bits in the SCR to 10b and the MSS bit in the SPMR to 1 selects slave operation. When the level on the SSn# pin is high, the SMISOn output pin will be in the high-impedance state and clock input through the SCKn pin will be ignored. When the level on the SSn# pin is low, clock input through the SCKn pin will be effective and transmission or reception can proceed.

If the input on the SSn# pin changes from low to high level during transmission or reception, the SMISOn output pin will be placed in the high-impedance state. Meanwhile, the internal processing for transmission or reception will continue at the rate of the clock input through the SCKn pin until processing for the character currently being transmitted or received is completed, after which it stops. At that time, an interrupt (the appropriate one from among TXI, RXI, and TEI) will be generated.

40.8.4 Relationship between Clock and Transmit/Receive Data

The CKPOL and CKPH bits in the SPMR can be used to set up the clock for use in transmission and reception in four different ways. The relation between the clock signal and the transmission and reception of data is shown in Figure 40.56. The relation is the same for both master and slave operation.

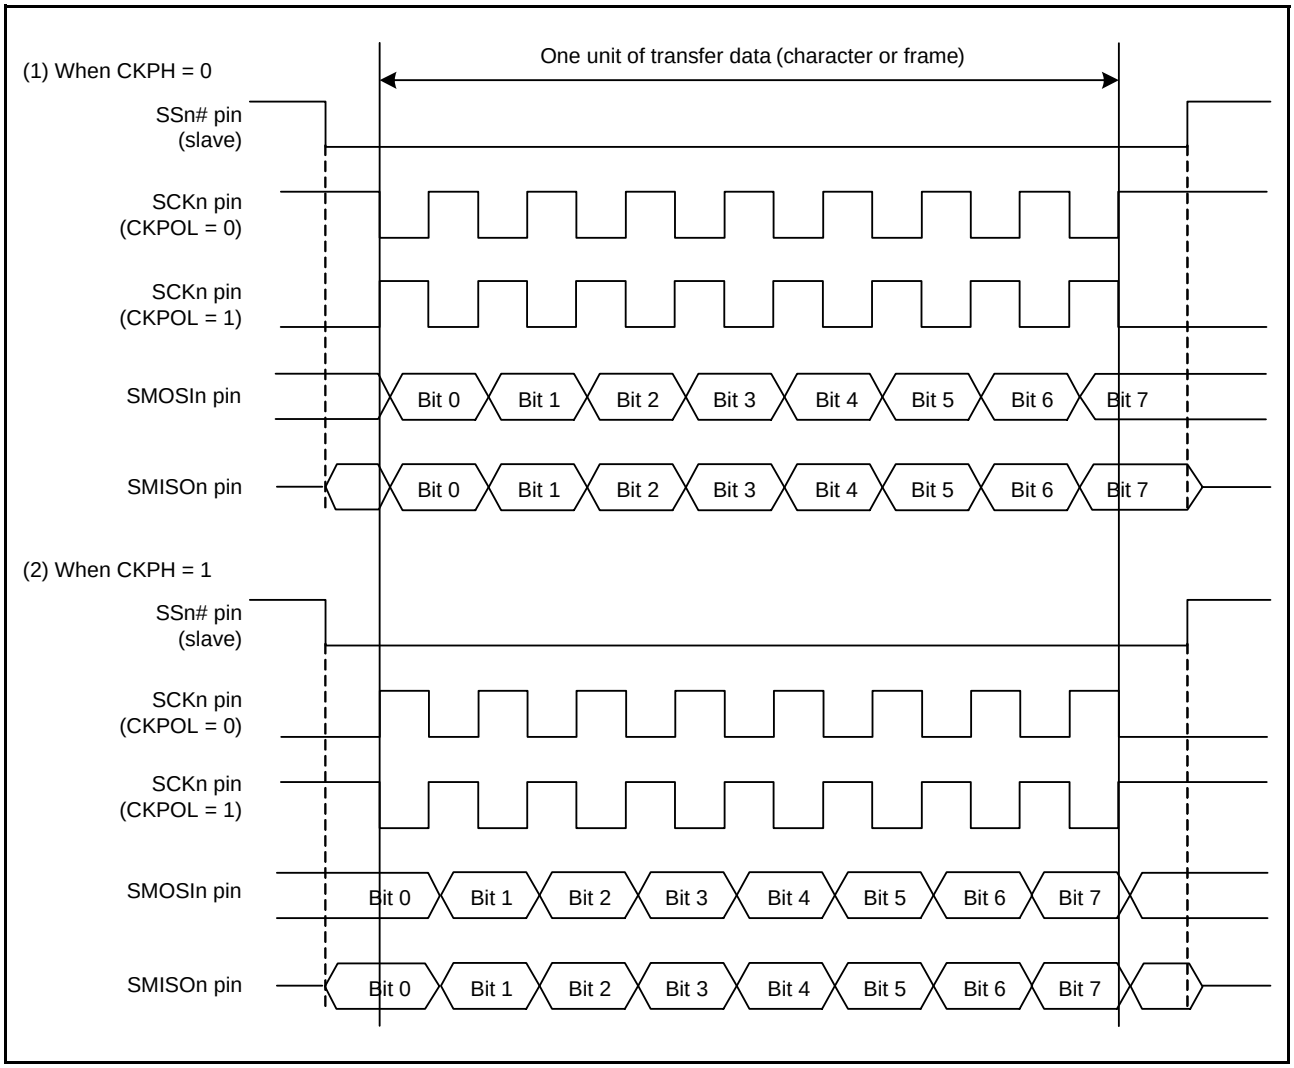


Figure 40.56 Relation between Clock Signal and Transmit/Receive Data in Simple SPI Mode

40.8.5 SCI Initialization (Simple SPI Mode)

The procedure is the same as for initialization in clock synchronous mode Figure 40.23, Sample SCI Initialization Flowchart. The CKPOL and CKPH bits in the SPMR must be set to ensure that the kind of clock signal they select is suitable for both master and slave devices.
For initialization, changes to the operating mode, changes to the transfer format, and so on, initialize the SCR register before proceeding with changes.
As well as setting the RE bit to 0, note that the SSR.ORER, FER, and PER flags, as well as the RDR, are not initialized. Note that changing the value of the TE bit from 1 to 0 or from 0 to 1 will lead to the generation of a transmit data empty interrupt (TXI) if the value of the TIE bit in the SCR is 1 at the time.

40.8.6 Transmission and Reception of Serial Data (Simple SPI Mode)

In master operation, ensure that the SSn# pin of the slave device on the other side of the transfer is at the low level before starting the transfer and at the high level on completion of the transfer. Otherwise, the procedures are the same as in clock synchronous mode.

40.9 Bit Rate Modulation Function

The bit rate modulation function corrects the bit rate by thinning out the specified amount of clocks from those input to the baud rate generator.
When the SEMR.BRME bit is 1, the baud rate generator validates and counts the average interval of the number of clocks set in the MDDR register out of the total 256 clocks input.
Figure 40.57 assumes the SCI is in asynchronous mode, bits SMR.CKS[1:0] are 00b, the BRR register is 00h, and the MDDR register is 160. In this example, the cycle of the base clock is evenly corrected to 256/160, and the bit rate is corrected to 160/256. Note that there is an imbalance in thinning out the internal clock, and expansion and contraction occur in the pulse width of the internal base clock.

Note: Do not use this function in clock synchronous mode and in the highest speed settings in simple SPI mode (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).

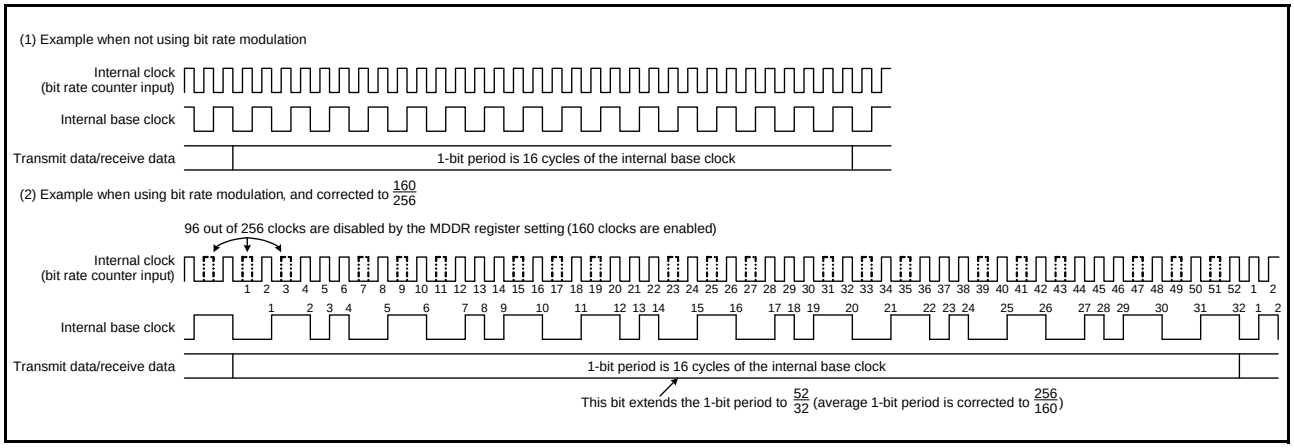

Figure 40.57 Example of the Base Clock When the Bit Rate Modulation Function is Used

40.10 Extended Serial Mode Control Section: Description of Operation

40.10.1 Serial Transfer Protocol

In conjunction with the SCIg module, the extended serial mode control section of the SCIh module can realize the serial transfer protocol composed of Start Frames and Information Frames that is shown in Figure 40.58.
A Start Frame is composed of a Break Field, Control Field 0, and Control Field 1. An Information Frame is composed of a number of Data Fields, a CRC16 Upper Field, and a CRC16 Lower Field.

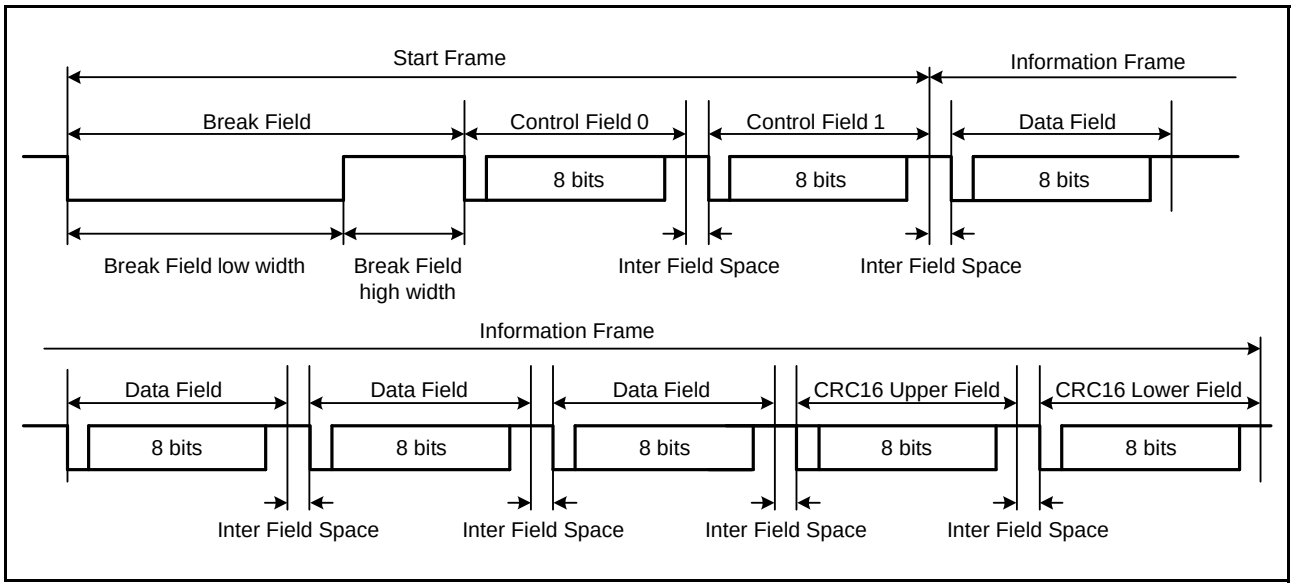

Figure 40.58 Protocol for Serial Transfer by the Extended Serial Mode Control Section

40.10.2 Transmitting a Start Frame

Figure 40.59 shows an example of operations to transmit a Start Frame, which is composed of the Break Field low width, Control Field 0, and Control Field 1. Figure 40.60 and Figure 40.61 are flowcharts for the transmission of a Start Frame.
Operations when the extended serial mode control section is to be used to transmit a Start Frame are as listed below. Be sure to use the SCI12 in asynchronous mode.

(1) With Break Field low width output mode as the operating mode for the timer, writing 1 to the TCR.TCST bit starts counting by the timer, and the low level will be output from the TXDX12 pin over the period corresponding to registers TCNT and TPRE settings.
(2) The output on the TXDX12 pin is inverted when the timer counter underflows, and the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.
(3) Write 0 to the TCR.TCST bit to stop counting by the timer, and send the data for Control Field 0 by using SCI12. After the Break Field low width output, stop counting before the next underflow occurs.
(4) When the data for Control Field 0 have been transmitted, send the data for Control Field 1.
(5) When the data for Control Field 1 have been transmitted, send an Information Frame.

Omit the Break Field and Control Field 0 to suit the structure of the Start Frame.

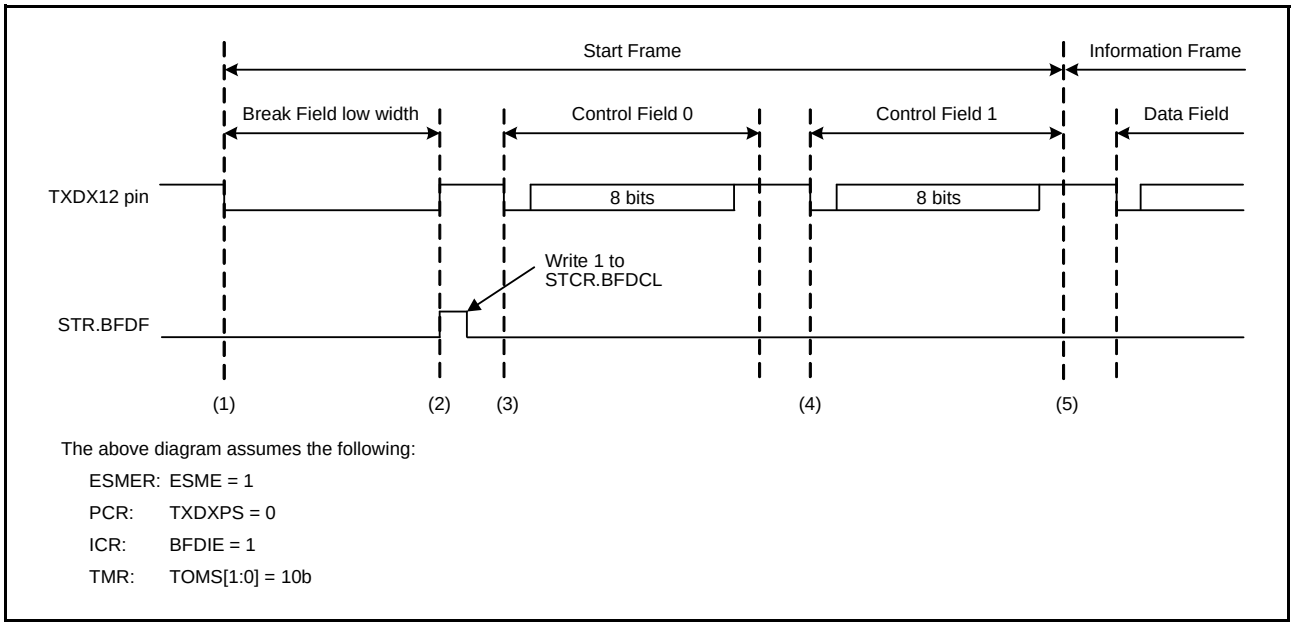

Figure 40.59 Example of Operations When Transmitting a Start Frame

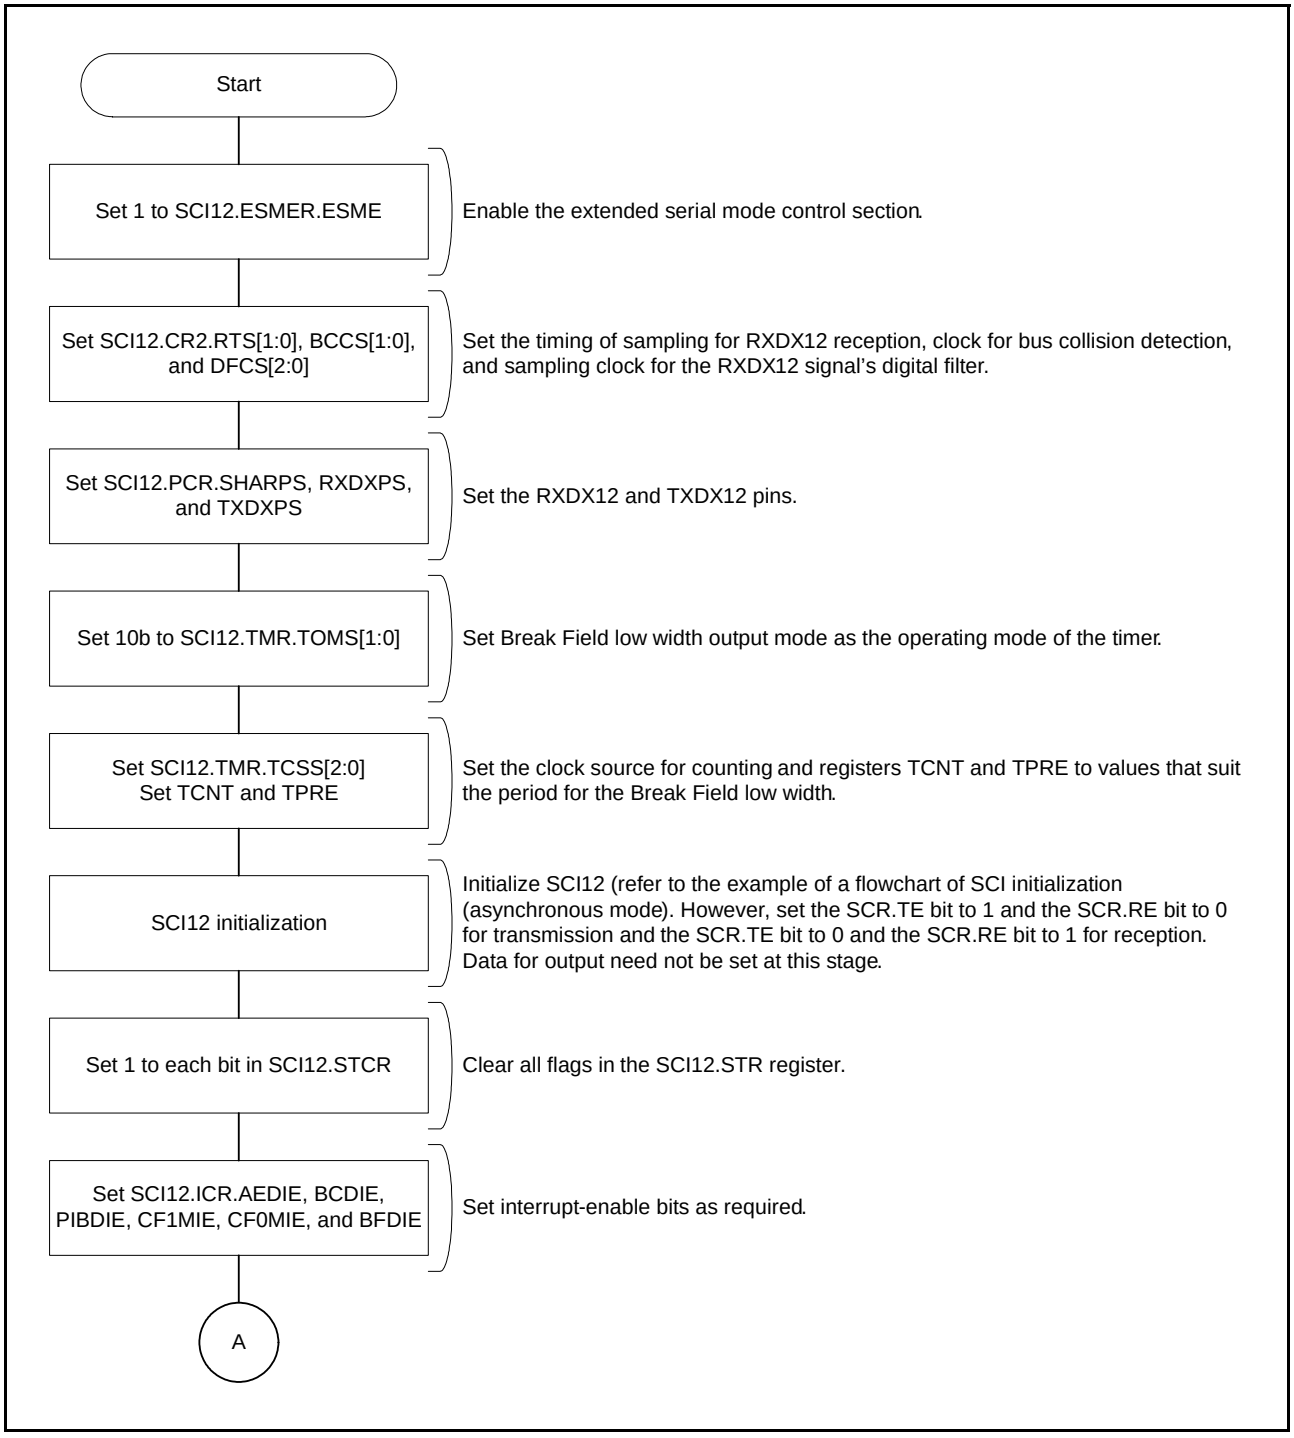

Figure 40.60 Example of Start Frame Transmission (1/2)

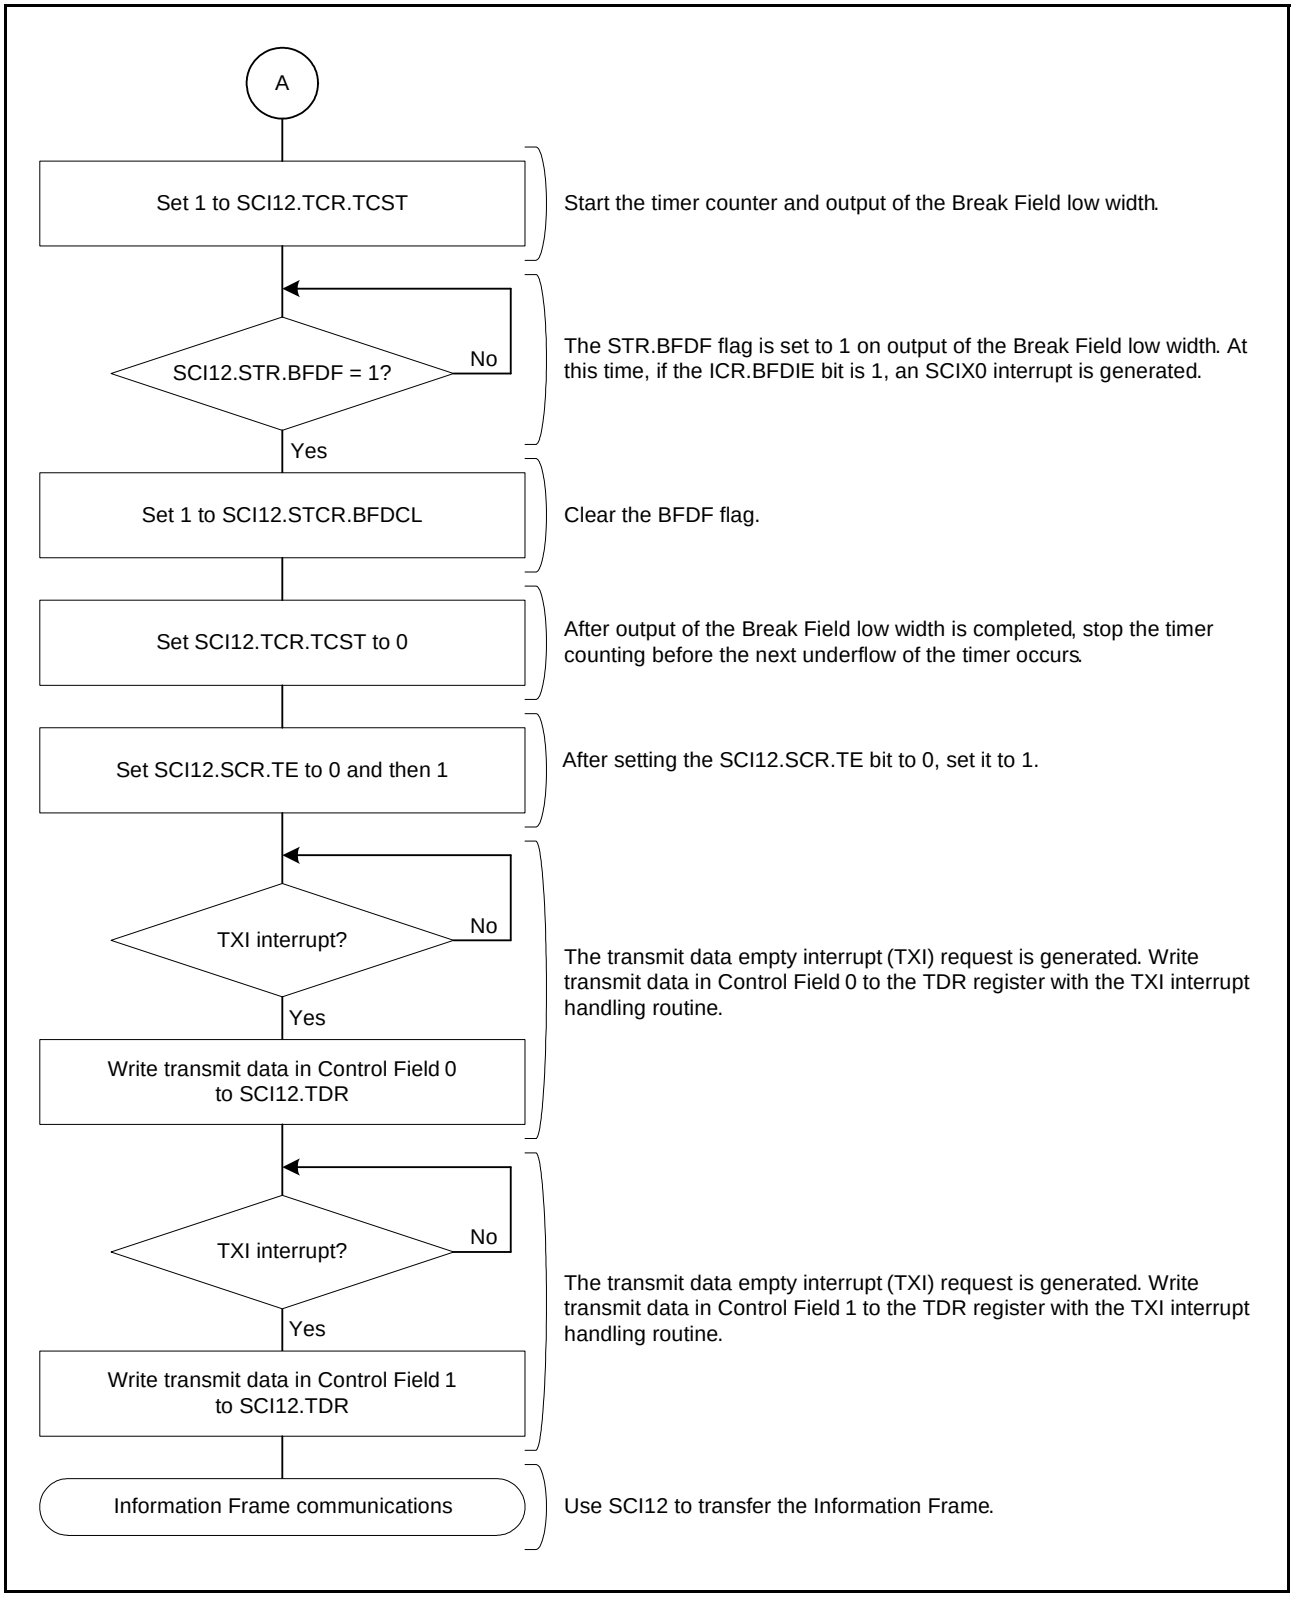

Figure 40.61 Example of Start Frame Transmission (2/2)

40.10.3 Receiving a Start Frame

The extended serial mode control section is capable of receiving Start Frames with the structures listed in Table 40.30.

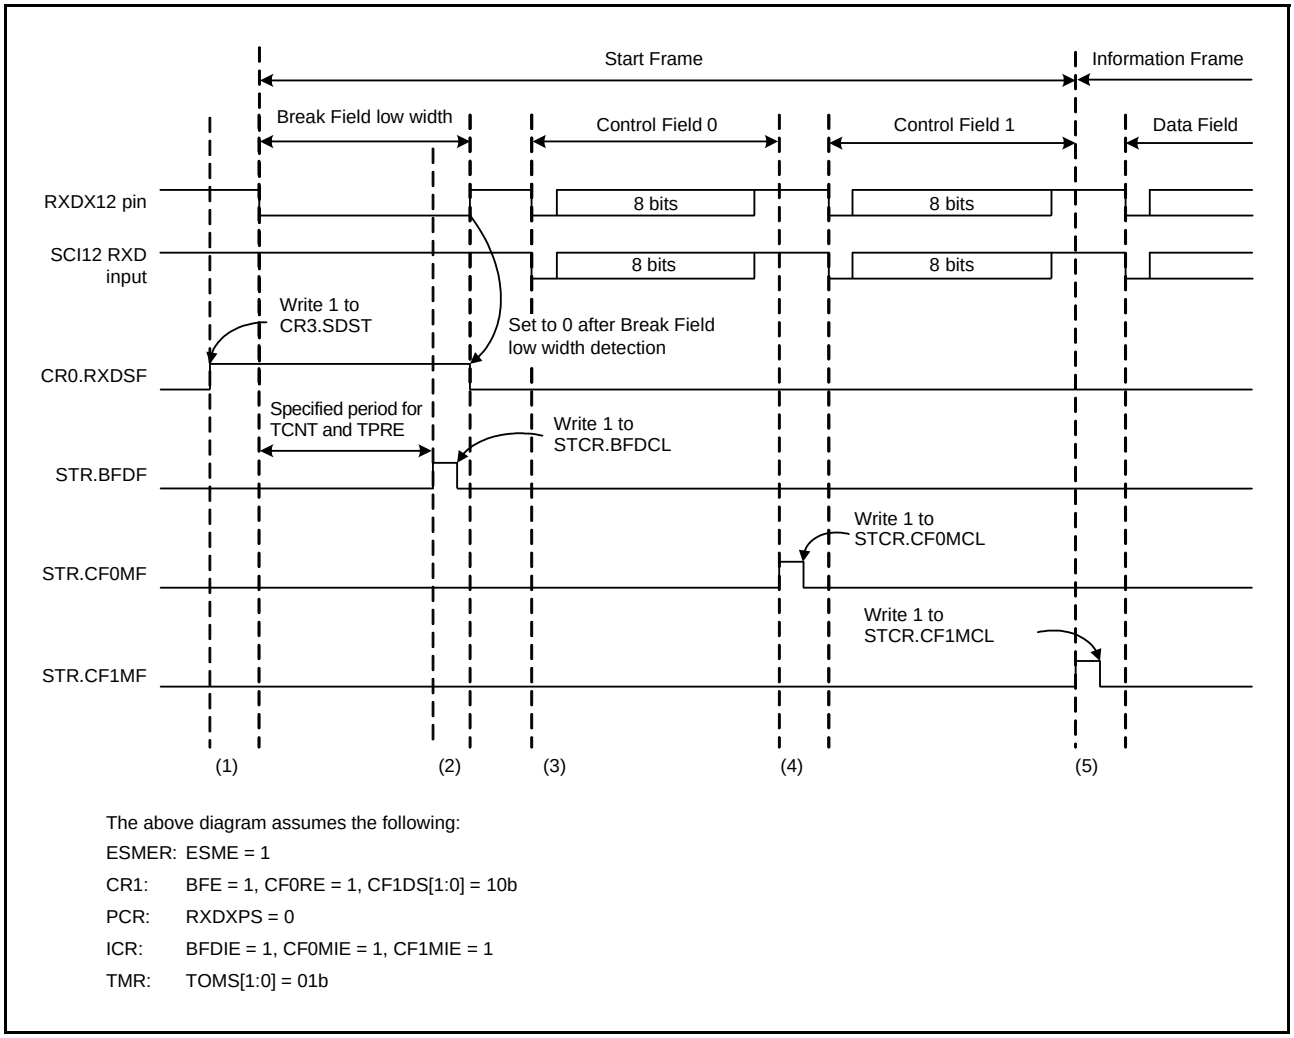
Table 40.30 Structures of Start Frames

Bit Setting		Structures of Start Frames
BFE	CF0RE	
0	0	Control Field 1 (8 bits) → Information Frame
0	1	Control Field 0 (8 bits) → Control Field 1 (8 bits) → Information Frame
1	0	Break Field (low width) → Control Field 1 (8 bits) → Information Frame
1	1	Break Field (low width) → Control Field 0 (8 bits) → Control Field 1 (8 bits) → Information Frame

Figure 40.62 shows an example of operations to receive a Start Frame, which is composed of the Break Field low width, Control Field 0, and Control Field 1. Figure 40.63 and Figure 40.64 are flowcharts for the reception of a Start Frame, and Figure 40.65 is a state transition diagram for the extended serial mode control section.
Operations when the extended serial mode control section is to be used to receive a Start Frame are as listed below. Be sure to use the SCI12 in asynchronous mode.

(1) With Break Field low width detection mode as the operating mode for the timer, writing 1 to the CR3.SDST bit enables detection of the Break Field low width. RXDX12 input to the SCI12 is disabled at this time.
(2) Low-level input on the RXDX12 pin continuing over a period longer than that corresponding to the settings of registers TCNT and TPRE is detected as the Break Field low width. At this time, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.
(3) When the input from the RXDX12 pin goes high after the Break Field low width, the CR0.RXDSF flag becomes 0 and reception of Control Field 0 by the SCI12 starts.
(4) If the data received in Control Field 0 match the data set in the CF0DR register, the STR.CF0MF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.CF0MIE bit is 1. Reception of Control Field 1 by the SCI12 starts after that. If the data received in Control Field 0 do not match the data set in the CF0DR register, a transition to the state prior to Break Field low width detection proceeds.
(5) If the data received in Control Field 1 match the data set in registers PCF1DR and SCF1DR, the STR.CF1MF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.CF1MIE bit is 1. Transfer of the Information Frame by the SCI12 starts after that. If the data received in Control Field 1 do not match the data set in either or both of registers PCF1DR and SCF1DR, a transition to the state prior to Break Field low width detection proceeds.

Omit the Break Field and Control Field 0 to suit the structure of the Start Frame.



The above diagram assumes the following:

ESMER: ESME = 1

CR1: BFE = 1, CF0RE = 1, CF1DS[1:0] = 10b

PCR: RXDXPS = 0

ICR: BFDIE = 1, CF0MIE = 1, CF1MIE = 1

TMR: TOMS[1:0] = 01b

Figure 40.62 Example of Operations at the Time of Start Frame Reception

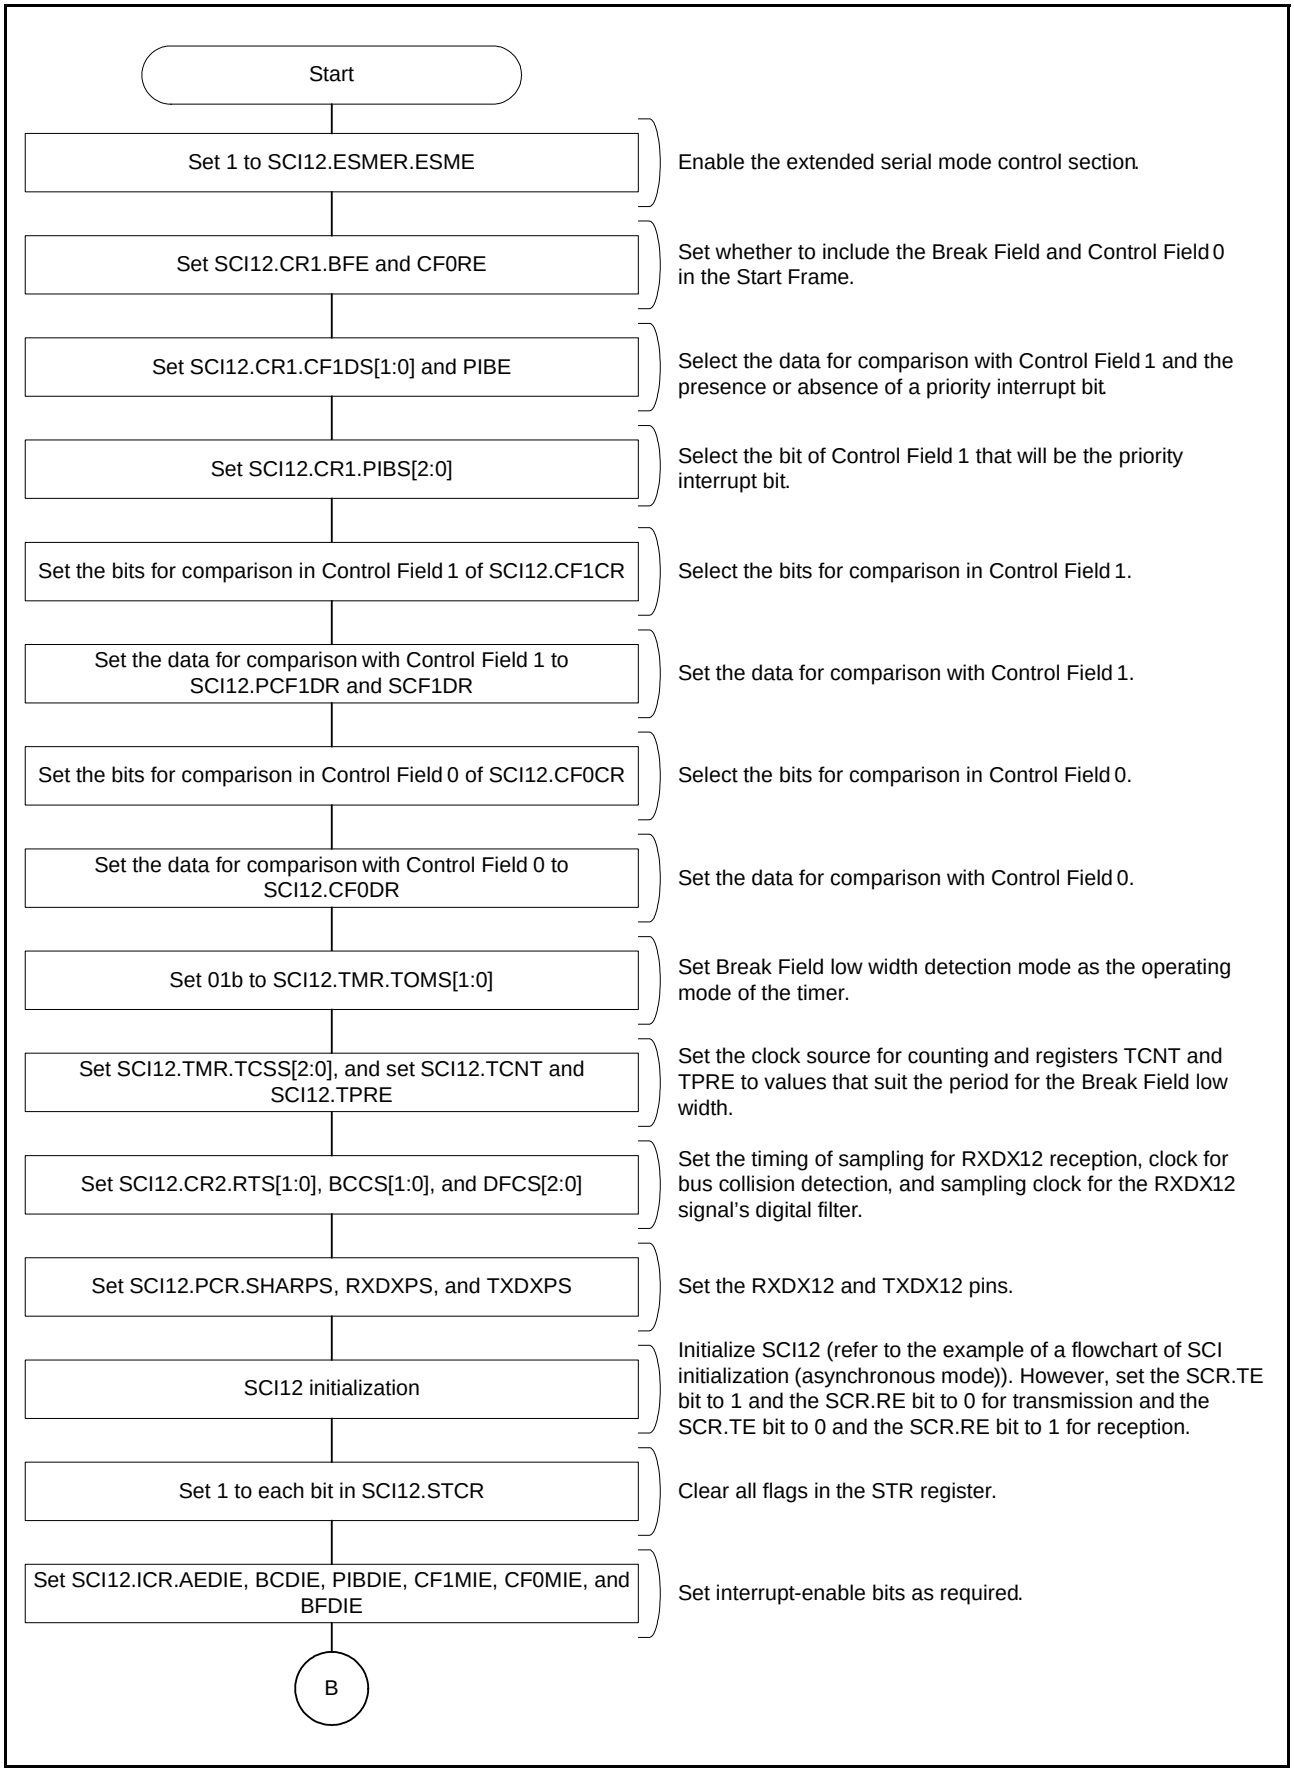


Figure 40.63 Sample Flowchart for Reception of a Start Frame (1)

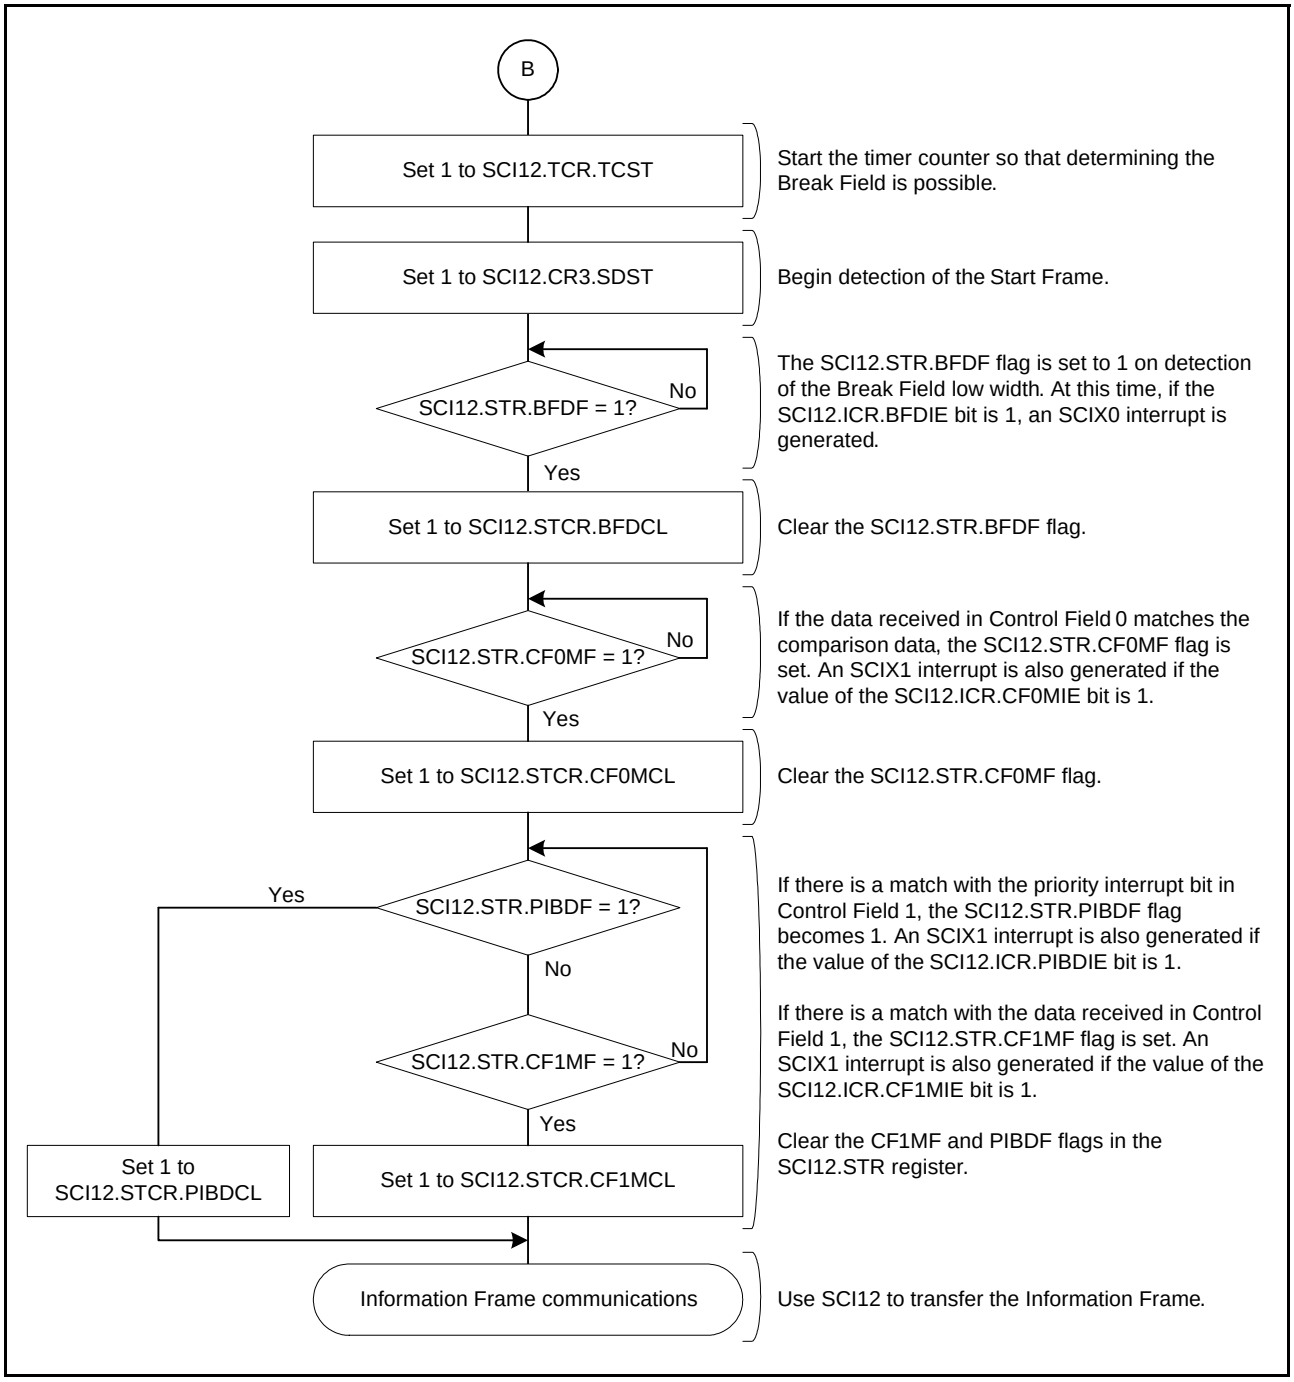

Figure 40.64 Sample Flowchart for Reception of a Start Frame (2)

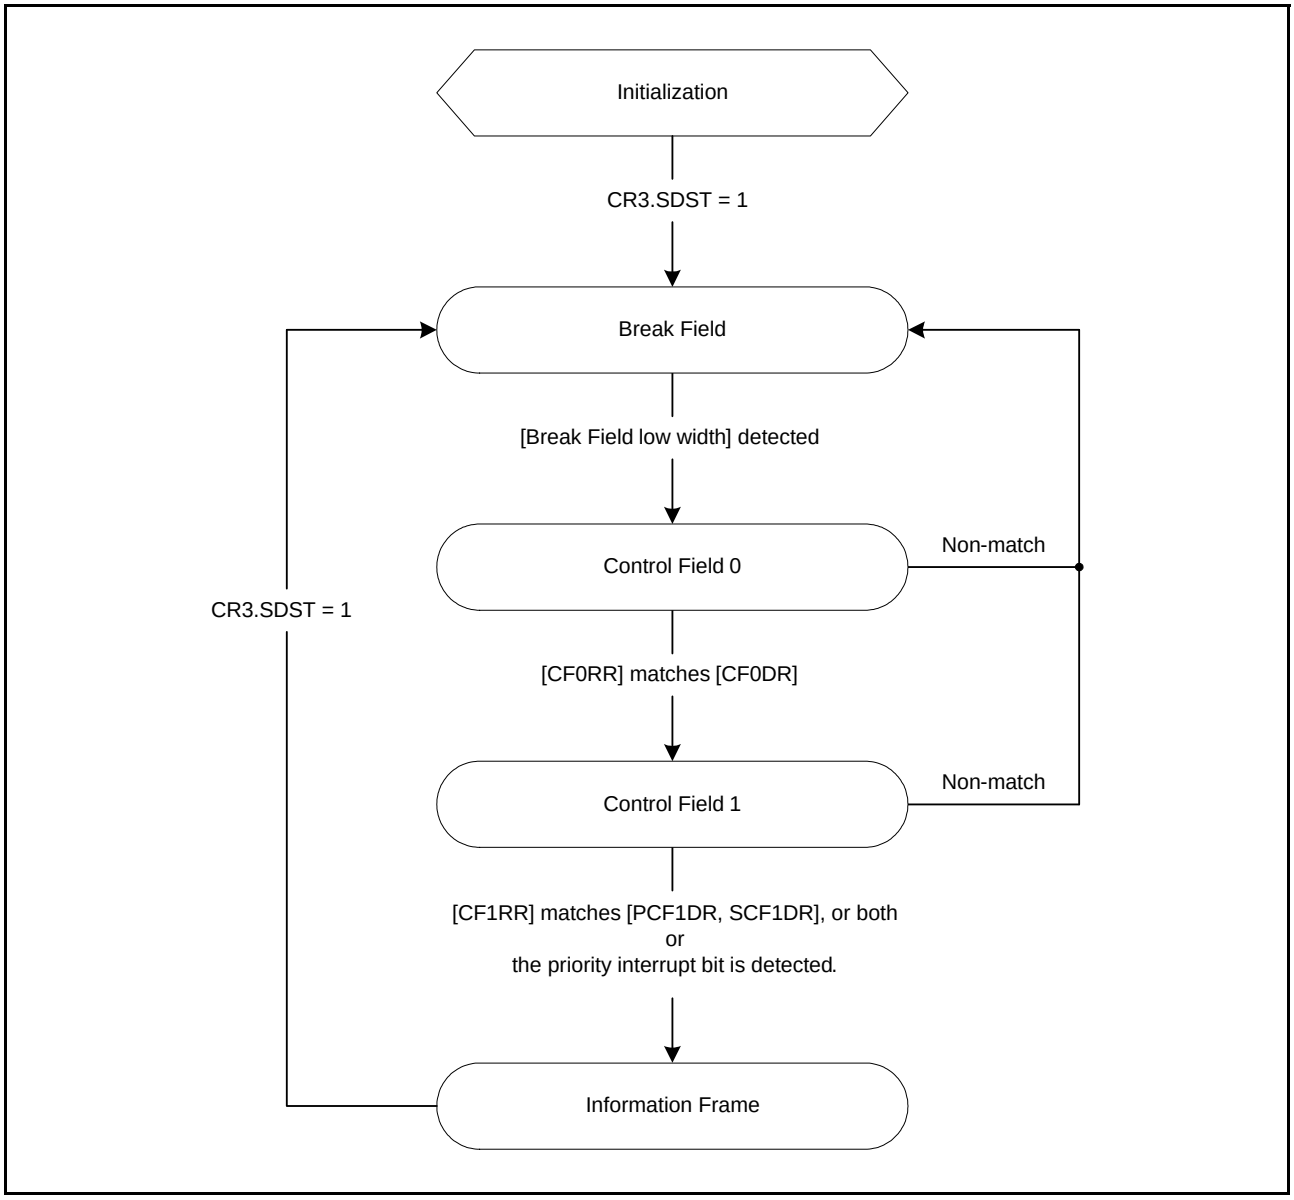

Figure 40.65 State Transitions When Receiving a Start Frame

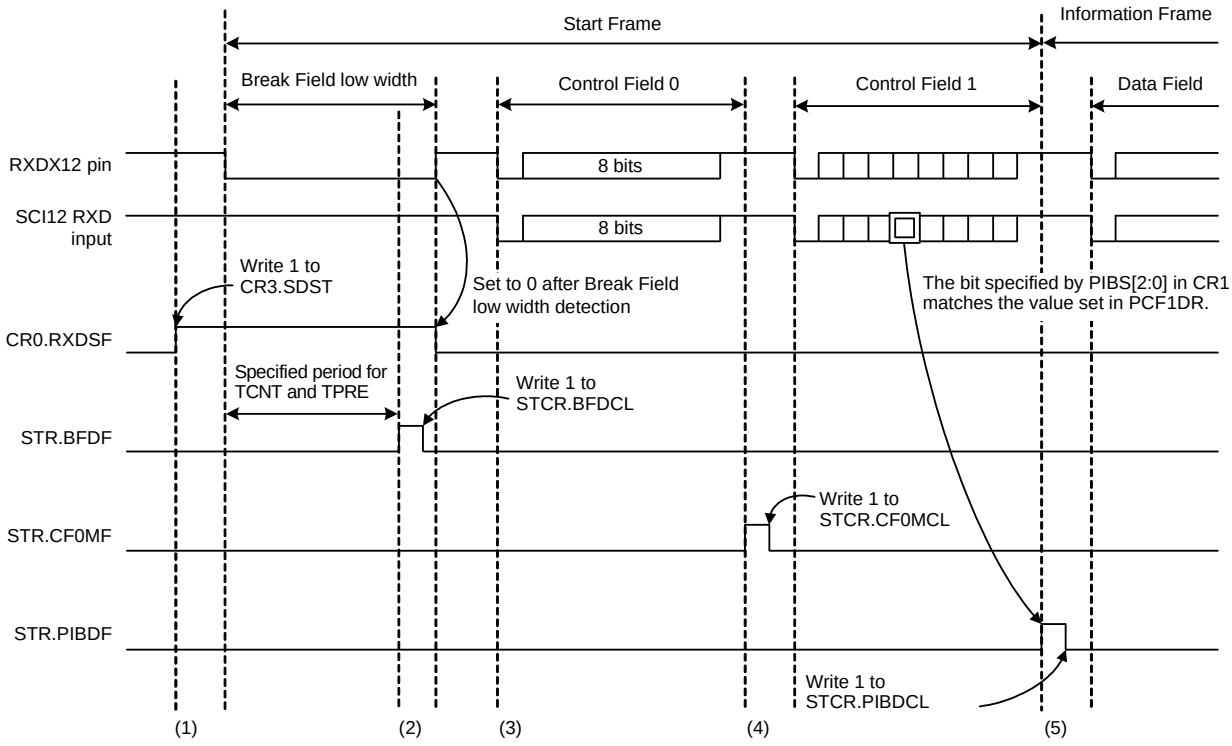
40.10.3.1 Priority Interrupt Bit

Figure 40.66 shows an example of operation in Start Frame reception where a priority interrupt bit is in use. Setting the CR1.PIBE bit to 1 enables the use of a priority interrupt bit.
Operations of the extended serial mode control section in start Frame reception where a priority interrupt bit is in use are as described below.

Steps (1) to (4) are the same as in Figure 40.62, for Start Frame reception.

(5) If the value of the bit selected by the CR1.PIBS[2:0] bits matches the corresponding bit in the PCF1DR register, the STR.PIBDF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.PIBDIE bit is 1. Transfer of the Information Frame by the SCI12 starts after that. If the data received in Control Field 1 do not match the data set in either or both of registers PCF1DR and SCF1DR and the priority interrupt bit is not detected, a transition to the state prior to Break Field low width detection proceeds.



The above diagram assumes the following:

ESMER: ESME = 1
CR1: BFE = 1, PIBE = 1, CF0RE = 0, CF1DS[1:0] = 10b, PIBS[2:0] = 011b
PCR: RXDXPS = 0
ICR: BFDIE = 1, CF0MIE = 1, PIBDIE = 1
TMR: TOMS[1:0] = 01b

Figure 40.66 Example of Operations When Receiving a Start Frame While the CR1.PIBE Bit is 1

40.10.4 Detection of Bus Collisions

Detection of bus collisions operate for cases where output of the Break Field low width and transmission of data by the SCI12 are in progress when the ESMER.ESME bit and the SCI12.SCI.TE bit are set to 1.

Figure 40.67 shows an example of operations with bus collision detection. Signals output through TXDX12 and input through RXDX12 are sampled with the bus collision detection clock set with the CR2.BCCS[1:0] bits as the sampling clock, and the STR.BCDF flag is set to 1 if the signals fail to match three times in a row. An SCIX2 interrupt is also generated if the value of the ICR.BCDIE bit is 1.

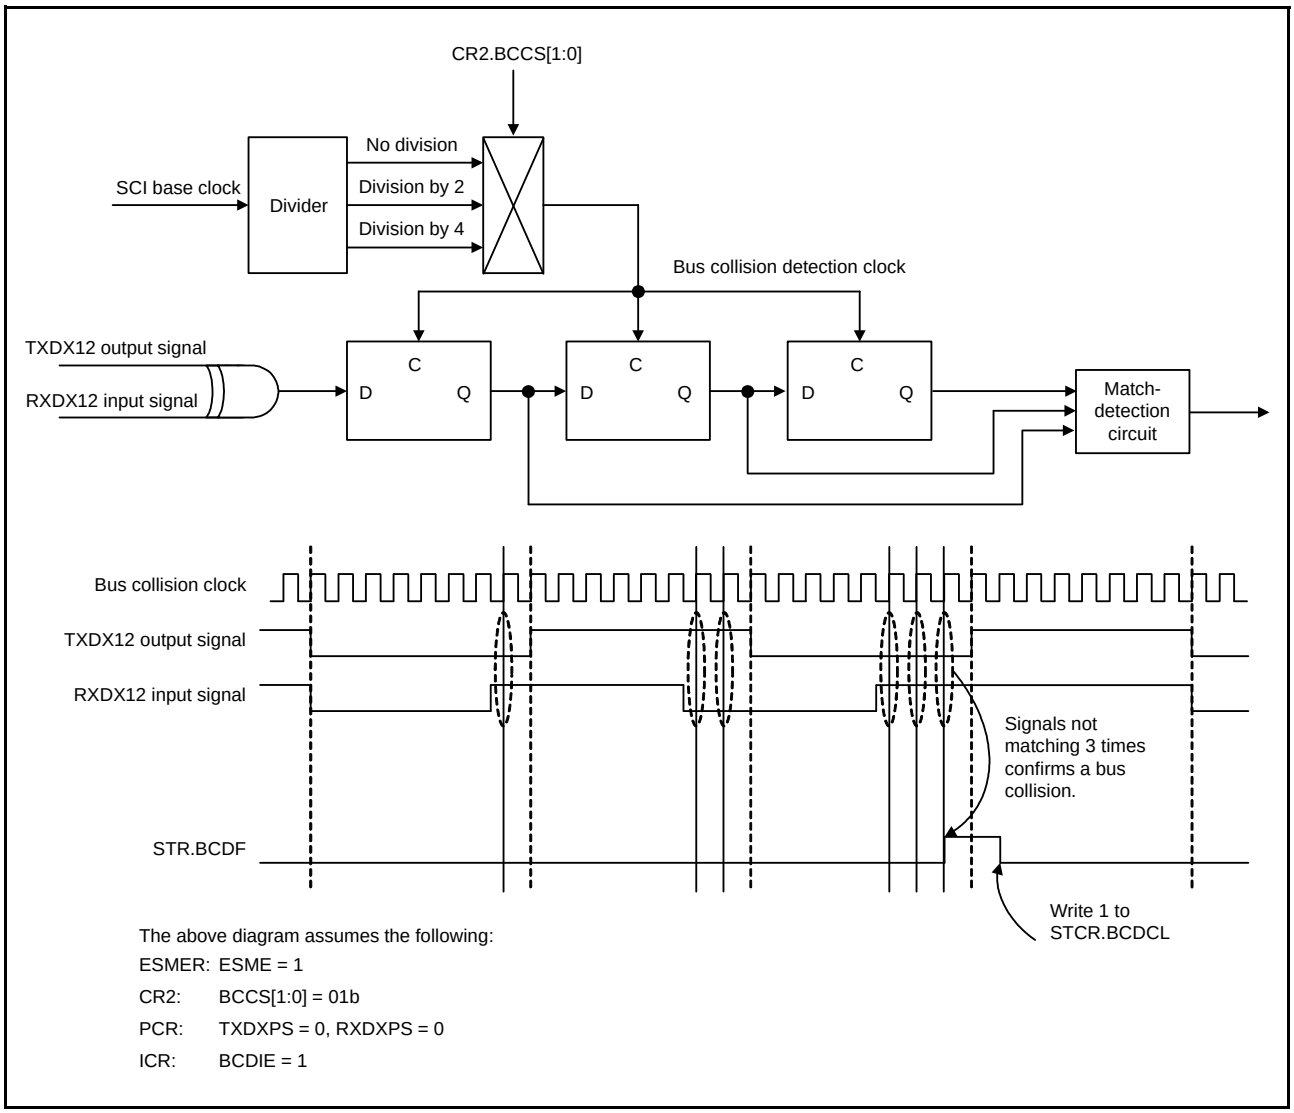


Figure 40.67 Example of Operations with Bus Collision Detection

40.10.5 Digital Filter for Input on the RXDX12 Pin

Signals input through the RXDX12 pin can be passed through a digital filter before they are conveyed to the internal circuits. The digital filter consists of three flip-flop circuit stages connected in series and a match-detecting circuit. The CR2.DFCS[2:0] bits select the sampling clock for the RXDX12 pin input signals. If the outputs of all three latches match, the given level is conveyed to subsequent circuits. If the levels do not match, the previous value is retained. In other words, levels are confirmed as being the signal if they are retained for at least three cycles of the sampling clock but judged to be noise rather than changes in the signal level if they change within three cycles of the sampling clock. Figure 40.68 shows an example of operations with the digital filter.

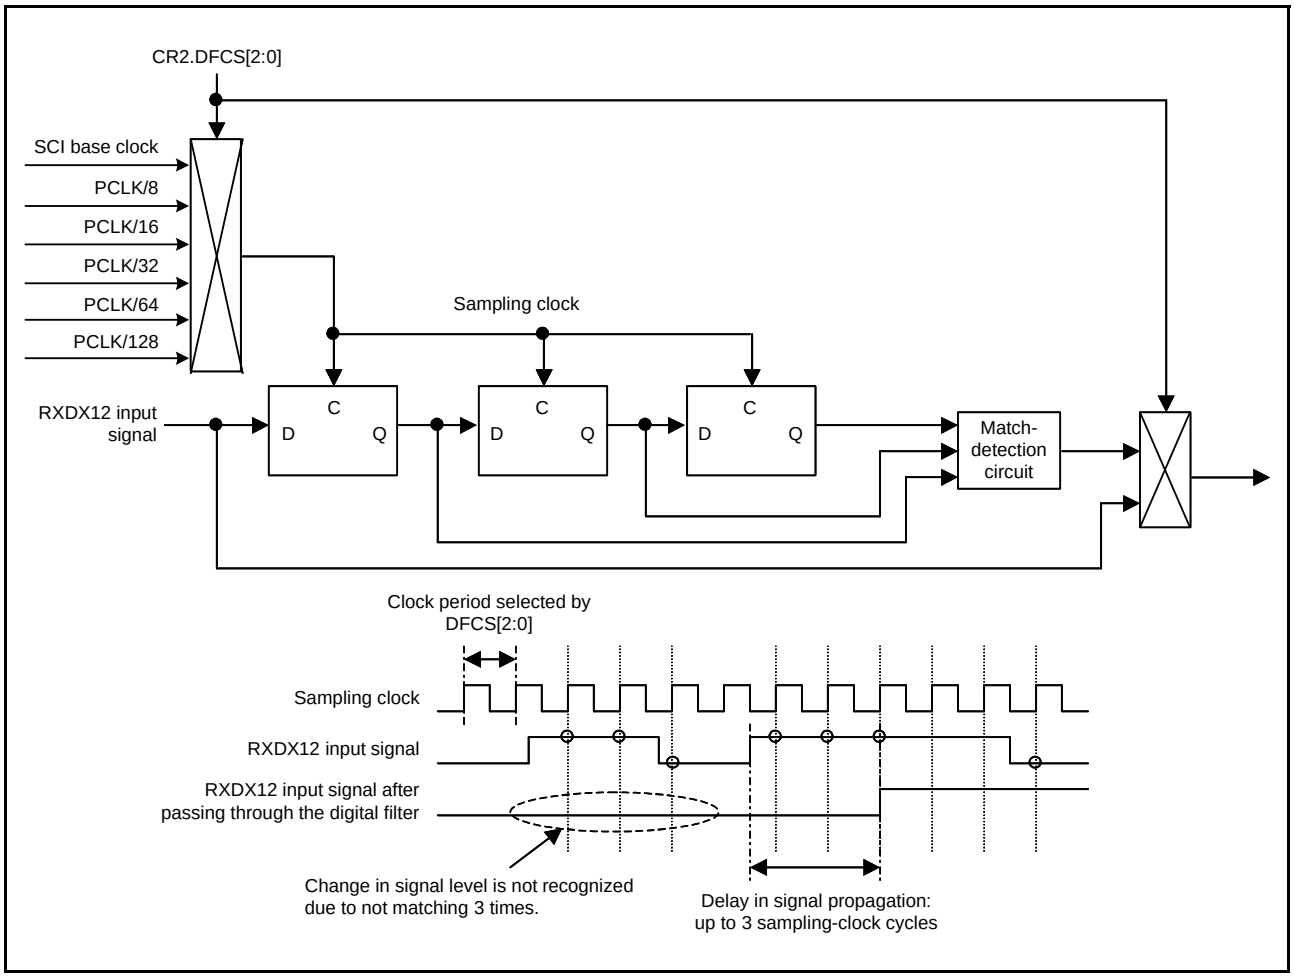

Figure 40.68 Example of Operations with the Digital Filter

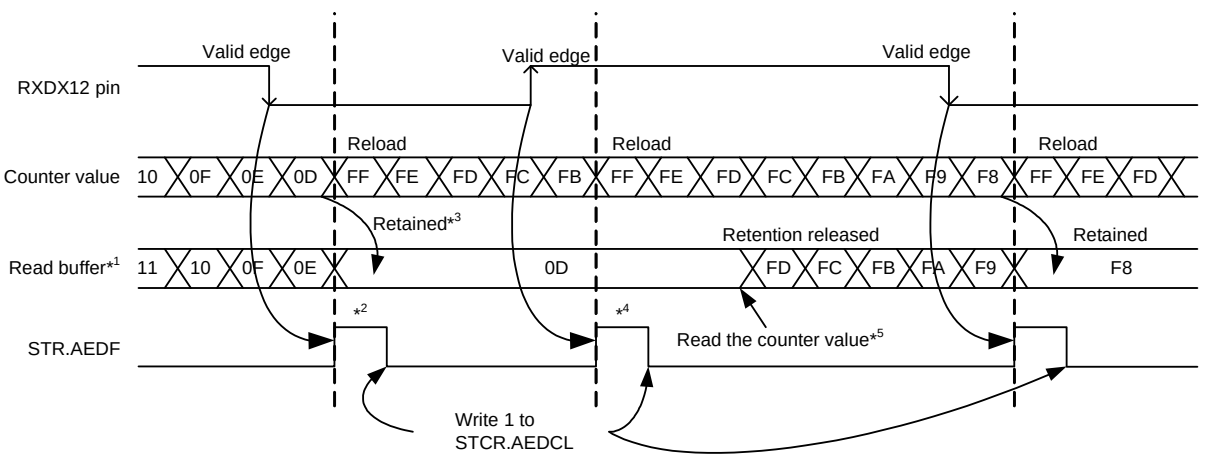
40.10.6 Bit Rate Measurement

The bit rate measurement function measures the intervals between rising and falling edges and between falling and rising edges of the signal input from the RXDX12 pin. Figure 40.69 shows an example of operations for bit rate measurement.

(1) Writing 1 to the CR0.BRME bit enables bit rate measurement. Only set the BRME bit to 1 when you wish to proceed with bit rate measurement. Furthermore, bit rate measurement will not proceed during a Break Field, even if the BRME bit is set to 1.
(2) After detection of the Break Field low width, bit rate measurement starts when the level input on the RXDX12 pin becomes high.
(3) Once bit rate measurement has started, counter values from the timer are retained in the read buffers on the input of valid edges from the RXDX12 pin (rising and falling edges) and the counter is reloaded. An SCIX3 interrupt is also generated if the value of the ICR.AEDIE bit is 1. Retention by registers TCNT and TPRE is released by reading these registers.
(4) The bit rate as calculated from the values counted during intervals between valid edges can be used for adjusting the rate by changing the settings of the SCI12. To disable the bit rate measurement after a match with Control Field 1, write 0 to the CR0.BRME bit.



Note 1. The TCNT or TPRE register indicates the contents of the read buffers.
Note 2. The STR.AEDF flag becomes 1 on detection of a valid edge.
Note 3. When an effective edge is detected, the current value of the counter is stored in the read buffer.
Note 4. The value retained in the read buffers due to one valid edge is not updated to the new value even if a further valid edge is detected.
Note 5. Retention of a value in a read buffer due to a valid edge is released by reading the TCNT or TPRE register.

Figure 40.69 Example of Operations for Bit Rate Measurement

40.10.7 Selectable Timing for Sampling Data Received through RXDX12

The extended serial mode control section provides a way of adjusting the timing for the sampling of data received through the RXDX12 pin of an SCI12 by setting the CR2.RTS[1:0] bits to select the rising edges of 8th, 10th, 12th, or 14th cycle of the SCI base clock. If the value of the SEMR.ABCS bit is 1, the bits select the rising edges of 4th, 5th, 6th, or 7th cycle of the PCLK clock of the SCI12. Figure 40.70 shows timing for the sampling of data received through RXDX12.

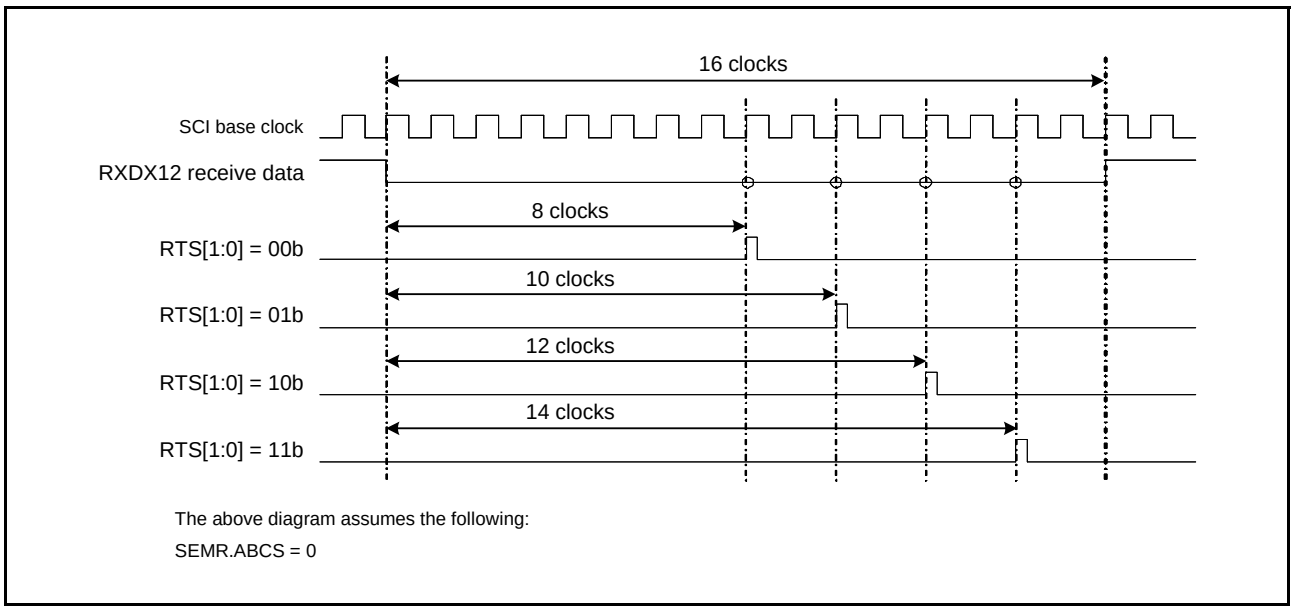


Figure 40.70 Timing for Sampling of Data Received through RXDX12

40.10.8 Timer

The timer has the following operating modes.

(1) Break Field Low Width Output Mode

This mode is for output through the TXDX12 pin of the low level over the Break Field low width at the transmission of a Start Frame. Setting the TMR.TOMS[1:0] bits to 10b switches operation to Break Field low width output mode. The TMR.TCSS[2:0] bits select the clock source for the counter. When the TCR.TCST bit is set to 1, the output on the TXDX12 pin goes to the low level and counting starts. When the timer underflows, the output on the TXDX12 pin goes to the high level and the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1. When 0 is written to the TCR.TCST bit, counting stops after reloading of registers TPRE and TCNT. After output of the Break Field low width is completed, stop the timer before it underflows again. Figure 40.71 shows an example of operations in Break Field low width output mode.

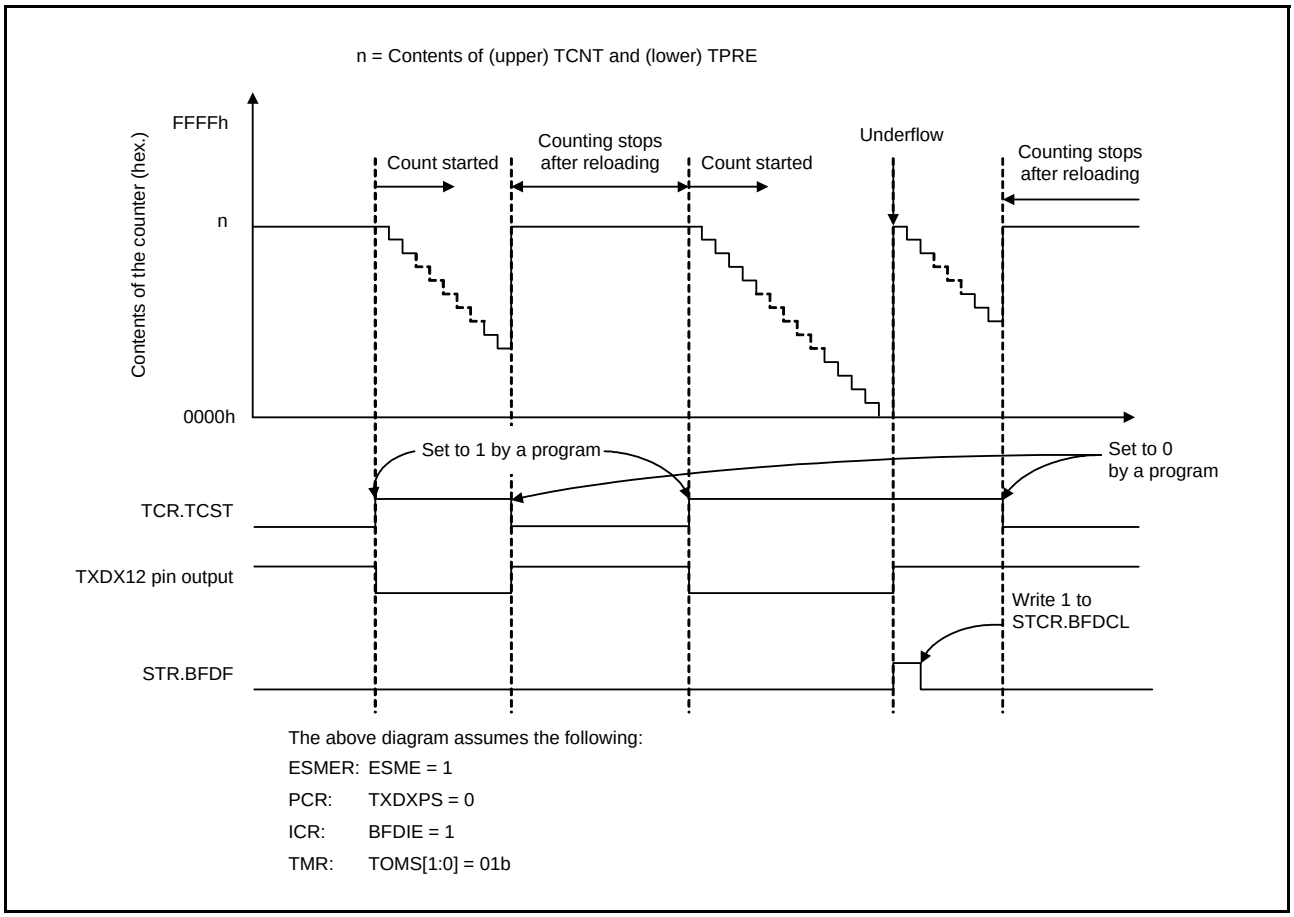

Figure 40.71 Example of Operations in Break Field Low Width Output Mode

(2) Break Field Low Width Determination Mode

This mode is for determining the Break Field low width in the input signal on the RXDX12 pin at the reception of a Start Frame. Setting the TMR.TOMS[1:0] bits to 01b switches operation to Break Field low width determination mode. The TMR.TCSS[2:0] bits select the clock source for the counter. When the TCR.TCST bit is set to 1, the interface enters the Break Field low width determinable state. Determination starts when a low level is input from the RXDX12 pin. When a high level is then input on the RXDX12 pin, registers TPRE and TCNT are reloaded and the interface enters the Break Field low width determinable state. When the timer underflows during Break Field low width determination, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1. If an underflow of the timer during data transfer cause a problem in the form of interrupt generation, stop the timer after Break Field low width determination. Figure 40.72 shows an example of operations in Break Field low width output mode.

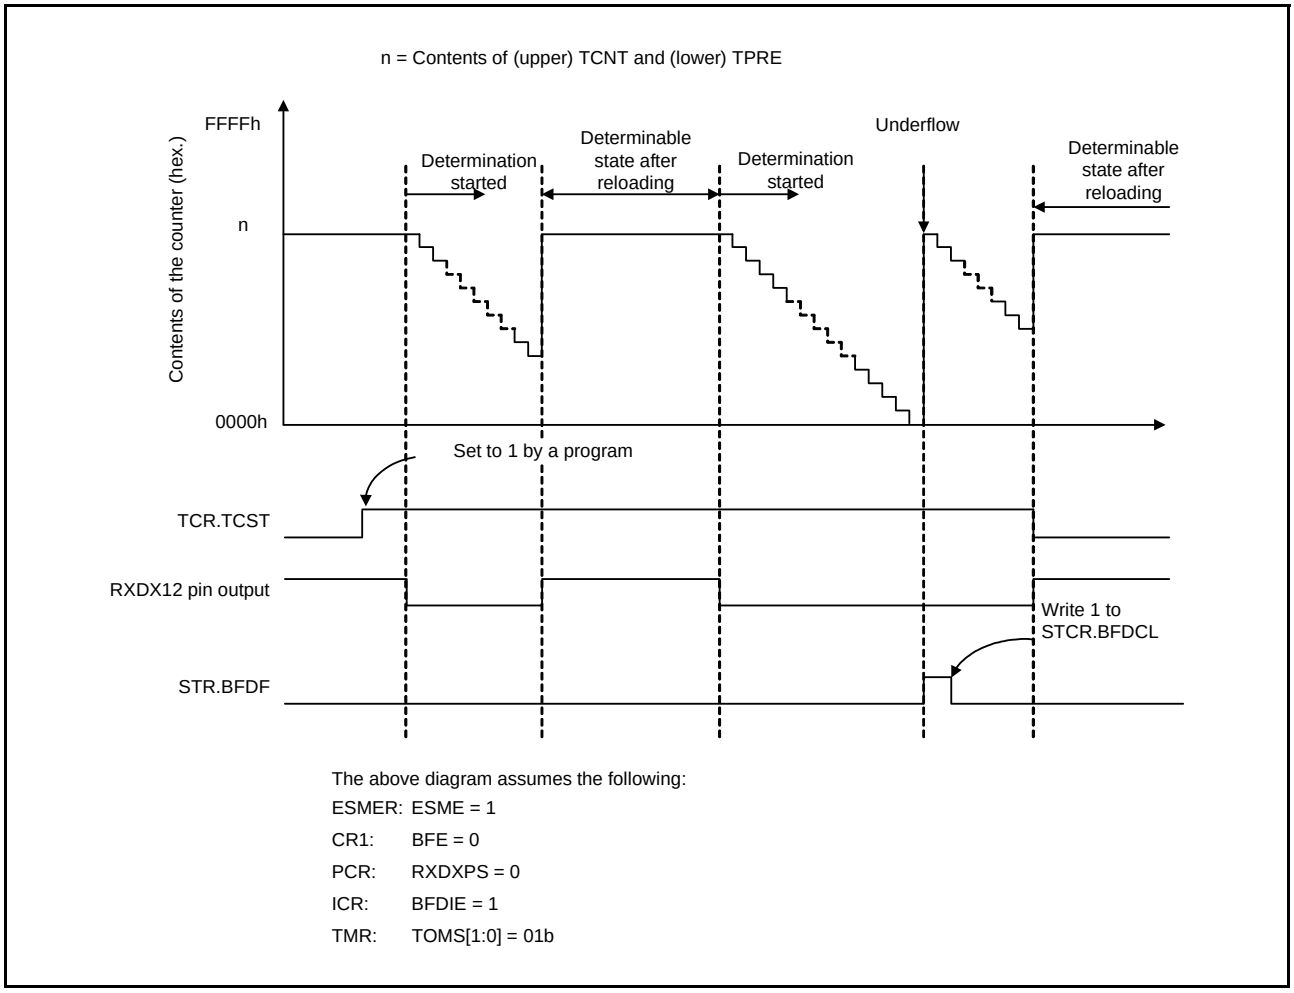

Figure 40.72 Example of Operations in Break Field Low Width Determination Mode

(3) Timer Mode

This mode is for counting cycles of the internal clock as the clock source. Setting the TMR.TOMS[1:0] bits to 00b switches operation to timer mode. The TMR.TCSS[2:0] bits select the clock source for the counter. Counting starts when 1 is written to the TCR.TCST bit and stops when 0 is written to the TCST bit. Registers TPRE and TCNT both count down. The TPRE register counts cycles of the clock source for counting, and underflows of the TPRE register provide the clock source for counting by the TCNT register. When the timer underflows, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.

40.11 Noise Cancellation Function

Figure 40.73 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of two stages of flip-flop circuits and a match-detection circuit. When the level on the pin matches in three consecutive samples taken at the set sampling interval, the matching level continues to be conveyed internally until the level on the pin again matches in three consecutive samples.

In asynchronous mode, the noise cancellation function can be applied on the RXDn input signal. The period of the base clock (1/16th of a bit-period when SEMR.ABCS = 0 and 1/8th of a bit-period when SEMR.ABCS = 1) is the sampling interval.

In simple I2C mode, the noise cancellation function can be applied on the SSDAn and SSCLn input signals. The sampling clock is the clock signal produced by frequency-dividing the signal from the clock source for the internal baud-rate generator by one, two, four, or eight as selected by the setting of the SNFR.NFCS[2:0] bits.

If the base clock is stopped with the noise filter enabled and then the clock input is started again, the noise filter operation resumes from where the clock was stopped. If SCR.TE and SCR.RE are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, it is determined that a level match is detected and is conveyed to the internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive samples.

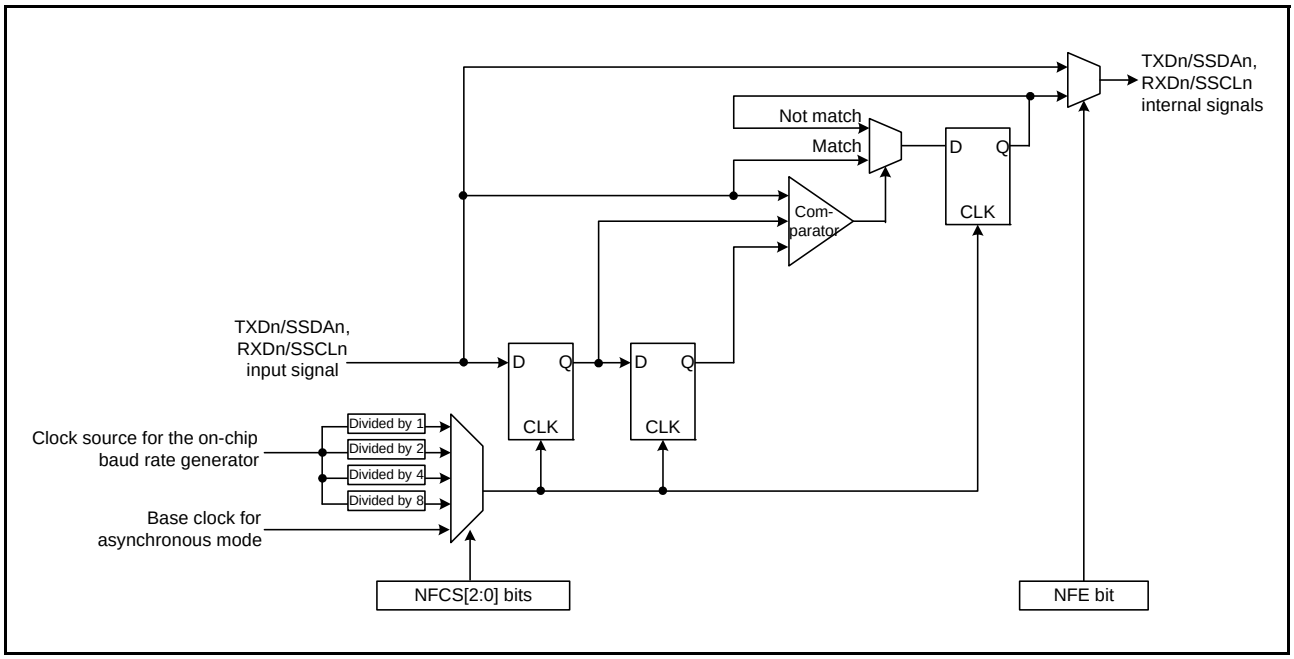

Figure 40.73 Block Diagram of Digital Noise Filter Circuit

40.12 Interrupt Sources

40.12.1 Buffer Operations for TXI and RXI Interrupts

If the conditions for a TXI and RXI interrupt are satisfied while the interrupt status flag in the interrupt controller is 1, the SCI does not output the interrupt request but retains it internally (with a capacity for retention of one request per source). When the value of the interrupt status flag in the interrupt controller becomes 0, the interrupt request retained within the SCI is output. The internally retained interrupt request is automatically discarded once the actual interrupt is output. Clearing of the corresponding interrupt enable bit (the TIE or RIE bit in the SCR) can also be used to discard an internally retained interrupt request.

40.12.2 Interrupts in Asynchronous Mode, Clock Synchronous Mode, and Simple SPI Mode

Table 40.31 lists interrupt sources in asynchronous mode, clock synchronous mode, and simple SPI mode. A different interrupt vector is assigned to each interrupt source, and individual interrupt sources can be enabled or disabled with the enable bits in the SCR register.

If the SCR.TIE bit is 1, a TXI interrupt request is generated when transmit data is transferred from the TDR or TDRL register*1 to the TSR. A TXI interrupt request can also be generated by setting the SCR.TE bit to 1 after setting the SCR.TIE bit to 1 or by using a single instruction to set the SCR.TE and SCR.TIE bit to 1 at the same time. A TXI interrupt request can activate the DTC or DMAC to handle data transfer.

A TXI interrupt request is not generated by setting the SCR.TE bit to 1 while the setting of the SCR.TIE bit is 0 or by setting the SCR.TIE bit to 1 while the setting of the SCR.TE bit is 1.*2

When new data is not written by the time of transmission of the last bit of the current transmit data and the setting of the SCR.TEIE bit is 1, the SSR.TEND flag becomes 1 and a TEI interrupt request is generated. Furthermore, when the setting of the SCR.TE bit is 1, the SSR.TEND flag retains the value 1 until further transmit data are written to the TDR or TDRL register*1, and setting the SCR.TEIE bit to 1 leads to the generation of a TEI interrupt request.

Writing data to the TDR or TDRL register*1 leads to clearing of the SSR.TEND flag and, after a certain time, discarding of the TEI interrupt request.

If the SCR.RIE bit is 1, an RXI interrupt request is generated when received data is stored in the RDR. An RXI interrupt request can activate the DTC or DMAC to handle data transfer.

Setting of any from among the ORER, FER, and PER flags in the SSR to 1 while the SCR.RIE bit is 1 leads to the generation of an ERI interrupt request. An RXI interrupt request is not generated at this time. Clearing all three flags (ORER, FER, and PER) leads to discarding of the ERI interrupt request.

Note 1. In the case where asynchronous mode and 9-bit data length are selected

Note 2. To temporarily disable TXI interrupts at the time of transmission of the last of the data and so on when you wish a new round of transmission to start after handling of the transmission-completed interrupt, control disabling and enabling of the interrupt by using the interrupt request enable bit in the interrupt controller rather than using the SCR.TIE bit. This can prevent the suppression of TXI interrupt requests in the transfer of new data.

Table 40.31 Interrupt Sources

Name	Interrupt Source	Interrupt Flag	DTC Activation	DMAC Activation	Priority
ERI	Receive error	ORER, FER, or PER	Not possible	Not possible	High
RXI	Receive data full	RDRF	Possible	Possible	↑
TXI	Transmit data empty	TDRE	Possible	Possible	
TEI	Transmit end	TEND	Not possible	Not possible	Low

40.12.3 Interrupts in Smart Card Interface Mode

Table 40.32 lists interrupt sources in smart card interface mode. A transmit end interrupt (TEI) request cannot be used in this mode.

Table 40.32 SCI Interrupt Sources

Name	Interrupt Source	Interrupt Flag	DTC Activation	DMAC Activation	Priority
ERI	Receive error or error signal detection	ORER, PER, or ERS	Not possible	Not possible	High
RXI	Receive data full	—	Possible	Possible	↑
TXI	Transmit data empty	TEND	Possible	Possible	Low

Data transmission/reception using the DTC or DMAC is also possible in smart card interface mode, similar to in the normal SCI mode. In transmission, when the TEND flag in the SSR register is set to 1, a TXI interrupt request is generated. This TXI interrupt request activates the DTC or DMAC allowing transfer of transmit data if the TXI request is specified beforehand as a source of DTC or DMAC activation. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept to 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission in the case of error occurrence. However, the ERS flag in the SSR register is not automatically cleared to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the RIE bit in the SCR register to 1 to enable an ERI interrupt request to be generated at error occurrence.

When transmitting/receiving data using the DTC or DMAC, be sure to make settings to enable the DTC or DMAC before making SCI settings. For DTC or DMAC settings, refer to section 18, DMA Controller (DMACAa) and section 20, Data Transfer Controller (DTCa).

In reception, an RXI interrupt request is generated when receive data is set to RDR. This RXI interrupt request activates the DTC or DMAC allowing transfer of receive data if the RXI request is specified beforehand as a source of DTC or DMAC activation. If an error occurs, the error flag is set. Therefore, the DTC or DMAC is not activated and an ERI interrupt request is issued to the CPU instead; the error flag must be cleared.

40.12.4 Interrupts in Simple I2C Mode

The interrupt sources in simple I2C mode are listed in Table 40.33. The STI interrupt is allocated to the transmit end interrupt (TEI) request. The receive error interrupt (ERI) request cannot be used.

The DTC or DMAC can also be used to handle transfer in simple I2C mode.

When the value of the IICINTM bit in the SIMR2 register is 1, an RXI request will be generated on the falling edge of the SSCLn signal for the eighth bit. If the RXI has been set up as an activating request for the DTC or DMAC beforehand, the RXI request will activate the DTC or DMAC to handle transfer of the received data. Furthermore, a TXI request is generated on the falling edge of the SSCLn signal for the ninth bit (acknowledge bit). If the TXI has been set up as an activating request for the DTC or DMAC beforehand, the TXI request will activate the DTC or DMAC to handle transfer of the transmit data.

When the value of the IICINTM bit in the SIMR2 register is 0, an RXI request (ACK detection) if the input on the SSDAn pin is at the low level or a TXI request (NACK detection) if the input on the SSDAn pin is at the high level will be generated on the rising edge of the SSCLn signal for the ninth bit (acknowledge bit). If the RXI has been set up as an activating request for the DTC or DMAC beforehand, the RXI request will activate the DTC or DMAC to handle transfer of the received data.

Also, if the DTC or DMAC is used for data transfer in reception or transmission, be sure to set up and enable the DTC or DMAC before setting up the SCI.

When the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits in the SIMR3 register are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

Table 40.33 SCI Interrupt Sources

Name	Interrupt Source		Interrupt Flag	DTC Activation	DMAC Activation	Priority
	IICINTM bit = 0	IICINTM bit = 1				
RXI	ACK detection	Reception	—	Possible	Possible	High
TXI	NACK detection	Transmission	—	Possible*1	Possible*1	
STI	Completion of generation of a start, restart, or stop condition		IICSTIF	Not possible	Not possible	Low

Note 1. Activation of the DTC or DMAC is only possible when the SIMR2.IICINTM bit is 1 (use reception and transmission interrupts).

40.12.5 Interrupt Requests from the Extended Serial Mode Control Section

The extended serial mode control section has a total of six types of interrupt request for generating the SCIX0 interrupt (Break Field low width detected), SCIX1 interrupt (Control Field 0 match, Control Field 1 match, priority interrupt bit detected), SCIX2 interrupt (bus collision detected), and SCIX3 interrupt (valid edge detected). When any of the interrupt factors is generated, the corresponding status flag is set to 1. Details of all of the interrupt requests are listed in Table 40.34.

Table 40.34 Interrupt Sources of the Extended Serial Mode Control Section

Interrupt Request	Status Flag	Interrupt Factors
SCIX0 interrupt (Break Field low width detected)	BFDF	• Detection of a Break Field low width longer than the interval corresponding to the timer setting • Completion of the output of a Break Field low width over the interval corresponding to the timer setting • Underflow of the timer
SCIX1 interrupt (Control Field 0 match)	CF0MF	The data received in Control Field 0 matching the value set in CF0DR
SCIX1 interrupt (Control Field 1 match)	CF1MF	The data received in Control Field 1 matching the value set in PCF1DR or SCF1DR
SCIX1 interrupt (priority interrupt bit detected)	PIBDF	The value of the bit specified as the priority interrupt bit matching the value set in PCF1DR
SCIX2 interrupt (bus collision detected)	BCDF	The output level on the TXDX12 pin and the input level on the RXDX12 pin not matching on three consecutive cycles of the bus collision detection clock
SCIX3 interrupt (valid edge detected)	AEDF	Detection of a valid edge during bit rate measurement

40.13 Event Linking

By employing interrupt request signals as event signals, SCI5 is able to provide linked operation through the event link controller (ELC) for modules selected in advance.
Event signals can be output regardless of the values of the corresponding interrupt request enable bits.

(1) Error (receive error, error signal detected) event output

- Indicates abnormal termination due to a parity error during reception in asynchronous mode.
- Indicates abnormal termination due to a framing error during reception in asynchronous mode.
- Indicates abnormal termination due to an overrun error during reception.
- Indicates detection of the error signal during transmission in smart card interface mode.

(2) Receive data full event output

- Indicates that received data have been set in the receive data register (RDR or RDRL).
- Indicates that ACK has been detected if the SIMR2.IICINTM bit is 0 in simple I^2C mode.
- Indicates that the 8th-bit SSCL5 falling edge has been detected if the SIMR2.IICINTM bit is 1 in simple I^2C mode.
- When the SIMR2.IICINTM bit is 1 during master transmission in simple I^2C mode, set the event link controller (ELC) so that receive data full events are not used.

(3) Transmit data empty event output

- Indicates that the SCR.TE bit has been changed from 0 to 1.
- Indicates that transmit data have been transferred from the transmit data register (TDR or TDRL) to the transmit shift register (TSR).
- Indicates that transmission has been completed in smart card interface mode.
- Indicates that NACK has been detected if the SIMR2.IICINTM bit is 0 in simple I^2C mode.
- Indicates that the ninth-bit SSCL5 falling edge has been detected if the SIMR2.IICINTM bit is 1 in simple I^2C mode.

(4) Transmit end event output

- Indicates the completion of transmission.
- Indicates that the starting condition, resumption condition, or termination condition has been generated in simple I^2C mode.

40.14 Usage Notes

40.14.1 Setting the Module Stop Function

Module stop control register B (MSTPCRB) is used to stop and start SCI operations. With the value after a reset, SCI operations are stopped. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

40.14.2 Break Detection and Processing

When a framing error is detected, a break can be detected by reading the RXDn pin value directly. In a break, the input from the RXDn pin becomes all 0s, and so the FER flag in the SSR register is set to 1 (framing error has occurred), and the PER flag in the SSR register may also be set to 1 (parity error has occurred). When the SEMR.RXDESEL bit is 0, the SCI continues the receive operation even after a break is received. Therefore, note that even if the FER flag is set to 0 (no framing error occurred), it will be set to 1 again. When the SEMR.RXDESEL bit is 1, the SCI sets the SSR.FER flag to 1 and stops receiving operation until a start bit of the next data frame is detected. If the SSR.FER flag is set to 0 at this time, the SSR.FER flag retains 0 during the break. When the RXDn pin becomes high and the break ends, detecting the beginning of the start bit at the first falling edge of the RXDn pin allows the SCI to start the receiving operation.

40.14.3 Mark State and Generating Breaks

When the SCR.TE bit is 0 (serial transmission is disabled), setting the I/O port function makes selection of the level and direction (input or output) of the TXDn pin possible. If this is done, the TXDn pin can be placed in the mark state to send a break at the time of data transmission. Until the SCR.TE bit is set to 1 (serial transmission is enabled), the I/O port function is used to set the TXDn pin to output high and set the pin mode to a general I/O port pin, and thus place the communication line in the mark state (state of having the value 1). On the other hand, to output a break at the time of data transmission, set the TXDn pin to output low and make the pin mode settings for a general I/O port pin. When the SCR.TE bit is set to 0, the transmitter is initialized regardless of the current state of transmission.

40.14.4 Receive Error Flags and Transmit Operations (Clock Synchronous Mode and Simple SPI Mode)

Transmission cannot be started when a receive error flag (ORER) in the SSR register is set to 1, even if data is written to the TDR register. Be sure to set the receive error flags to 0 before starting transmission. Note also that the receive error flags cannot be set to 0 even if the RE bit in the SCR register is set to 0 (serial reception is disabled).

40.14.5 Writing Data to the TDR Register

Data can be written to registers TDR, TDRH, and TDRL. However, if new data is written to registers TDR, TDRH, and TDRL when transmit data is remaining in registers TDR, TDRH, and TDRL, the previous data in registers TDR, TDRH, and TDRL is lost because it has not been transferred to the TSR register yet. Be sure to write transmit data to registers TDR, TDRH, and TDRL in the TXI interrupt request handling routine.

40.14.6 Restrictions on Clock Synchronous Transmission (Clock Synchronous Mode and Simple SPI Mode)

When the external clock source is used as a synchronization clock, the following restrictions apply.

(1) Start of transmission

Update TDR by the CPU, DMAC, or DTC and wait for at least five PCLK cycles before allowing the transmit clock to be input (refer to Figure 40.74).

(2) Continuous transmission

(a) Write the next transmit data to TDR or TDRL before the falling edge of the transmit clock (bit 7) (refer to Figure 40.74).

(b) When updating TDR after bit 7 has started to transmit, update TDR while the synchronization clock is in the low-level period, and set the high-level width of the transmit clock (bit 7) to four PCLK cycles or longer (refer to Figure 40.74).

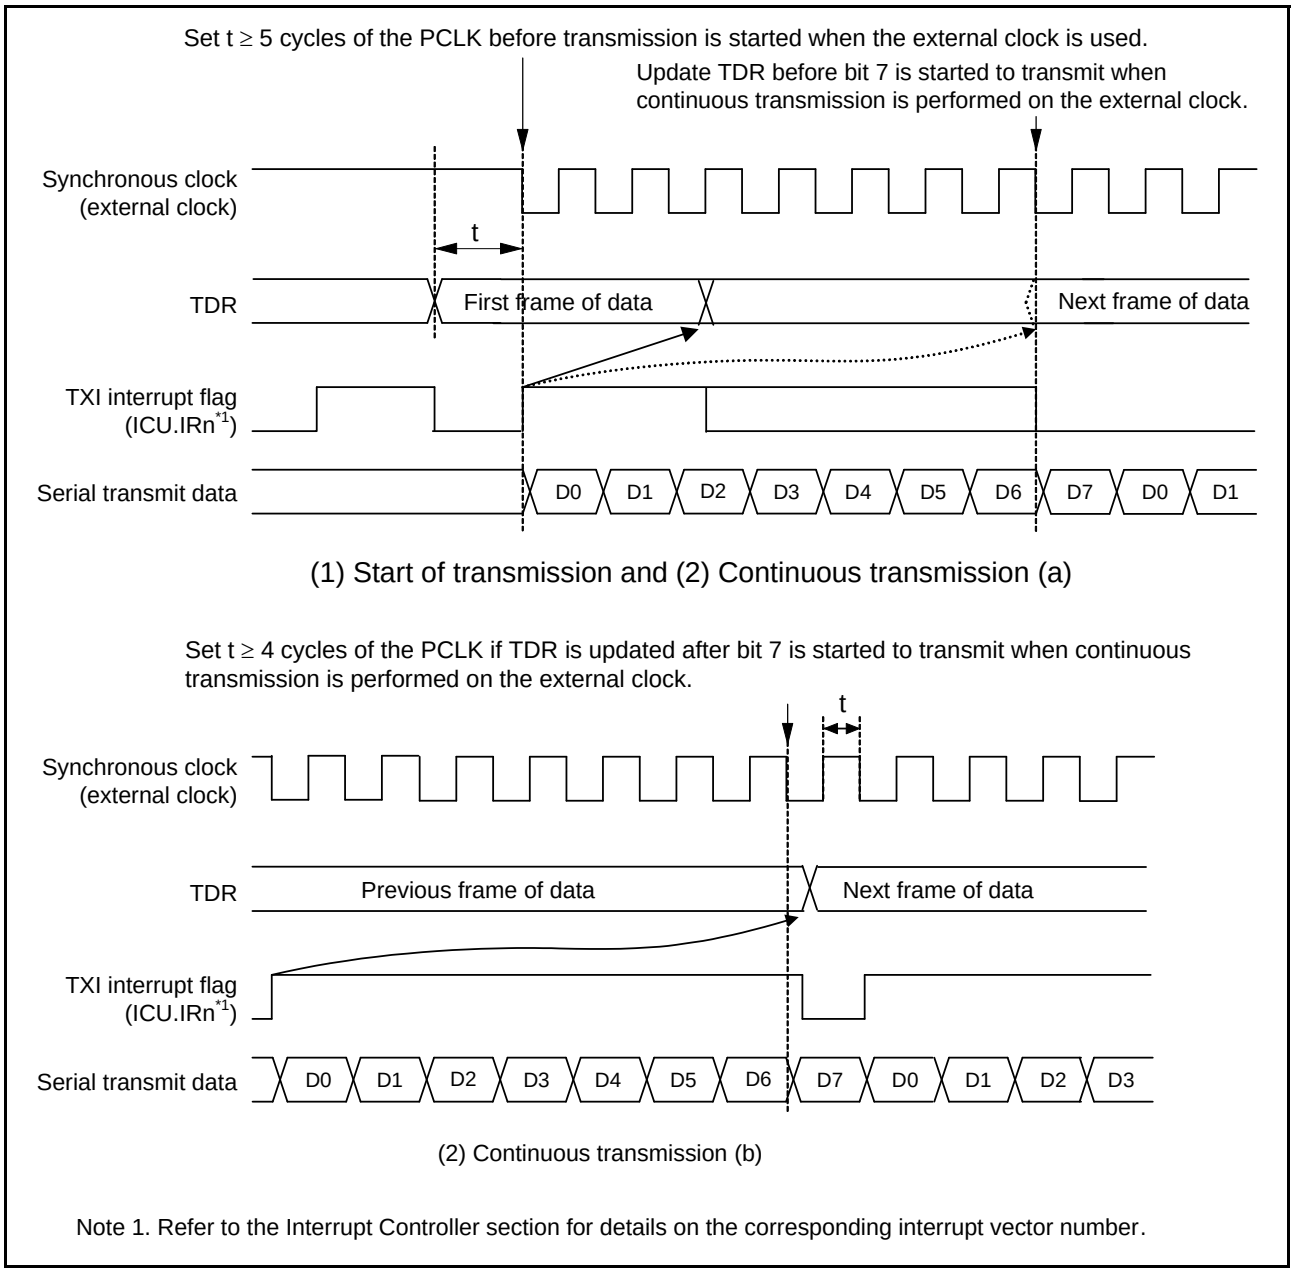

Figure 40.74 Restrictions on Use of External Clock in Clock Synchronous Transmission

40.14.7 Restrictions on Using DMAC or DTC

When using the DMAC or DTC to read RDR, RDRH, and RDRL, be sure to set the receive data full interrupt (RXI) as the activation source of the relevant SCI.

40.14.8 Notes on Starting Transfer

At the point where transfer starts when the interrupt status flag (IRn.IR bit) in the interrupt controller is 1, follow the procedure below to clear interrupt requests before permitting operations (by setting the SCR.TE or SCR.RE bit to 1). For details on the interrupt status flag, refer to section 15, Interrupt Controller (ICUA).

- Confirm that transfer has stopped (the setting of the SCR.TE or SCR.RE bits is 0).
- Set the corresponding interrupt enable bit (SCR.TIE or SCR.RIE) to 0.
- Read the corresponding interrupt enable bit (SCR.TIE or SCR.RIE bit) to check that it has become 0.
- Set the interrupt status flag (IRn.IR bit) in the interrupt controller to 0.

40.14.9 SCI Operations during Low Power Consumption State

(1) Transmission

When making settings for the module stopped state or in transitions to software standby, stop operations (by setting the TIE, TE, and TEIE bits in the SCR to 0) after switching the TXDn pin to the general I/O port pin function. Setting the TE bit to 0 resets the TSR register and the TEND bit in the SSR. Depending on the port settings, output pins may output the level before a transition to the low power consumption state is made after release from the module stopped state or software standby mode. When transitions to these states are made during transmission, the data being transmitted become indeterminate.

To transmit data in the same transmission mode after cancellation of the low power consumption state, set the TE bit to 1, read SSR, and write data to TDR sequentially to start data transmission. To transmit data with a different transmission mode, initialize the SCI first.

Figure 40.75 shows a sample flowchart for transition to software standby mode during transmission. Figure 40.76 and Figure 40.77 show the port pin states during transition to software standby mode.

Before specifying the module stop state or making a transition to software standby mode from the transmission mode using DTC/DMA transfer, stop the transmit operations (TE = 0). To start transmission after cancellation using the DTC/DMAC, set the TE and TIE bits to 1. The TXI interrupt flag is set to 1 and transmission starts using the DTC/DMAC.

(2) Reception

Before specifying the module stop state or making a transition to software standby mode, stop the receive operations (RE = 0 in the SCR register). If transition is made during data reception, the data being received will be invalid.

To receive data in the same reception mode after cancellation of the low power consumption state, set the RE bit to 1, and then start reception. To receive data in a different reception mode, initialize the SCI first.

Figure 40.78 shows a sample flowchart for transition to software standby mode during reception.

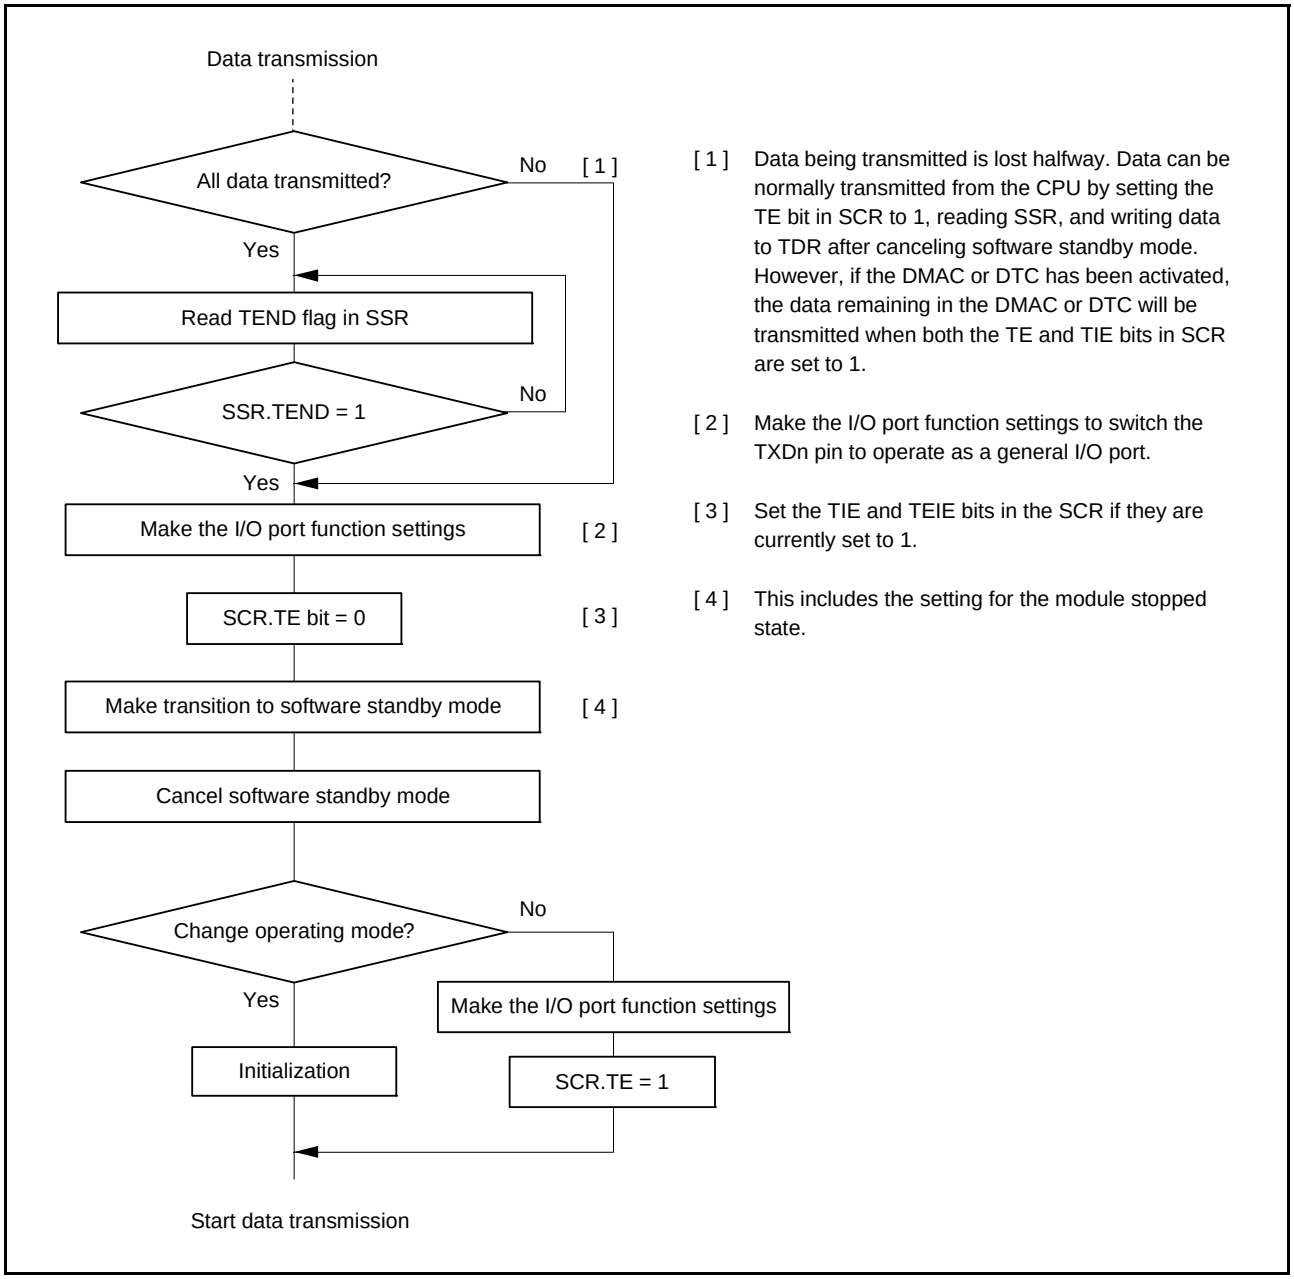

Figure 40.75 Example of Flowchart for Transition to Software Standby Mode during Transmission

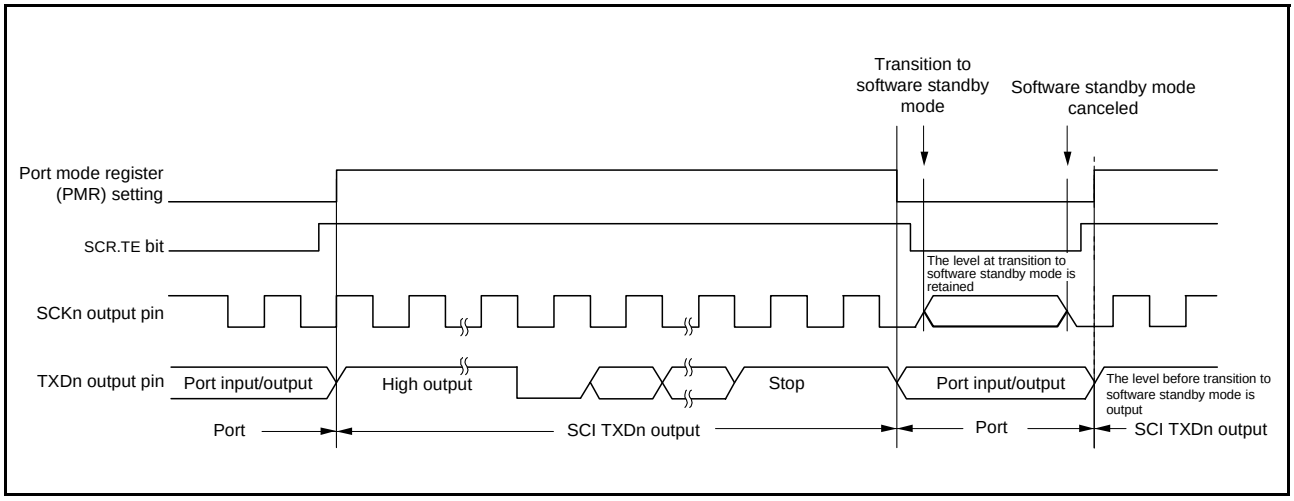

Figure 40.76 Port Pin States during Transition to Software Standby Mode (Internal Clock, Asynchronous Transmission)

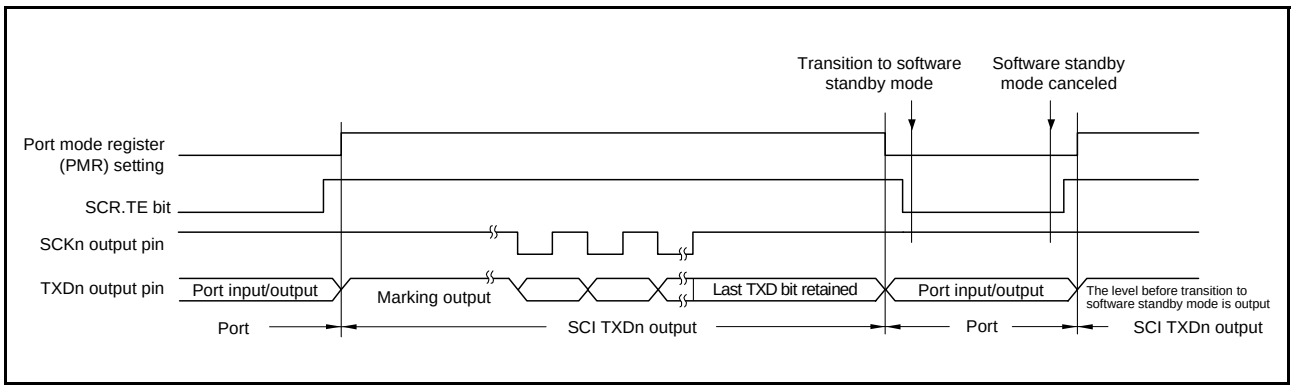

Figure 40.77 Port Pin States during Transition to Software Standby Mode (Internal Clock, Clock Synchronous Transmission)

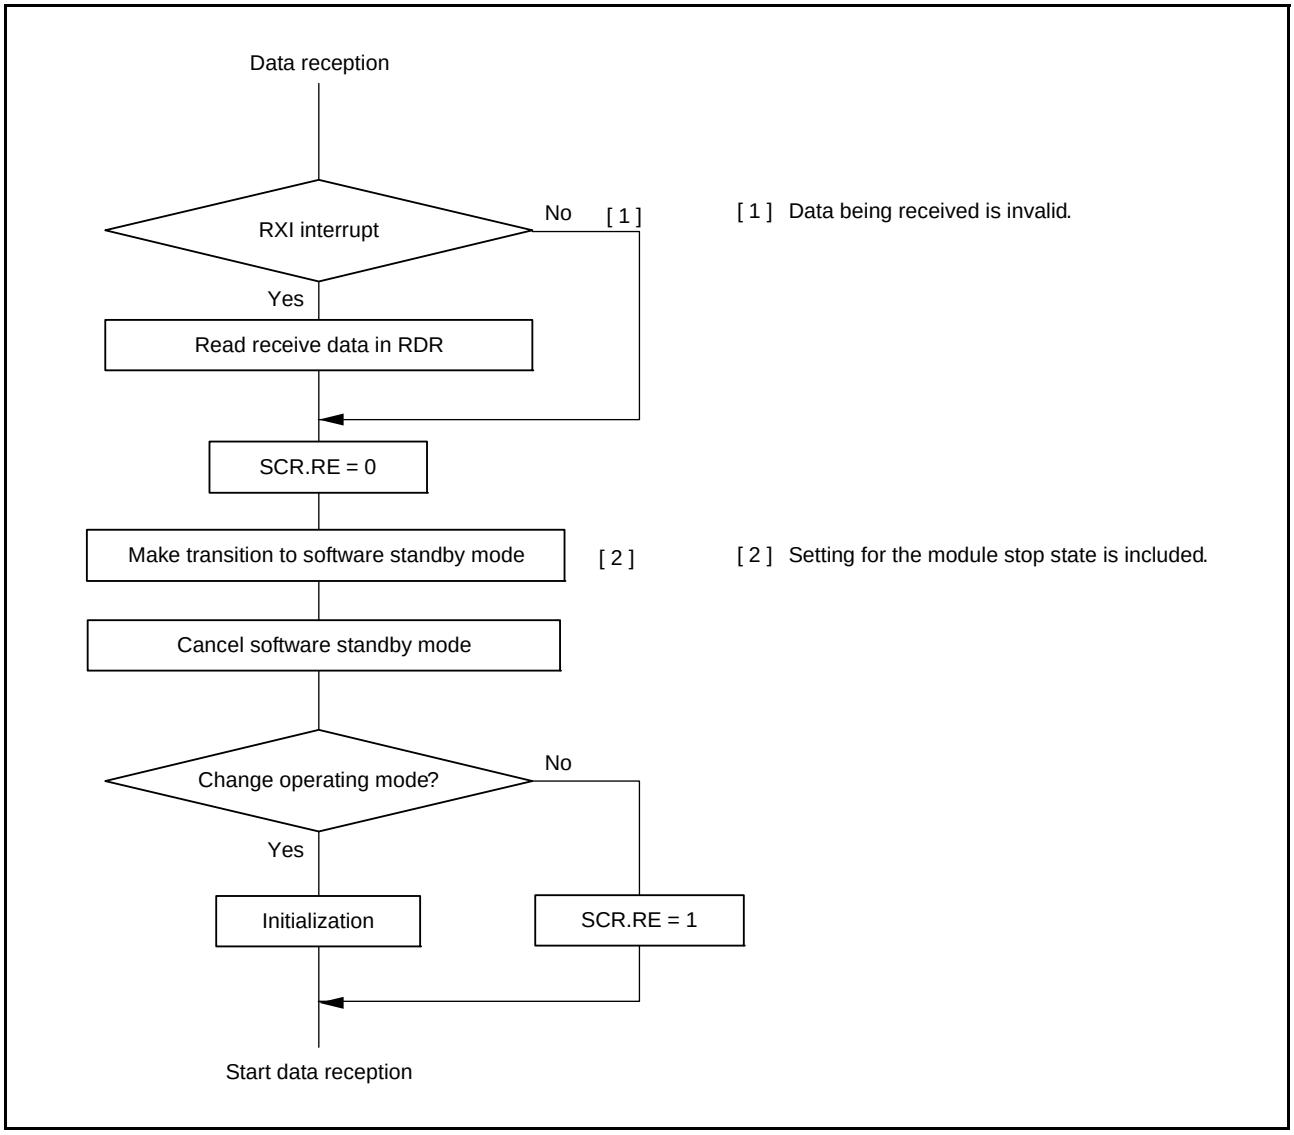

Figure 40.78 Example of Flowchart for Transition to Software Standby Mode during Reception

40.14.10 External Clock Input in Clock Synchronous Mode and Simple SPI Mode

In clock synchronous mode and simple SPI mode, the external clock SCKn must be input as follows:
High-pulse period, low-pulse period = 2 PCLK cycles or more, period = 6 PCLK cycles or more

40.14.11 Limitations on Simple SPI Mode

(1) Master Mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set by the SPMR.CKPH and CKPOL bits when the SPMR.SSE bit is 1.
  This prevents the clock line from being placed in the high-impedance state when the SCR.TE bit is set to 0 or unexpected edges from being generated on the clock line when the SCR.TE bit is changed from 0 to 1. When the SPMR.SSE bit is 0 in single master mode, pulling up or pulling down the clock line is not necessary because the clock line is not placed in the high-impedance state even when the SCR.TE bit is set to 0.
- In the case of the setting for clock delay (SPMR.CKPH bit is 1), the receive data full interrupt (RXI) is generated before the final clock edge on the SCKn pin as indicated in Figure 40.79. If the TE and RE bits in the SCR become 0 at this time before the final edge of the clock signal on the SCKn pin, the SCKn pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Furthermore, an RXI interrupt may lead to the input signal on the SSn# pin of a connected slave going to the high level before the final edge of the clock signal on the SCKn pin, leading to incorrect operation of the slave.
- In a multi-master configuration, take care because the SCKn pin output becomes high-impedance while the input on the SSn# pin is at the low level if a mode fault error occurs as the current character is being transferred, stopping supply of the clock signal to the connected slave. Remake the settings for the connected slave to avoid misaligned bits when transfer is restarted.

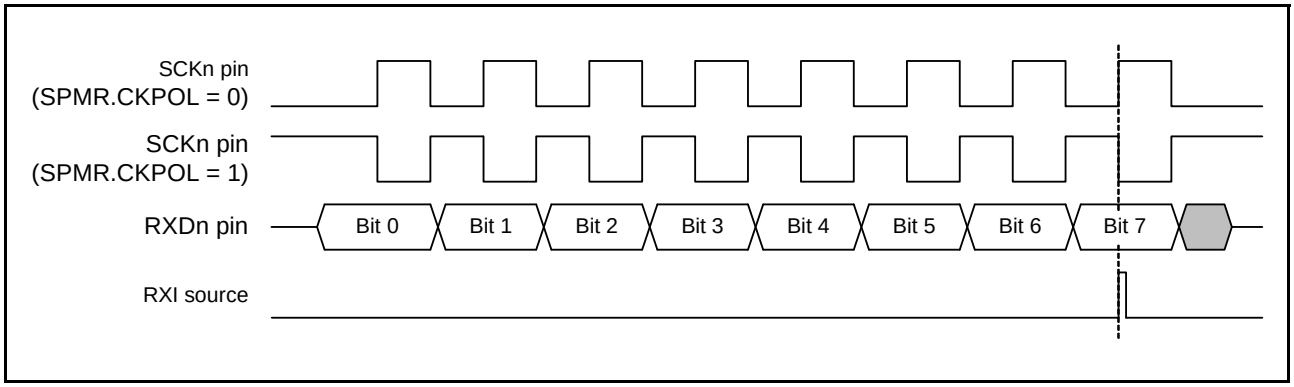

Figure 40.79 Timing of the RXI Interrupt in Simple SPI Mode (with Clock Delay)

(2) Slave Mode

- Secure at least five cycles of the PCLK from writing transmit data in the TDR register to start of the external clock input. Also secure at least five cycles of the PCLK from input of low level on the SSn# pin to start of the external clock input.
- Provide an external clock signal from the master the same as the transmit/receive data length.
- Control the input on the SSn# pin before the start and after the end of data transfer.
- When the level being input on the SSn# pin is to be changed from low to high while the current character is being transferred, set the TE and RE bits in the SCR to 0 and, after remaking the settings, restart transfer of the first byte.

40.14.12 Limitation 1 on Usage of the Extended Serial Mode Control Section

When the PCR.SHARPS bit is set to 1, output on the TXDX12/RXDX12 pin is only possible when the following conditions apply.

- The timer of the SCIh module is in Break Field low width output mode and the value of the TCR.TCST bit is 1 (when the TCST bit is set to 1, the high level continues to be output for up to one cycle of the clock source for counting by the timer counter before output of the low level)
- The value of the SCI12.SCR.TE bit is 1.

40.14.13 Limitation 2 on Usage of the Extended Serial Mode Control Section

An SCIg interrupt request is generated even if the extended serial mode is enabled. However, the SCIg interrupt should not be used during reception of a Start Frame because SCIh uses an SCIg interrupt request.
The two ways of dealing with this are described below. When a receive error is detected, clear the error flag of the SCIg and initialize the control section of the SCIh.

(1) Set the SCR.RIE bit of the SCIg to 0 to disable the output of interrupt requests. Check the error flags in the SSR register for SCIg on completion of the reception of a Start Frame, because an ERI interrupt is not generated if a receive error occurs. After reception of the Start Frame is completed, set the SCR.RIE bit of the SCIg to 1 by the time the first byte of the Information Frame is received.

(2) Set the SCR.RIE bit of the SCIg to 1 to disable RXI interrupts and enable ERI interrupts for ICU.
Clear the IRn.IR flag to enable the acceptance of RXI interrupts by ICU by the time the first byte of the Information Frame is received after the completion of Start Frame reception.

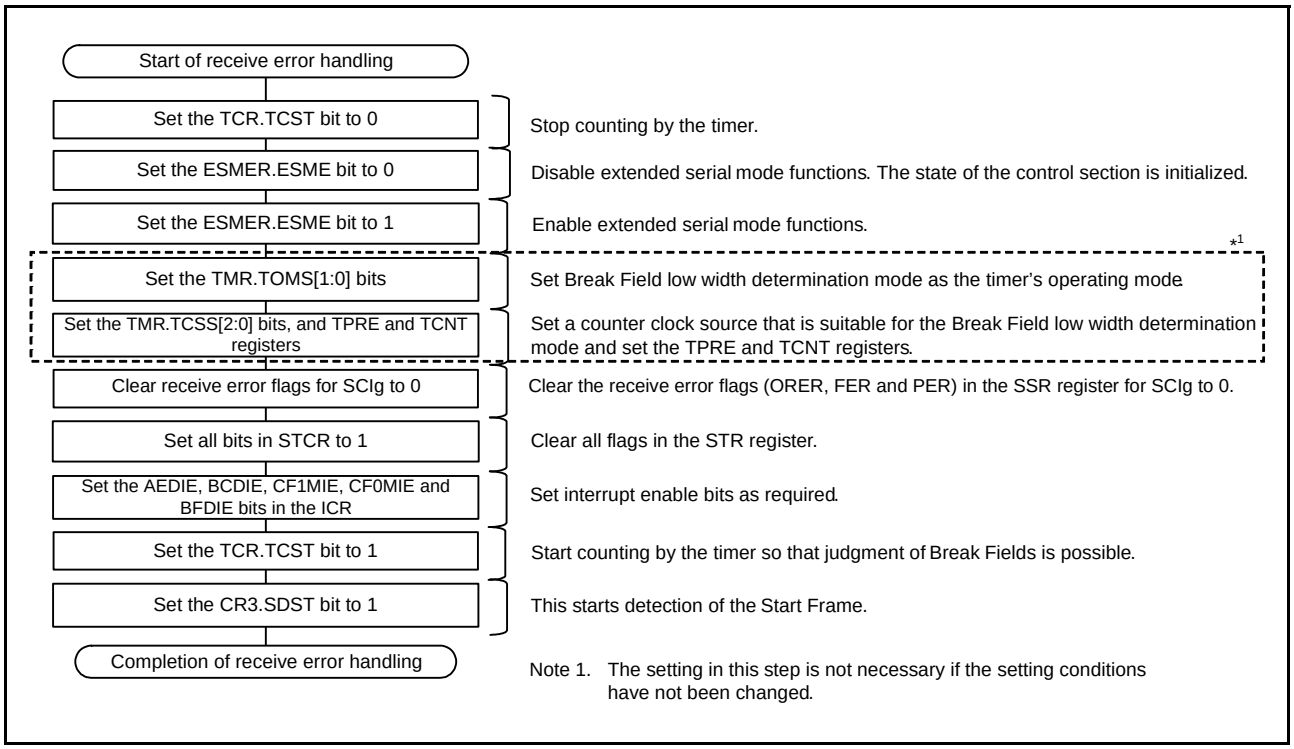

Figure 40.80 Example of Flowchart for Receive Error Handling (during Reception of the Start Frame)

40.14.14 Note on Transmit Enable Bit (TE Bit)

When setting the SCR.TE bit to 0 (serial transmission is disabled) while the pin function is “TXDn”, output of the pin becomes high impedance.

Prevent the TXDn line from becoming high impedance by any of the following ways:

(1) Connect a pull-up resistor to the TXDn line.

(2) Change the pin function to “general-purpose I/O port, output” before setting the SCR.TE bit to 0.
Set the SCR.TE bit to 1 before changing the pin function to “TXDn”.

40.14.15 Note on Stopping Reception When Using the RTS Function in Asynchronous Mode

One clock cycle of PCLK is required for the time from setting the SCR.RE bit to 0 to stopping the RTS signal generator in asynchronous mode.

When reading the RDR (or RDRL) register after setting the SCR.RE bit to 0, confirm that the RE bit has been set to 0 before reading the RDR (or RDRL) register to prevent these two processes from being performed consecutively.

41. FIFO Embedded Serial Communications Interface (SCIFA)

This MCU has four channels of serial communications interface with FIFO (SCIFA) that support both asynchronous and clock synchronous serial communication. The SCIFA has 16-stage transmit FIFO buffers and 16-stage receive FIFO buffers which allows the MCU to perform continuous high-speed communication.

41.1 Overview

Table 41.1 lists the SCIFA Specifications.

Table 41.1 SCIFA Specifications

Item		Description
Channels		SCIFA8, SCIFA9, SCIFA10, and SCIFA11
Communication methods		Asynchronous and clock synchronous
Full duplex communication		Transmitter: Continuous data transmission possible using 16-stage FIFO buffering Receiver: Continuous data reception possible using 16-stage FIFO buffering
Bit order		LSB first or MSB first
Interrupt sources		TEIF : Transmit end
		TXIF : Transmit FIFO data empty
		RXIF : Receive FIFO data full
		DRIF : Receive data ready (only valid in asynchronous communication mode)
		ERIF : Receive error
		BRIF : Break detect or overrun error
Asynchronous mode	Character length	7 or 8 bits
	Stop bit	1 or 2 bits
	Parity	Even parity, odd parity, or none
	Receive error detection	A parity error, overrun error, or framing error can be detected as a receive error.
	Hardware flow control	Controls data transmission and reception using the CTS# and RTS# pins.
	Break signal detection	Break signal detection by hardware
	Clock source	Internal clock or external clock selectable
	Noise cancellation	Incorporates a digital noise filter in the RXD pin input path.
Clock synchronous mode	Character length	8 bits
	Receive error detection	An overrun error can be detected as a receive error.
	Clock source	Internal clock or external clock selectable
Bit rate modulation function		Errors can be reduced using the on-chip baud rate generator's output correction

Figure 41.1 shows the SCIFA Block Diagram.

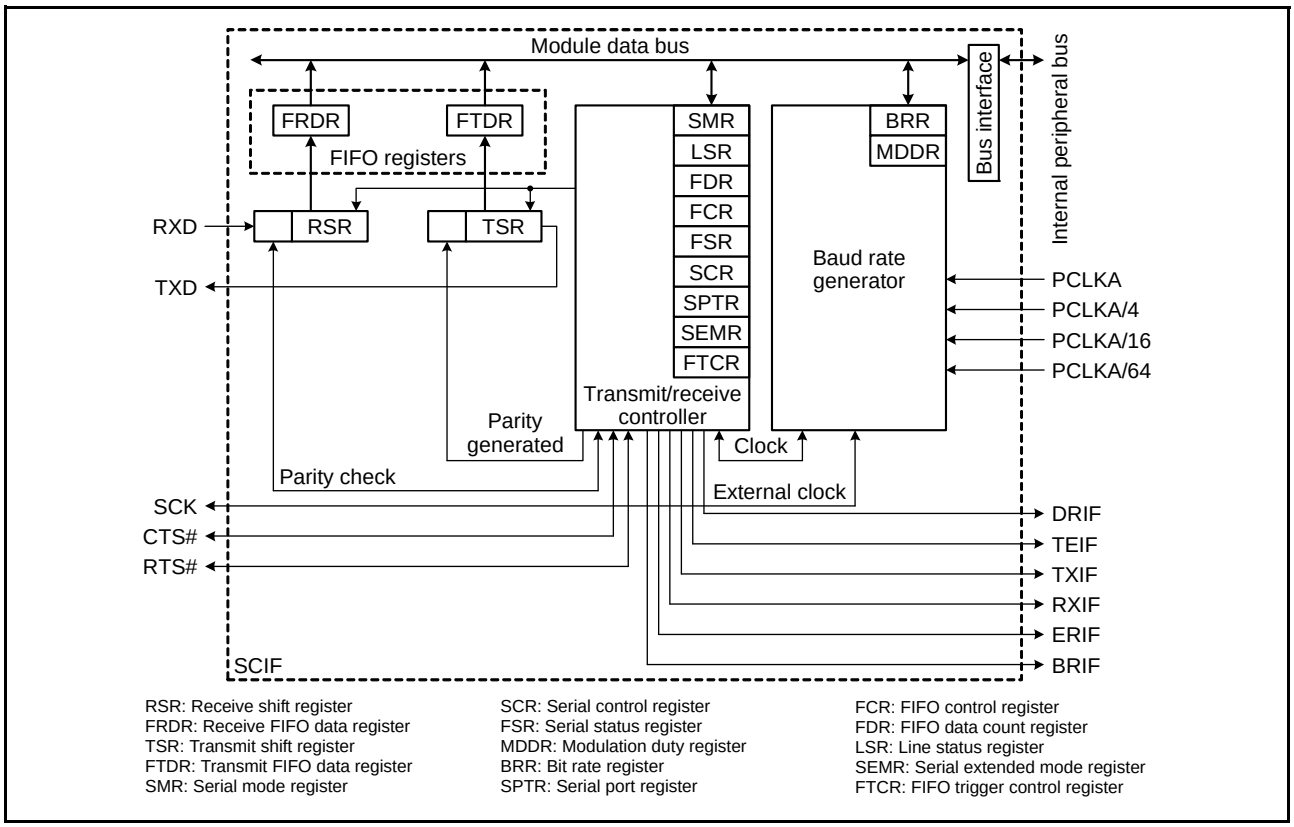

Figure 41.1 SCIFA Block Diagram

Table 41.2 shows the SCIFA I/O Pins.

Table 41.2 SCIFA I/O Pins

Channel	Pin Symbol *1	I/O	Function
SCIFA8	SCK8	I/O	Transmit/receive clock I/O, general output
	RXD8	Input	Receive data
	TXD8	Output	Transmit data
	CTS8#	I/O	Input for hardware flow control (clear to send), general output
	RTS8#	Output	Output for hardware flow control (request to send), general output
SCIFA9	SCK9	I/O	Transmit/receive clock I/O, general output
	RXD9	Input	Receive data
	TXD9	Output	Transmit data
	CTS9#	I/O	Input for hardware flow control (clear to send), general output
	RTS9#	Output	Output for hardware flow control (request to send), general output
SCIFA10	SCK10	I/O	Transmit/receive clock I/O, general output
	RXD10	Input	Receive data
	TXD10	Output	Transmit data
	CTS10#	I/O	Input for hardware flow control (clear to send), general output
	RTS10#	Output	Output for hardware flow control (request to send), general output
SCIFA11	SCK11	I/O	Transmit/receive clock I/O, general output
	RXD11	Input	Receive data
	TXD11	Output	Transmit data
	CTS11#	I/O	Input for hardware flow control (clear to send), general output
	RTS11#	Output	Output for hardware flow control (request to send), general output

Note 1. In this section, the channel number is omitted and pin symbols are abbreviated to SCK, RXD, TXD, CTS#, and RTS#.

41.2 Register Descriptions

41.2.1 Receive Shift Register (RSR)

Bit	b7	b6	b5	b4	b3	b2	b1	b0
Symbol								
Value after reset	0	0	0	0	0	0	0	0

The RSR register is a shift register used for receiving serial data. The RSR register converts serial data input from the RXD pin to parallel data. After receiving 1 byte of serial data, the SCIFA transfers the received data to the FRDR register. The CPU cannot directly access the RSR register.

41.2.2 Receive FIFO Data Register (FRDR)

Addresses: SCIFA8.FRDR 000D 000Ah, SCIFA9.FRDR 000D 002Ah, SCIFA10.FRDR 000D 004Ah, SCIFA11.FRDR 000D 006Ah

Bit	b7	b6	b5	b4	b3	b2	b1	b0
Symbol								
Value after reset	0	0	0	0	0	0	0	0

The FRDR register is a 16-stage FIFO buffer used for storing received serial data. After 1 byte of serial data is received, the SCIFA transfers the received data from the RSR register into the FRDR register. Data can continuously be received until the 16-stage FIFO buffer is full. If the FRDR register is read when there is no received data in the FRDR register, the read value is undefined. When FRDR register is full of received data, subsequent received serial data is lost. The FRDR register is a read-only register.

41.2.3 Transmit Shift Register (TSR)

Bit	b7	b6	b5	b4	b3	b2	b1	b0
Symbol								
Value after reset	1	1	1	1	1	1	1	1

The TSR register is a shift register used for transmitting serial data. The SCIFA temporarily transfers transmit data from the FTDR register to the TSR register, and then transmits 1 bit of serial data at a time from the TXD pin. After transmitting 1 byte of serial data, the SCIFA transfers the next transmit data from the FTDR register to the TSR register. The CPU cannot directly access the TSR register.

41.2.4 Transmit FIFO Data Register (FTDR)

Addresses: SCIFA8.FTDR 000D 0006h, SCIFA9.FTDR 000D 0026h, SCIFA10.FTDR 000D 0046h, SCIFA11.FTDR 000D 0066h

Bit	b7	b6	b5	b4	b3	b2	b1	b0
Symbol								
Value after reset	1	1	1	1	1	1	1	1

The FTDR register is a 16-stage FIFO buffer used for storing data for serial transmission. When the TSR register becomes empty, transmit data written to the FTDR register is transferred to the TSR register by the SCIFA. Data can be continuously transmitted until the 16-stage FIFO buffer is empty. When the FTDR register is full of transmit data, no more data can be written. Even when attempting to write data, the data written is ignored. The FTDR register is a write-only register.

41.2.5 Serial Mode Register (SMR)

Addresses: SCIFA8.SMR 000D 0000h, SCIFA9.SMR 000D 0020h, SCIFA10.SMR 000D 0040h, SCIFA11.SMR 000D 0060h

Bit	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	—	—	—	—	—	—	—	—	CM	CHR	PE	PM	STOP	—	CKS[1:0]	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKS[1:0]	Clock Select Bits	b1 b0 0 0: PCLKA 0 1: PCLKA/4 1 0: PCLKA/16 1 1: PCLKA/64	R/W
b2	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b3	STOP	Stop Bit Length Select Bit	0: 1 stop bit 1: 2 stop bits	R/W
b4	PM	Parity Type Select Bit	0: Even parity 1: Odd parity	R/W
b5	PE	Parity Control Bit	0: Parity bit is neither added nor checked 1: Parity bit is added and checked	R/W
b6	CHR	Character Length Select Bit	0: 8 bits 1: 7 bits *1	R/W
b7	CM	Communication Mode Select Bit	0: Asynchronous mode 1: Clock synchronous mode	R/W
b15 to b8	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. When the CHR bit is 1, the MSB (b7) in the FTDR register is not transmitted.

The SMR register designates the serial communication data format, and designates the clock source for the baud rate generator.

CKS[1:0] Bits (Clock Select Bits)

These bits select the clock source for the baud rate generator. Refer to section 41.2.8, Bit Rate Register (BRR) for relation between the clock source, bit rate register settings, and bit rates.

STOP Bit (Stop Bit Length Select Bit)

While in asynchronous mode, this bit selects the stop bit length from 1 bit or 2 bits. A stop bit is only added when transmitting in asynchronous mode. The bit setting value is ignored in clock synchronous mode because no stop bits are added. When receiving data, only the first bit of the stop bit is checked, regardless of the stop bit setting. If the second bit of the stop bit is 1, it is treated as a stop bit, but if the second bit of the stop bit is 0, it is treated as the start bit of the next transmitted character.

PM Bit (Parity Type Select Bit)

In asynchronous mode, this bit selects how many parity bits are added during transmission, performs parity check when receiving data, and selects even or odd parity. This bit is only valid when the PE bit is 1 while in asynchronous mode. This bit is invalid when the PE bit is 0 while in clock synchronous mode.

PE Bit (Parity Control Bit)

In asynchronous mode, this bit selects whether to add a parity bit during data transmission, and whether to check the parity on data reception. Regardless of the PE bit setting, a parity bit is neither added nor checked in clock synchronous mode.

CHR Bit (Character Length Select Bit)

In asynchronous mode, this bit selects the valid bit length of transfer data from 7 bits or 8 bits. Regardless of the CHR bit setting, the data length is always 8 bits in clock synchronous mode.

CM Bit (Communication Mode Select Bit)

This bit selects the SCIFA operating mode from asynchronous mode or clock synchronous mode.

41.2.6 Serial Control Register (SCR)

Addresses SCIFA8.SCR 000D 0004h, SCIFA9.SCR 000D 0024h, SCIFA10.SCR 000D 0044h, SCIFA11.SCR 000D 0064h

Bit	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	—	—	—	—	—	—	—	—	TIE	RIE	TE	RE	REIE	TEIE	CKE[1:0]	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKE[1:0]	Clock Enable Bits	In asynchronous mode b1 b0 0 0: The baud rate generator output is the clock source, and the SCK pin status is determined by the SPTR.SCKIO and SCKDT bit settings. 0 1: The baud rate generator output is the clock source. When the SEMR.ABCS0 bit is 0, the SCK pin outputs a clock 16 times faster than the bit rate; when the SEMR.ABCS0 bit is 1, the SCK pin outputs a clock eight times faster than the bit rate. 1 0: The external clock is the clock source. When the SEMR.ABCS0 bit is 0, an external clock 16 times faster than the bit rate is input to the SCK pin; when the SEMR.ABCS0 bit is 1, an external clock eight times faster than the bit rate is input to the SCK pin. 1 1: Do not set this value. In clock synchronous mode b1 b0 0 0: The baud rate generator output is the clock source, and the synchronous clock is output by the SCK pin. 0 1: The baud rate generator output is the clock source, and the synchronous clock is output by the SCK pin. 1 0: The external clock is the clock source, and the synchronous clock is input to the SCK pin. 1 1: Do not set this value.	R/W
b2	TEIE	Transmit End Interrupt Request Enable Bit	0: TEIF interrupt request disabled 1: TEIF interrupt request enabled	R/W
b3	REIE	Receive Error Interrupt Request Enable Bit	0: ERIF interrupt request and BRIF interrupt request disabled 1: ERIF interrupt request and BRIF interrupt request enabled	R/W
b4	RE	Reception Enable Bit	0: Serial reception disabled 1: Serial reception enabled	R/W
b5	TE	Transmission Enable Bit	0: Serial transmission disabled 1: Serial transmission enabled	R/W
b6	RIE	Receive Interrupt Request Enable Bit	0: RXIF interrupt request, DRIF interrupt request, ERIF interrupt request, and BRIF interrupt request disabled 1: RXIF interrupt request, DRIF interrupt request, ERIF interrupt request, and BRIF interrupt request enabled	R/W
b7	TIE	Transmit Interrupt Request Enable Bit	0: TXIF interrupt disabled 1: TXIF interrupt enabled	R/W
b15 to b8	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

The SCR register designates the transmission and reception operations, enables and disables interrupt requests, and designates the clock source for data transfer.

CKE[1:0] Bits (Clock Enable Bits)

These bits select the clock source for the SCIFA. These bits also select whether the clock is output from the SCK pin or input to the SCK pin. To output a synchronous clock in clock synchronous mode, set the SMR.CM bit to 1 and then set the CKE[1:0] bits.

TEIE Bit (Transmit End Interrupt Request Enable Bit)

Set this bit to enable and disable generation of the TEIF interrupt request. To cancel the TEIF interrupt request, confirm that the FSR.TEND flag is 1, and then either set the TEND flag to 0 or set the TEIE bit to 0.

REIE Bit (Receive Error Interrupt Request Enable Bit)

Set this bit to enable and disable generation of the ERIF interrupt request and BRIF interrupt request. To cancel the ERIF and BRIF interrupt requests, confirm that the FSR.ER, BRK, or ORER flag is 1, set the ER, BRK, or ORER flag to 0, and then set bits RIE and REIE to 0.

RE Bit (Reception Enable Bit)

Set this bit to enable and disable serial reception. When the RE bit is 1, data reception starts when either a start bit is detected in asynchronous mode, or a synchronous clock is detected in clock synchronous mode. Before setting the RE bit to 1, select the communication format in the SMR register, and in the FCR register, set the receive FIFO and perform a reset.

Note: Flags FSR.DR, ER, BRK, RDF, FER, PER, and the LSR.ORER flag do not become 0 even when the RE bit is set to 0.

TE Bit (Transmission Enable Bit)

Set this bit to enable and disable serial transmission. When the TE bit is set to 1 and transmit data is written to the FTDR register, serial transmission starts. Before setting the TE bit to 1, select the communication format in the SMR register, and in the FCR register, set the transmit FIFO and perform a reset.

RIE Bit (Receive Interrupt Request Enable Bit)

This bit enables and disables generation of the RXIF interrupt request, DRIF interrupt request, ERIF interrupt request, and BRIF interrupt request. To cancel an RXIF interrupt request, confirm that the FSR.RDF flag is 1 before setting it to 0, or set the RIE bit to 0. To cancel the DRIF interrupt request, confirm that the FSR.DR flag is 1 before setting it to 0, or set the RIE bit to 0. To cancel the ERIF interrupt request and BRIF interrupt request, set bits RIE and REIE to 0.

TIE Bit (Transmit Interrupt Request Enable Bit)

This bit enables and disables generation of the TXIF interrupt request. To cancel the TXIF interrupt request, write transmit data that is equal to or greater than the transmit FIFO threshold value to the FTDR register, confirm that the FSR.TDFE flag is 1 before setting it to 0, or set the TIE bit to 0.

41.2.7 Serial Status Register (FSR)

Addresses SCIFA8.FSR 000D 0008h, SCIFA9.FSR 000D 0028h, SCIFA10.FSR 000D 0048h, SCIFA11.FSR 000D 0068h

Bit	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	—	—	—	—	—	—	—	—	ER	TEND	TDFE	BRK	FER	PER	RDF	DR
Value after reset	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DR	Receive Data Ready Flag *1	0: All receive data is read from the FRDR register (receive FIFO is empty) during data reception or after data reception is completed normally 1: After data reception is completed normally, the next receive data is not received for a given period	R(/W) *2
b1	RDF	Receive FIFO Data Full Flag	0: The amount of receive data stored in the FRDR register is less than the receive FIFO threshold 1: The amount of receive data stored in the FRDR register is the receive FIFO threshold or more	R(/W) *2
b2	PER	Parity Error Flag *1, *3	0: The start data in the FRDR register is not in the parity error state 1: The start data in the FRDR register is in the parity error state	R
b3	FER	Framing Error Flag *1, *3	0: The start data in the FRDR register is not in the framing error state 1: The start data in the FRDR register is in the framing error state	R
b4	BRK	Break Signal Detection Flag	0: Break signal not detected 1: Break signal detected *4	R(/W) *2
b5	TDFE	Transmit FIFO Data Empty Flag	0: The amount of transmit data written to the FTDR register is more than the transmit FIFO threshold 1: The amount of transmit data written to the FTDR register is the transmit FIFO threshold or less	R(/W) *2
b6	TEND	Transmission Complete Flag	0: Waiting for data to transmit or data is being transmitted 1: Transmission complete	R(/W) *2
b7	ER	Reception Error Flag *1	0: Data is being received or reception was completed normally 1: A framing error or parity error occurred during data reception	R(/W) *2
b15 to b8	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. This bit is valid in asynchronous mode.
Note 2. This flag can only be written to when it is being cleared. To clear this flag, confirm that the flag is 1 and then set it to 0.
Note 3. These flags are updated each time data is read from the FRDR register. When using the DTC or DMAC to read the received data, these flags cannot be used to detect errors.
Note 4. When a break signal is detected, storing receive data (00h) to the FRDR register is stopped. When the break signal has ended and the RXD signal is “marked”, storing receive data to the FRDR register resumes.

The FSR register indicates the transmission and reception status. The ER, TEND, TDFE, BRK, RDF, and DR flags cannot be written. To set these flags to 0, confirm that they are 1, and then write 0.
Because the PER and FER flags are updated each time data is read from the FRDR register, there is no way to detect errors after the data has been read. When using the DTC or DMAC to read the received data, use flags PER[3:0] and FER[3:0] in the LSR register. If any of the values of these flags are decremented after the DTC or DMA transfer, this means that the corresponding error has occurred in the read data.

DR Flag (Receive Data Ready Flag)

After receiving data in asynchronous mode, when the amount of data stored in the FRDR register is less than the receive FIFO threshold value, if the next data is not received even after 15 elementary time units (ETUs) elapse from the time the last stop bit is detected, then this flag becomes 1. However, this flag does not become 1 in clock synchronous mode.

— This flag becomes 1 under the following condition:

- When the data stored to the FRDR register is less than the receive FIFO threshold value, the next data is not received even after 15 ETUs *1 elapse from the time the last stop bit is detected.

— This flag becomes 0 under any of the following conditions:

- After confirming that the DR flag is 1, it is set to 0.
- All receive data in the FRDR register is read.

Note 1. 15 ETUs is equivalent to 1.5 frames of an 8-bit, 1 stop bit format.

RDF Flag (Receive FIFO Data Full Flag)

When receive data is transferred to the FRDR register, this flag indicates that the amount of data stored in the FRDR register is the receive FIFO threshold value or more.

— This flag becomes 1 under the following condition:

- Receive data stored in the FRDR register is the receive FIFO threshold value or more. *1

— This flag becomes 0 under any of the following conditions:

- After confirming that the RDF flag is 1, it is set to 0.
- DTC or DMA transfer is used to read the receive data from the FRDR register (do not set the RDF flag to 0 during DTC or DMA transfer).

Note 1. Since the FRDR register is a 16-byte FIFO register, the maximum amount of data that can be read when RDF flag is 1 is indicated by the FDR.R[4:0] flags. After reading all the data in the FRDR register, continuing a read access results in an undefined value.

PER Flag (Parity Error Flag)

When in asynchronous mode, this flag indicates whether there is a parity error in the next data to be read from the FRDR register.

— This flag becomes 1 under the following condition:

- There is a parity error in the next data to be read from the FRDR register.

— This flag becomes 0 under the following condition:

- There is no parity error in the next data to be read from the FRDR register.

FER Flag (Framing Error Flag)

When in asynchronous mode, this flag indicates whether there is a framing error in the next data to be read from the FRDR register.

— This flag becomes 1 under the following condition:

- There is a framing error in the next data to be read from the FRDR register.

— This flag becomes 0 under the following condition:

- There is no framing error in the next data to be read from the FRDR register.

BRK Flag (Break Signal Detection Flag)

This flag indicates that a break signal was detected while receiving data.

— This flag becomes 1 under the following condition:

- Data that includes a framing error is received, followed by at least one frame length of a “space” (low) being received.

— This flag becomes 0 under the following condition:

- After confirming the BRK flag is 1, it is set to 0.

TDFE Flag (Transmit FIFO Data Empty Flag)

This flag indicates that data has been transferred from the FTDR register to the TSR register, it indicates the amount of data in FTDR has become the transmit FIFO threshold value or lower, and it indicates that transmit data can be written to the FTDR register.

— This flag becomes 1 under any of the following conditions:

- The SCR.TE bit is 0.
- The amount of transmit data written to the FTDR register is less than or equal to the transmit FIFO threshold value.

— This flag becomes 0 under any of the following conditions:

- After confirming that the TDFE flag is 1, it is set to 0.
- DTC or DMA transfer *1 is used to write transmit data to the FTDR register *2

Note 1. The last block transferred during block transfer.
Note 2. Do not clear the TDFE flag during DTC or DMA transfer.
Note 3. Because the FTDR register is a 16-byte FIFO register, when the TDFE flag is 1, the maximum amount of data that can be written to the FTDR register is (16 - FDR.T[4:0]). All other data written to the FTDR register above that value is ignored.

TEND Flag (Transmission Complete Flag)

This flag indicates that the FTDR register does not contain valid data when transmitting the last bit of a serial character, so the transmission is halted.

— This flag becomes 1 under the following condition:

- When transmitting one frame of data, there is no transmit data in the FTDR register when the last bit is transmitted.

— This flag becomes 0 under any of the following conditions:

- Transmit data is written to the FTDR register.
- After confirming that the TEND flag is 1, it is set to 0.

ER Flag (Reception Error Flag)

This flag indicates that a reception error (framing error or parity error) occurred in the frame that was just received. *1

— This flag becomes 1 under any of the following conditions:

- The stop bit in the received frame is 0. *2
- During data reception, the SMR.PM bit setting did not match the combined number of 1's in the receive data and the parity bit.

— This flag becomes 0 under the following condition:

- After confirming that the ER flag is 1, it is set to 0.

Note 1. The ER flag value is not affected by setting the SCR.RE bit to 0. Even if a receive error occurs, the receive data is transferred to the FRDR register, and reception continues. Read the FSR.FER and PER flags to check if the data read from the FRDR register includes a receive error.
Note 2. When using 2 stop bits, only the first stop bit is checked; the second stop bit is not checked.

41.2.8 Bit Rate Register (BRR)

Addresses: SCIFA8.BRR 000D 0002h, SCIFA9.BRR 000D 0022h, SCIFA10.BRR 000D 0042h, SCIFA11.BRR 000D 0062h

Bit	b7	b6	b5	b4	b3	b2	b1	b0
Symbol								
Value after reset	1	1	1	1	1	1	1	1

The BRR register is used to adjust the bit rate. The BRR register is located in the same address as the MDDR register. The BRR register is can be accessed when the SEMR.MDDRS bit is 0. Rewrite this register when bits SCR.TE and RE are both 0.

The BRR register setting value can be calculated using the formulas in Table 41.3.

Table 41.3 Formulas for Calculating the BRR Register Setting Value

Mode		Operate the SCIFA at 16 Times the Bit Rate (SEMR.ABCS0 bit is 0)	Operate the SCIFA at 8 Times the Bit Rate (SEMR.ABCS0 bit is 1)
Asynchronous mode	Baud rate generator is in normal mode (SEMR.BGDM bit is 0)	$N = \frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 2 \times 16 \times B} - 1$	$N = \frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 2 \times 8 \times B} - 1$
	Baud rate generator is in high-speed mode (SEMR.BGDM bit is 1)	$N = \frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 16 \times B} - 1$	$N = \frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 8 \times B} - 1$
Clock synchronous mode		$N = \frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 4 \times B} - 1$	

N: BRR register setting value ($0 \le N \le 255$)
$f_{(PCLKA)}$: Frequency of the peripheral module clock [MHz]
n: SMR.CKS[1:0] bit setting value (n = 0 to 3) (see Table 41.4)
B: Bit rate [bps] (set a value that satisfies the Electrical Characteristics)

Table 41.4 SMR.CKS[1:0] Bit Settings

SMR.CKS[1:0] Bit Setting Value	n	Clock Input to the Baud Rate Generator
00b	0	PCLKA
01b	1	PCLKA/4
10b	2	PCLKA/16
11b	3	PCLKA/64

The bit rate error [%] while in asynchronous mode can be calculated using the formulas in Table 41.5.

Table 41.5 Bit Rate Error While in Asynchronous Mode

Mode	Operate the SCIFA at 16 Times the Bit Rate (SEMR.ABCS0 bit is 0)	Operate the SCIFA at 8 Times the Bit Rate (SEMR.ABCS0 bit is 1)
Baud rate generator is in normal mode (SEMR.BGDM bit is 0)	$\left(\frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 2 \times 16 \times B \times (N+1)} - 1\right) \times 100$	$\left(\frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 2 \times 8 \times B \times (N+1)} - 1\right) \times 100$
Baud rate generator is in high-speed mode (SEMR.BGDM bit is 1)	$\left(\frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 16 \times B \times (N+1)} - 1\right) \times 100$	$\left(\frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 8 \times B \times (N+1)} - 1\right) \times 100$

Table 41.6 and Table 41.7 list examples of BRR register setting in asynchronous mode, and Table 41.8 lists examples of BRR register setting in clock synchronous mode.

Table 41.6 Bit Rates and BRR Register Settings in Asynchronous Mode *1 (1/2)

28800	0	25	0.16	0	27	0.76	0	29	1.27	0	32	–1.36	0	34	–0.79	0	36	–0.29	0	38	0.16
31250	0	23	0.00	0	25	0.00	0	27	0.00	0	29	0.00	0	31	0.00	0	33	0.00	0	35	0.00
38400	0	19	–2.34	0	20	0.76	0	22	–0.93	0	23	1.73	0	25	0.16	0	27	–1.18	0	28	1.02
115200	0	6	–6.99	0	6	0.76	0	7	–5.06	0	7	1.73	0	8	–3.55	0	8	2.48	0	9	–2.34
500000	0	1	–25.0	0	1	–18.8	0	1	–12.5	0	1	–6.25	0	1	0.00	0	1	6.25	0	1	12.5

Note 1. These values assume bits SEMR.ABCS0 and SEMR.BGDM are both 0. When either the SEMR.ABCS0 bit or SEMR.BGDM bit is set to 1, the bit rate is doubled. When bits SEMR.ABCS0 and SEMR.BGDM are both 1, the bit rate is quadrupled. Configure settings so the range of error is no greater than 1%.

Note 2. Continuous transmit/receive is not possible.

Table 41.7 Bit Rates and BRR Settings *1 in Asynchronous Mode (2/2)

Bit Rate [bps]	PCLKA (MHz)

Blank: Setting is prohibited.

—: Setting is possible, but causes a bit rate error.

Note 1. Configure settings so the range of error is no greater than 1%.

Note 2. Continuous transmit/receive is not possible.

Table 41.9 lists the maximum bit rates for various frequencies in asynchronous mode and clock synchronous mode when the baud rate generator is used.

Table 41.9 Maximum Bit Rates for Various Frequencies with Baud Rate Generator

PCLKA [MHz]	Asynchronous Mode *1			Clock Synchronous Mode *2					
				Discontinuous Transmission/Reception			Continuous Transmission/Reception		
	Maximum Bit Rate [bps]	Settings		Maximum bit rate [bps]	Settings		Maximum bit rate [bps]	Settings	
		n	N		n	N		n	N

28	875,000	0	0	7,000,000	0	0	3,500,000	0	1
30	937,500	0	0	7,500,000	0	0	3,750,000	0	1
32	1,000,000	0	0	8,000,000	0	0	4,000,000	0	1
34	1,062,500	0	0	8,500,000	0	0	4,250,000	0	1
36	1,125,000	0	0	9,000,000	0	0	4,500,000	0	1
38	1,187,500	0	0	9,500,000	0	0	4,750,000	0	1
40	1,250,000	0	0	10,000,000	0	0	5,000,000	0	1
42	1,312,500	0	0	10,500,000	0	0	5,250,000	0	1
44	1,375,000	0	0	11,000,000	0	0	5,500,000	0	1
46	1,437,500	0	0	11,500,000	0	0	5,750,000	0	1
48	1,500,000	0	0	12,000,000	0	0	6,000,000	0	1
50	1,562,500	0	0	—	—	—	—	—	—
60	1,875,000	0	0	—	—	—	—	—	—
80	2,500,000	0	0	—	—	—	—	—	—
100	3,125,000	0	0	—	—	—	—	—	—
120	3,750,000	0	0	—	—	—	—	—	—

Note 1. The maximum bit rate in asynchronous mode assume bits SEMR.ABCS0 and SEMR.BGDM are both 0. If either the SEMR.ABCS0 bit or SEMR.BGDM bit is 1, the bit rate is doubled. When bits SEMR.ABCS0 and SEMR.BGDM are both 1, the bit rate is quadrupled. Configure settings so the range of error falls within 1%.

Note 2. The maximum bit rate setting should satisfy the electrical characteristics.

Table 41.10 lists the maximum rates for external clock inputs in asynchronous mode and clock synchronous mode.

Table 41.10 Maximum Bit Rates with External Clock Input

PCLKA [MHz]	External Input Clock [MHz]		Maximum Bit Rate [bps]	
	Asynchronous mode	Clock synchronous mode	Asynchronous mode *1	Clock synchronous mode *2
10	2.5	1.6667	156,250	1,666,667
12	3.0	2.0000	187,500	2,000,000
14	3.5	2.3333	218,750	2,333,333

20	5.0	3.3333	312,500	3,333,333
22	5.5	3.6667	343,750	3,666,667
24	6.0	4.0000	375,000	4,000,000
26	6.5	4.3333	406,250	4,333,333
28	7.0	4.6667	437,500	4,666,667
30	7.5	5.0000	468,750	5,000,000
32	8.0	5.3333	500,000	5,333,333
34	8.5	5.6667	531,250	5,666,667
36	9.0	6.0000	562,500	6,000,000
38	9.5	6.3333	593,750	6,333,333
40	10.0	6.6667	625,000	6,666,667
42	10.5	7.0000	656,250	7,000,000
44	11.0	7.3333	687,500	7,333,333
46	11.5	7.6667	718,750	7,666,667
48	12.0	8.0000	750,000	8,000,000
50	12.5	8.3333	781,250	8,333,333
60	15.0	5	937,500	5,000,000
80	20.0	6.6667	1,250,000	6,666,667
100	25.0	8.3333	1,562,500	8,333,333
120	30.0	—	1,875,000	—

Note 1. These are the values when the SEMR.ABCS0 bit is 0. The bit rate is doubled with the SEMR.ABCS0 bit is 1.
Note 2. The maximum bit rate setting should satisfy the electrical characteristics.

41.2.9 Modulation Duty Register (MDDR)

Addresses: SCIFA8.MDDR 000D 0002h, SCIFA9.MDDR 000D 0022h, SCIFA10.MDDR 000D 0042h, SCIFA11.MDDR 000D 0062h

Bit	b7	b6	b5	b4	b3	b2	b1	b0
	1							
Value after reset	1	1	1	1	1	1	1	1

The MDDR register corrects the bit rate adjusted by the BRR register. When the SEMR.BRME bit is set to 1, the bit rate generated by the on-chip baud rate generator is corrected. The MDDR register is located in the same address as the BRR register, and the MDDR register can be accessed when the SEMR.MDDRS bit is 1. Rewrite this register when bits SCR.TE and RE are both 0. Bit 7 in this register is fixed to 1.

The formulae in Table 41.11 can be used to calculate the bit rate when using the bit rate modulation function.

Table 41.11 Calculating the Bit Rate When Using the Bit Rate Modulation Function

Mode		Operate the SCIFA at 16 Times the Bit Rate (SEMR.ABCS0 bit is 0)	Operate the SCIFA at 8 Times the Bit Rate (SEMR.ABCS0 bit is 1)
Asynchronous mode	Baud rate generator is in normal mode (SEMR.BGDM bit is 0)	$B = \frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 2 \times 16 \times \frac{256}{MDDR} \times (N+1)}$	$B = \frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 2 \times 8 \times \frac{256}{MDDR} \times (N+1)}$
	Baud rate generator is in high-speed mode (SEMR.BGDM bit is 1)	$B = \frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 16 \times \frac{256}{MDDR} \times (N+1)}$	$B = \frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 8 \times \frac{256}{MDDR} \times (N+1)}$
Clock synchronous mode		$B = \frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 4 \times \frac{256}{MDDR} \times (N+1)}$	

B: Bit rate [bps]
$f_{(PCLKA)}$: Frequency of the peripheral module clock [MHz]
n: SMR.CKS[1:0] bit setting value (n = 0 to 3) (see Table 41.4.).
MDDR: MDDR register setting value ($128 \le MDDR \le 256$)
N: BRR register setting value ($0 \le N \le 255$) (the bit rate value must satisfy the electrical characteristics).

The formulae in Table 41.12 can be used to calculate the average bit rate error when using the bit rate modulation function in asynchronous mode.

Table 41.12 Bit Rate Error When Using the Bit Rate Modulation Function in Asynchronous Mode

Mode	Operate the SCIFA at 16 Times the Bit Rate (SEMR.ABCS0 bit is 0)	Operate the SCIFA at 8 Times the Bit Rate (SEMR.ABCS0 bit is 1)
Baud rate generator normal mode (SEMR.BGDM bit is 0)	$\left(\frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 2 \times 16 \times B \times \frac{256}{MDDR} \times (N+1)} - 1\right) \times 100$	$\left(\frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 2 \times 8 \times B \times \frac{256}{MDDR} \times (N+1)} - 1\right) \times 100$
Baud rate generator double speed mode (SEMR.BGDM bit is 1)	$\left(\frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 16 \times B \times \frac{256}{MDDR} \times (N+1)} - 1\right) \times 100$	$\left(\frac{f_{(PCLKA)} \times 10^6}{2^{2n} \times 8 \times B \times \frac{256}{MDDR} \times (N+1)} - 1\right) \times 100$

41.2.10 FIFO Control Register (FCR)

b5, b4	TTRG[1:0]	Transmit FIFO Threshold Setting Bits	b7 b6 0 0: 8 (8) *1 0 1: 4 (12) *1	b7 b6 1 0: 2 (14) *1 1 1: 0 (16) *1	R/W
b7, b6	RTRG[1:0]	Receive FIFO Threshold Setting Bits	Asynchronous mode b7 b6 0 0: 1 0 1: 4 1 0: 8 1 1: 14	Clock synchronous mode b7 b6 0 0: 1 0 1: 2 1 0: 8 1 1: 14	R/W
b10 to b8	RSTRG[2:0]	RTS# Output Threshold Setting Bits	b10 b8 0 0 0: 15 0 0 1: 1 0 1 0: 4 0 1 1: 6	b10 b8 1 0 0: 8 1 0 1: 10 1 1 0: 12 1 1 1: 14	R/W
b15 to b11	—	Reserved	These bits are 0 when read. Set them to 0 when writing.		R/W

Note 1. Values in parentheses represent the number of empty bytes in the FTDR register when the TDFE flag becomes 1.

The FCR register is used to reset the amount of data stored in the FTDR and FRDR registers, set the transmit FIFO threshold value, and set the receive FIFO threshold value. This register also enables and disables loopback testing.

LOOP Bit (Loopback Test Control Bit)

When the LOOP bit is set to 1, the TXD and RXD pins are connected internally, and a loopback test is enabled.

RFRST Bit (FRDR Register Reset Bit)

When the RFRST bit is set to 1, the FRDR register is reset and emptied of all receive data. After setting the RFRST bit to 1, set it back to 0.

TFRST Bit (FTDR Register Reset Bit)

When the TFRST bit is set to 1, the FTDR register is reset and emptied of all transmit data. After setting the TFRST bit to 1, set it back to 0.

MCE Bit (Flow Control Bit)

This bit enables and disables the hardware flow control by the modem control signals (CTS# and RTS#). Set the MCE bit to 0 in clock synchronous mode.

Note: Regardless of the input value, the level of the CTS# pin has no effect on transmit operation of frames being transmitted. The level of RTS# pin has no effect on the receive operation.

TTRG[1:0] Bits (Transmit FIFO Threshold Setting Bits)

When the FTCR.TTRGS bit is 0, the transmit FIFO threshold value is determined by the TTRG[1:0] bit setting. When the FTCR.TTRGS bit is 1, the transmit FIFO threshold value is determined by the FTCR.TFTC[4:0] bit setting. When the amount of data stored in the FTDR register becomes the transmit FIFO threshold value or less, and the FSR.TDFE flag becomes 1. At that time, if the SCR.TIE bit is 1, a TXIF interrupt request is generated.

RTRG[1:0] Bits (Receive FIFO Threshold Setting Bits)

When the FTCR.RTRGS bit is 0, the receive FIFO threshold value is determined by the RTRG[1:0] bit setting. When the FTCR.RTRGS bit is 1, the receive FIFO threshold value is determined by the FTCR.RFTC[4:0] bit setting. When the amount of data stored in the FRDR register becomes the receive FIFO threshold value or more, the FSR.RDF flag becomes 1, and the FRDR register becomes read accessible. At that time, if the SCR.RIE bit is 1, an RXIF interrupt request is generated.

RSTRG[2:0] Bits (RTS# Output Threshold Setting Bits)

When the amount of receive data stored in the FRDR register becomes the RSTRG[2:0] bit value or higher, the RTS# signal becomes high. This bit is only valid when the MCE bit is set to 1 while in asynchronous mode.

41.2.11 FIFO Data Count Register (FDR)

Addresses: SCIFA8.FDR 000D 000Eh, SCIFA9.FDR 000D 002Eh, SCIFA10.FDR 000D 004Eh, SCIFA11.FDR 000D 006Eh

Bit	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	—	—	—	T[4:0]					—	—	—	R[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	R[4:0]	Receive FIFO Storage Data Count Flags	These flags indicate the amount of receive data stored in the FRDR register.	R
b7 to b5	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b12 to b8	T[4:0]	Transmit FIFO Storage Data Count Flags	These flags indicate the amount of untransmitted data stored in the FTDR register.	R
b15 to b13	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

The FDR register indicates the amount of data stored in the FTDR register and FRDR register.

R[4:0] Flags (Receive FIFO Storage Data Count Flags)

These flags indicate the amount of receive data stored in the FRDR register. 00h indicates there is no receive data, and 10h indicates the FRDR register is full.

T[4:0] Flags (Transmit FIFO Storage Data Count Flags)

These flags indicate the amount of non-transmitted data stored in the FTDR register. 00h indicates there is no transmit data, and 10h indicates the FTDR register is full.

41.2.12 Serial Port Register (SPTR)

Addresses: SCIFA8.SPTR 000D 0010h, SCIFA9.SPTR 000D 0030h, SCIFA10.SPTR 000D 0050h, SCIFA11.SPTR 000D 0070h

Bit	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	—	—	—	—	—	—	—	—	RTS2IO	RTS2DT	CTS2IO	CTS2DT	SCKIO	SCKDT	SPB2IO	SPB2DT
Value after reset	0	0	0	0	0	0	0	0	0	x	0	x	0	x	0	x

x: undefined

Bit	Symbol	Bit Name	Description	R/W
b0	SPB2DT	Serial Port Break Data Bit	Combine bits SPB2DT, SPB2IO, and the SCR.TE bit to control the TXD pin. Refer to Table 41.13 for details. Reading the SPB2DT bit returns the status of the RXD pin.	R/W
b1	SPB2IO	Serial Port Break I/O Bit		R/W
b2	SCKDT	SCK Port Data Bit	When the SMR.CM bit is 0 (asynchronous mode), combine bits SCKDT, SCKIO, and SCR.CKE[1:0] to control the SCK pin. Refer to Table 41.17 for details. Reading the SCKDT bit returns the status of the SCK pin.	R/W
b3	SCKIO	SCK Port I/O Bit		R/W
b4	CTS2DT	CTS# Port Data Select Bit	Combine bits CTS2DT, CTS2IO, and FCR.MCE to control the CTS# pin. Refer to Table 41.14 for details. Reading the CTS2DT bit returns the status of the CTS# pin.	R/W
b5	CTS2IO	CTS# Port Output Designated Bit		R/W
b6	RTS2DT	RTS# Port Data Select Bit	Combine bits RTS2DT, RTS2IO, and FCR.MCE to control the RTS# pin. Refer to Table 41.15 for details. Reading the RTS2DT bit returns the status of the RTS# pin.	R/W
b7	RTS2IO	RTS# Port Output Designated Bit		R/W
b15 to b8	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note: Do not use the read-modify-write instructions for this register. Use the MOV instruction instead.

The SPTR register is used for directly controlling the SCIFA I/O pins by software.

SPB2DT Bit (Serial Port Break Data Bit)

This bit designates the output level of the TXD pin when the SCR.TE bit is 0. Refer to Table 41.13 for details. When this bit is read, the status of the RXD pin is read regardless of the SPB2IO bit value. However, the RXD pin function must be selected in the MPC module.

SPB2IO Bit (Serial Port Break I/O Bit)

This bit designates the TXD pin input and output when the SCR.TE bit is 0. When directly controlling the TXD port by software, set the SPB2IO bit to 1 (output).

Table 41.13 Controlling the TXD Pin

SCR.TE Bit Setting	SPB2IO Bit Setting	SPB2DT Bit Setting	TXD Pin Status
0	0	0 or 1	Hi-Z
0	1	0	Low output
0	1	1	High output
1	0 or 1	0 or 1	Pin for outputting transmit data

SCKDT Bit (SCK Port Data Bit)

When the SMR.CM bit is 0 (asynchronous mode) and the SCR.CKE[1:0] bits are 00b, this bit selects the output level for the SCK pin. See Table 41.17 for details. When this bit is read, the SCK pin status can be read despite the SCKIO bit value. However, the SCK pin function must be selected in the MPC module.

SCKIO Bit (SCK Port I/O Bit)

When the SMR.CM bit is 0 (asynchronous mode) and the SCR.CKE[1:0] bits are 00b, this bit designates the SCK pin to input/output. When using this function, set the SCKIO bit to 1 (output).

CTS2DT Bit (CTS# Port Data Select Bit)

When the FCR.MCE bit is 0, this bit selects the output level for the CTS# pin. Refer to Table 41.14 for details. When this bit is read, the CTS# pin status can be read despite the CTS2IO bit value. However, the CTS# pin function must be

selected in the MPC module.

CTS2IO Bit (CTS# Port Output Designated Bit)

This bit designates the CTS# pin input and output when the SCR.TE bit is 0. When using this function, set the CTS2IO bit to 1 (output).

Table 41.14 Controlling the CTS# Pin

FCR.MCE Bit Setting	CTS2IO Bit Setting	CTS2DT Bit Setting	CTS# Pin Status
0	0	0 or 1	Hi-Z
0	1	0	Low output
0	1	1	High output
1	0 or 1	0 or 1	Input to the flow control logic

RTS2DT Bit (RTS# Port Data Select Bit)

This bit designates the output level of the RTS# pin when the FCR.MCE bit is 0. Refer to Table 41.15 for details. When this bit is read, the RTS# pin status can be read despite the RTS2IO bit value. However, the RTS# pin function must be selected in the MPC module.

RTS2IO Bit (RTS# Port Output Designated Bit)

This bit designates the RTS# pin input and output when the FCR.MCE bit is 0. When using this function, set the RTS2IO bit to 1 (output).

Table 41.15 Controlling the RTS# Pin

FCR.MCE Bit Setting	RTS2IO Bit Setting	RTS2DT Bit Setting	RTS# Pin Status
0	0	0 or 1	Hi-Z
0	1	0	Low output
0	1	1	High output
1	0 or 1	0 or 1	Sequence output in accordance with flow control logic

41.2.13 Line Status Register (LSR)

Addresses: SCIFA8.LSR 000D 0012h, SCIFA9.LSR 000D 0032h, SCIFA10.LSR 000D 0052h, SCIFA11.LSR 000D 0072h

Bit	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	—	—	—	—	PER[3:0]				—	—	FER[3:0]				—	ORER
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ORER	Overrun Error Flag	0: Overrun error did not occur *1 1: Overrun error occurred *2	R(/W) *3
b1	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b5 to b2	FER[3:0]	Framing Error Count Flags	Among the receive data that is stored in the FRDR register, these flags indicate the amount of data that is in the framing error state.	R
b7, b6	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b11 to b8	PER[3:0]	Parity Error Count Flags	Among the receive data that is stored in the FRDR register, these flags indicate the amount of data that is in the parity error state.	R
b15 to b12	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. The ORER flag does not become 0 even if the SCR.RE bit is set to 0.
Note 2. If an overrun error occurs, data already stored in the FRDR register is not overwritten, and the data that caused the error is discarded. After the ORER flag becomes 1, subsequent serial reception cannot continue.
Note 3. The ORER flag can be written only to clear the flag. To clear the flag, confirm that the flag is 1 before setting it to 0.

LSR is a 16-bit register. Flags PER[3:0] and FER[3:0] indicate the number of receive errors that occurred to the data stored in the FRDR register.

ORER Flag (Overrun Error Flag)

This flag indicates that reception stopped when an overrun error occurred during the receive operation.

— This flag becomes 1 under the following condition:

- While 16-byte data is being stored in the receive FIFO, the next serial reception is completed.

— This flag becomes 0 under the following condition:

- After confirming that the ORER flag is 1, it is set to 0.

Note: When the internal clock is selected while the SCIFA is in clock synchronous mode, the amount of receive data can be controlled, so no overrun occurs.

FER[3:0] Flags (Framing Error Count Flags)

When the FSR.ER flag is 1, these flags indicate the amount of data that is in the framing error state from among the receive data stored in the FRDR register. When the FRDR register receives 16 bytes of data and all of the received data is in the framing error state, the FER[3:0] flags become 0000b. When received data with a framing error is read from the FRDR register, the value of the FER[3:0] flags is decremented by one.

PER[3:0] Flags (Parity Error Count Flags)

When the FSR.ER flag is 1, these flags indicate the amount of data that is in the parity error state from among the receive data stored in the FRDR register. When the FRDR register receives 16 bytes of data and all of the received data is in the parity error state, the PER[3:0] flags become 0000b. When received data with a parity error is read from the FRDR register, the value of the PER[3:0] flags is decremented by one.

41.2.14 FIFO Trigger Control Register (FTCR)

Addresses: SCIFA8.FTCR 000D 0016h, SCIFA9.FTCR 000D 0036h, SCIFA10.FTCR 000D 0056h, SCIFA11.FTCR 000D 0076h

Bit	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	RTRGS	—	—	RFTC[4:0]					TTRGS	—	—	TFTC[4:0]				
Value after reset	0	0	0	1	1	1	1	1	0	0	0	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	TFTC[4:0]	Transmit FIFO Threshold Setting Bits	b4 b0 0 0 0 0 0: Transmit FIFO threshold value becomes 0 ⋮ 0 1 1 1 1: Transmit FIFO threshold value becomes 15 Do not set these bits to a value from 10000b to 11111b.	R/W
b6, b5	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b7	TTRGS	Transmit FIFO Threshold Select Bit	0: Transmit FIFO threshold value set in the FCR.TTRG[1:0] bits 1: Transmit FIFO threshold value set in the FTCR.TFTC[4:0]bits	R/W
b12 to b8	RFTC[4:0]	Receive FIFO Threshold Setting Bits	b12 b8 0 0 0 0 1: Receive FIFO threshold value becomes 1 ⋮ 0 1 1 1 1: Receive FIFO threshold value becomes 15 Do not set these bits to 00000b, or 10000b to 11111b.	R/W
b14, b13	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b15	RTRGS	Receive FIFO Threshold Select Bit	0: Receive FIFO threshold value set in the FCR.RTRG[1:0] bits 1: Receive FIFO threshold value set in the FTCR.RFTC[4:0] bits	R/W

The FTCR register is used for writing the threshold value to the transmit FIFO and reading the threshold value from the receive FIFO.

TFTC[4:0] Bits (Transmit FIFO Threshold Setting Bits)

These bits set the transmit FIFO threshold value when the TTRGS bit is 1. When the TTRGS bit is 0, the FCR.TTRG[1:0] bit value becomes valid, and the TFTC[4:0] bit value becomes invalid. When the amount of transmit data stored in the FTDR register (transmit FIFO) becomes less than or equal to the value set in the TFTC[4:0] bits, the FSR.TDFE flag becomes 1, and a write access is requested for transmit data. At this point, if the SCR.TIE bit is 1, a TXIF interrupt request is generated.

RFTC[4:0] Bits (Receive FIFO Threshold Setting Bits)

These bits set the receive FIFO threshold value when the RTRGS bit is 1. When the RTRGS bit is 0, the FCR.RTRG[1:0] bit value becomes valid, and the RFTC[4:0] bit value becomes invalid. When the amount of receive data stored in the FRDR register (receive FIFO) becomes equal to or more than the value set in the RFTC[4:0] bits, the FSR.RDF flag becomes 1, and a read access is requested for receive data. At this point, if the SCR.RIE bit is 1, an RXIF interrupt request is generated.

41.2.15 Serial Extended Mode Register (SEMR)

Addresses SCIFA8.SEMR 000D 0014h, SCIFA9.SEMR 000D 0034h, SCIFA10.SEMR 000D 0054h, SCIFA11.SEMR 000D 0074h

Bit	b7	b6	b5	b4	b3	b2	b1	b0
Symbol	BGDM	—	BRME	MDDRS	DIR	NFEN	—	ABCS0
Value after reset	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ABCS0	Asynchronous Mode Base Clock Select Bit	0: 16 cycles of the baud rate generator's output is a 1-bit period 1: 8 cycles of the baud rate generator's output is a 1-bit period	R/W
b1	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b2	NFEN	Noise Canceller Control Bit	0: RXD pin noise canceller disabled 1: RXD pin noise canceller enabled	R/W
b3	DIR	Data Transfer Direction Select Bit	0: Data transfer with LSB first 1: Data transfer with MSB first	R/W
b4	MDDRS	Modulation Register Select Bit	0: BRR register is accessible 1: MDDR register is accessible	R/W
b5	BRME	Bit Rate Modulation Control Bit	0: Bit rate modulation function disabled 1: Bit rate modulation function enabled	R/W
b6	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b7	BGDM	Baud Rate Generator Operating Speed Select Bit	0: In baud rate generator normal mode, the baud rate generator operates on a clock signal produced by the clock source divided by 2 1: In baud rate generator double speed mode, the baud rate generator operates on the clock signal produced by the clock source (no division)	R/W

The SEMR register controls SCIFA operation.

ABCS0 Bit (Asynchronous Mode Base Clock Select Bit)

While in asynchronous mode, set this bit to select the correspondence between the base clock (baud rate generator output) and a 1-bit period. The ABCS0 bit is only valid in asynchronous mode.

NFEN Bit (Noise Canceller Control Bit)

Set this bit to enable and disable the noise cancelling function on input signals from the RXD pin. This function can only be enabled in asynchronous mode. Refer to section 41.3.5, Noise Cancellation for details. Set this bit to 0 in clock synchronous mode.

DIR Bit (Data Transfer Direction Select Bit)

Set this bit to select the bit order (LSB first or MSB first) of transmit/receive data. This bit is only valid when the character length is 8 bits.

MDDRS Bit (Modulation Register Select Bit)

The BRR register and MDDR register are allocated to the same address. Set this bit to select which register is accessed when accessing that address.

BGDM Bit (Baud Rate Generator Operating Speed Select Bit)

Set this bit to select the operating mode for the baud rate generator. When the BGDM bit is 1, the baud rate generator operates in double speed mode. The baud rate generator double speed mode is only enabled when the SCIFA is in asynchronous mode and bits SCR.CKE[1:0] are 00b. Set the BGDM bit to 0 when bits SCR.CKE[1:0] are 01b, 10b, or 11b, and when in clock synchronous mode.

41.3 Operation

The SCIFA can be operated in asynchronous mode or clock synchronous mode.

41.3.1 Operating the SCIFA in Asynchronous Mode

Figure 41.2 shows the general format for asynchronous serial communication. In asynchronous serial communication, the communication line is normally in the “marked” state (high). The SCIFA monitors the communication line. When the line becomes “space” (low), that is regarded as the start bit, and the SCIFA starts serial communication. Full duplex communication is available as the SCIFA’s transmitter and receiver operate independently. As the transmit buffer and receive buffer are each configured as 16-stage FIFO buffers, data can be written and read during transmission or reception, and transmission and reception can be set to continuous.
In asynchronous mode, the SCIFA synchronizes the receive data and base clock at the start bit’s falling edge. When bits SEMR.ABCS0 and SEMR.BGDM are 0, the base clock of the SCIFA becomes 16 times the frequency of a 1-bit period, and each bit of the receive data is sampled at the eighth clock, so receive data is acquired in the middle of every bit. When either the SEMR.ABCS0 bit or SEMR.BGDM bit is 1, the base clock of the SCIFA becomes eight times the frequency of a 1-bit period, and each bit of the receive data is sampled at the fourth clock, so receive data is acquired in the middle of every bit.

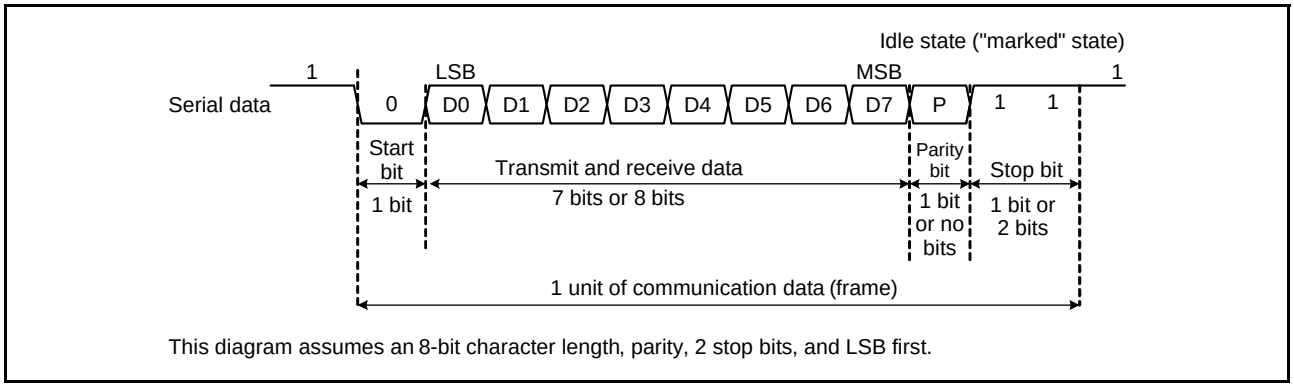

Figure 41.2 Data Format for Asynchronous Serial Communication

41.3.1.1 Serial Transmit/Receive Data Formats in Asynchronous Mode

Table 41.16 lists the formats that can be set in asynchronous mode. There are eight formats available, and the format can be selected by setting the SMR register.

Table 41.16 Serial Transmit/Receive Formats in Asynchronous Mode

SMR Register Setting				Serial Transmit/Receive Format and Frame Length											
CM	CHR	PE	STOP	1	2	3	4	5	6	7	8	9	10	11	12
0	0	0	0	Start	8-bit data								Stop		
			1	Start	8-bit data								Stop	Stop	
		1	0	Start	8-bit data								Parity	Stop	
			1	Start	8-bit data								Parity	Stop	Stop
	1	0	0	Start	7-bit data							Stop			
			1	Start	7-bit data							Stop	Stop		
		1	0	Start	7-bit data							Parity	Stop		
			1	Start	7-bit data							Parity	Stop	Stop	

41.3.1.2 Sampling Timing of Receive Data and the Reception Margin While in Asynchronous Mode

The SCIFA operates with a base clock frequency of eight times or 16 times the bit rate. The SCIFA imports receive data at the rising edge of the base clock's fourth clock or eighth clock. This timing is shown in Figure 41.3.

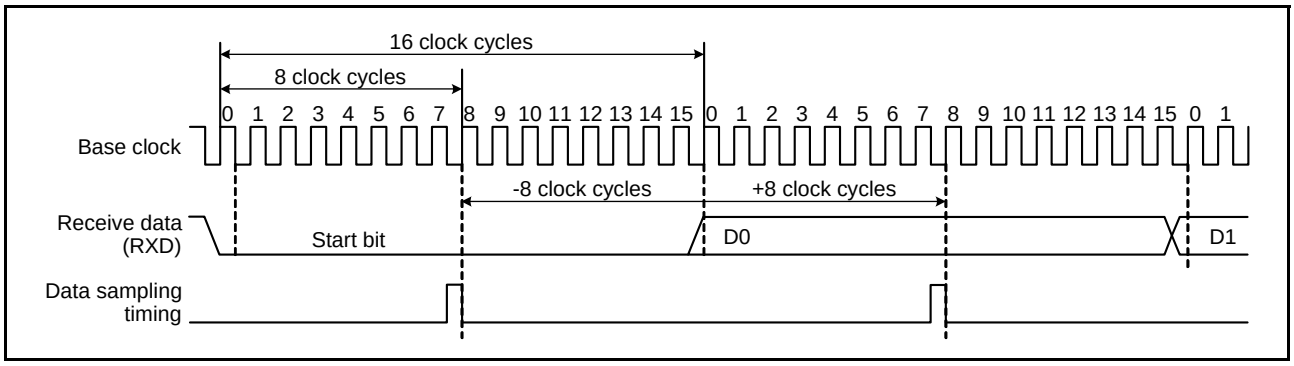

Figure 41.3 Sampling Timing and Reception Margin of Receive Data in Asynchronous Mode

The reception margin of receive data in asynchronous mode can be calculated using the following formula.

$$M = \left(0.5 - \frac{1}{2n} - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right) \times 100[\%]$$

M: Reception margin [%]
N: Clock frequency ratio of the bit rate (N = 8 or 16)
D: Clock duty (D = 0 to 1.0)
L: Frame length (L = 9 to 12)
F: Absolute value of the difference in the clock frequencies
Assuming N = 16, F = 0, and D = 0.5, the following formula gives the reception margin as 46.875%.

$$M = \left(0.5 - \frac{1}{2 \times 16} - 0 - 0\right) \times 100$$

$$= 46.875$$

However, as this is a theoretical value, allow a 20% to 30% margin in system designs.

41.3.1.3 Clocks

The clock source for asynchronous mode can be selected from the internal clock generated by the baud rate generator, or the external clock input from the SCK pin. Refer to Table 41.17 for details on the clock source and register settings while the SCIFA is in asynchronous mode.
When inputting an external clock from the SCK pin, input a clock that has a frequency that is eight times or 16 times the bit rate used.
When operating the SCIFA with the internal clock, the clock can be output from the SCK pin. The frequency of the clock being output at this time is eight times or 16 times the bit rate.

Table 41.17 Setting Values to Registers in Clock Asynchronous Mode and Clock

SMR	SCR		SPTR		Clock Source	SCK Pin Function
CM	CKE[1]	CKE[0]	SCKIO	SCKDT		
0	0	0	0	0 or 1	Internal	Input pin (input signal is invalid)
			1	0		SCK pin outputs a low
			1	1		SCK pin outputs a high
		1	0 or 1	0 or 1		Outputs a clock with frequency that is 8 times or 16 times *1 the bit rate
	1	0	0 or 1	0 or 1	External	Inputs a clock with frequency that is 8 times or 16 times *1 the bit rate
		1	0 or 1	0 or 1	Do not set this value.	

Note 1. When using a clock that is 16 times the bit rate, set bits SEMR.ABCS0 and BGDM to 0. When using a clock that is eight times the bit rate, set the ABCS0 bit to 1 and set the BGDM bit to 0.

41.3.1.4 SCIFA Initialization in Asynchronous Mode

Figure 41.4 shows an example of the initialization when SCIFA is in asynchronous mode.
Set the SCR.TE and RE bits to 0 before initializing SCIFA. Also, set the SCR.TE and RE bits to 0 before changing the operating mode and communications format of SCIFA. When changing the SCIFA operating mode and communications format, follow the procedure in Figure 41.4.
The TSR register is initialized when the SCR.TE bit is set to 0. However, even if the SCR.RE bit is set to 0, the FSR.RDF, PER, FER flags, the LSR.ORER flag, and the FRDR register are not initialized, and their content is retained. To continue data reception, the FSR.RDF, PER, FER flags, the LSR.ORER flag, and the FRDR register must be initialized.
Typically, in order to set the SCR.TE bit to 0 to stop transmission, the user must first confirm that the FSR.TEND flag is 1 (transmission completed), but transmission can be stopped while data is being transmitted. In this case, the TXD pin status is dependent on the values of the SPTR.SPB2IO and SPB2DT bits. Also, after transmission is stopped, if transmission is restarted, set the FCR.TFRST bit to 1 and then reset the FTDR register.

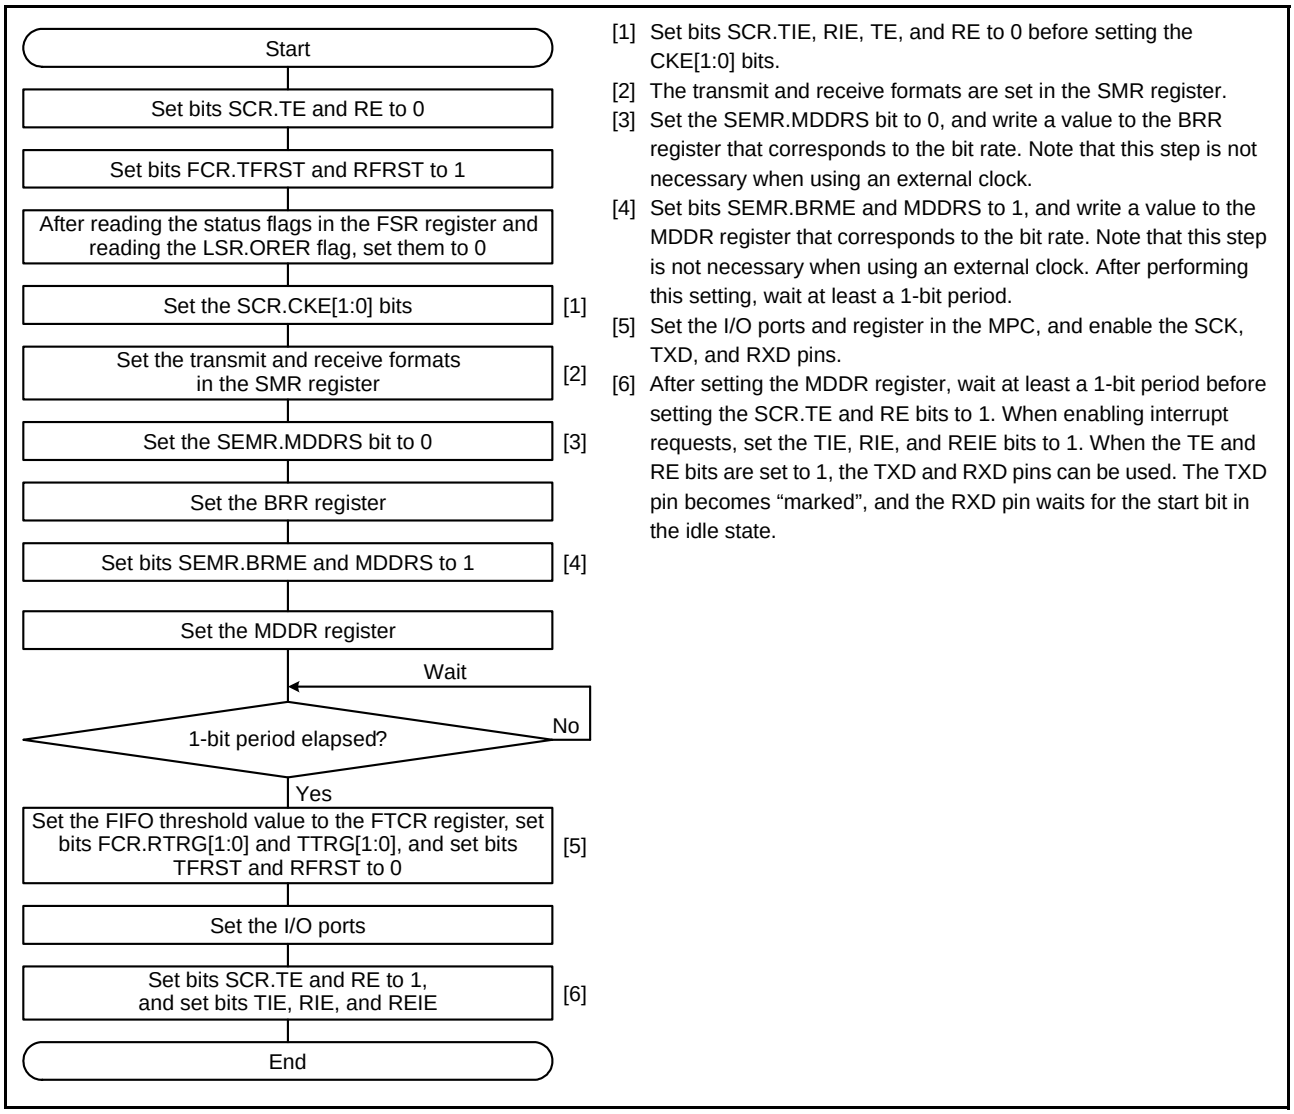

Figure 41.4 SCIFA Initialization in Asynchronous Mode

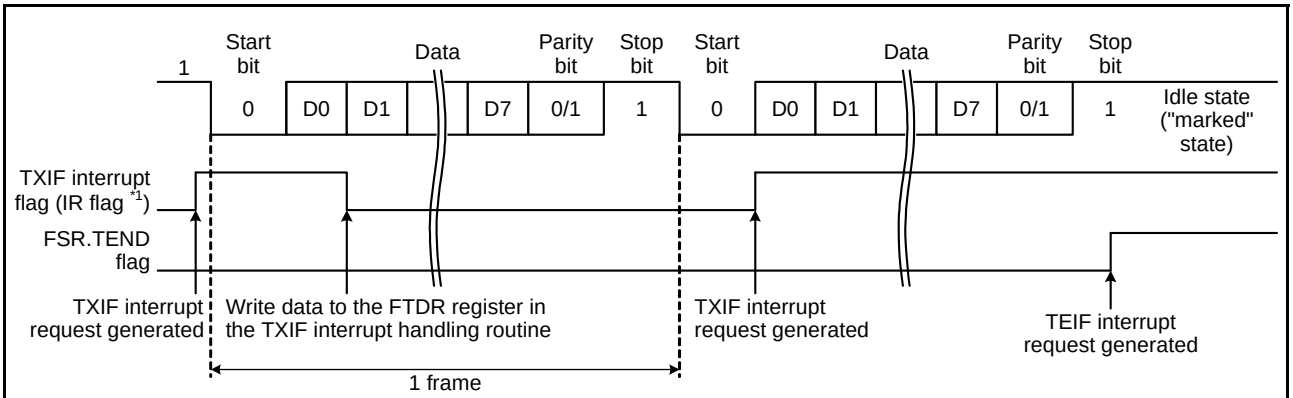
41.3.1.5 Transmitting Serial Data in Asynchronous Mode

This section describes data transmission in asynchronous mode.

1. When data is written to the FTDR register, the SCIFA transfers data from the FTDR register to the TSR register. Before writing transmit data to the FTDR register, confirm the FSR.TDFE flag is 1. The amount of transmit data bytes that can be written is calculated as (16 - FDR.T[4:0]).
2. When data transfer from the FTDR register to the TSR register starts, the SCIFA continuously transmits data until data written to the FTDR register is gone. When the amount of data written in the FTDR register is less than or equal to the transmit FIFO threshold value *1, the FSR.TDFE flag becomes 1. At this time, if the SCR.TIE bit is 1, the SCIFA generates the TXIF interrupt request.
3. The TXD pin outputs the start bit, transmit data, parity bit (when the SMR.PE bit is 1), and the stop bit (in that order).
4. When the stop bit is output, the SCIFA checks if there is any untransmitted data in the FTDR register. If the FTDR register contains data, it is transferred to the TSR register, and after the stop bit is output, the next frame of data starts transmitting. If there is no data in the FTDR register, set the FSR.TEND flag to 1 and output the stop bit before configuring the TXD pin to the “marked” state.
5. When the FCR.MCE bit is 1 (hardware flow control is enabled), the SCIFA starts or stops data transmission according to the value being input to the CTS# pin. If the CTS# pin becomes high during data transmission, when that frame is done transmitting, stop transmission, and configure the TXD pin to the “marked” state. If the CTS# pin becomes low while data transmission is stopped, SCIFA starts data transmission. Refer to Figure 41.5 for details on SCIFA operation when not using hardware flow control, and refer to Figure 41.6 for details on SCIFA operation when using hardware flow control.

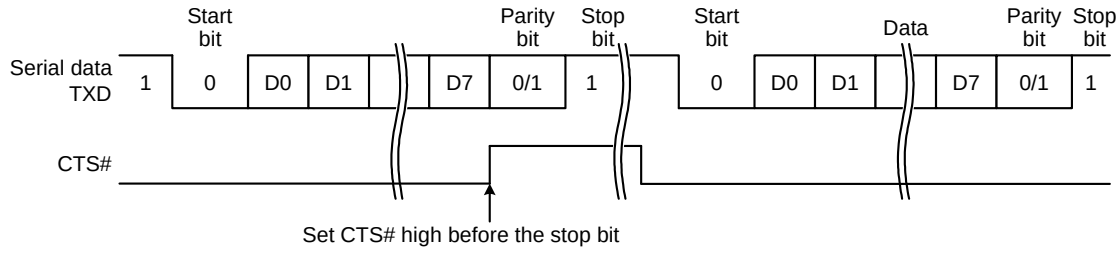
Note 1. When the FTCR.TTRGS bit is 0, the FCR.TTRG[1:0] bits determine the transmit FIFO threshold value; when the FTCR.TTRGS bit is 1, the FTCR.TFTC[4:0] bits determine the transmit FIFO threshold value.



The above diagram assumes 8-bit data, parity, 1 stop bit, LSB first, and no hardware flow control.

Note 1: Refer to the section 15. Interrupt Controller (ICUA) for the corresponding interrupt number.

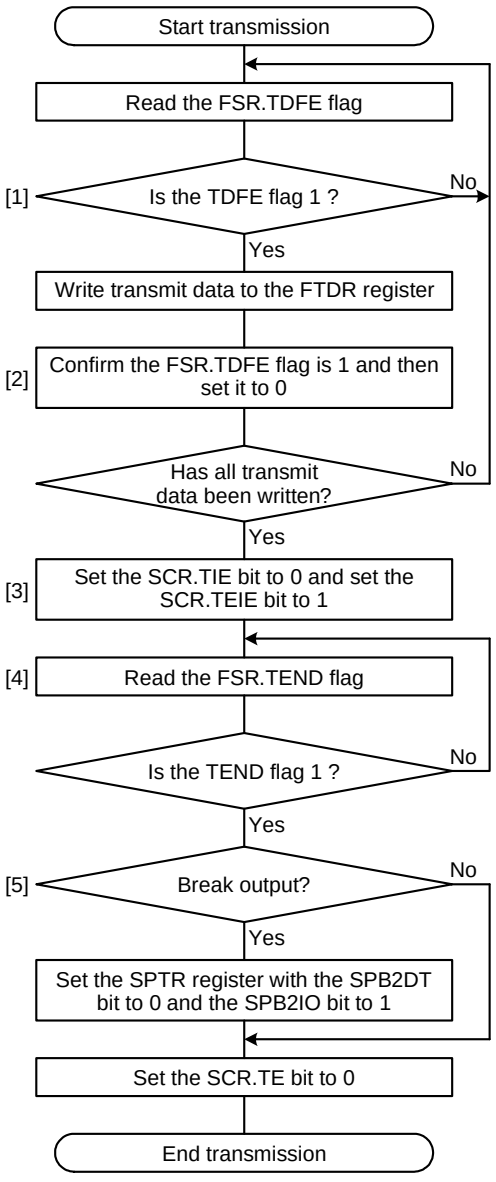
Figure 41.5 SCIFA Operation When Transmitting Data (1/2)



The above diagram assumes 8-bit data, parity, 1 stop bit, LSB first, and hardware flow control.

Figure 41.6 SCIFA Operation When Transmitting Data (2/2)

Figure 41.7 shows an example of Transmitting Serial Data in Asynchronous Mode.



[1] Confirm the status of the SCIFA and write the transmit data:
Read the FSR register, confirm that the TDFE flag is 1, then write transmit data to the FTDR register. The amount of data that can be write accesses is (16 – FDR.T[4:0]). The TXIF interrupt request can be used to determine if the TDFE flag has changed from 0 to 1.

[2] Procedure to continue serial transmission:
To continue serial transmission, confirm that the FSR.TDFE flag is 1, and then set it to 0. When using DMAC or DTC to write transmit data to the FTDR register, the TDFE flag automatically becomes 0, making this step unnecessary (do not manipulate the TDFE flag).

[3] Procedure to end serial transmission when using the TXIF interrupt or TEIF interrupt:
After writing the final transmit data to the FTDR register, set the SCR.TIE bit to 0 and set the SCR.TEIE bit to 1. When using the DMAC or DTC to write transmit data to the FTDR register, configure settings to enable the transfer end interrupt. When the last transmit data is written to the FTDR register, generate the CPU interrupt request, and rewrite the TIE and TEIE bit in the CPU interrupt handling. The procedure is not necessary when not using the TXIF interrupt request or TEIF interrupt request.

[4] Confirming serial transmission has ended:
Read the FSR register and confirm the TEND flag became 1. The TEIF interrupt request can be used to confirm that the TEND flag became 1.

[5] Outputting a break during serial transmission:
When sending a break during serial transmission, set the SPTR register with an immediate value of 0 for the SPB2DT bit and 1 for the SPB2IO bit before setting the SCR.TE bit to 0.*1

Note 1. The SPTR register cannot be rewritten in 1-bit units and requires 16-bit units instead.

Figure 41.7 Transmitting Serial Data in Asynchronous Mode

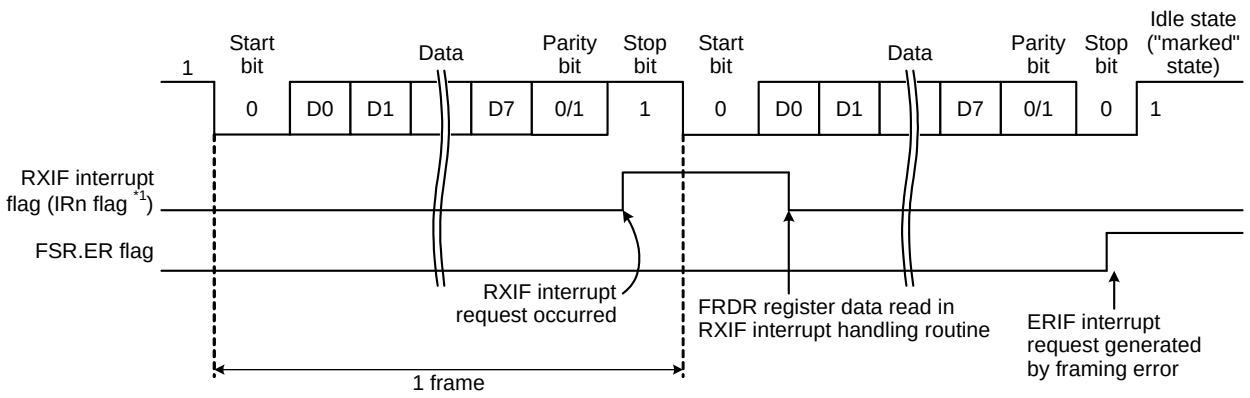
41.3.1.6 Receiving Serial Data in Asynchronous Mode

This section describes data reception in asynchronous mode.

1. When the SCIFA detects a start bit, reception starts, and the receive data is stored in the RSR register.
2. The SCIFA confirms the status of the flags in the FSR and LSR registers, confirms that a receive error (parity error, overrun error, or framing error) has not occurred, and also confirms that a break signal has not been detected. When these items have been confirmed, the SCIFA transfers the received data from the RSR register to the FRDR register.

Note: Received data is stored in the FRDR register even if a parity error or framing error occurs.

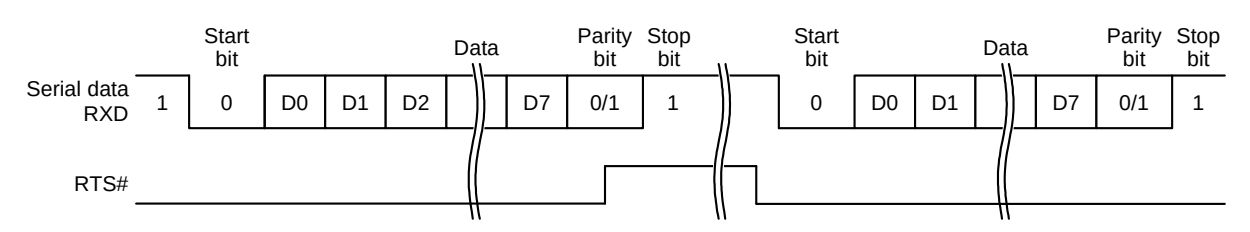
3. If the amount of data stored in the FRDR register is equal to or greater than the receive FIFO threshold value, the FSR.RDF flag becomes 1. At this time, if the SCR.RIE bit is 1, the SCIFA generates the RXIF interrupt request.
4. When the data stored in the FRDR register is less than the receive FIFO threshold value, if the next data is not received even after 15 ETUs elapse after the last stop bit in the received data, the FSR.DR flag becomes 1. At this time, if the SCR.RIE bit is 1, the SCIFA generates the DRIF interrupt request.
5. When the FSR.RE flag becomes 1, if the SCR.RIE bit or REIE bit is 1, the SCIFA generates the ERIF interrupt request. Also, when the FSR.BRK flag or LSR.ORER flag becomes 1, if the SCR.RIE bit or REIE bit is 1, the SCIFA generates the BRIF interrupt request.
6. When the FCR.MCE bit is 1 (hardware flow control enabled), if there is space in the FRDR register, the SCIFA outputs a low from the RTS# pin. When the RTS# pin is high, if the amount of data stored in the FRDR is equal to or greater than the FCR.RSTRG[2:0] bit setting, waiting for transmission is indicated. Refer to Figure 41.8 for details on SCIFA operation when not using hardware flow control, and refer to Figure 41.9 for details on SCIFA operation when using hardware flow control.



The above diagram assumes 8-bit data, parity, 1 stop bit, LSB first, and no hardware flow control.

Note 1: Refer to the section 15. Interrupt Controller (ICUA) for the corresponding interrupt number.

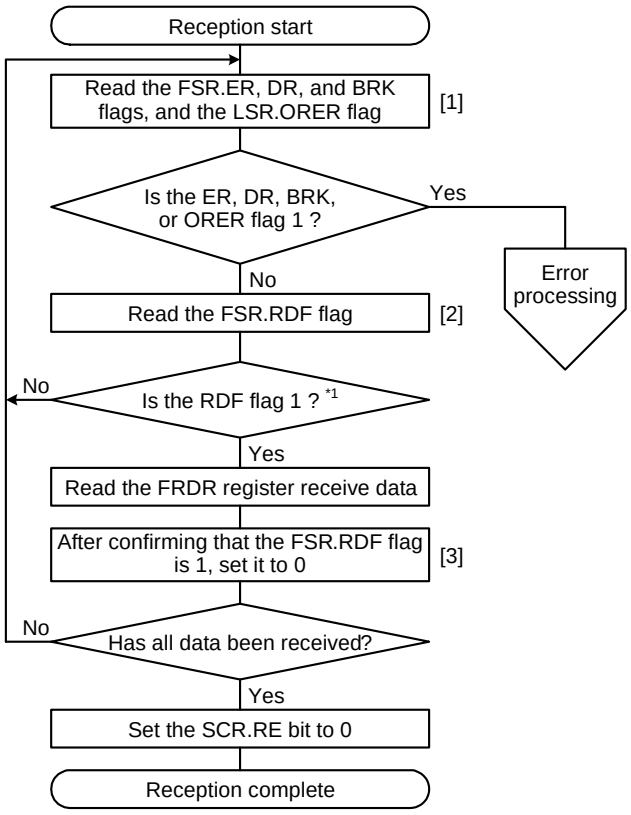
Figure 41.8 SCIFA Operation When Receiving Data (1/2)



The above diagram assumes 8-bit data, parity, 1 stop bit, LSB first, and hardware flow control.

Figure 41.9 SCIFA Operation When Receiving Data (2/2)

Figure 41.10 shows Receiving Serial Data in Asynchronous Mode (1/2).



[1] Receive error processing and break detection:
When a receive error occurs, read flags FSR.ER, DR, BRK, and the LSR.ORER flag to determine the type of error. After performing predetermined error processing, set the ER, DR, BRK, and ORER flags to 0. When a framing error occurs, the break can be detected by reading the RXD pin value. BRIF, ERIF, or DRIF interrupt requests indicate that the corresponding error has occurred.

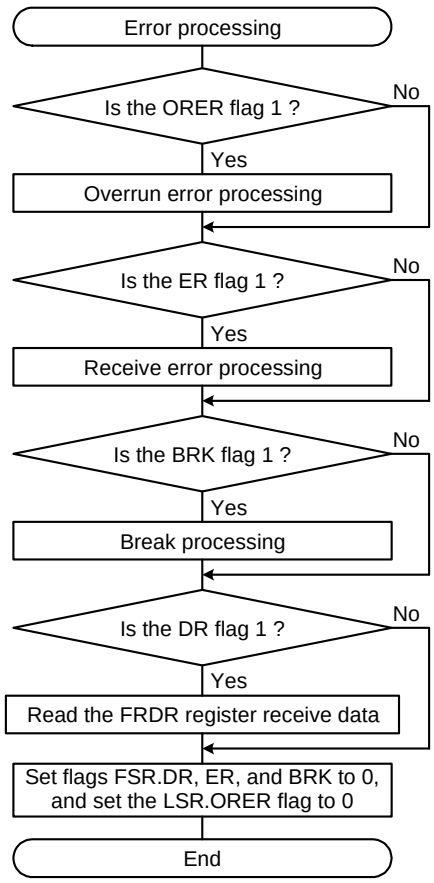
[2] Confirm the status of the SCIFA and read the receive data:
After reading the FSR register to confirm that the RDF flag is 1, read data stored in the FRDR register for at least the receive FIFO threshold value. The number of bytes of receive data that can be read can be confirmed by reading the FDR.R[4:0] flags. An RXIF interrupt request can be used to determine when the RDF flag changes from 0 to 1.

[3] Procedure to continue serial reception when using the CPU to read data from the FRDR register:
When continuing serial reception, after confirming that the FSR.RDF flag is 1, set it to 0. When triggering DMAC or DTC to read receive data from the FRDR register, the RDF flag automatically becomes 0, making this procedure unnecessary (do not manipulate the RDF flag).

Note 1. Set the amount of receive data to an integral multiple of the receive FIFO threshold value. When the amount of receive data is not set to an integral multiple of the receive FIFO threshold value, the program returns to step [1] and enters an endless loop, so timeout processing should be performed using an alternate timer, etc.

Figure 41.10 Receiving Serial Data in Asynchronous Mode (1/2)

Figure 41.11 shows Receiving Serial Data in Asynchronous Mode (2/2).



Note 1. Read the FSR.FER and PER flags to check if a framing error or parity error occurred in the receive data read from the FRDR register.

Note 2. When a break signal is received, if the BRK flag is 1, the receive data is not transferred to the FRDR register. Note that the last data in the FRDR register is 00h, and break data that includes a framing error is stored to the FRDR register.

Figure 41.11 Receiving Serial Data in Asynchronous Mode (2/2)

41.3.2 SCIFA Operation in Clock Synchronous Mode

Figure 41.12 shows a general format clock of the synchronous serial communication. In clock synchronous mode, data is transmitted and received during the period with the clock pulse. When transmitting data in clock synchronous mode, the SCIFA outputs data during the period from one falling edge to the next falling edge of the synchronous clock. After transmitting the 8th bit, the SCIFA holds the communication line at the value of the last bit output. When receiving data in clock synchronous mode, the SCIFA receives data in synchronization with the rising edge. The SCIFA's transmitter and receiver operate independently meaning full duplex communication is possible over the shared synchronous clock. Also, the transmit buffer and receive buffer are configured with a 16-stage FIFO buffer, meaning data can be read and written during transmission/reception, and continuous transmission/reception is possible.

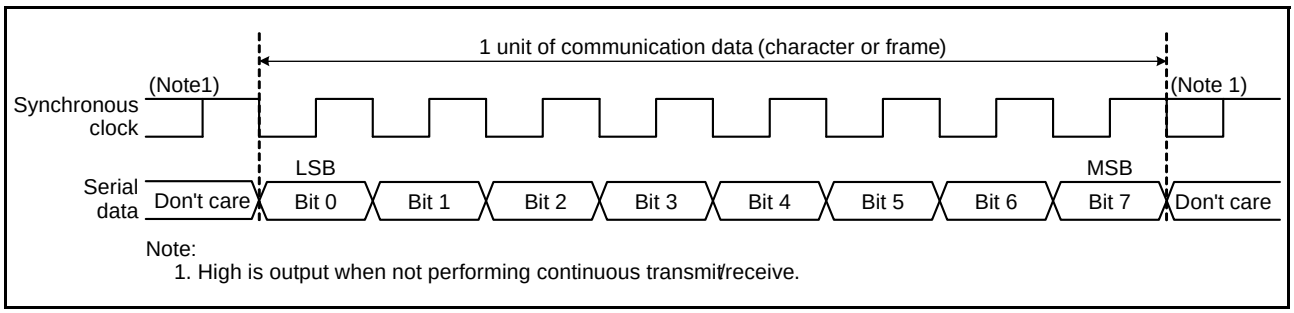


Figure 41.12 Data Format When Using Clock Synchronous Communication With LSB First

41.3.2.1 Format of Transmit/Receive Data in Clock Synchronous Mode

In clock synchronous mode, only 8 bits can be transmitted or received in 1 frame of data. The parity bit cannot be added.

41.3.2.2 Clocks

While in clock synchronous mode, the clock source is selectable from the internal clock generated by the baud rate generator, or the external clock input from the SCK pin.
Refer to Table 41.18 for information on the clock source and register setting values while in clock synchronous mode. The synchronous clock outputs eight pulses in one frame of data transmission and reception, and the synchronous clock is fixed high when data is not being transmitted or received. During a receive operation only, if the internal clock is selected as the clock source, while the SCR.RE bit is 1, a clock pulse is output until the amount of data in the receive FIFO reaches the receive FIFO threshold value.

Table 41.18 Clock Source and Register Settings in Clock Synchronous Mode

SMR	SCR		SPTR		Clock Source	SCK Pin Function
CM	CKE[1]	CKE[0]	SCKIO	SCKDT		
1	0	0 or 1	0 or 1	0 or 1	Internal	Outputs a synchronous clock
	1	0	0 or 1	0 or 1	External	Inputs a synchronous clock
		1	0 or 1	0 or 1	Do not set this value.	

41.3.2.3 SCIFA Initialization in Clock Synchronous Mode

Figure 41.13 shows SCIFA Initialization in Clock Synchronous Mode.

Before starting data transmission and reception, set bits SCR.TE and RE to 0, and initialize the SCIFA using the procedure in the figure below. When the SCR.TE bit is set to 0, the TSR register is initialized. However, even if the SCR.RE bit is set to 0, the FSR.RDF flag, LSR.ORER flag, and FRDR register are not initialized, and their values are retained. To continue data reception, the FSR.RDF flag, LSR.ORER flag, and FRDR register must be initialized.

If the SCIFA is not initialized as shown in the following figure, and the operating mode is changed from asynchronous mode to clock synchronous mode, confirm that the ORER, PER, and FER flags are set to 0.

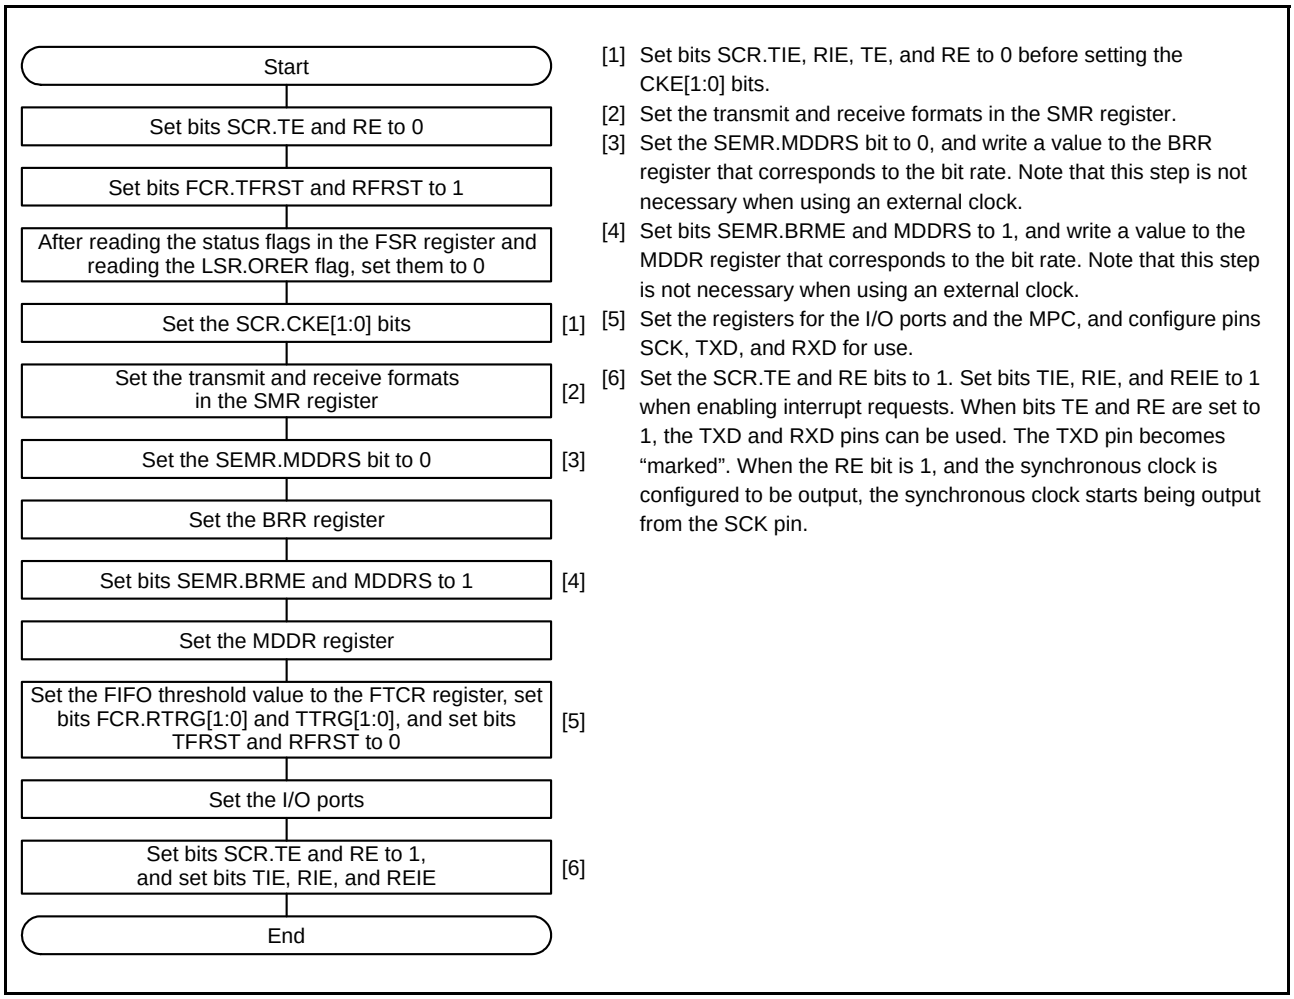

Figure 41.13 SCIFA Initialization in Clock Synchronous Mode

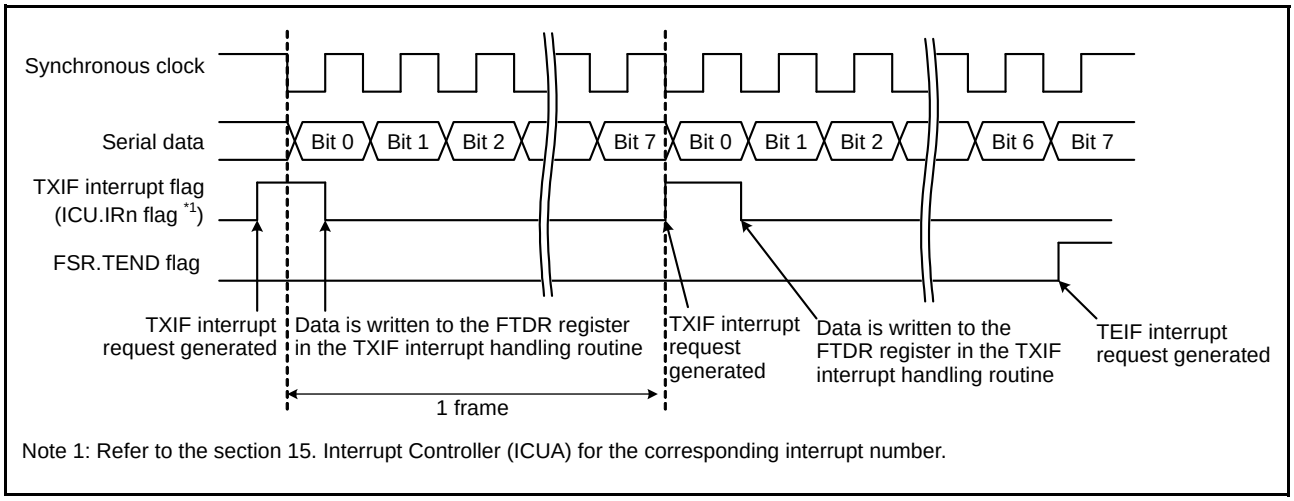
41.3.2.4 Transmitting Serial Data in Clock Synchronous Mode

This sections describes transmitting serial data in clock synchronous mode.

1. When data is written to the FTDR register, the SCIFA transfers data from the FTDR register to the TSR register. Confirm that the FSR.TDFE flag is 1 before writing transmit data to the FTDR register. The amount of transmit data that can be written to the FTDR register is calculated as (16 - FDR.T[4:0]).
2. When the data transfer from the FTDR register to the TSR register starts, the SCIFA continues transmitting data until data written to the FTDR register is gone. If the amount of data written to the FTDR register is less than or equal to the transmit FIFO threshold value *1, the FSR.TDFE flag becomes 1. At this point, if the SCR.TIE bit is 1, the SCIFA generates the TXIF interrupt request.
3. When a clock is output from the SCK pin, the SCIFA outputs eight pulses of the synchronous clock. When a clock is input to the SCK pin, the SCIFA outputs data synchronous to the input clock.
4. The SCIFA checks whether there is any untransmitted data in the FTDR register when the last bit is transmitted. If there is untransmitted data in the FTDR register, the data is transferred to the TSR register, and transmission of the next frame of data starts. If there is no untransmitted data in the FTDR register, the FSR.TEND flag becomes 1, and after the last bit is transmitted, the TXD pin retains the output level of the last bit. When transmission is complete, the SCK pin becomes “marked”.

Note 1. When the FTCR.TTRGS bit is 0, the transmit FIFO threshold value is determined by the FCR.TTRG[1:0] bits; when the FTCR.TTRGS bit is 1, the transmit FIFO threshold value is determined by the FTCR.TFTC[4:0] bits.

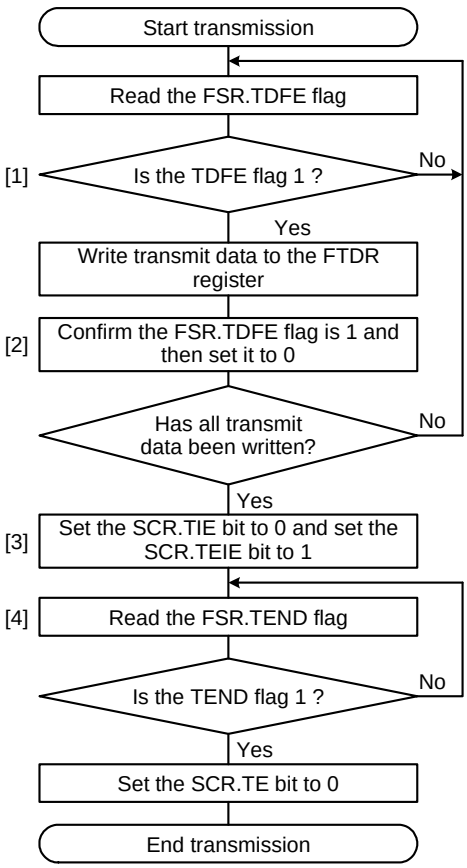
Figure 41.14 shows SCIFA Operation When Transmitting Data With LSB First.



Note 1: Refer to the section 15. Interrupt Controller (ICUA) for the corresponding interrupt number.

Figure 41.14 SCIFA Operation When Transmitting Data With LSB First

Figure 41.15 shows an example of Transmitting Serial Data in Clock Synchronous Mode.



[1] Confirm the status of the SCIFA and write transmit data:
Read the FSR register, confirm that the TDFE flag is 1, and then write the transmit data to the FTDR register. The amount of transmit data that can be written to the FTDR is calculated by (16 - FDR.T[4:0]). The TXIF interrupt request can be used to confirm that the TDFE flag changed from 0 to 1.

[2] Procedure to continue serial transmission when using the CPU to write to the FTDR register:
When continuing serial transmission, confirm that the FSR.TDFE flag is 1 and then set it to 0. When the DMAC or DTC is triggered to write transmit data to the FTDR register, the TDFE flag automatically becomes 0, making this step unnecessary (do not manipulate the TDFE flag).

[3] Procedure to end serial transmission when using the TXIF interrupt or TEIF interrupt:
When the last byte of transmit data is written to the FTDR register, set the SCR.TIE bit to 0 and set the SCR.TEIE bit to 1. When the DMAC or DTC is triggered to write transmit data to the FTDR register, enable the transfer end interrupt, and when the last byte of transmit data is written to the FTDR register, generate the CPU interrupt request, and rewrite bits TIE and TEIE in the CPU interrupt handling. This step is not necessary when the TXIF interrupt request and TEIF interrupt request are not used.

[4] Confirming serial transmission is complete:
Read the FSR register and confirm that the TEND flag is 1. The TEIF interrupt request can be used to confirm that the TEND flag is 1.

In step [1], the FDR.T[4:0] flags (amount of untransmitted data in the FTDR register) can be used to check the number of bytes of data that can be written to the FTDR register.

Figure 41.15 Transmitting Serial Data in Clock Synchronous Mode

41.3.2.5 Receiving Serial Data in Clock Synchronous Mode

Figure 41.16 shows an example of receiving data in clock synchronous mode.

1. The SCIFA synchronizes with the input or output of the synchronous clock, and writes receive data to the RSR register.
2. The SCIFA confirms the value of the LSR.ORER flag is 0, and confirms that the FRDR register has space available. After those items have been confirmed, the SCIFA sets the FSR.RDF flag to 1, and transfers receive data from the RSR register to the FRDR register.
3. When the amount of receive data in the FRDR register is equal to or greater than the receive FIFO threshold value, the FSR.RDF flag becomes 1. At this time, if the SCR.RIE bit is 1, the SCIFA generates the RXIF interrupt request. Also, when the LSR.ORER flag becomes 1, if the SCR.RIE bit or REIE bit is set to 1, the SCIFA generates the BRIF interrupt request.

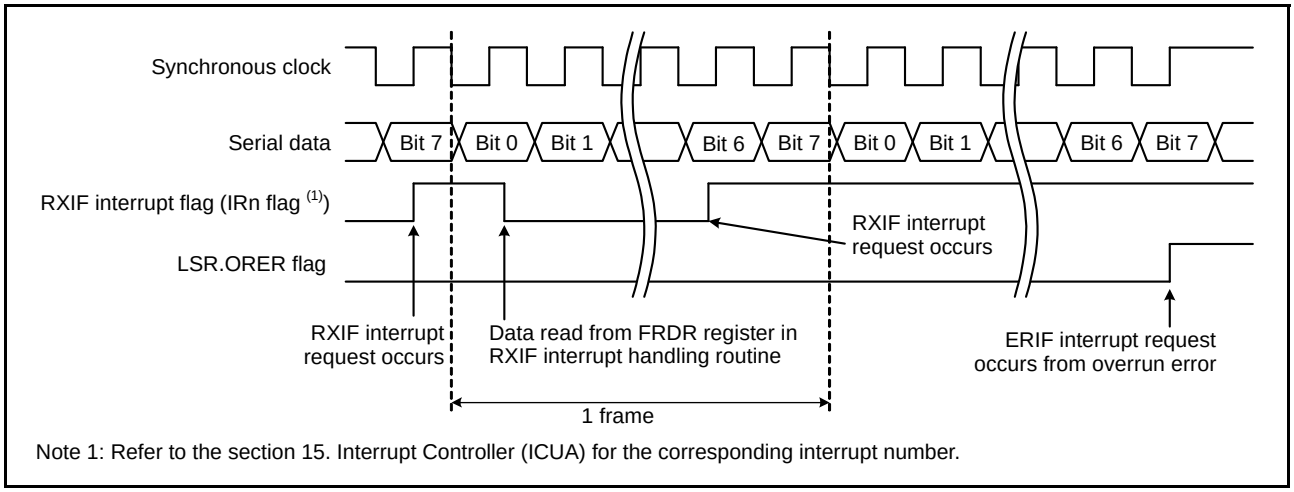


Figure 41.16 SCIFA Operation When Receiving Data With the LSB First

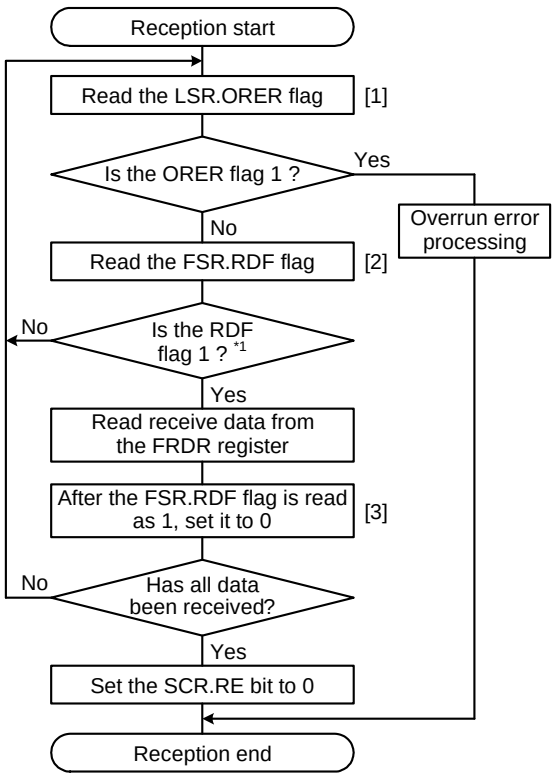
Figure 41.17 shows an example of Receiving Serial Data in Clock Synchronous Mode.



[1] Receive error processing:
When a receive error occurs, read the LSR.ORER flag, after performing predetermined error processing, set the ORER flag to 0. Data reception cannot be restarted while the ORER flag is 1. The BRIF interrupt request can be used to confirm that the ORER flag became 1.

[2] Confirm the status of SCIFA and read receive data:
Read the FSR register, confirm that the RDF flag is 1, and then read at least the receive FIFO threshold value of receive data stored in the FRDR register. Read the FDR.R[4:0] flags to confirm how much receive data can be read. The RXIF interrupt request can be used to confirm that the RDF flag changed from 0 to 1.

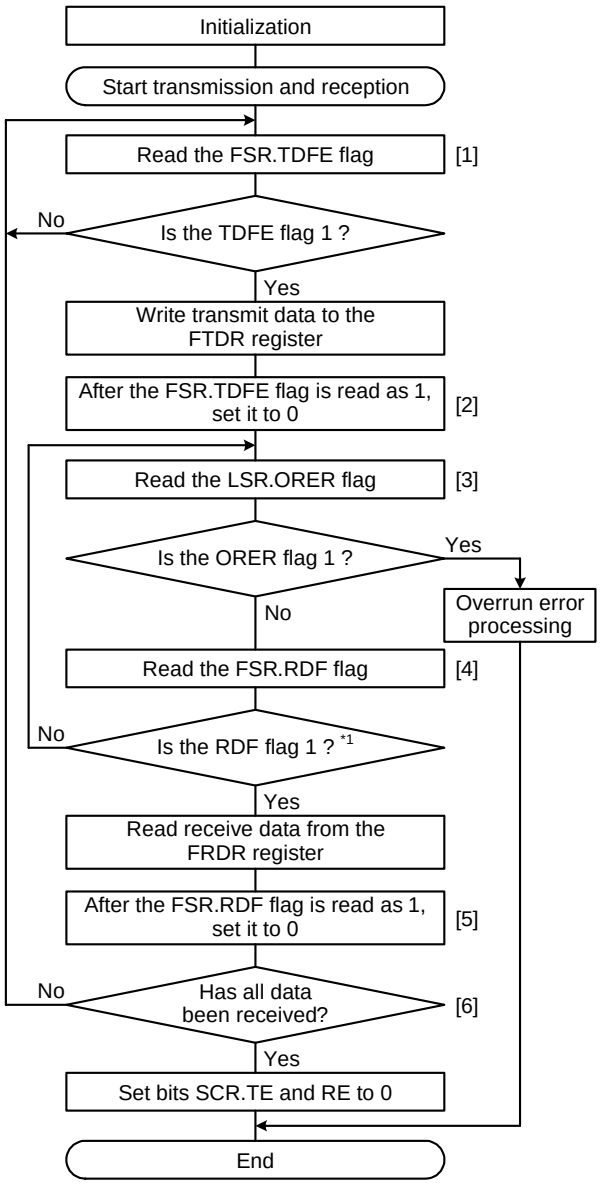
[3] Procedure to continue serial reception when using the CPU to read from the FRDR register:
When continuing serial reception, confirm that the FSR.RDF flag is 1 and then set it to 0. When the DMAC or DTC are triggered to read receive data from the FRDR register, the RDF flag automatically becomes 0, making this step unnecessary (do not rewrite the RDF flag).

Note 1. Set the amount of receive data to an integral multiple of the receive FIFO threshold value. When the amount of receive data is not set to an integral multiple of the receive FIFO threshold value, the program returns to step [1] and enters an endless loop, so timeout processing should be performed using a timer, etc.

Figure 41.17 Receiving Serial Data in Clock Synchronous Mode

41.3.2.6 Simultaneously Transmitting and Receiving Serial Data in Clock Synchronous Mode

Figure 41.18 shows and example of Simultaneously Transmitting and Receiving Serial Data in Clock Synchronous Mode. When simultaneously transmitting and receiving serial data in clock synchronous mode, enable transmission and reception, and then perform the procedure in the figure below.



[1] Confirm the status of the SCIFA and write transmit data:
Read the FSR register, confirm that the TDFE flag is 1, and then write the transmit data to the FTDR register. The TXIF interrupt request can be used to confirm that the TDFE flag changed from 0 to 1.

[2] Procedure to continue serial transmission when using the CPU to write to the FTDR register:
When continuing serial transmission, confirm that the FSR.TDFE flag is 1 and then set it to 0. When the DMAC or DTC is triggered to write transmit data to the FTDR register, the TDFE flag automatically becomes 0, making this step unnecessary (do not manipulate the TDFE flag).

[3] Receive error processing:
When receive error occurs, read the LSR.ORER flag, and after performing predetermined error processing, set the ORER flag to 0. Data reception cannot be restarted while the ORER flag is 1. The BRIF interrupt request can be used to confirm that the ORER flag became 1.

[4] Confirm the status of the SCIFA and read receive data:
Read the FSR register, confirm that the RDF flag is 1, and then read the receive data from the FRDR register. The RXIF interrupt request can be used to confirm that the RDF flag changed from 0 to 1.

[5] Procedure to continue serial reception when using the CPU to read from the FRDR register:
When continuing serial reception, confirm that the FSR.RDF flag is 1 and then set it to 0. When the DMAC or DTC is triggered to read receive data from the FRDR register, the RDF flag automatically becomes 0, making this step unnecessary (do not manipulate the RDF flag).

[6] Procedure to continue serial transmission and reception (supplement):
When continuing serial transmission and reception, read the FRDR register before the FRDR register overflows and the ORER flag becomes 1, and set the RDF flag to 0. Also, before transmitting the last bit of the last data written to the FTDR register, write data to the FTDR register, and set the TDFE flag to 0. Furthermore, when the DMAC or DTC is triggered to write data to the FTDR register or read data from the FRDR register, the TDFE and RDF flags automatically become 0, so they do not need to be cleared manually (do not manipulate the TDFE or RDF flag).

Note: When toggling from a transmit or receive operation to simultaneous transmission and reception, set bits TE and RE to 0, and then set them to 1 simultaneously.

Note 1. Set the amount of receive data to an integral multiple of the receive FIFO threshold value. When the amount of receive data is not set to an integral multiple of the receive FIFO threshold value, the program returns to step [1] and enters an endless loop, so timeout processing should be performed using a timer, etc.

Figure 41.18 Simultaneously Transmitting and Receiving Serial Data in Clock Synchronous Mode

41.3.3 Bit Rate Modulation Function

The bit rate modulation function corrects the bit rate by thinning out the specified amount of clocks from those input to the baud rate generator.

When the SEMR.BRME bit is 1, the baud rate generator validates and counts the average interval of the number of clocks set in the MDDR register out of the total 256 clocks input.

Figure 41.19 assumes the SCIFA is in asynchronous mode, bits SMR.CKS[1:0] are 00b, the BRR register is 00h, and the MDDR register is 160. In this example, the cycle of the base clock is evenly corrected to $\frac{256}{160}$, and the bit rate is corrected to $\frac{160}{256}$. Note that there is an imbalance in thinning out the internal clock, and expansion and contraction occur in the pulse width of the internal base clock.

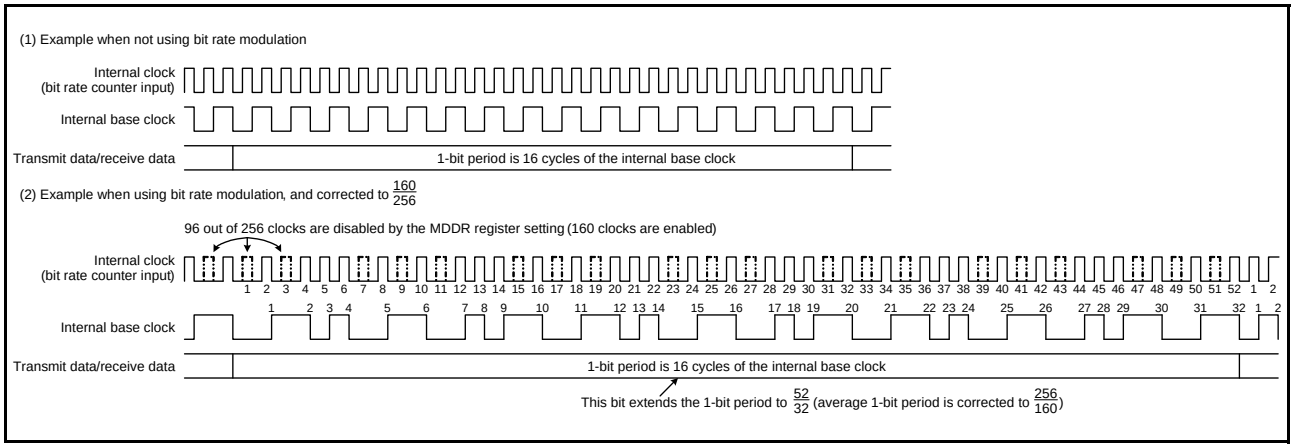


Figure 41.19 Example of the Base Clock When the Bit Modulation Function is Used

41.3.4 Relation Between the SPTR Register and SCIFA Pins

Figure 41.20 to Figure 41.23 show the relation between the SPTR register and the SCIFA pins.

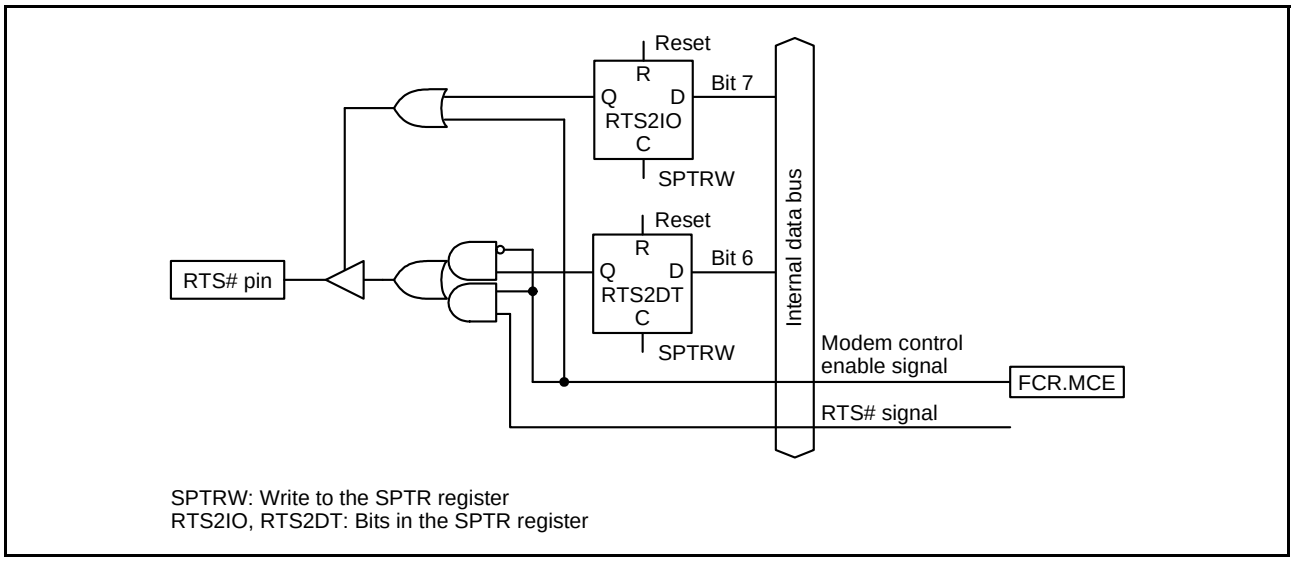

Figure 41.20 Relation Between the RTS# Pin and Bits RTS2IO and RTS2DT

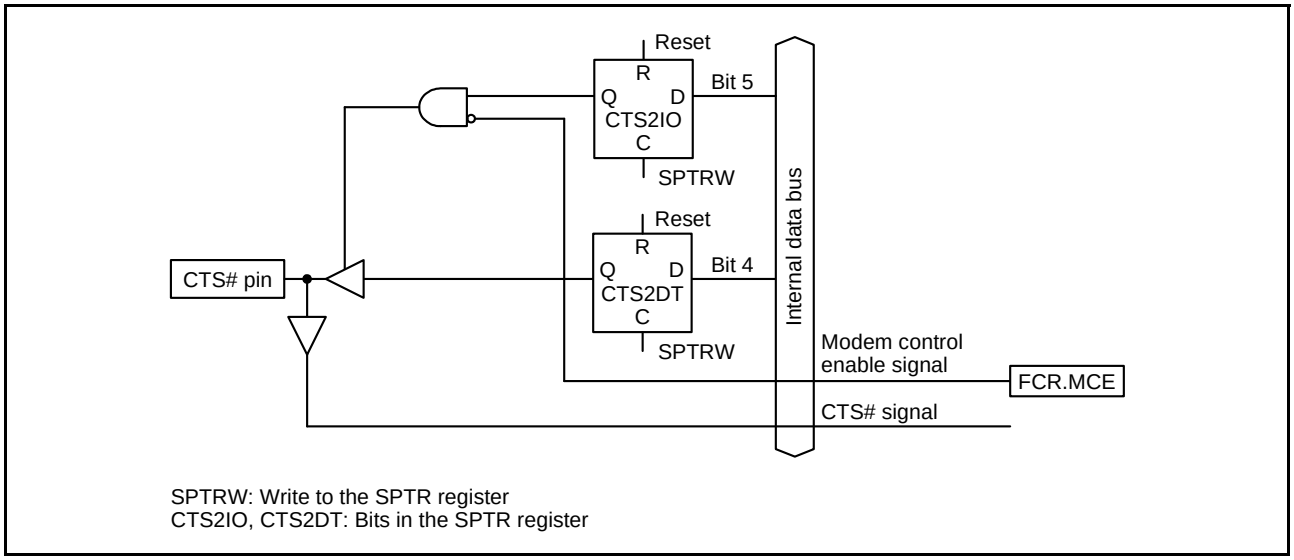

Figure 41.21 Relation Between the CTS# Pin and Bits CTS2IO and CTS2DT

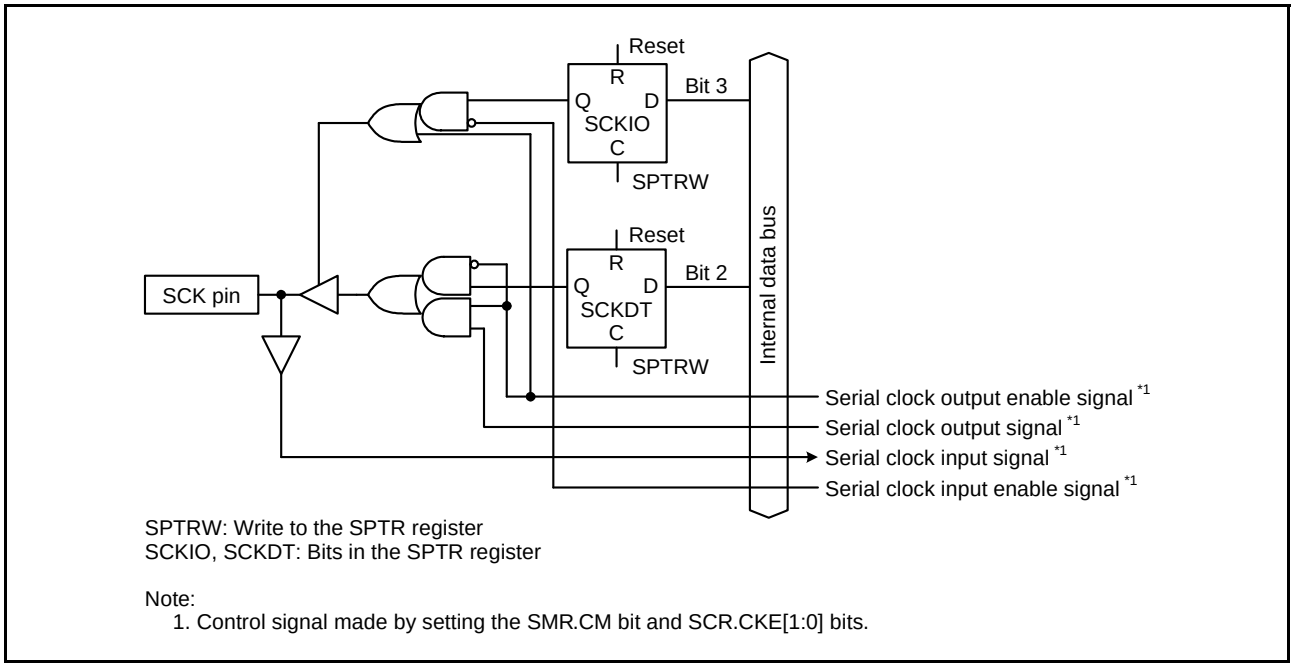

Figure 41.22 Relation Between the SCK Pin and Bits SCKIO and SCKDT

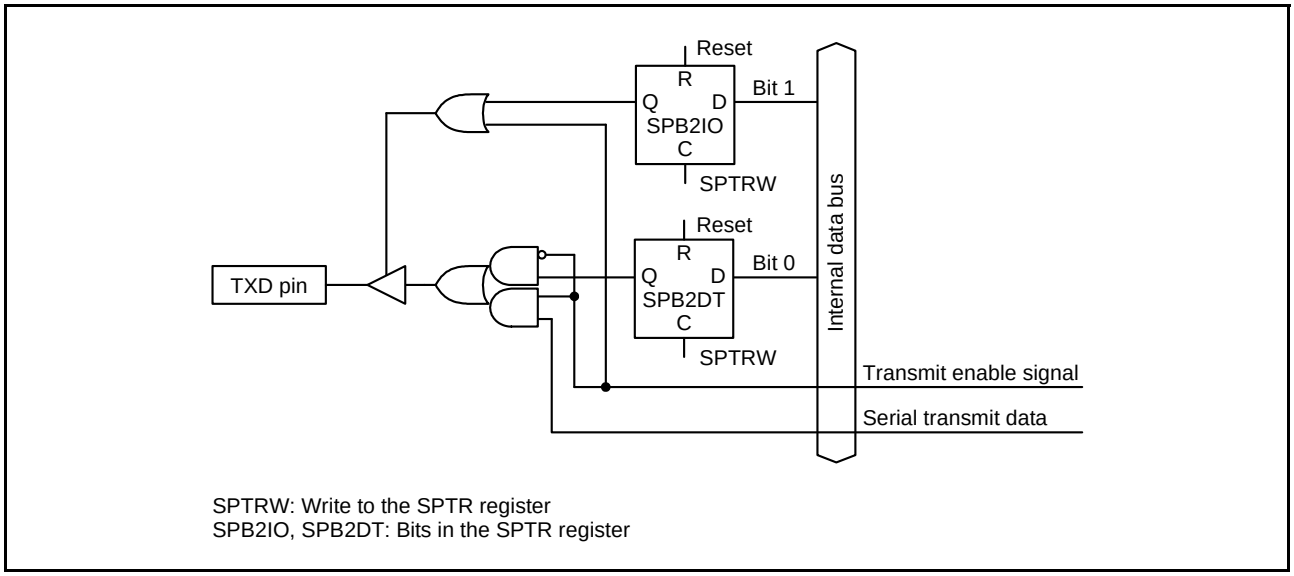

Figure 41.23 Relation Between the TXD Pin and Bits SPB2IO and SPB2DT

41.3.5 Noise Cancellation

Figure 41.24 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a two-stage flip-flop circuit and a match detection circuit. When the input signals of the noise filter and the output signals of the two-stage flip-flop circuit all match, that level is conveyed as an internal signal. If the levels do not match, the previous value is retained. When the same level is retained for three or more cycles of the sampling clock for the noise filter, the SCIFA determines it to be a valid receive signal. When there is change in the signal level less than three cycles, the SCIFA determines the signal to be noise and not a receive signal.

In asynchronous mode, the noise cancellation can be applied to the RXD pin. The receive signal of the RXD pin is taken in to the flip-flop circuit of the noise filter on the clock with a frequency eight times or 16 times the bit rate *1.

When the noise filter is enabled, if the base clock is stopped and then restarted, noise filter operation resumes from the state where the base clock was stopped. If the SCR.RE bit is set to 0 while the base clock is being input, the noise filter sets the RXD internal signal to 0. The match detection circuit continues to operate even when reception is stopped, the three previous sampling results are output at the same time reception resumes.

Note 1. When the SEMR.ABCS0 bit and SEMR.BGDM bit are both 0, the frequency is 16 times the bit rate, and when either the SEMR.ABCS0 bit and SEMR.BGDM bit is 1, the frequency is eight times the bit rate.

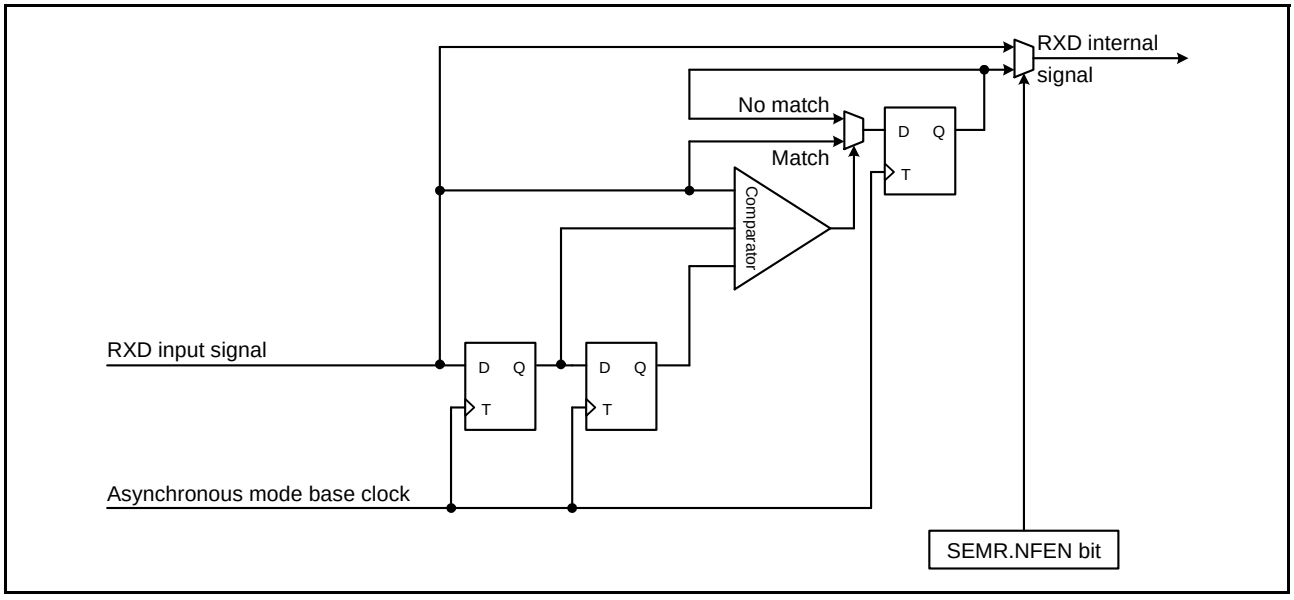

Figure 41.24 Block Diagram of the Digital Noise Filter Circuit

41.4 Interrupts

The SCIFA has six interrupt sources as listed in Table 41.19.
The interrupt sources can be enabled or disabled using bits in Table 41.19. Interrupt sources are individually input to the interrupt controller.
When transmitting data, if the amount of data written to the FTDR register is equal to or less than the transmit FIFO threshold value, the FSR.TDFE flag becomes 1, and the TXIF interrupt request is generated. When receiving data, if the amount of data stored in the FRDR is greater than or equal to the receive FIFO threshold value, the FSR.RDF flag becomes 1, and the RXIF interrupt request is generated.
While in asynchronous mode, if the amount of data stored in the FRDR register is less than the receive FIFO threshold value, and if the next data is not received even after 15 ETUs elapse *1 after the last stop bit, when the FSR.DR flag becomes 1, the SCIFA generates the DRIF interrupt request. While in clock synchronous mode, the DRIF interrupt request is not generated.
The SCIFA generates the BRIF interrupt request when the FSR.BRK flag and LSR.ORER flag become 1, it generates the ERIF interrupt request when the ER flag becomes 1, and it generates the TEIF interrupt request when the TEND flag becomes 1.
When setting the SCR.RIE bit to 0 and the REIE bit to 1, the ERIF interrupt request and BRIF interrupt request can be generated without generating the RXIF interrupt request.
The TXIF interrupt indicates that transmit data can be written to the FTDR register, and the RXIF interrupt indicates that there is receive data in the FRDR register.

Note 1. Equivalent to 1.5 frames of 8-bit data with a 1 stop bit format.

Table 41.19 SCIFA Interrupt Sources

Interrupt Source	Description	Interrupt Enable Bit	DMAC/DTC Triggerable	Priority Level
BRIF	Interrupt caused by break (BRK) or overrun (ORER)	RIE or REIE	No	High
ERIF	Interrupt caused by a framing error or parity error (ER)	RIE or REIE	No	↕
RXIF	Interrupt caused by receive FIFO data full (RDF)	RIE	Yes	
TXIF	Interrupt caused by transmit FIFO data empty (TDFE)	TIE	Yes	
TEIF	Interrupt caused by transmit end (TEND)	TEIE	No	
DRIF	Interrupt caused by receive data ready (DR)	RIE	No	Low

Note: When performing CPU processing, flags are cleared after blocks are transferred. When triggering the DTC or DMAC, flag access is disabled.

41.5 Notes on Using the SCIFA

41.5.1 Relation Between the FTDR Register and the FSR.TDFE Flag

When the amount of data written to the FTDR register is equal to or less than the transmit FIFO threshold value, if the FSR.TDFE flag is read as 1 and then set to 0, it becomes 1 again. In order to set the FSR.TDFE flag to 0, after the amount of data written to the FTDR register surpasses the transmit FIFO threshold value, confirm that the flag is 1 and then set it to 0. When using DTC or DMAC to write data to the FTDR register, when the DTC or DMA transfer is complete, the FSR.TDFE flag becomes 0. The amount of transmit data stored in the FTDR register can be checked by reading the FSR.T[4:0] flags.

41.5.2 Relation Between the FRDR Register and the FSR.RDF Flag

When the amount of data written to the FRDR register is equal to or more than the receive FIFO threshold value, if the FSR.RDF flag is read as 1 and then set to 0, it becomes 1 again. In order to set the FSR.RDF flag to 0, after the amount of data read from the FRDR register becomes less than the receive FIFO threshold value, confirm that the flag is 1 and then set it to 0. When using the DTC or DMAC to read data from the FRDR register, when the DTC or DMA transfer is complete, the FSR.RDF flag becomes 0. The amount of receive data stored in the FRDR register can be checked by reading the FDR.R[4:0] flags.

41.5.3 Detecting a Break Signal and Processing

Break signals are automatically detected by hardware, but a break signal can also be detected by directly reading the RXD pin value when a framing error is detected. In a break, all input from the RXD pin becomes low, the FER flag becomes 1, and the PER flag may become 1. If a break signal is detected, transfer of receive data to the FRDR register stops, but the SCIFA continues to monitor the RXD pin. Reception starts again when the break is released (when the RXD pin becomes high).

41.5.4 Outputting a Break Signal

The signal output from the TXD pin is dependent on the settings of the SCR.TE bit, SPTR.SPB2IO bit, and SPTR.SPB2DT bit. These bits can be set to output a break signal. Between initializing the SCIFA and setting the SCR.TE bit to 1, the TXD pin does not function as a transmit data output pin. Between initializing the SCIFA and setting the SCR.TE bit to 1, if the SPB2IO and SPB2DT bits are set to 1, output from the TXD pin can be configured as “marked” (high). To output a break signal during data transmission, after setting the SPB2IO bit to 1 and the SPB2DT bit to 0, set the SCR.TE bit to 0. When the SCR.TE bit is set to 0, irrelevant to the current transmission status, the transmitter is initialized, and the TXD pin outputs a low depending on the setting of the SPB2DT bit.

41.5.5 Note on the FSR.FER and PER Flags

The status indicated by the FSR.FER and PER flags is the status of the data in the FRDR register to be read next. If the CPU, DMAC, or DTC is used to read the FRDR register, the framing error and parity error information in the relevant data disappears. To check the framing error and parity error in the receive data, read the FSR register before reading the FRDR register.

41.5.6 Note on Inputting an External Clock in Clock Synchronous Mode

To set bits SCR.TE and RE to 1, wait at least four cycles of the PCLKA after the external clock (SCK) changes from low to high, and then set the pins. In order to input the external clock (start communication), set bits SCR.TE and RE to 1, and then wait for at least one cycle of the external clock before inputting the external clock.

41.5.7 Module-Stop Function Setting

SCIFA operation can be enabled or disabled by setting bits MSTPCRC.MSTPC24 (SCIFA11), MSTPC25 (SCIFA10), MSTPC26 (SCIFA9), and MSTPC27 (SCIFA8). After a reset, SCIFA operation is stopped. Registers in the SCIFA can be accessed by exiting the module-stop state. Refer to section 11, Low Power Consumption for details.

42. I2C-bus Interface (RIICa)

This MCU has a two-channel I2C-bus interface (RIIC0, RIIC2).
The RIIC module conforms with the NXP I2C-bus (Inter-IC bus) interface and provides a subset of its functions.
In this section, “PCLK” is used to refer to PCLKB.

42.1 Overview

Table 42.1 lists the specifications of the RIIC, Figure 42.1 shows a block diagram of the RIIC, and Figure 42.2 shows an example of I/O pin connections to external circuits (I2C-bus configuration example). Table 42.2 lists the I/O pins of the RIIC.

Table 42.1 RIIC Specifications (1/2)

Item	Description
Communications format	• I2C-bus format or SMBus format • Master mode or slave mode selectable • Automatic securing of the various setup times, hold times, and bus-free times for the transfer rate
Transfer rate	Fast-mode Plus is supported (up to 1 Mbps)
SCL clock	For master operation, the duty cycle of the SCL clock is selectable in the range from 4 to 96%.
Issuing and detecting conditions	Start, restart, and stop conditions are automatically generated. Start conditions (including restart conditions) and stop conditions are detectable.
Slave address	• Up to three different slave addresses can be set. • 7-bit and 10-bit address formats are supported (along with the use of both at once). • General call addresses, device ID addresses, and SMBus host addresses are detectable.
Acknowledgment	• For transmission, the acknowledge bit is automatically loaded. Transfer of the next data for transmission can be automatically suspended on detection of a not-acknowledge bit. • For reception, the acknowledge bit is automatically transmitted. If a wait between the eighth and ninth clock cycles has been selected, software control of the value in the acknowledge field in response to the received value is possible.
Wait function	• In reception, the following periods of waiting can be obtained by holding the SCL clock at the low level: Waiting between the eighth and ninth clock cycles Waiting between the ninth clock cycle and the first clock cycle of the next transfer
SDA output delay function	Timing of the output of transmitted data, including the acknowledge bit, can be delayed.
Arbitration	• For multi-master operation Operation to synchronize the SCL clock in cases of conflict with the SCL signal from another master is possible. When issuing the start condition would create conflict on the bus, loss of arbitration is detected by testing for non-matching between the internal signal for the SDA line and the level on the SDA line. In master operation, loss of arbitration is detected by testing for non-matching between the signal on the SDA line and the internal signal for the SDA line. • Loss of arbitration due to detection of the start condition while the bus is busy is detectable (to prevent the issuing of double start conditions). • Loss of arbitration in transfer of a not-acknowledge bit due to the internal signal for the SDA line and the level on the SDA line not matching is detectable. • Loss of arbitration due to non-matching of internal and line levels for data is detectable in slave transmission.
Timeout function	The internal timeout function is capable of detecting long-interval stop of the SCL clock.
Noise cancellation	The interface incorporates digital noise filters for both the SCL and SDA signals, and the width for noise cancellation by the filters is adjustable by software.
Interrupt sources	Four sources: • Error in transfer or occurrence of events Detection of arbitration, NACK, timeout, a start condition including a restart condition, or a stop condition • Receive data full (including matching with a slave address) • Transmit data empty (including matching with a slave address) • Transmit end

Table 42.1 RIIC Specifications (2/2)

Item	Description
Low power consumption function	Module stop state can be set.
RIIC operating modes	• Four Master transmit mode, master receive mode, slave transmit mode, and slave receive mode
Event link function (output)	• Four sources (RIIC0): Error in transfer or occurrence of events Detection of arbitration, NACK, timeout, a start condition including a restart condition, or a stop condition • Receive data full (including matching with a slave address) • Transmit data empty (including matching with a slave address) • Transmit end

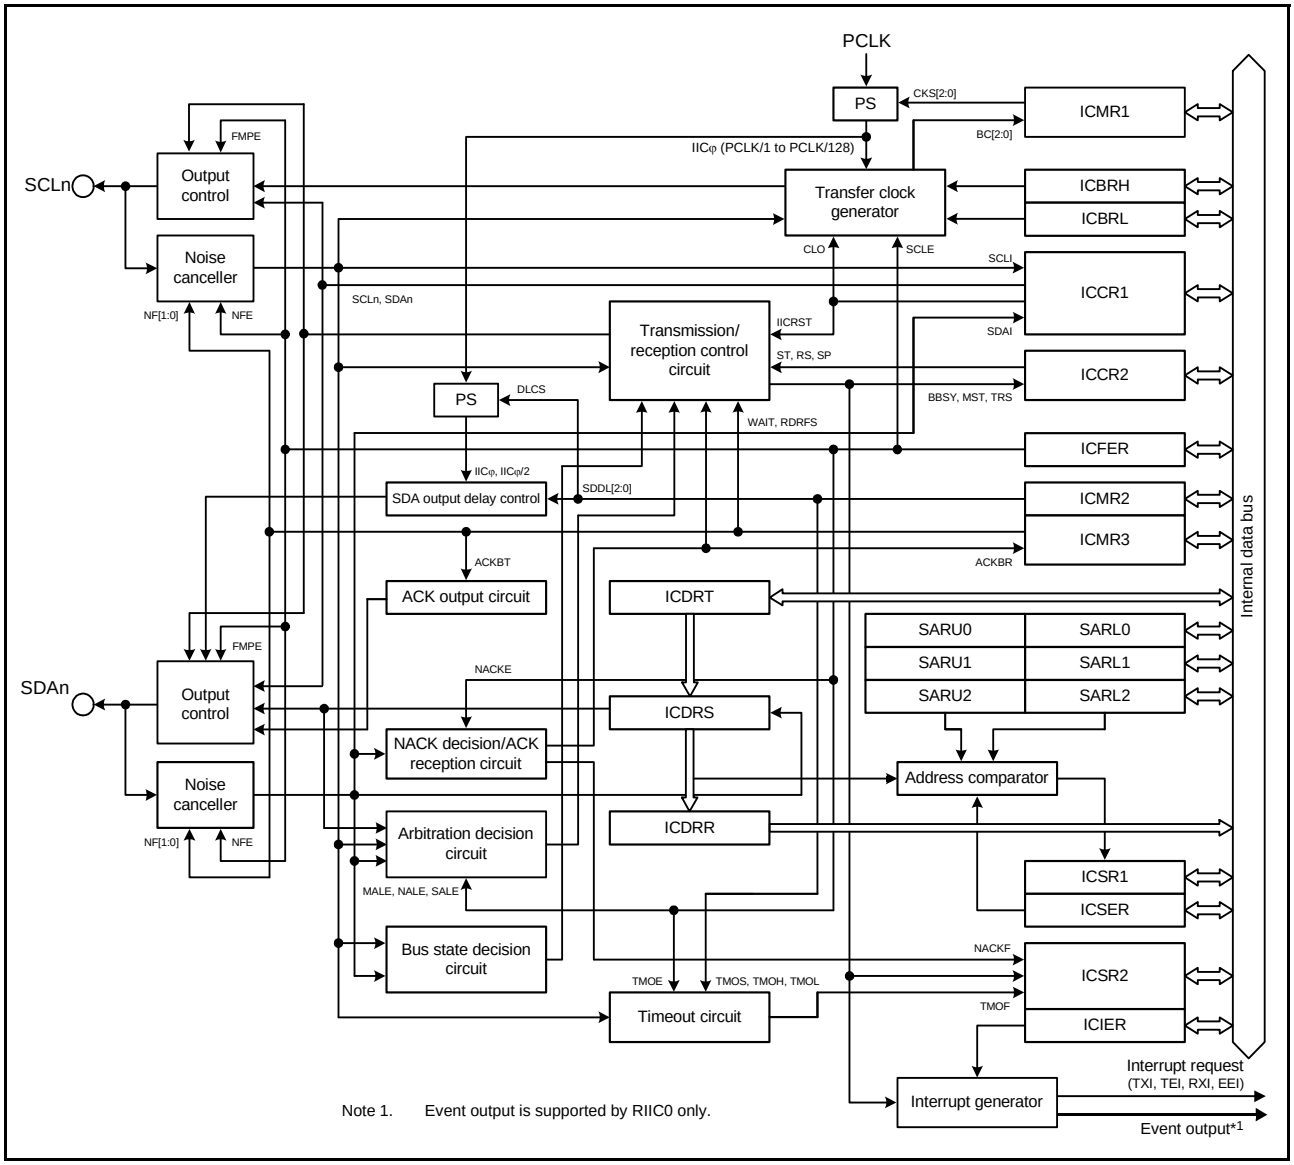

Figure 42.1 RIIC Block Diagram (n=0, 2)

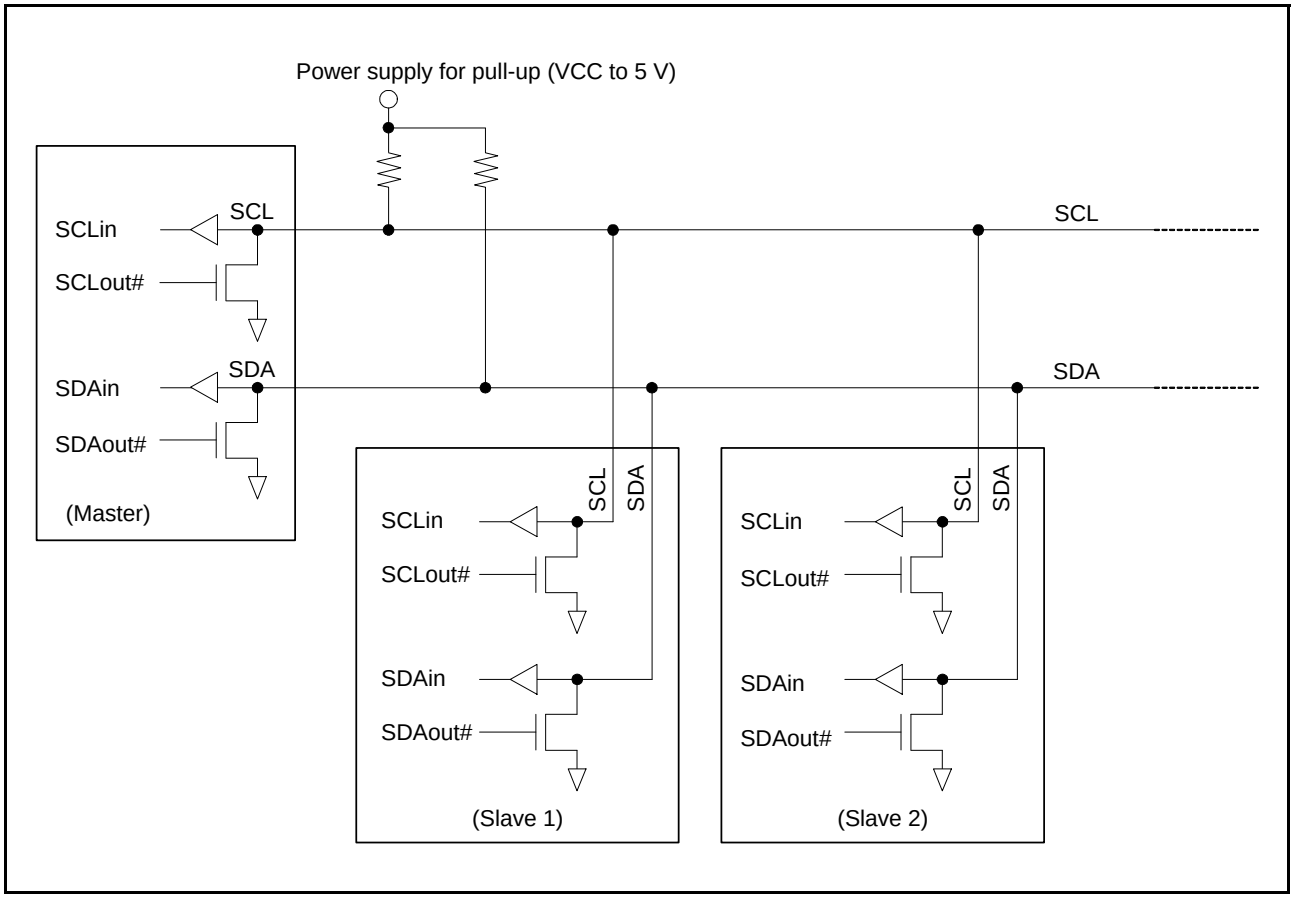

Figure 42.2 I/O Pin Connection to the External Circuit (I2C-bus Configuration Example)

The input level of the signals for RIIC is CMOS when I2C-bus is selected (ICMR3.SMBS bit is 0), or TTL when SMBus is selected (ICMR3.SMBS bit is 1).

Table 42.2 RIIC Pin Configuration

Channel	Pin Name	I/O	Function
RIIC0	SCL0	I/O	RIIC0 serial clock I/O pin
	SDA0	I/O	RIIC0 serial data I/O pin
RIIC2	SCL2	I/O	RIIC2 serial clock I/O pin
	SDA2	I/O	RIIC2 serial data I/O pin

42.2 Register Descriptions

42.2.1 I2C-bus Control Register 1 (ICCR1)

Address(es): RIIC0.ICCR1 0008 8300h, RIIC2.ICCR1 0008 8340h

	b7	b6	b5	b4	b3	b2	b1	b0
	ICE	IICRST	CLO	SOWP	SCLO	SDAO	SCLI	SDAI
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	SDAI	SDA Line Monitor	0: SDAn line is low. 1: SDAn line is high.	R
b1	SCLI	SCL Line Monitor	0: SCLn line is low. 1: SCLn line is high.	R
b2	SDAO	SDA Output Control/Monitor	• Read: 0: The RIIC has driven the SDAn pin low. 1: The RIIC has released the SDAn pin. • Write: 0: The RIIC drives the SDAn pin low. 1: The RIIC releases the SDAn pin.	R/W
b3	SCLO	SCL Output Control/Monitor	• Read: 0: The RIIC has driven the SCLn pin low. 1: The RIIC has released the SCLn pin. • Write: 0: The RIIC drives the SCLn pin low. 1: The RIIC releases the SCLn pin. (High level output is achieved through an external pull-up resistor.)	R/W
b4	SOWP	SCLO/SDAO Write Protect	0: SCLO and SDAO bits can be written. 1: SCLO and SDAO bits are protected. (This bit is read as 1.)	R/W
b5	CLO	Extra SCL Clock Cycle Output	0: Does not output an extra SCL clock cycle (default). 1: Outputs an extra SCL clock cycle. (The CLO bit is cleared automatically after one clock cycle is output.)	R/W
b6	IICRST	I2C-bus Interface Internal Reset	0: Releases the RIIC reset or internal reset. 1: Initiates the RIIC reset or internal reset. (Clears the bit counter and the SCLn/SDAn output latch)	R/W
b7	ICE	I2C-bus Interface Enable	0: Disable (SCLn and SDAn pins in inactive state) 1: Enable (SCLn and SDAn pins in active state) (Combined with the IICRST bit to select either RIIC or internal reset.)	R/W

SDAO Bit (SDA Output Control/Monitor) and SCLO Bit (SCL Output Control/Monitor)

These bits are used to directly control the SDAn and SCLn signals output from the RIIC.

When writing to these bits, also write 0 to the SOWP bit.

The result of setting these bits is input to the RIIC via the input buffer. When slave mode is selected, a start condition may be detected and the bus may be released depending on the bit settings.

Do not rewrite these bits during a start condition, stop condition, restart condition, or during transmission or reception. Operation after rewriting under the above conditions is not guaranteed.

When reading these bits, the state of signals output from the RIIC can be read.

CLO Bit (Extra SCL Clock Cycle Output)

This bit is used to output an extra SCL clock cycle for debugging or error processing.
Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error.
For details on this function, refer to section 42.11.2, Extra SCL Clock Cycle Output Function.

IICRST Bit (I2C-bus Interface Internal Reset)

This bit is used to reset the internal states of the RIIC.
Setting this bit to 1 initiates an RIIC reset or internal reset.
Whether an RIIC reset or internal reset is initiated is determined according to the combination with the ICE bit. Table 42.3 lists the resets of the RIIC.
The RIIC reset resets all registers and internal states of the RIIC, and the internal reset resets the bit counter (ICMR1.BC[2:0] bits), the I2C-bus shift register (ICDRS), and the I2C-bus status registers (ICSR1 and ICSR2) as well as the internal states of the RIIC. For the reset conditions for each register, refer to section 42.14, Resets and Register and Function States When Issuing Each Condition.
An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the RIIC without initializing the port settings and the control and setting registers of the RIIC when the bus or RIIC hangs up due to a communication error.
If the RIIC hangs up in a low level output state, resetting the internal states cancels the low level output state and releases the bus with the SCLn pin and SDAn pin at a high impedance.

Note: If an internal reset is initiated using the IICRST bit for a bus hang-up occurred during communication with the master device in slave mode, the states may become different between the slave device and the master device (due to the difference in the bit counter information). For this reason, do not initiate an internal reset in slave mode, but initiate restoration processing from the master device. If an internal reset is necessary because the RIIC hangs up with the SCLn line in a low level output state in slave mode, initiate an internal reset and then issue a restart condition from the master device or resume communication from the start condition issuance after issuing a stop condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start condition or restart condition from the master device, synchronization will be lost because the master and slave devices operate asynchronously.

Table 42.3 RIIC Resets

IICRST	ICE	State	Specifications
1	0	RIIC reset	Resets all registers and internal states of the RIIC.
	1	Internal reset	Resets the ICMR1.BC[2:0] bits, registers ICSR1, ICSR2, and ICDRS, and the internal states of the RIIC.

ICE Bit (I2C-bus Interface Enable)

This bit selects the active or inactive state of the SCLn and SDAn pins. It can also be combined with the IICRST bit to initiate two types of resets. See Table 42.3, RIIC Resets, for the types of resets.
Set the ICE bit to 1 when using the RIIC. The SCLn and SDAn pins are placed in the active state when the ICE bit is set to 1.
Set the ICE bit to 0 when the RIIC is not to be used. The SCLn and SDAn pins are placed in the inactive state when the ICE bit is set to 0. Do not assign the SCLn or SDAn pin to the RIIC when setting up the multi-function pin controller (MPC). Note that the slave address comparison operation is carried out if the pins are assigned to the RIIC.

42.2.2 I2C-bus Control Register 2 (ICCR2)

Address(es): RIIC0.ICCR2 0008 8301h, RIIC2.ICCR2 0008 8341h

	b7	b6	b5	b4	b3	b2	b1	b0
	BBSY	MST	TRS	—	SP	RS	ST	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	ST	Start Condition Issuance Request	0: Does not request to issue a start condition. 1: Requests to issue a start condition.	R/W
b2	RS	Restart Condition Issuance Request	0: Does not request to issue a restart condition. 1: Requests to issue a restart condition.	R/W
b3	SP	Stop Condition Issuance Request	0: Does not request to issue a stop condition. 1: Requests to issue a stop condition.	R/W
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	TRS	Transmit/Receive Mode	0: Receive mode 1: Transmit mode	R/W*1
b6	MST	Master/Slave Mode	0: Slave mode 1: Master mode	R/W*1
b7	BBSY	Bus Busy Detection Flag	0: The I2C-bus is released (bus free state). 1: The I2C-bus is occupied (bus busy state).	R

Note 1. When the ICMR1.MTWP bit is set to 1, bits MST and TRS can be written to.

ST Bit (Start Condition Issuance Request)

This bit is used to request transition to master mode and issuance of a start condition.

When this bit is set to 1 to request to issue a start condition, a start condition is issued when the BBSY flag is set to 0 (bus free state).

For details on the start condition issuance, refer to section 42.10, Start Condition/Restart Condition/Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the ST bit

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition has been issued (a start condition is detected)
- When the ICSR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Note: Set the ST bit to 1 (start condition issuance request) when the BBSY flag is set to 0 (bus free state). Note that arbitration may be lost due to a start condition issuance error if the ST bit is set to 1 (start condition issuance request) when the BBSY flag is set to 1 (bus busy state).

RS Bit (Restart Condition Issuance Request)

This bit is used to request that a restart condition be issued in master mode.
When this bit is set to 1 to request to issue a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode).
For details on the restart condition issuance, refer to section 42.10, Start Condition/Restart Condition/Stop Condition Issuing Function.
[Setting condition]

- When 1 is written to the RS bit with the ICCR2.BBSY flag set to 1

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition has been issued (a start condition is detected)
- When the ICSR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Note: Do not set the RS bit to 1 while issuing a stop condition.
Note: If 1 (requests to issue a restart condition) is written to the RS bit in slave mode, the restart condition is not issued but the RS bit remains set to 1. If the operating mode changes to master mode with the bit not being cleared, note that the restart condition may be issued.

SP Bit (Stop Condition Issuance Request)

This bit is used to request that a stop condition be issued in master mode.
When this bit is set to 1 to request to issue a stop condition, a stop condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode).
For details on the stop condition issuance, refer to section 42.10, Start Condition/Restart Condition/Stop Condition Issuing Function.
[Setting condition]

- When 1 is written to the SP bit with both the BBSY flag and the ICCR2.MST bit set to 1

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition has been issued (a stop condition is detected)
- When the ICSR2.AL (arbitration-lost) flag is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Note: Writing to the SP bit is not possible while the setting of the BBSY flag is 0 (bus free state).
Note: Do not set the SP bit to 1 while a restart condition is being issued.

TRS Bit (Transmit/Receive Mode)

This bit indicates transmit or receive mode.
The RIIC is in receive mode when the TRS bit is set to 0 and is in transmit mode when the bit is set to 1. Combination of this bit and the MST bit indicates the operating mode of the RIIC.
The value of TRS bit is automatically changed to 1 for transmit mode or 0 for receive mode by issuing or detection of a start condition and setting of the R/W# bit. Although writing to the TRS bit is possible when the ICMR1.MTWP bit is set to 1, writing to this bit is not necessary during normal usage.
[Setting conditions]

- When a start condition is issued normally according to the start condition issuance request (when a start condition is detected with the ST bit set to 1)
- When a restart condition is issued normally according to the restart condition issuance request (when a restart condition is detected with the RS bit set to 1)
- When the R/W# bit added to the slave address is set to 0 in master mode
- When the address received in slave mode matches the address enabled in the ICSER register, with the R/W# bit set to 1
- When 1 is written to the TRS bit with the ICMR1.MTWP bit set to 1

[Clearing conditions]

- When a stop condition is detected
- The ICSR2.AL (arbitration-lost) flag being set to 1
- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended
- In slave mode, a match between the received address and the address enabled in the ICSER register when the value of the received R/W# bit is 0 (including cases where the received address is the general call address)
- In slave mode, a restart condition is detected (a start condition is detected with ICCR2.BBSY flag is 1 and ICCR2.MST bit is 0)
- When 0 is written to the TRS bit with the ICMR1.MTWP bit set to 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

MST Bit (Master/Slave Mode)

This bit indicates master or slave mode.
The RIIC is in slave mode when the MST bit is set to 0 and is in master mode when the bit is set to 1. Combination of this bit and the TRS bit indicates the operating mode of the RIIC.
The value of the MST bit is automatically changed to 1 for master mode or 0 for slave mode by issuing of a start condition and issuing or detection of a stop condition, etc. Although writing to the MST bit is possible when the ICMR1.MTWP bit is set to 1, writing to this bit is not necessary during normal usage.
[Setting conditions]

- When a start condition is issued normally according to the start condition issuance request (when a start condition is detected with the ST bit set to 1)
- When 1 is written to the MST bit with the ICMR1.MTWP bit set to 1

[Clearing conditions]

- When a stop condition is detected
- When the ICSR2.AL (arbitration-lost) flag is set to 1
- When 0 is written to the MST bit with the ICMR1.MTWP bit set to 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

BBSY Flag (Bus Busy Detection Flag)

The BBSY flag indicates whether the I2C-bus is occupied (bus busy state) or released (bus free state).
This bit is set to 1 when the SDAn line changes from high to low under the condition of SCLn line = high, assuming that a start condition has been issued.
When the SDAn line changes from low to high under the condition of SCLn line = high, this bit is set to 0 after the bus free time (specified in the ICBRL register) start condition is not detected, assuming that a stop condition has been issued.
[Setting condition]

- When a start condition is detected

[Clearing conditions]

- When the bus free time (specified in the ICBRL register) start condition is not detected after detecting a stop condition
- When 1 is written to the ICCR1.IICRST bit with the ICCR1.ICE bit set to 0 (RIIC reset)

42.2.3 I2C-bus Mode Register 1 (ICMR1)

Address(es): RIIC0.ICMR1 0008 8302h, RIIC2.ICMR1 0008 8342h

	b7	b6	b5	b4	b3	b2	b1	b0
	MTWP	CKS[2:0]			BCWP	BC[2:0]		
Value after reset:	0	0	0	0	1	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	BC[2:0]	Bit Counter	b2 b0 0 0 0: 9 bits 0 0 1: 2 bits 0 1 0: 3 bits 0 1 1: 4 bits 1 0 0: 5 bits 1 0 1: 6 bits 1 1 0: 7 bits 1 1 1: 8 bits	R/W*1
b3	BCWP	BC Write Protect	0: Enables a value to be written in the BC[2:0] bits. (This bit is read as 1.)	R/W*1
b6 to b4	CKS[2:0]	Internal Reference Clock Select	Select the internal reference clock (IICφ) source for the RIIC. b6 b4 0 0 0: PCLK/1 clock 0 0 1: PCLK/2 clock 0 1 0: PCLK/4 clock 0 1 1: PCLK/8 clock 1 0 0: PCLK/16 clock 1 0 1: PCLK/32 clock 1 1 0: PCLK/64 clock 1 1 1: PCLK/128 clock	R/W
b7	MTWP	MST/TRS Write Protect	0: Disables writing to the ICCR2.MST and TRS bits. 1: Enables writing to the ICCR2.MST and TRS bits.	R/W

Note 1. Rewrite the BC[2:0] bits and set the BCWP bit to 0 at the same time.

BC[2:0] Bits (Bit Counter)

These bits function as a counter that indicates the number of bits remaining to be transferred at the detection of a rising edge on the SCLn line. Although these bits are writable and readable, it is not necessary to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one (data is transferred with an additional acknowledge bit) between transferred bytes when the SCLn line is at a low level.

The values of the BC[2:0] bits return to 000b at the end of a data transfer including the acknowledge bit or when a start condition including a restart condition is detected.

42.2.4 I2C-bus Mode Register 2 (ICMR2)

Address(es): RIIC0.ICMR2 0008 8303h, RIIC2.ICMR2 0008 8343h

	b7	b6	b5	b4	b3	b2	b1	b0
	DLCS	SDDL[2:0]			—	TMOH	TMOL	TMOS
Value after reset:	0	0	0	0	0	1	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMOS	Timeout Detection Time Select	0: Long mode is selected. 1: Short mode is selected.	R/W
b1	TMOL	Timeout L Count Control	0: Count-up is disabled while the SCLn line is at a low level. 1: Count-up is enabled while the SCLn line is at a low level.	R/W
b2	TMOH	Timeout H Count Control	0: Count-up is disabled while the SCLn line is at a high level. 1: Count-up is enabled while the SCLn line is at a high level.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6 to b4	SDDL[2:0]	SDA Output Delay Counter	• When ICMR2.DLCS bit is 0 (IICφ) b6 b4 0 0 0: No output delay 0 0 1: 1 IICφ cycle 0 1 0: 2 IICφ cycles 0 1 1: 3 IICφ cycles 1 0 0: 4 IICφ cycles 1 0 1: 5 IICφ cycles 1 1 0: 6 IICφ cycles 1 1 1: 7 IICφ cycles • When ICMR2.DLCS bit is 1 (IICφ/2) b6 b4 0 0 0: No output delay 0 0 1: 1 or 2 IICφ cycles 0 1 0: 3 or 4 IICφ cycles 0 1 1: 5 or 6 IICφ cycles 1 0 0: 7 or 8 IICφ cycles 1 0 1: 9 or 10 IICφ cycles 1 1 0: 11 or 12 IICφ cycles 1 1 1: 13 or 14 IICφ cycles	R/W
b7	DLCS	SDA Output Delay Clock Source Select	0: The internal reference clock (IICφ) is selected as the clock source of the SDA output delay counter. 1: The internal reference clock divided by 2 (IICφ/2) is selected as the clock source of the SDA output delay counter.*1	R/W

Note 1. The DLCS bit setting of 1 (IICφ/2) only becomes valid when SCL pin is low. When SCL pin is high, the DLCS bit setting of 1 becomes invalid and the clock source becomes the internal reference clock (IICφ).

TMOS Bit (Timeout Detection Time Select)

This bit is used to select long mode or short mode for the timeout detection time when the timeout function is enabled (ICFER.TMOE bit is 1). When this bit is set to 0, long mode is selected. When this bit is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16-bit counter. In short mode, the counter functions as a 14-bit counter. While the SCLn line is in the state that enables this counter as specified by bits TMOH and TMOL, the counter counts up in synchronization with the internal reference clock (IICφ) as a count source.
For details on the timeout function, refer to section 42.11.1, Timeout Function.

TMOL Bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCLn line is held low when the timeout function is enabled (ICFER.TMOE bit is 1).

TMOH Bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCLn line is held high when the timeout function is enabled (ICFER.TMOE bit is 1).

SDDL[2:0] Bits (SDA Output Delay Counter)

The SDA output can be delayed by the SDDL[2:0] setting. This counter works with the clock source selected by the DLCS bit. The setting of this function can be used for all types of SDA output, including the transmission of the acknowledge bit.

Set the SDA output delay time to meet the I2C-bus specification (within the data enable time/acknowledge enable time*1) or the SMBus specification (within the data hold time: 300 ns or more, and SCL-clock low-level period - the data setup time: 250 ns). Note that, if a value outside the specification is set, communication with communication devices may malfunction or it may seemingly become a start condition or stop condition depending on the bus state.

For details on this function, refer to section 42.5, SDA Output Delay Function.

Note 1. Data enable time/acknowledge enable time
3,450 ns (up to 100 kbps: Standard-mode (Sm))
900 ns (up to 400 kbps: Fast-mode (Fm))
450 ns (up to 1 Mbps: Fast-mode Plus (Fm+))

42.2.5 I2C-bus Mode Register 3 (ICMR3)

Address(es): RIIC0.ICMR3 0008 8304h, RIIC2.ICMR3 0008 8344h

	b7	b6	b5	b4	b3	b2	b1	b0
	SMBS	WAIT	RDRFS	ACKWP	ACKBT	ACKBR	NF[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	NF[1:0]	Noise Filter Stage Select	b1 b0 0 0: Noise of up to one IICφ cycle is filtered out (single-stage filter). 0 1: Noise of up to two IICφ cycles is filtered out (2-stage filter). 1 0: Noise of up to three IICφ cycles is filtered out (3-stage filter). 1 1: Noise of up to four IICφ cycles is filtered out (4-stage filter).	R/W
b2	ACKBR	Receive Acknowledge	0: 0 is received as the acknowledge bit (ACK reception). 1: 1 is received as the acknowledge bit (NACK reception).	R
b3	ACKBT	Transmit Acknowledge	0: 0 is sent as the acknowledge bit (ACK transmission). 1: 1 is sent as the acknowledge bit (NACK transmission).	R/W*1
b4	ACKWP	ACKBT Write Protect	0: Modification of the ACKBT bit is disabled. 1: Modification of the ACKBT bit is enabled.	R/W*1
b5	RDRFS	RDRF Flag Set Timing Select	0: The RDRF flag is set at the rising edge of the ninth SCL clock cycle. (The SCLn line is not held low at the falling edge of the eighth clock cycle.) 1: The RDRF flag is set at the rising edge of the eighth SCL clock cycle. (The SCLn line is held low at the falling edge of the eighth clock cycle.) Low-hold is released by writing a value to the ACKBT bit.	R/W*2
b6	WAIT	WAIT	0: No WAIT (The period between ninth clock cycle and first clock cycle is not held low.) 1: WAIT (The period between ninth clock cycle and first clock cycle is held low.) Low-hold is released by reading the ICDRR register.	R/W*2
b7	SMBS	SMBus/I2C-bus Select	0: The I2C-bus is selected. 1: The SMBus is selected.	R/W

Note 1. Write to the ACKBT bit only while the ACKWP bit is already 1. If it is attempted to write 1 to both the ACKWP and ACKBT bits at the same time, the ACKBT bit will not be set to 1.

Note 2. The WAIT and RDRFS bits are valid only in receive mode (invalid in transmit mode).

NF[1:0] Bits (Noise Filter Stage Select)

These bits are used to select the number of stages in the digital noise filter.

For details on the digital noise filter function, refer to section 42.6, Digital Noise Filter Circuit.

Note: Set the noise range to be filtered out by the noise filter within a range less than the SCLn line high-level period or low-level period. If the noise filter width is set to a value of [the shorter one of either SCL high width or SCL low width] – {1.5 × t_{IICcyc} (cycle time of internal reference clock (IICφ)) + 120 ns (pulse width suppressed by the analog noise filter, a reference value)} or a greater value, the SCL clock is regarded as noise by the noise filter function of the RIIC, which may prevent the RIIC from operating normally.

ACKBR Bit (Receive Acknowledge)

This bit is used to store the acknowledge bit information received from the receive device in transmit mode.
[Setting condition]

- When 1 is received as the acknowledge bit with the ICCR2.TRS bit set to 1

[Clearing conditions]

- When 0 is received as the acknowledge bit with the ICCR2.TRS bit set to 1
- When 1 is written to the ICCR1.IICRST bit while the ICCR1.ICE bit is 0 (RIIC reset)

ACKBT Bit (Transmit Acknowledge)

This bit is used to set the bit to be sent at the acknowledge timing in receive mode.
[Setting condition]

- When 1 is written to this bit with the ACKWP bit set to 1

[Clearing conditions]

- When 0 is written to this bit with the ACKWP bit set to 1
- When stop condition issuance is detected (when a stop condition is detected with the ICCR2.SP bit set to 1)
- When 1 is written to the ICCR1.IICRST bit while the ICCR1.ICE bit is 0 (RIIC reset)

ACKWP Bit (ACKBT Write Protect)

This bit is used to control the modification of the ACKBT bit.

RDRFS Bit (RDRF Flag Set Timing Select)

This bit is used to select the RDRF flag set timing in receive mode and also to select whether to hold the SCLn line low at the falling edge of the eighth SCL clock cycle.
When the RDRFS bit is 0, the SCLn line is not held low at the falling edge of the eighth SCL clock cycle, and the RDRF flag is set to 1 at the rising edge of the ninth SCL clock cycle.
When the RDRFS bit is 1, the RDRF flag is set to 1 at the rising edge of the eighth SCL clock cycle and the SCLn line is held low at the falling edge of the eighth SCL clock cycle. The low-hold of the SCLn line is released by writing a value to the ACKBT bit.
After data is received with this setting, the SCLn line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT bit is 0) or NACK (ACKBT bit is 1) according to receive data.

WAIT Bit (WAIT)

This bit is used to control whether to hold the period between the ninth SCL clock cycle and the first SCL clock cycle low until the I2C-bus receive data register (ICDRR) is completely read each time single-byte data is received in receive mode.
When the WAIT bit is 0, the receive operation is continued without holding the period between the ninth and the first SCL clock cycle low. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.
When the WAIT bit is 1, the SCLn line is held low from the falling edge of the ninth clock cycle until the ICDRR register value is read each time single-byte data is received. This enables receive operation in byte units.

Note: When the value of the WAIT bit is to be read, be sure to read the ICDRR register beforehand.

SMBS Bit (SMBus/I2C-bus Select)

Setting this bit to 1 selects the SMBus and enables the ICSER.HOAE bit.

42.2.6 I2C-bus Function Enable Register (ICFER)

Address(es): RIIC0.ICFER 0008 8305h, RIIC2.ICFER 0008 8345h

	b7	b6	b5	b4	b3	b2	b1	b0
	FMPE	SCLE	NFE	NACKE	SALE	NALE	MALE	TMOE
Value after reset:	0	1	1	1	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMOE	Timeout Function Enable	0: The timeout function is disabled. 1: The timeout function is enabled.	R/W
b1	MALE	Master Arbitration-Lost Detection Enable	0: Master arbitration-lost detection is disabled. (Disables the arbitration-lost detection function and does not clear the ICCR2.MST and TRS bits automatically when arbitration is lost.) 1: Master arbitration-lost detection is enabled. (Enables the arbitration-lost detection function and clears the ICCR2.MST and TRS bits automatically when arbitration is lost.)	R/W
b2	NALE	NACK Transmission Arbitration-Lost Detection Enable	0: NACK transmission arbitration-lost detection is disabled. 1: NACK transmission arbitration-lost detection is enabled.	R/W
b3	SALE	Slave Arbitration-Lost Detection Enable	0: Slave arbitration-lost detection is disabled. 1: Slave arbitration-lost detection is enabled.	R/W
b4	NACKE	NACK Reception Transfer Suspension Enable	0: Transfer operation is not suspended during NACK reception (transfer suspension disabled). 1: Transfer operation is suspended during NACK reception (transfer suspension enabled).	R/W
b5	NFE	Digital Noise Filter Circuit Enable	0: No digital noise filter circuit is used. 1: A digital noise filter circuit is used.	R/W
b6	SCLE	SCL Synchronous Circuit Enable	0: No SCL synchronous circuit is used. 1: An SCL synchronous circuit is used.	R/W
b7	FMPE*1	Fast-Mode Plus Enable	0: No Fm+ slope control circuit is used for the SCLn pin and SDAn pin. 1: An Fm+ slope control circuit is used for the SCLn pin and SDAn pin.	R/W

Note 1. The Fast-mode Plus enable bit (FMPE) is only supported by RIIC0. In RIIC2, bit 7 is reserved.

TMOE Bit (Timeout Function Enable)

This bit is used to enable or disable the timeout function.

For details on the timeout function, refer to section 42.11.1, Timeout Function.

MALE Bit (Master Arbitration-Lost Detection Enable)

This bit is used to specify whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE Bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode (such as when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with different number of receive bytes).

SALE Bit (Slave Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

NACKE Bit (NACK Reception Transfer Suspension Enable)

This bit is used to specify whether to continue or discontinue the transfer operation when NACK is received from the slave device in transmit mode. Normally, set this bit to 1.
When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended.
When the NACKE bit is 0, the next transfer operation is continued regardless of the received acknowledge content.
For details on the NACK reception transfer suspension function, refer to section 42.8.2, NACK Reception Transfer Suspension Function.

SCLE Bit (SCL Synchronous Circuit Enable)

This bit is used to specify whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.
When the SCLE bit is set to 0 (no SCL synchronous circuit used), the RIIC does not synchronize the SCL clock with the SCL input clock. In this setting, the RIIC outputs the SCL clock with the transfer rate set in registers ICBRH and ICBRL regardless of the SCLn line state. For this reason, if the bus load of the I2C-bus line is much larger than the specification value or if the SCL clock output overlaps in multiple masters, the short-cycle SCL clock that does not meet the specification may be output. When no SCL synchronous circuit is used, it also affects the issuance of a start condition, restart condition, and stop condition, and the continuous output of extra SCL clock cycles.
This bit must not be set to 0 except for checking the output of the set transfer rate.

FMPE Bit (Fast-Mode Plus Enable)

This bit is used to specify whether to use a slope control circuit for Fast-mode Plus (Fm+).
When this bit is set to 1, a slope control circuit conforming to the Fast-mode Plus (Fm+) slope control specification (tof) of the I2C-bus is selected. When this bit is set to 0, a slope control circuit conforming to the Standard-mode (Sm) and Fast-mode (Fm) slope control specification (tof) of the I2C-bus is selected.
Set this bit to 1 when using the transmission rate within a range up to 1 Mbps (Fast-mode Plus (Fm+)) of the I2C-bus specification. Set this bit to 0 when using the transmission rate at other rates (up to 100 kbps (Sm), up to 400 kbps (Fm)) or for SMBus (10 to 100 kbps).

42.2.7 I2C-bus Status Enable Register (ICSER)

Address(es): RIIC0.ICSER 0008 8306h, RIIC2.ICSER 0008 8346h

	b7	b6	b5	b4	b3	b2	b1	b0
	HOAE	—	DIDE	—	GCAE	SAR2E	SAR1E	SAR0E
Value after reset:	0	0	0	0	1	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	SAR0E	Slave Address Register 0 Enable	0: Slave address in registers SARL0 and SARU0 is disabled. 1: Slave address in registers SARL0 and SARU0 is enabled.	R/W
b1	SAR1E	Slave Address Register 1 Enable	0: Slave address in registers SARL1 and SARU1 is disabled. 1: Slave address in registers SARL1 and SARU1 is enabled.	R/W
b2	SAR2E	Slave Address Register 2 Enable	0: Slave address in registers SARL2 and SARU2 is disabled. 1: Slave address in registers SARL2 and SARU2 is enabled.	R/W
b3	GCAE	General Call Address Enable	0: General call address detection is disabled. 1: General call address detection is enabled.	R/W
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	DIDE	Device-ID Address Detection Enable	0: Device-ID address detection is disabled. 1: Device-ID address detection is enabled.	R/W
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	HOAE	Host Address Enable	0: Host address detection is disabled. 1: Host address detection is enabled.	R/W

SARyE Bit (Slave Address Register y Enable) (y = 0 to 2)

This bit is used to enable or disable the slave address set in registers SARLy and SARUy.

When this bit is set to 1, the slave address set in registers SARLy and SARUy is enabled and is compared with the received slave address.

When this bit is set to 0, the slave address set in registers SARLy and SARUy is disabled and is ignored even if it matches the received slave address.

GCAE Bit (General Call Address Enable)

This bit is used to specify whether to ignore the general call address (0000 000b + 0 (write): All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the RIIC recognizes the received slave address as the general call address independently of the slave addresses set in registers SARLy and SARUy (y = 0 to 2) and performs data receive operation.

When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

DIDE Bit (Device-ID Address Detection Enable)

This bit is used to specify whether to recognize and execute the device-ID address when a device ID (1111 100b) is received in the first byte after a start condition or restart condition is detected.

When this bit is set to 1, if the received first byte matches the device ID, the RIIC recognizes that the device-ID address has been received. When the following R/W# bit is 0 (write), the RIIC recognizes the second and the following bytes as slave addresses and continues the receive operation.

When this bit is set to 0, the RIIC ignores the received first byte even if it matches the device ID address and recognizes the first byte as a normal slave address.

For details on the device-ID address detection, refer to section 42.7.3, Device-ID Address Detection.

HOAE Bit (Host Address Enable)

This bit is used to specify whether to ignore received host address (0001 000b) when the ICMR3.SMBS bit is 1.

When this bit is set to 1 while the ICMR3.SMBS bit is 1, if the received slave address matches the host address, the RIIC recognizes the received slave address as the host address independently of the slave addresses set in registers SARLy and SARUy (y = 0 to 2) and performs the receive operation.

When the ICMR3.SMBS bit or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

42.2.8 I2C-bus Interrupt Enable Register (ICIER)

Address(es): RIIC0.ICIER 0008 8307h, RIIC2.ICIER 0008 8347h

	b7	b6	b5	b4	b3	b2	b1	b0
	TIE	TEIE	RIE	NAKIE	SPIE	STIE	ALIE	TMOIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMOIE	Timeout Interrupt Request Enable	0: Timeout interrupt (TMOI) request is disabled. 1: Timeout interrupt (TMOI) request is enabled.	R/W
b1	ALIE	Arbitration-Lost Interrupt Request Enable	0: Arbitration-lost interrupt (ALI) request is disabled. 1: Arbitration-lost interrupt (ALI) request is enabled.	R/W
b2	STIE	Start Condition Detection Interrupt Request Enable	0: Start condition detection interrupt (STI) request is disabled. 1: Start condition detection interrupt (STI) request is enabled.	R/W
b3	SPIE	Stop Condition Detection Interrupt Request Enable	0: Stop condition detection interrupt (SPI) request is disabled. 1: Stop condition detection interrupt (SPI) request is enabled.	R/W
b4	NAKIE	NACK Reception Interrupt Request Enable	0: NACK reception interrupt (NAKI) request is disabled. 1: NACK reception interrupt (NAKI) request is enabled.	R/W
b5	RIE	Receive Data Full Interrupt Request Enable	0: Receive data full interrupt (RXI) request is disabled. 1: Receive data full interrupt (RXI) request is enabled.	R/W
b6	TEIE	Transmit End Interrupt Request Enable	0: Transmit end interrupt (TEI) request is disabled. 1: Transmit end interrupt (TEI) request is enabled.	R/W
b7	TIE	Transmit Data Empty Interrupt Request Enable	0: Transmit data empty interrupt (TXI) request is disabled. 1: Transmit data empty interrupt (TXI) request is enabled.	R/W

TMOIE Bit (Timeout Interrupt Request Enable)

This bit is used to enable or disable timeout interrupt (TMOI) requests when the ICSR2.TMOF flag is set to 1. A TMOI interrupt request is canceled by setting the TMOF flag or the TMOIE bit to 0.

ALIE Bit (Arbitration-Lost Interrupt Request Enable)

This bit is used to enable or disable arbitration-lost interrupt (ALI) requests when the ICSR2.AL flag is set to 1. An ALI interrupt request is canceled by setting the AL flag or the ALIE bit to 0.

STIE Bit (Start Condition Detection Interrupt Request Enable)

This bit is used to enable or disable start condition detection interrupt (STI) requests when the ICSR2.START flag is set to 1. An STI interrupt request is canceled by setting the START flag or the STIE bit to 0.

SPIE Bit (Stop Condition Detection Interrupt Request Enable)

This bit is used to enable or disable stop condition detection interrupt (SPI) requests when the ICSR2.STOP flag is set to 1. An SPI interrupt request is canceled by setting the STOP flag or the SPIE bit to 0.

NAKIE Bit (NACK Reception Interrupt Request Enable)

This bit is used to enable or disable NACK reception interrupt (NAKI) requests when the ICSR2.NACKF flag is set to 1. An NAKI interrupt request is canceled by setting the NACKF flag or the NAKIE bit to 0.

RIE Bit (Receive Data Full Interrupt Request Enable)

This bit is used to enable or disable receive data full interrupt (RXI) requests when the ICSR2.RDRF flag is set to 1.

TEIE Bit (Transmit End Interrupt Request Enable)

This bit is used to enable or disable transmit end interrupt (TEI) requests when the ICSR2.TEND flag is set to 1. An TEI interrupt request is canceled by setting the TEND flag or the TEIE bit to 0.

TIE Bit (Transmit Data Empty Interrupt Request Enable)

This bit is used to enable or disable transmit data empty interrupt (TXI) requests when the ICSR2.TDRE flag is set to 1.

42.2.9 I2C-bus Status Register 1 (ICSR1)

Address(es): RIIC0.ICSR1 0008 8308h, RIIC2.ICSR1 0008 8348h

	b7	b6	b5	b4	b3	b2	b1	b0
	HOA	—	DID	—	GCA	AAS2	AAS1	AAS0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	AAS0	Slave Address 0 Detection Flag	0: Slave address 0 is not detected. 1: Slave address 0 is detected.	R/(W) *1
b1	AAS1	Slave Address 1 Detection Flag	0: Slave address 1 is not detected. 1: Slave address 1 is detected.	R/(W) *1
b2	AAS2	Slave Address 2 Detection Flag	0: Slave address 2 is not detected. 1: Slave address 2 is detected.	R/(W) *1
b3	GCA	General Call Address Detection Flag	0: General call address is not detected. 1: General call address is detected.	R/(W) *1
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	DID	Device-ID Address Detection Flag	0: Device-ID command is not detected. 1: Device-ID command is detected. • This bit is set to 1 when the first byte received immediately after a start condition is detected matches a value of (device ID (1111 100b) + 0 (write)).	R/(W) *1
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	HOA	Host Address Detection Flag	0: Host address is not detected. 1: Host address is detected. • This bit is set to 1 when the received slave address matches the host address (0001 000b).	R/(W) *1

Note 1. Only 0 can be written to clear the flag.

AASy Flag (Slave Address y Detection Flag) (y = 0 to 2)

[Setting conditions]

For 7-bit address format: SARUy.FS bit = 0

- When the received slave address matches the SARLy.SVA[6:0] bits value with the ICSER.SARyE bit set to 1 (slave address y detection enabled)
  This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the first byte.

For 10-bit address format: SARUy.FS bit = 1

- When the received slave address matches a value of (11110b + SARUy.SVA[1:0] bits) and the following address matches the SARLy value with the ICSER.SARyE bit set to 1 (slave address y detection enabled)
  This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the second byte.

[Clearing conditions]

- When 0 is written to the AASy flag after reading the AASy flag to be 1
- When a stop condition is detected
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

For 7-bit address format: SARUy.FS bit = 0

- When the received slave address does not match the SARLy.SVA[6:0] bits value with the ICSER.SARyE bit set to 1 (slave address y detection enabled)
  This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the first byte.

For 10-bit address format: SARUy.FS bit = 1

- When the received slave address does not match a value of (11110b + SARUy.SVA[1:0] bits) with the ICSER.SARyE bit set to 1 (slave address y detection enabled)
  This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the first byte.
- When the received slave address matches a value of (11110b + SARUy.SVA[1:0] bits) and the following address does not match the SARLy value with the ICSER.SARyE bit set to 1 (slave address y detection enabled)
  This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the second byte.

GCA Flag (General Call Address Detection Flag)

[Setting condition]

- When the received slave address matches the general call address (0000 000b + 0 (write)) with the ICSER.GCAE bit set to 1 (general call address detection is enabled)
  This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the first byte.

[Clearing conditions]

- When 0 is written to the GCA flag after reading GCA flag to be 1
- When a stop condition is detected
- When the received slave address does not match the general call address (0000 000b + 0 (write)) with the ICSER.GCAE bit set to 1 (general call address detection is enabled)
  This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the first byte.
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

DID Flag (Device-ID Address Detection Flag)

[Setting condition]

- When the first byte received immediately after a start condition or restart condition is detected matches a value of (device ID (1111 100b) + 0 (write)) with the ICSER.DIDE bit set to 1 (device-ID address detection is enabled)
  This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the first byte.

[Clearing conditions]

- When 0 is written to the DID flag after reading DID flag to be 1
- When a stop condition is detected
- When the first byte received immediately after a start condition or restart condition is detected does not match a value of (device ID (1111 100b)) with the ICSER.DIDE bit set to 1 (device-ID address detection is enabled)
  This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the first byte.
- When the first byte received immediately after a start condition or restart condition is detected matches a value of (device ID (1111 100b) + 0 (write)) and the second byte does not match any of slave addresses 0 to 2 with the ICSER.DIDE bit set to 1 (device-ID address detection is enabled)
  This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the second byte.
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

HOA Flag (Host Address Detection Flag)

[Setting condition]

- When the received slave address matches the host address (0001 000b) with the ICSER.HOAE bit set to 1 (host address detection is enabled)
  This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the first byte.

[Clearing conditions]

- When 0 is written to the HOA flag after reading HOA flag to be 1
- When a stop condition is detected
- When the received slave address does not match the host address (0001 000b) with the ICSER.HOAE bit set to 1

(host address detection is enabled)
This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the first byte.

- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

42.2.10 I2C-bus Status Register 2 (ICSR2)

Address(es): RIIC0.ICSR2 0008 8309h, RIIC2.ICSR2 0008 8349h

	b7	b6	b5	b4	b3	b2	b1	b0
	TDRE	TEND	RDRF	NACKF	STOP	START	AL	TMOF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMOF	Timeout Detection Flag	0: Timeout is not detected. 1: Timeout is detected.	R/(W) *1
b1	AL	Arbitration-Lost Flag	0: Arbitration is not lost. 1: Arbitration is lost.	R/(W) *1
b2	START	Start Condition Detection Flag	0: Start condition is not detected. 1: Start condition is detected.	R/(W) *1
b3	STOP	Stop Condition Detection Flag	0: Stop condition is not detected. 1: Stop condition is detected.	R/(W) *1
b4	NACKF	NACK Detection Flag	0: NACK is not detected. 1: NACK is detected.	R/(W) *1
b5	RDRF	Receive Data Full Flag	0: The ICDRR register contains no receive data. 1: The ICDRR register contains receive data.	R/(W) *1
b6	TEND	Transmit End Flag	0: Data is being transmitted. 1: Data has been transmitted.	R/(W) *1
b7	TDRE	Transmit Data Empty Flag	0: The ICDRT register contains transmit data. 1: The ICDRT register contains no transmit data.	R

Note 1. Only 0 can be written to clear the flag.

TMOF Flag (Timeout Detection Flag)

This flag is set to 1 when the RIIC recognizes timeout after the SCLn line state remains unchanged for a certain period.
[Setting condition]

- When the SCLn line state remains unchanged for the period specified by bits ICMR2.TMOH, TMOL, and TMOS while the ICFER.TMOE bit is 1 (the timeout function is enabled) in master mode or in slave mode and the received slave address matches.

[Clearing conditions]

- When 0 is written to the TMOF bit after reading TMOF = 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

AL Flag (Arbitration-Lost Flag)

This flag shows that bus mastership has been lost (loss in arbitration) due to a bus conflict or some other reason when a start condition is issued or an address and data are transmitted. The RIIC monitors the level on the SDAn line during transmission and, if the level on the line does not match the value of the bit being output, sets the value of the AL flag to 1 to indicate that the bus is occupied by another device.
The RIIC can also set the flag to indicate the detection of loss of arbitration during NACK transmission in master mode or during data transmission in slave mode.

[Setting conditions]

When master arbitration-lost detection is enabled: ICFER.MALE = 1

- When the internal SDA output state does not match the SDAn line level at the rising edge of SCL clock except for the ACK period during data (including slave address) transmission in master transmit mode (when the SDAn line is driven low while the internal SDA output is at a high level (the SDAn pin is in the high-impedance state))
- When a start condition is detected while the ICCR2.ST bit is 1 (start condition issuance request) or the internal SDA output state does not match the SDAn line level
- When the ICCR2.ST bit is set to 1 (start condition issuance request) with the ICCR2.BBSY flag set to 1.

When NACK arbitration-lost detection is enabled: ICFER.NALE = 1

- When the internal SDA output state does not match the SDAn line level at the rising edge of SCL clock in the ACK period during NACK transmission in receive mode

When slave arbitration-lost detection is enabled: ICFER.SALE = 1

- When the internal SDA output state does not match the SDAn line level at the rising edge of SCL clock except for the ACK period during data transmission in slave transmit mode

[Clearing conditions]

- When 0 is written to the AL flag after reading AL = 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Table 42.4 Relationship between Arbitration-Lost Generation Sources and Arbitration-Lost Enable Functions

ICFER			ICSR2		
MALE	NALE	SALE	AL	Error	Arbitration-Lost Generation Source
1	×	×	1	Start condition issuance error	When internal SDA output state does not match SDAn line level when a start condition is detected while the ICCR2.ST bit is 1
					When ICCR2.ST bit is set to 1 with ICCR2.BBSY flag set to 1
			1	Transmit data mismatch	When transmit data (including slave address) does not match the bus state in master transmit mode
×	1	×	1	NACK transmission mismatch	When ACK is detected during transmission of NACK in master receive mode or slave receive mode
×	×	1	1	Transmit data mismatch	When transmit data does not match the bus state in slave transmit mode

×: Don't care

START Flag (Start Condition Detection Flag)

[Setting condition]

- When a start condition (or a restart condition) is detected

[Clearing conditions]

- When 0 is written to the START bit after reading START = 1
- When a stop condition is detected
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

STOP Flag (Stop Condition Detection Flag)

[Setting condition]

- When a stop condition is detected

[Clearing conditions]

- When 0 is written to the STOP bit after reading STOP = 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

NACKF Flag (NACK Detection Flag)

[Setting condition]

- When acknowledge is not received (NACK is received) from the receive device in transmit mode with the ICFER.NACKE bit set to 1 (transfer suspension enabled)

[Clearing conditions]

- When 0 is written to the NACKF bit after reading NACKF = 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Note: When the NACKF flag is set to 1, the RIIC suspends data transmission/reception. Writing to the ICDRT register in transmit mode or reading from the ICDRR register in receive mode with the NACKF flag set to 1 does not enable data transmit/receive operation. To restart data transmission/reception, set the NACKF flag to 0.

RDRF Flag (Receive Data Full Flag)

[Setting conditions]

- When receive data has been transferred from the ICDRS register to the ICDRR register
  This flag is set to 1 at the rising edge of the eighth or ninth SCL clock cycle (selected by the ICMR3.RDRFS bit)
- When the received slave address matches after a start condition (or a restart condition) is detected with the ICCR2.TRS bit set to 0

[Clearing conditions]

- When 0 is written to the RDRF bit after reading RDRF = 1
- When data is read from the ICDRR register
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

TEND Flag (Transmit End Flag)

[Setting condition]

- At the rising edge of the ninth SCL clock cycle while the TDRE flag is 1

[Clearing conditions]

- When 0 is written to the TEND bit after reading TEND = 1
- When data is written to the ICDRT register
- When a stop condition is detected
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

TDRE Flag (Transmit Data Empty Flag)

[Setting conditions]

- When data has been transferred from the ICDRT register to the ICDRS register and the ICDRT register becomes empty
- When the ICCR2.TRS bit is set to 1
- When the received slave address matches while the TRS bit is 1

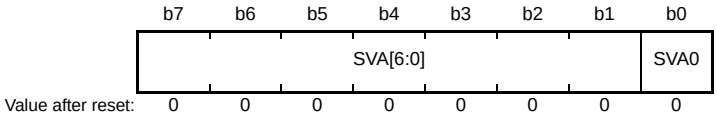
[Clearing conditions]

- When data is written to the ICDRT register
- When the ICCR2.TRS bit is set to 0
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Note: When the NACKF flag is set to 1 while the ICFER.NACKE bit is 1, the RIIC suspends data transmission/reception. Here, if the TDRE flag is 0 (next transmit data has been written), data is transferred to the ICDRS register and the ICDRT register becomes empty at the rising edge of the ninth clock cycle, but the TDRE flag is not set to 1.

42.2.11 Slave Address Register Ly (SARLy) (y = 0 to 2)

Address(es): RIIC0.SARL0 0008 830Ah, RIIC2.SARL0 0008 834Ah, RIIC0.SARL1 0008 830Ch, RIIC2.SARL1 0008 834Ch, RIIC0.SARL2 0008 830Eh, RIIC2.SARL2 0008 834Eh



Bit	Symbol	Bit Name	Description	R/W
b0	SVA0	10-Bit Address LSB	A slave address is set.	R/W
b7 to b1	SVA[6:0]	7-Bit Address/10-Bit Address Lower Bits	A slave address is set.	R/W

SVA0 Bit (10-Bit Address LSB)

When the 10-bit address format is selected (SARUy.FS bit is 1), this bit functions as the LSB of a 10-bit address and forms the lower 8 bits of a 10-bit address in combination with the SVA[6:0] bits.

When the ICSER.SARyE bit is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1, this bit is valid. While the SARUy.FS bit or SARyE bit is 0, the setting of this bit is ignored.

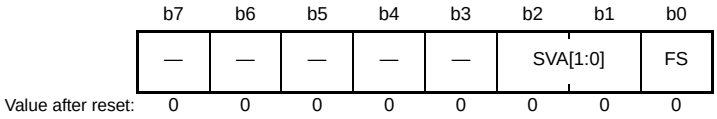
SVA[6:0] Bits (7-Bit Address/10-Bit Address Lower Bits)

When the 7-bit address format is selected (SARUy.FS bit is 0), these bits function as a 7-bit address. When the 10-bit address format is selected (SARUy.FS bit is 1), these bits function as the lower 8 bits of a 10-bit address in combination with the SVA0 bit.

While the ICSER.SARyE bit is 0, the setting of these bits is ignored.

42.2.12 Slave Address Register Uy (SARUy) (y = 0 to 2)

Address(es): RIIC0.SARU0 0008 830Bh, RIIC2.SARU0 0008 834Bh, RIIC0.SARU1 0008 830Dh, RIIC2.SARU1 0008 834Dh, RIIC0.SARU2 0008 830Fh, RIIC2.SARU2 0008 834Fh



Bit	Symbol	Bit Name	Description	R/W
b0	FS	7-Bit/10-Bit Address Format Select	0: The 7-bit address format is selected. 1: The 10-bit address format is selected.	R/W
b2, b1	SVA[1:0]	10-Bit Address Upper Bits	A slave address is set.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

FS Bit (7-Bit/10-Bit Address Format Select)

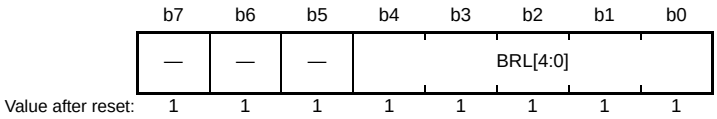
This bit is used to select 7-bit address or 10-bit address for slave address y (in registers SARLy and SARUy).
When the ICSER.SARyE bit is set to 1 (registers SARLy and SARUy enabled) and the SARUy.FS bit is 0, the 7-bit address format is selected for slave address y, the SARLy.SVA[6:0] bits setting is valid, and the settings of the SVA[1:0] bits and the SARLy.SVA0 bit are ignored.
When the ICSER.SARyE bit is set to 1 (registers SARLy and SARUy enabled) and the SARUy.FS bit is 1, the 10-bit address format is selected for slave address y and the settings of the SVA[1:0] bits and SARLy are valid.
While the ICSER.SARyE bit is 0 (registers SARLy and SARUy disabled), the setting of the SARUy.FS bit is invalid.

SVA[1:0] Bits (10-Bit Address Upper Bits)

When the 10-bit address format is selected (FS = 1), these bits function as the upper 2 bits of a 10-bit address.
When the ICSER.SARyE bit is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1, these bits are valid.
While the SARUy.FS bit or SARyE bit is 0, the setting of these bits is ignored.

42.2.13 I2C-bus Bit Rate Low-Level Register (ICBRL)

Address(es): RIIC0.ICBRL 0008 8310h, RIIC2.ICBRL 0008 8350h



Bit	Symbol	Bit Name	Description	R/W
b4 to b0	BRL[4:0]	Bit Rate Low-Level Period	Low-level period of SCL clock	R/W
b7 to b5	—	Reserved	These bits are read as 1. The write value should be 1.	R/W

ICBRL is a 5-bit register to set the low-level period of SCL clock.
It also works to generate the data setup time for automatic SCL low-hold operation (refer to section 42.8, Automatic Low-Hold Function for SCL); when the RIIC is used only in slave mode, this register needs to be set to a value longer than the data setup time*1.
ICBRL counts the low-level period with the internal reference clock (IICφ) specified by the ICMR1.CKS[2:0] bits.
If the digital noise filter is enabled (the ICFER.NFE bit is 1), set the ICBRL register to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the ICMR3.NF[1:0] bits.

Note 1. Data setup time (tSU: DAT)
250 ns (up to 100 kbps: Standard-mode (Sm))
100 ns (up to 400 kbps: Fast-mode (Fm))
50 ns (up to 1 Mbps: Fast-mode plus (Fm+))

42.2.14 I2C-bus Bit Rate High-Level Register (ICBRH)

Address(es): RIIC0.ICBRH 0008 8311h, RIIC2.ICBRH 0008 8351h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	BRH[4:0]				
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	BRH[4:0]	Bit Rate High-Level Period	High-level period of SCL clock	R/W
b7 to b5	—	Reserved	These bits are read as 1. The write value should be 1.	R/W

ICBRH is a 5-bit register to set the high-level period of SCL clock. ICBRH is valid in master mode. If the RIIC is used only in slave mode, this register need not to set the high-level period.
ICBRH counts the high-level period with the internal reference clock (IICφ) specified by the ICMR1.CKS[2:0] bits.
If the digital noise filter is enabled (the ICFER.NFE bit is 1), set the ICBRH register to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the ICMR3.NF[1:0] bits.

The I2C transfer rate and the SCL clock duty are calculated using the following expression.
Transfer rate = 1 / {[(ICBRH + 1) + (ICBRL + 1)] / IICφ*1 + SCLn line rising time [tr] + SCLn line falling time [tf]}
Duty cycle = {SCLn line rising time [tr]*2 + (ICBRH + 1) / IICφ} / {SCLn line falling time [tf]*2 + (ICBRL + 1) / IICφ}

Note 1. IICφ = PCLK × Division ratio
Note 2. The SCLn line rising time [tr] and SCLn line falling time [tf] depend on the total bus line capacitance [Cb] and the pull-up resistor [Rp]. For details, see the I2C-bus specification from NXP Semiconductors.

Table 42.5 lists examples of ICBRH/ICBRL settings.

Table 42.5 Examples of ICBRH/ICBRL Settings for Transfer Rate

Transfer Rate (kbps)	Operating Frequency PCLK (MHz)								
	8			10			12.5

Note: ICBRH/ICBRL settings in these tables are calculated using the following values:
SCLn line rising time (tr): 100 kbps or less (Sm): 1000 ns, 400 kbps or less (Fm): 300 ns, 1 Mbps or less (Fm+): 120 ns
SCLn line falling time (tf): 400 kbps or less (Sm/Fm): 300 ns, 1 Mbps or less (Fm+): 120 ns
For the specified values of SCLn line rising time (tr) and SCLn line falling time (tf), see the I2C-bus specification from NXP Semiconductors.

42.2.15 I2C-bus Transmit Data Register (ICDRT)

Address(es): RIIC0.ICDRT 0008 8312h, RIIC2.ICDRT 0008 8352h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

When the ICDRT register detects a space in the I2C-bus shift register (ICDRS), it transfers the transmit data that has been written to the ICDRT register to the ICDRS register and starts transmitting data in transmit mode.
The double-buffer structure of the ICDRT register and the ICDRS register allows continuous transmit operation if the next transmit data has been written to the ICDRT register while the ICDRS register data is being transmitted.
The ICDRT register can always be read and written. Write transmit data to the ICDRT register once when a transmit data empty interrupt (TXI) request is generated.

42.2.16 I2C-bus Receive Data Register (ICDRR)

Address(es): RIIC0.ICDRR 0008 8313h, RIIC2.ICDRR 0008 8353h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

When 1 byte of data has been received, the received data is transferred from the I2C-bus shift register (ICDRS) to the ICDRR register to enable the next data to be received.
The double-buffer structure of the ICDRS register and the ICDRR register allows continuous receive operation if the received data has been read from the ICDRR register while the ICDRS register is receiving data.
The ICDRR register cannot be written. Read data from the ICDRR register once when a receive data full interrupt (RXI) request is generated.
If the ICDRR register receives the next receive data before the current data is read from the ICDRR register (while the ICSR2.RDRF flag is 1), the RIIC automatically holds the SCL clock low one cycle before the RDRF flag is set to 1 next.

42.2.17 I2C-bus Shift Register (ICDRS)

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	—	—	—	—	—	—	—	—

The ICDRS register is an 8-bit shift register to transmit and receive data.
During transmission, transmit data is transferred from the ICDRT register to the ICDRS register and is sent from the SDAn pin. During reception, data is transferred from the ICDRS register to the ICDRR register after 1 byte of data has been received.
The ICDRS register cannot be accessed directly.

42.3 Operation

42.3.1 Communication Data Format

The I2C-bus format consists of 8-bit data and 1-bit acknowledge. The first byte following a start condition or restart condition is an address byte used to specify a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is issued.
Figure 42.3 shows the I2C-bus format, and Figure 42.4 shows the I2C-bus timing.

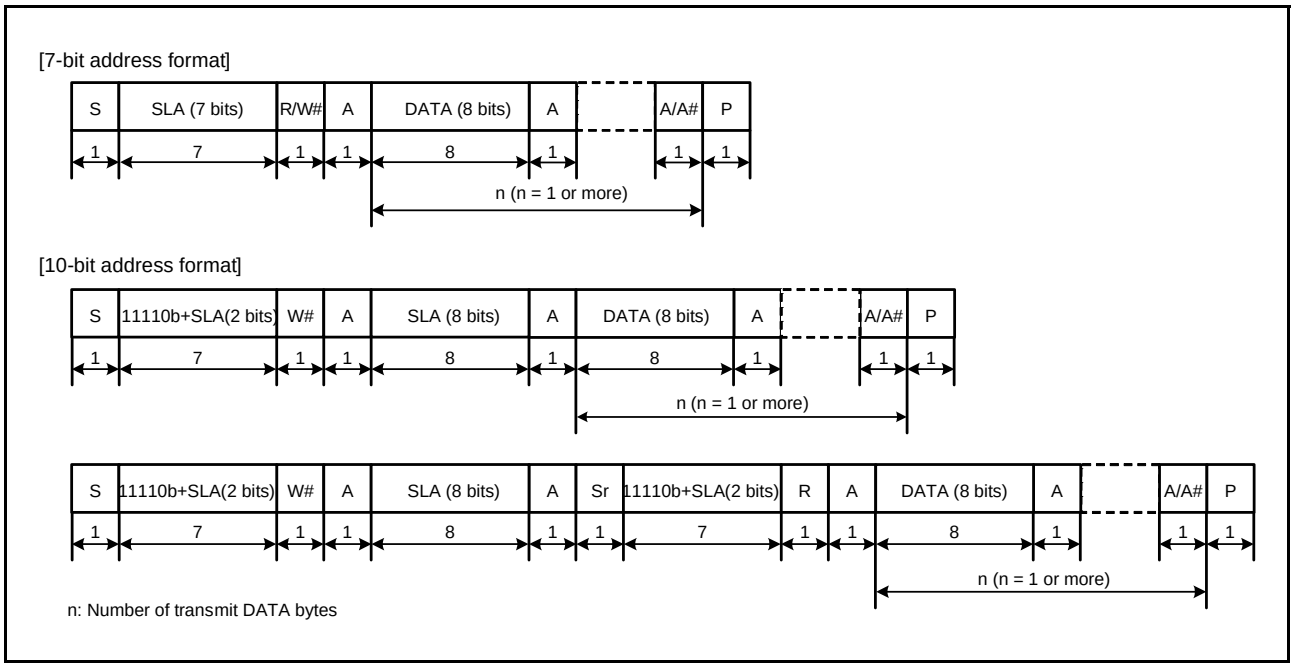

Figure 42.3 I2C-bus Format

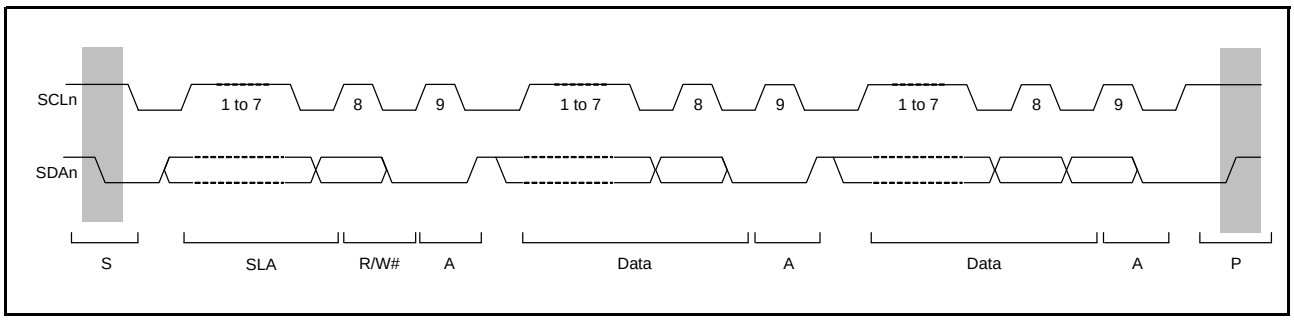

Figure 42.4 I2C-bus Timing (SLA = 7 Bits)

S: Start condition. The master device drives the SDAn line low from high level while the SCLn line is at a high level.

SLA: Slave address, by which the master device selects a slave device.

R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W is 1, or from the master device to the slave device when R/W is 0.

A: Acknowledge. The receive device drives the SDAn line low. (In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.)

A#: Not Acknowledge. The receive device drives the SDAn line high.

Sr: Restart condition. The master device drives the SDAn line low from the high level after the setup time has elapsed with the SCLn line at the high level.

DATA: Transmitted or received data

P: Stop condition. The master device drives the SDAn line high from low level while the SCLn line is at a high level.

42.3.2 Initial Settings

Before starting data transmission and reception, initialize the RIIC according to the procedure in Figure 42.5.
Set the ICCR1.ICE bit to 1 (internal reset) after setting the ICCR1.IICRST bit to 1 (RIIC reset) with the ICCR1.ICE bit set to 0 (SCLn and SDAn pins in inactive state). This initializes the various flags and internal state of the ICSR1 register. After that, set registers SARLy, SARUy, ICSER, ICMR1, ICBRH, and ICBRL (y = 0 to 2), and set the other registers as necessary (for initial settings of the RIIC, see Figure 42.5). When the necessary register settings have been completed, set the ICCR1.IICRST bit to 0 (releases the RIIC reset). This step is not necessary if initialization of the RIIC has already been completed.

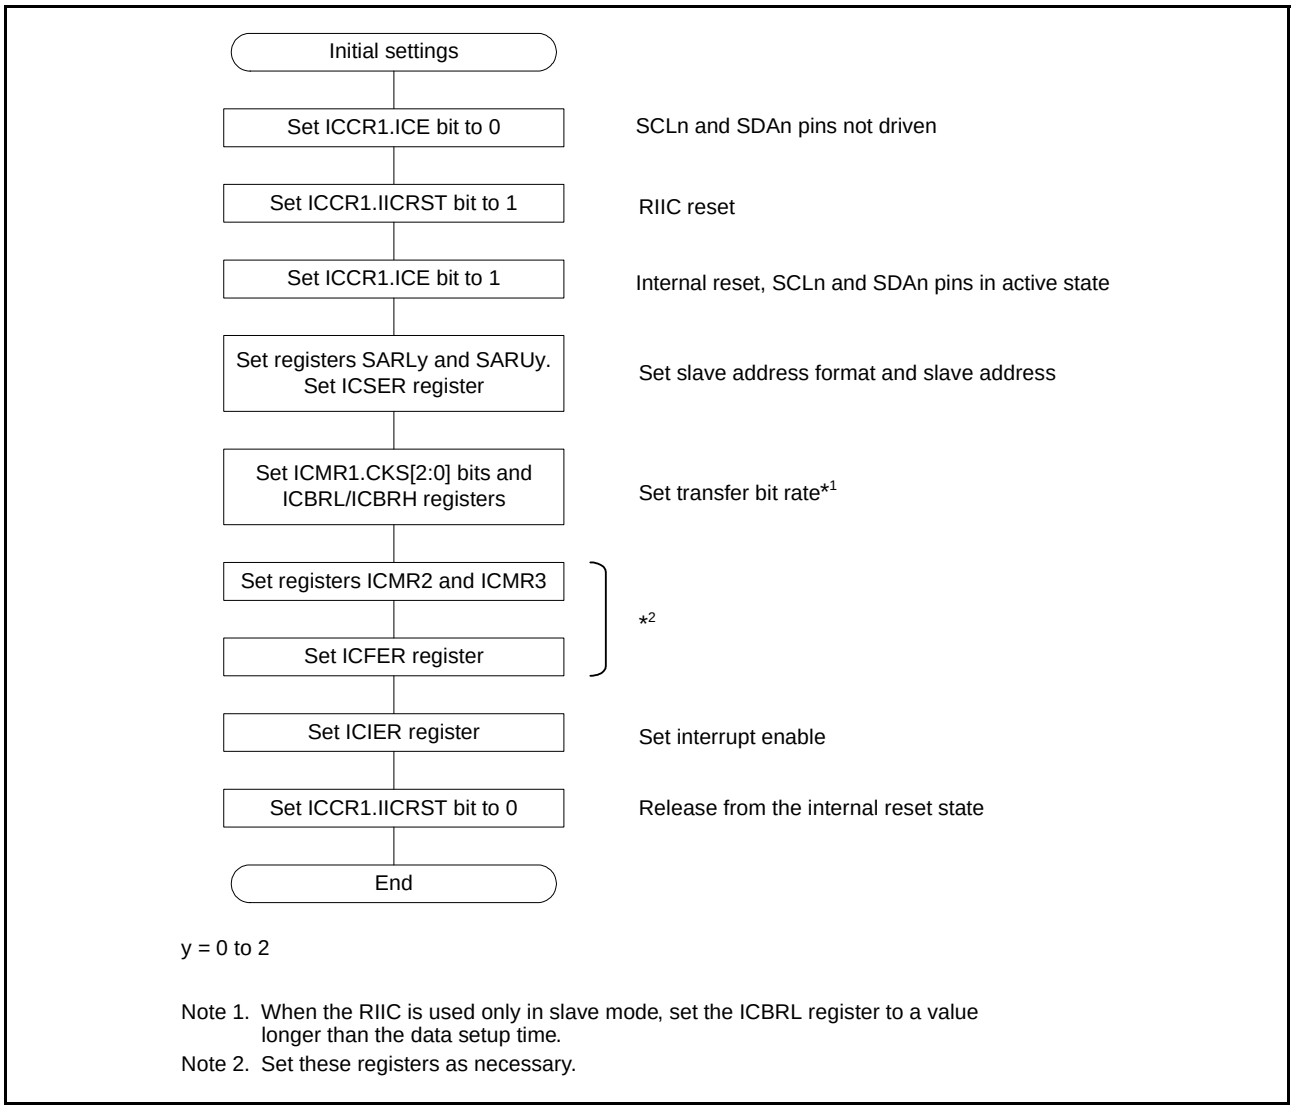

Figure 42.5 Example of RIIC Initialization Flowchart

42.3.3 Master Transmit Operation

In master transmit operation, the RIIC outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgments. Figure 42.6 shows an example of usage of master transmission and Figure 42.7 to Figure 42.9 show the timing of operations in master transmission.
The following describes the procedure and operations for master transmission.

(1) Initial settings. For details, refer to section 42.3.2, Initial Settings.
(2) Read the ICCR2.BBSY flag to check that the bus is open, and then set the ICCR2.ST bit to 1 (start condition issuance request). Upon receiving the request, the RIIC issues a start condition. At the same time, the BBSY flag and the ICSR2.START flag are automatically set to 1 and the ST bit is automatically set to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line have matched while the ST bit is 1, the RIIC recognizes that issuing of the start condition as requested by the ST bit has been successfully completed, and bits MST and TRS in the ICCR2 register are automatically set to 1, placing the RIIC in master transmit mode. The ICSR2.TDRE flag is also automatically set to 1 in response to setting of the TRS bit to 1.
(3) Check that the ICSR2.TDRE flag is 1, and then write the value for transmission (the slave address and the R/W# bit) to the ICDRT register. Once the data for transmission are written to the ICDRT register, the TDRE flag is automatically set to 0, the data are transferred from the ICDRT register to the ICDRS register, and the TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the RIIC continues in master transmit mode.
Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
For data transmission with an address in the 10-bit format, start by writing 1111 0b, the 2 higher-order bits of the slave address, and W to the ICDRT register as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to the ICDRT register.
(4) After confirming that the ICSR2.TDRE flag is 1, write the data for transmission to the ICDRT register. The RIIC automatically holds the SCLn line low until the data for transmission are ready or a stop condition is issued.
(5) After all bytes of data for transmission have been written to the ICDRT register, wait until the value of the ICSR2.TEND flag returns to 1, and then set the ICCR2.SP bit to 1 (stop condition issuance request). Upon receiving a stop condition issuance request, the RIIC issues the stop condition.
(6) Upon detecting the stop condition, the RIIC automatically sets bits MST and TRS in the ICCR2 register to 00b and enters slave receive mode. Furthermore, it automatically sets the TDRE and TEND flags to 0, and sets the ICSR2.STOP flag to 1.
(7) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

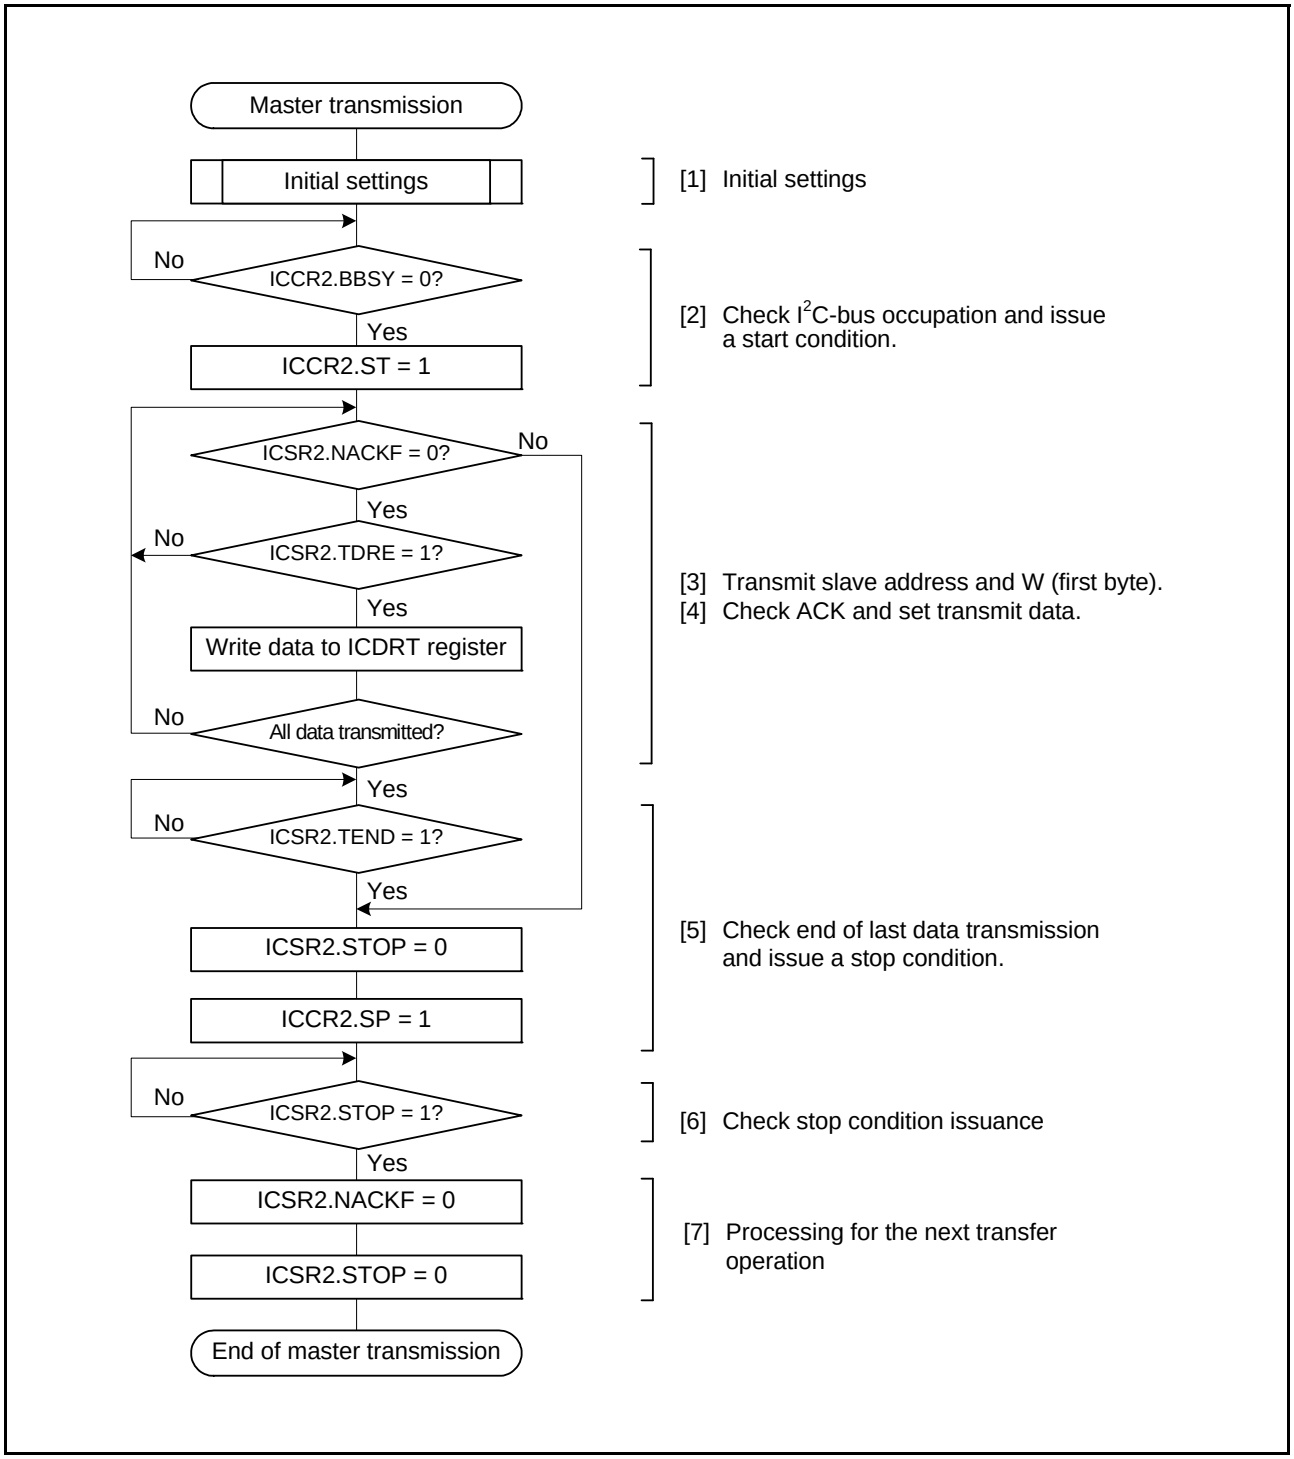

Figure 42.6 Example of Master Transmission Flowchart

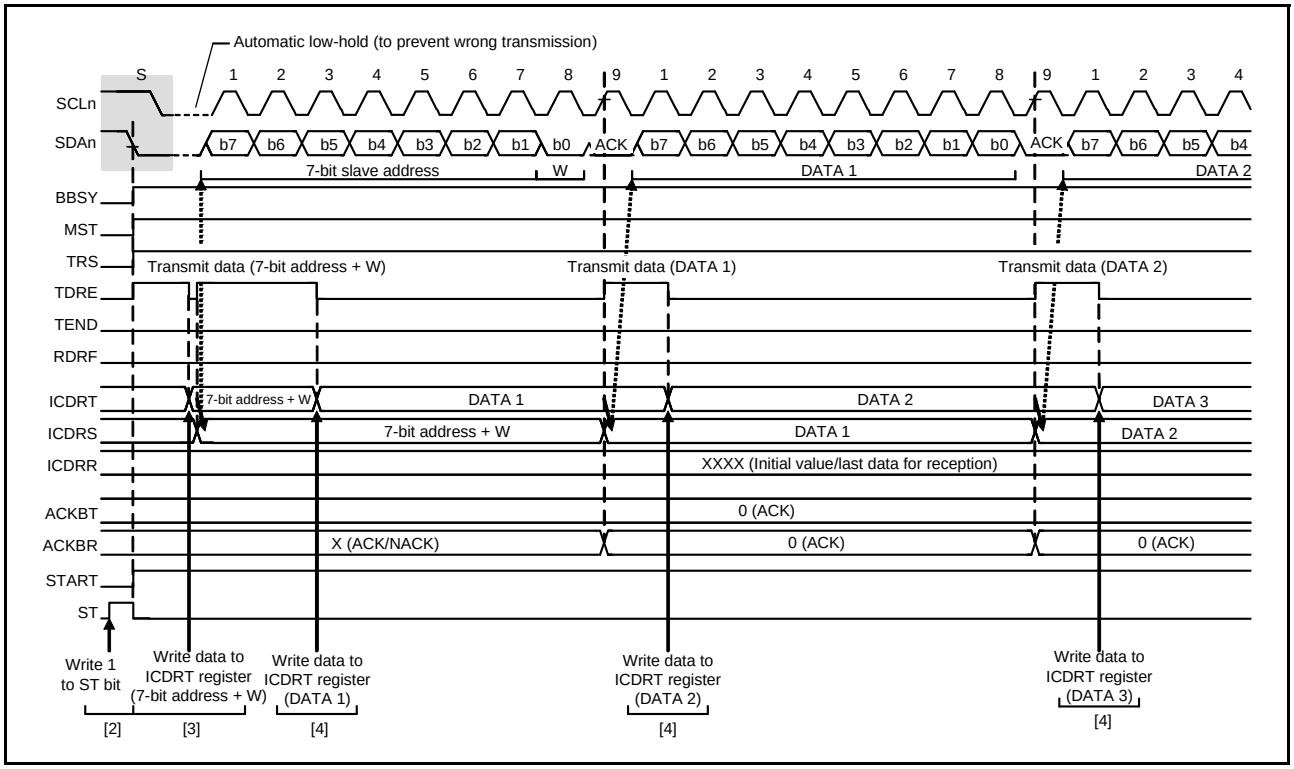

Figure 42.7 Master Transmit Operation Timing (1) (7-Bit Address Format)

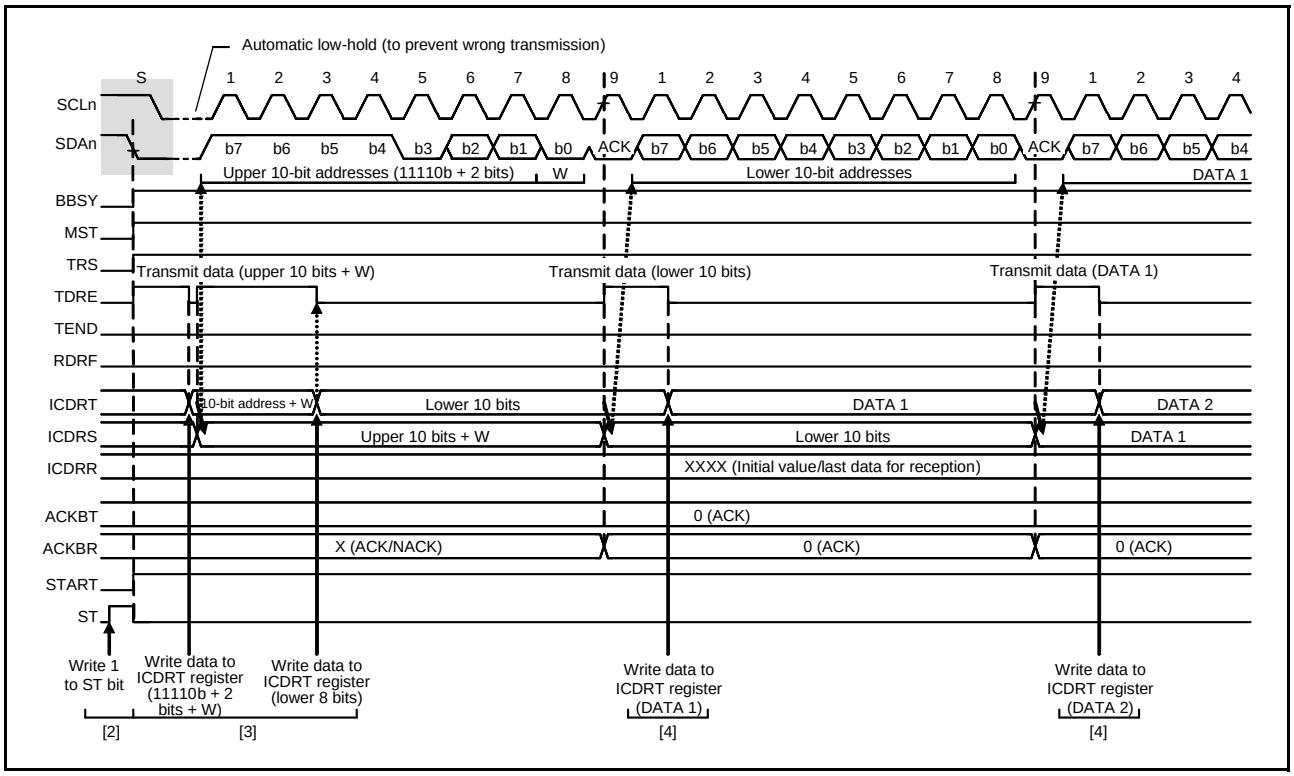

Figure 42.8 Master Transmit Operation Timing (2) (10-Bit Address Format)

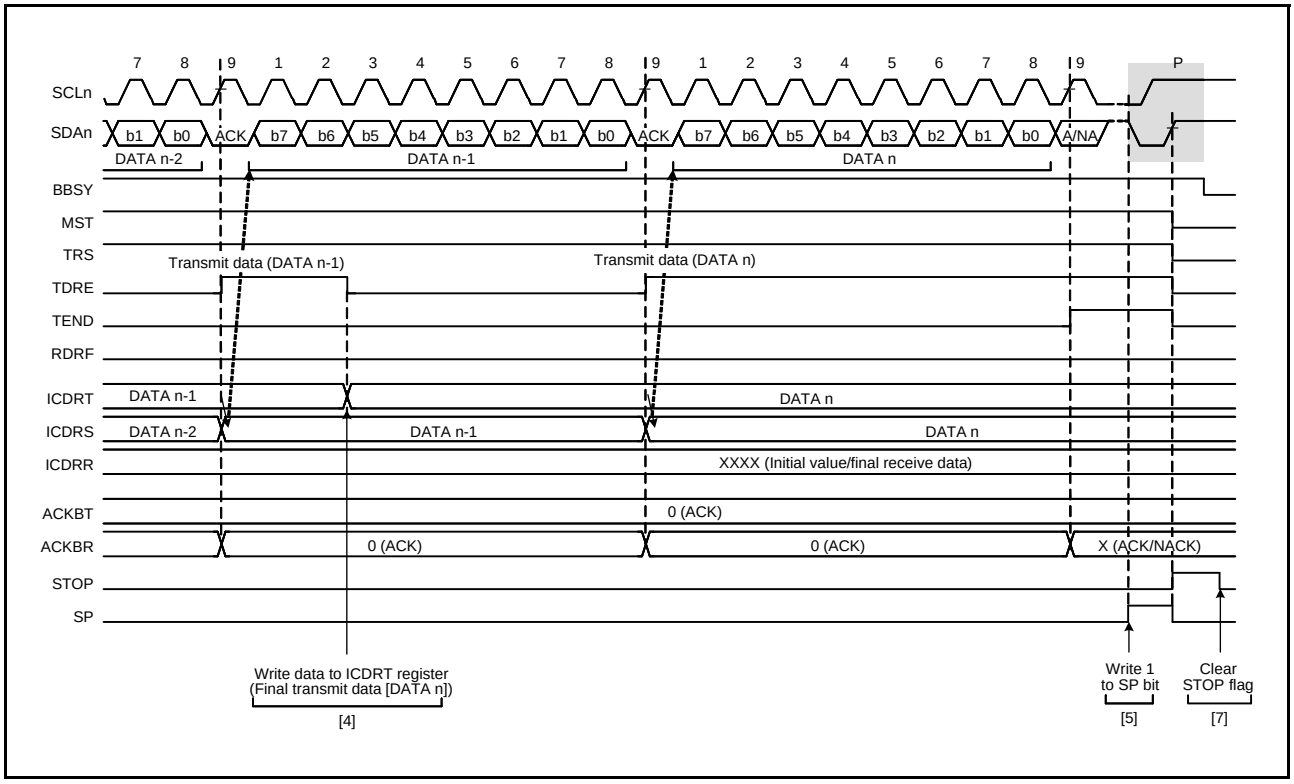

Figure 42.9 Master Transmit Operation Timing (3)

42.3.4 Master Receive Operation

In master receive operation, the RIIC as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because the RIIC must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.
Figure 42.10 and Figure 42.11 show examples of usage of master reception (7-bit address format) and Figure 42.12 to Figure 42.14 show the timing of operations in master reception.
The following describes the procedure and operations for master reception.

(1) Initial settings. For details, refer to section 42.3.2, Initial Settings.

(2) Read the ICCR2.BBSY flag to check that the bus is open, and then set the ICCR2.ST bit to 1 (start condition issuance request). Upon receiving the request, the RIIC issues a start condition. When the RIIC detects the start condition, the BBSY flag and the ICSR2.START flag are automatically set to 1 and the ST bit is automatically set to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDAn line have matched while the ST bit is 1, the RIIC recognizes that issuing of the start condition as requested by the ST bit has been successfully completed, and bits MST and TRS in the ICCR2 register are automatically set to 1, placing the RIIC in master transmit mode. The ICSR2.TDRE flag is also automatically set to 1 in response to setting of the TRS bit to 1.

(3) Check that the ICSR2.TDRE flag is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to the ICDRT register. Once the data for transmission are written to the ICDRT register, the TDRE flag is automatically set to 0, the data are transferred from the ICDRT register to the ICDRS register, and the TDRE flag is again set to 1. Once the byte containing the slave address and R/W# bit has been transmitted, the value of the ICCR2.TRS bit is automatically updated to select transmit or receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the TRS bit is set to 0 on the rising edge of the ninth cycle of SCL clock, placing the RIIC in master receive mode. At this time, the TDRE flag is set to 0 and the ICSR2.RDRF flag is automatically set to 1.

Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a restart condition. After that, transmitting 1111 0b, the two higher-order bits of the slave address, and the R bit places the RIIC in master receive mode.

(4) Dummy read the ICDRR register after confirming that the ICSR2.RDRF flag is 1; this makes the RIIC start output of the SCL clock and start data reception.

(5) After 1 byte of data has been received, the ICSR2.RDRF flag is set to 1 on the rising edge of the eighth or ninth cycle of SCL clock (the clock signal) as selected by the ICMR3.RDRFS bit. Reading the ICDRR register at this time will produce the received data, and the RDRF flag is automatically set to 0 at the same time. Furthermore, the value of the acknowledgment field received during the ninth cycle of SCL clock is returned as the value set in the ICMR3.ACKBT bit. Furthermore, if the next byte to be received is the next to last byte, set the ICMR3.WAIT bit to 1 (for wait insertion) before reading the ICDRR register (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the ICMR3.ACKBT bit to 1 (NACK) in step (6), due to other interrupts, etc., this fixes the SCLn line to the low level on the falling edge of the ninth clock cycle in reception of the last byte, so the state is such that issuing a stop condition is possible.

(6) When the ICMR3.RDRFS bit is 0 and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the ICMR3.ACKBT bit to 1 (NACK).

(7) After reading the byte before last from the ICDRR register, if the value of the ICSR2.RDRF flag is confirmed to be 1, write 1 to the ICCR2.SP bit (stop condition issuance request) and then read the last byte from the ICDRR register. When the ICDRR register is read, the RIIC is released from the wait state and issues the stop condition after low-level output in the ninth clock cycle is completed or the SCLn line is released from the low-hold state.

(8) Upon detecting the stop condition, the RIIC automatically sets bits MST and TRS in the ICCR2 register to 00b and enters slave receive mode. Furthermore, detection of the stop condition leads to setting of the ICSR2.STOP flag to 1.

(9) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

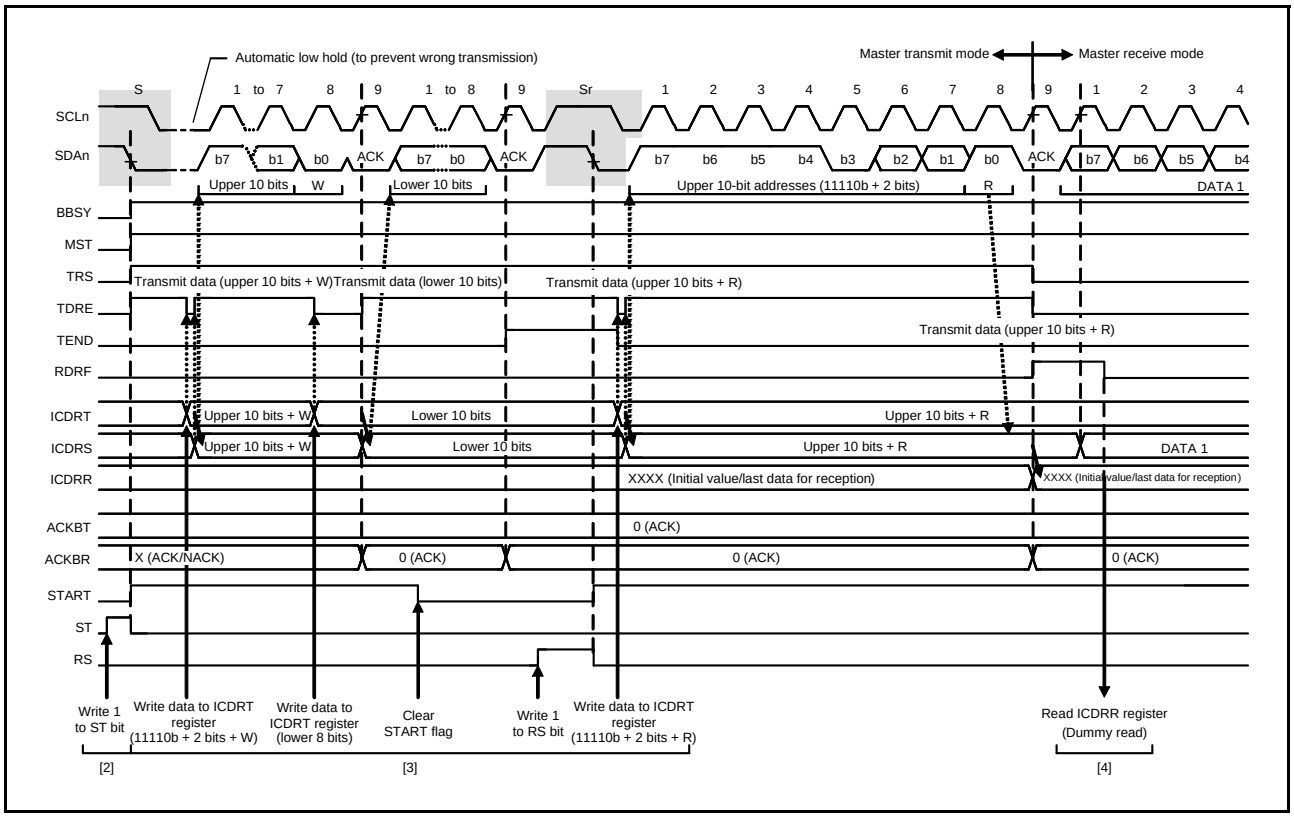

Figure 42.13 Master Receive Operation Timing (2) (10-Bit Address Format, When RDRFS bit is 0)

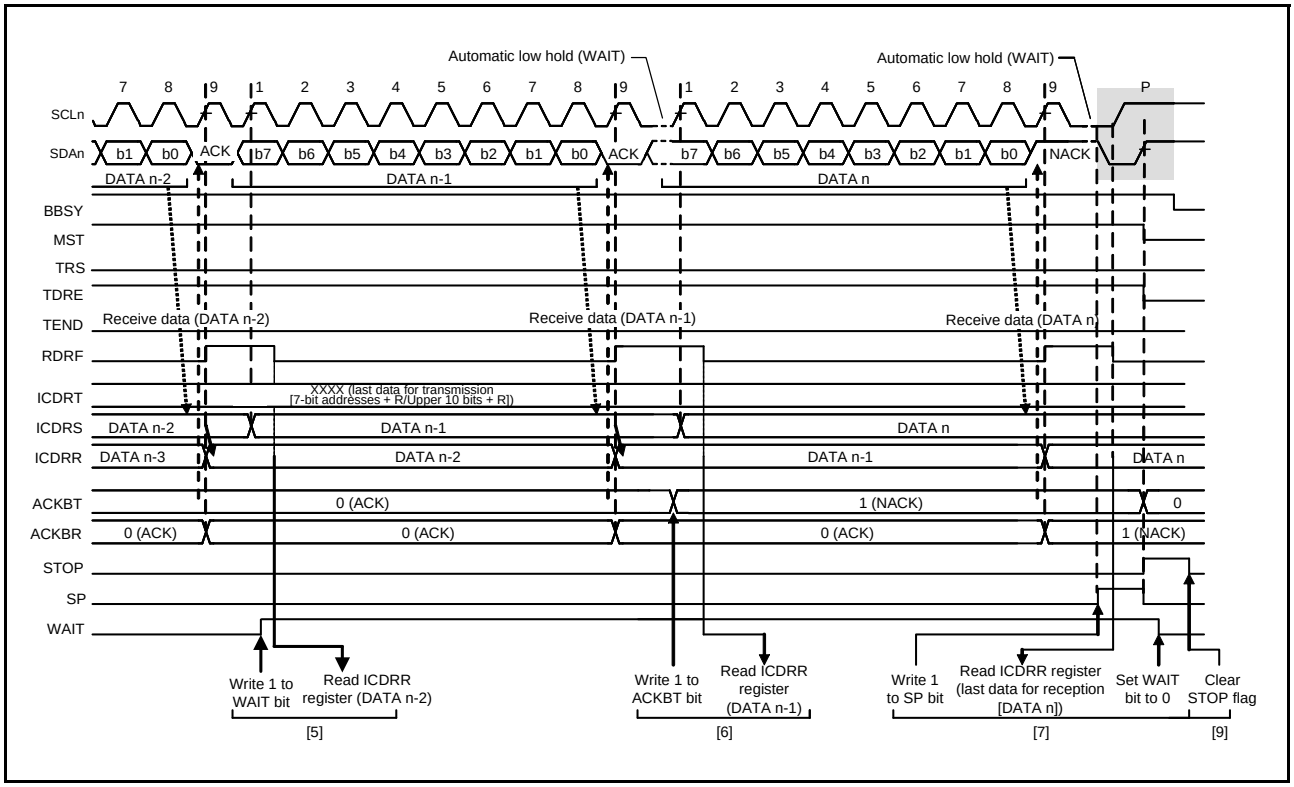

Figure 42.14 Master Receive Operation Timing (3) (When RDRFS bit is 0)

42.3.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL clock, the RIIC transmits data as a slave device, and the master device returns acknowledgments.

Figure 42.15 shows an example of usage of slave transmission and Figure 42.16 and Figure 42.17 show the timing of operations in slave transmission.

The following describes the procedure and operations for slave transmission.

(1) Initial settings. For details, refer to section 42.3.2, Initial Settings.
After initial settings, the RIIC will stay in the standby state until it receives a slave address that it matches.

(2) After receiving a matching slave address, the RIIC sets one of the corresponding bits ICSR1.HOA, GCA, and AASy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 1, the RIIC automatically places itself in slave transmit mode by setting both the ICCR2.TRS bit and the ICSR2.TDRE flag to 1.

(3) After the ICSR2.TDRE flag is confirmed to be 1, write the data for transmission to the ICDRT register. At this time, if the RIIC receives no acknowledge from the master device (receives an NACK signal) while the ICFER.NACKE bit is 1, the RIIC suspends transfer of the next data.

(4) Wait until the ICSR2.TEND flag is set to 1 while the ICSR2.TDRE flag is 1, after the ICSR2.NACKF flag is set to 1 or the last byte for transmission is written to the ICDRT register. When the ICSR2.NACKF flag or the TEND flag is 1, the RIIC drives the SCLn line low on the ninth falling edge of SCL clock.

(5) When the ICSR2.NACKF flag or the ICSR2.TEND flag is 1, dummy read the ICDRR register to complete the processing. This releases the SCLn line.

(6) Upon detecting the stop condition, the RIIC automatically sets bits ICSR1.HOA, GCA, and AASy (y = 0 to 2), flags ICSR2.TDRE and TEND, and the ICCR2.TRS bit to 0, and enters slave receive mode.

(7) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

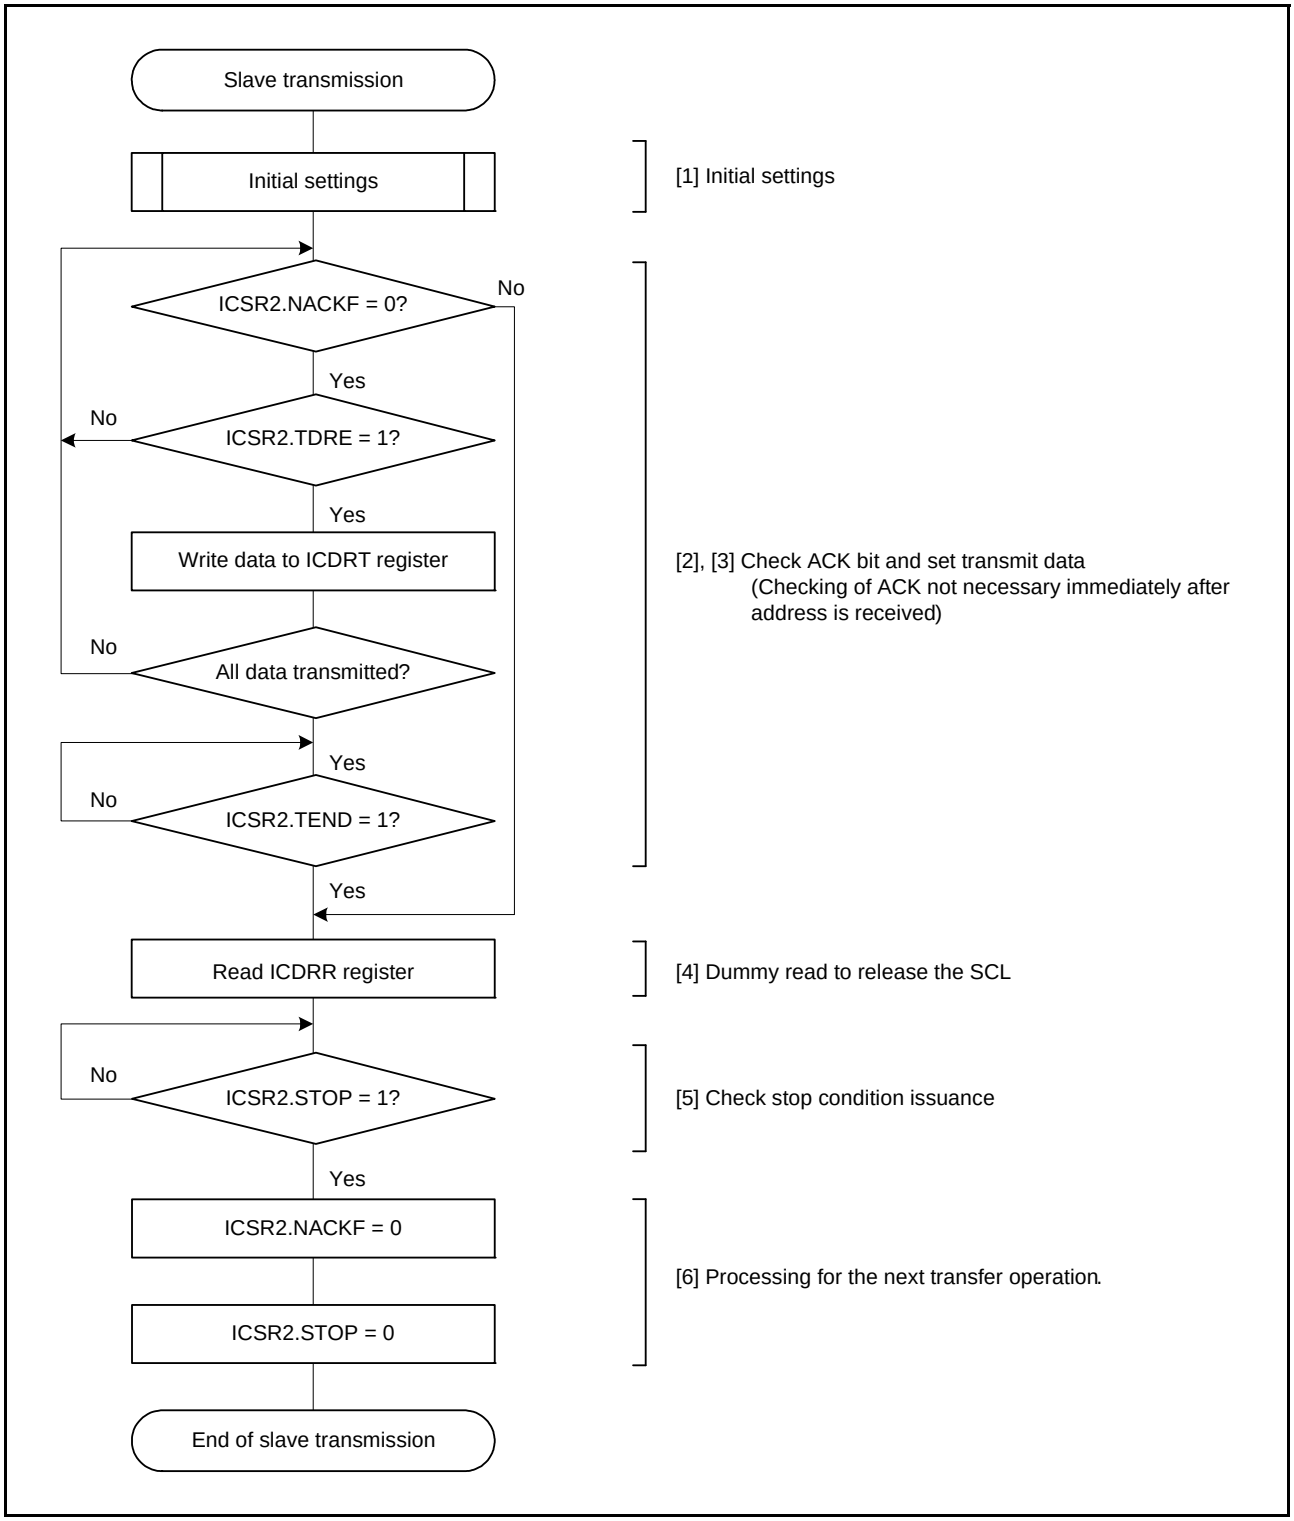

Figure 42.15 Example of Slave Transmission Flowchart

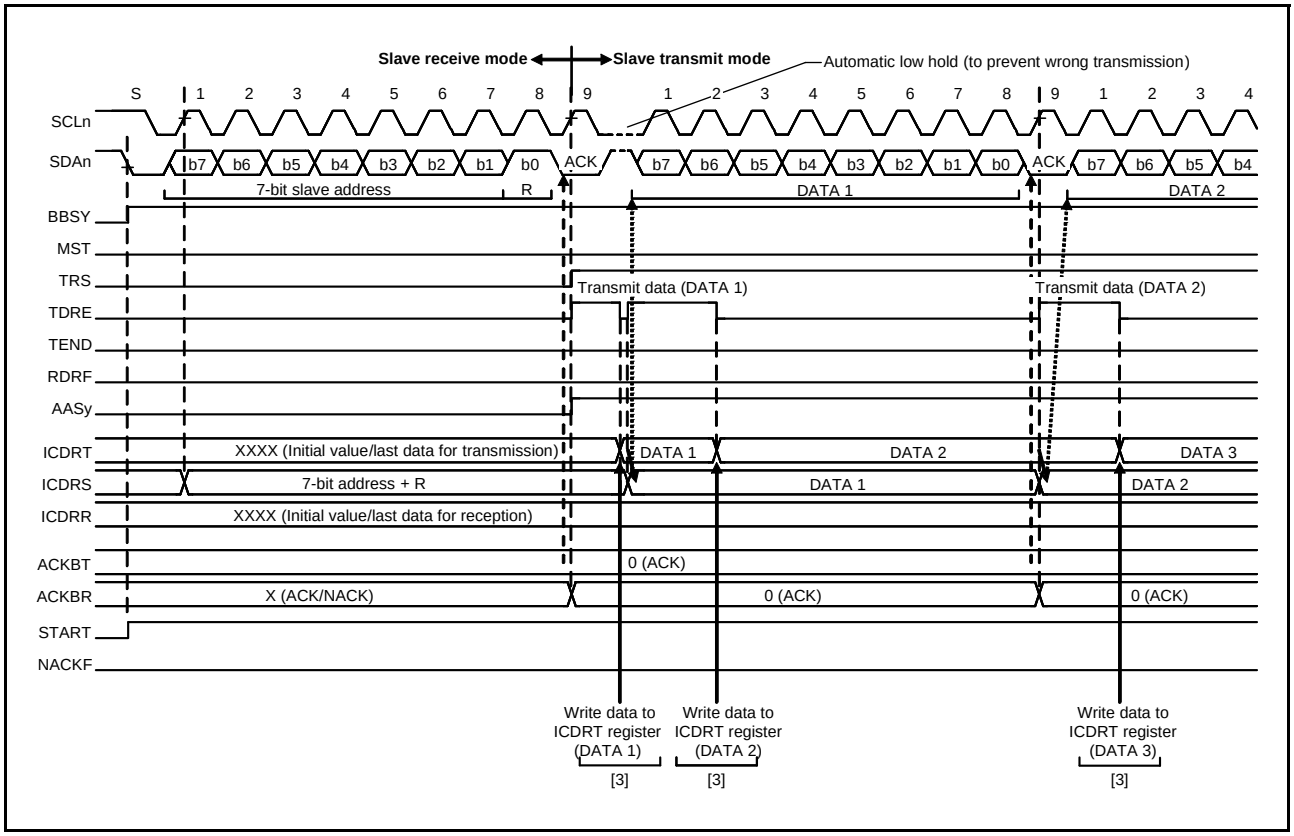

Figure 42.16 Slave Transmit Operation Timing (1) (7-Bit Address Format)

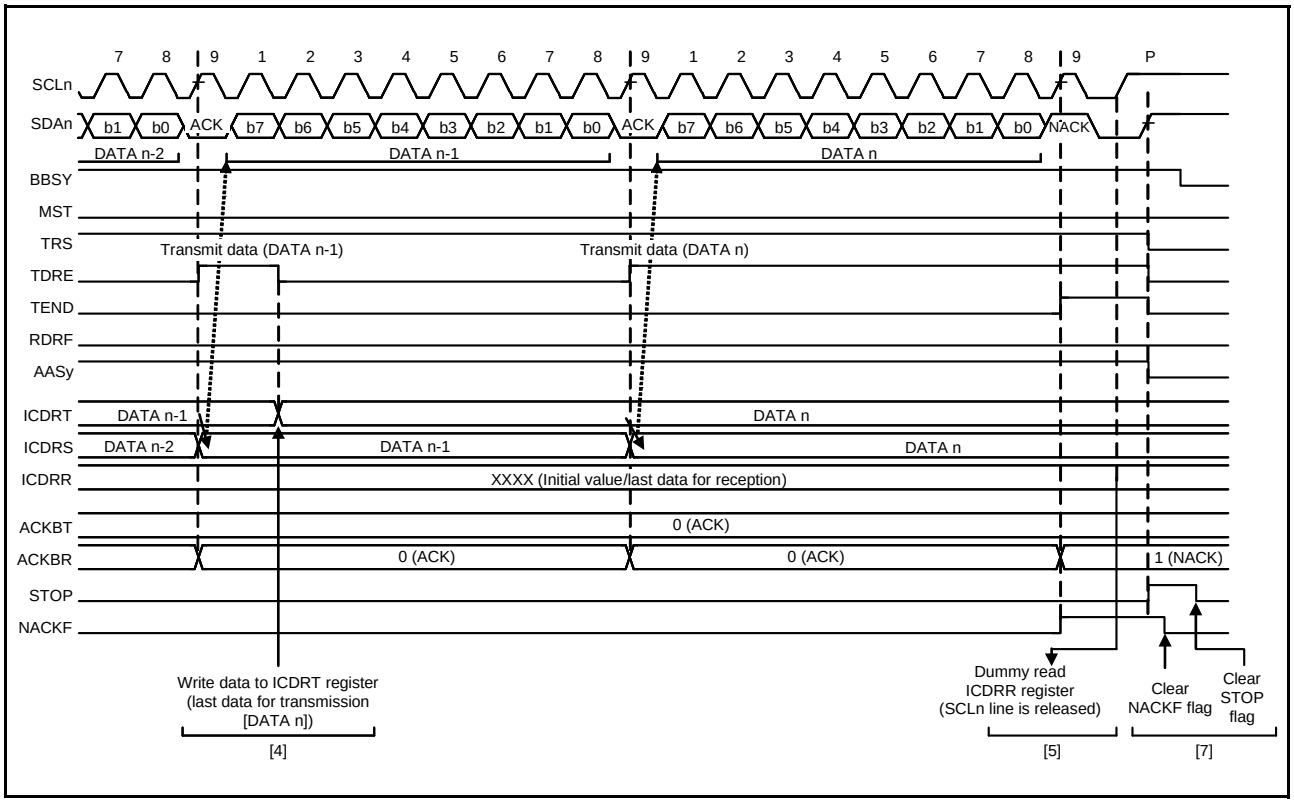

Figure 42.17 Slave Transmit Operation Timing (2)

42.3.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL clock and transmit data, and the RIIC returns acknowledgments as a slave device.

Figure 42.18 shows an example of usage of slave reception and Figure 42.19 and Figure 42.20 show the timing of operations in slave reception.

The following describes the procedure and operations for slave reception.

(1) Initial settings. For details, refer to section 42.3.2, Initial Settings.
After initial settings, the RIIC will stay in the standby state until it receives a slave address that it matches.

(2) After receiving a matching slave address, the RIIC sets one of the corresponding bits ICSR1.HOA, GCA, and AASy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 0, the RIIC continues to place itself in slave receive mode and sets the ICSR2.RDRF flag to 1.

(3) After the ICSR2.STOP flag is confirmed to be 0 and the ICSR2.RDRF flag to be 1, dummy read the ICDRR register (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected).

(4) When the ICDRR register is read, the RIIC automatically sets the ICSR2.RDRF flag to 0. If reading of the ICDRR register is delayed and a next byte is received while the RDRF flag is still set to 1, the RIIC holds the SCLn line low from one SCL cycle before the timing with which RDRF should be set. In this case, reading the ICDRR register releases the SCLn line from being held at the low level.
When the ICSR2.STOP flag is 1 and the ICSR2.RDRF flag is also 1, read the ICDRR register until all the data is completely received.

(5) Upon detecting the stop condition, the RIIC automatically clears bits ICSR1.HOA, GCA, and AASy (y = 0 to 2) to 0.

(6) After checking that the ICSR2.STOP flag is 1, set the ICSR2.STOP flag to 0 for the next transfer operation.

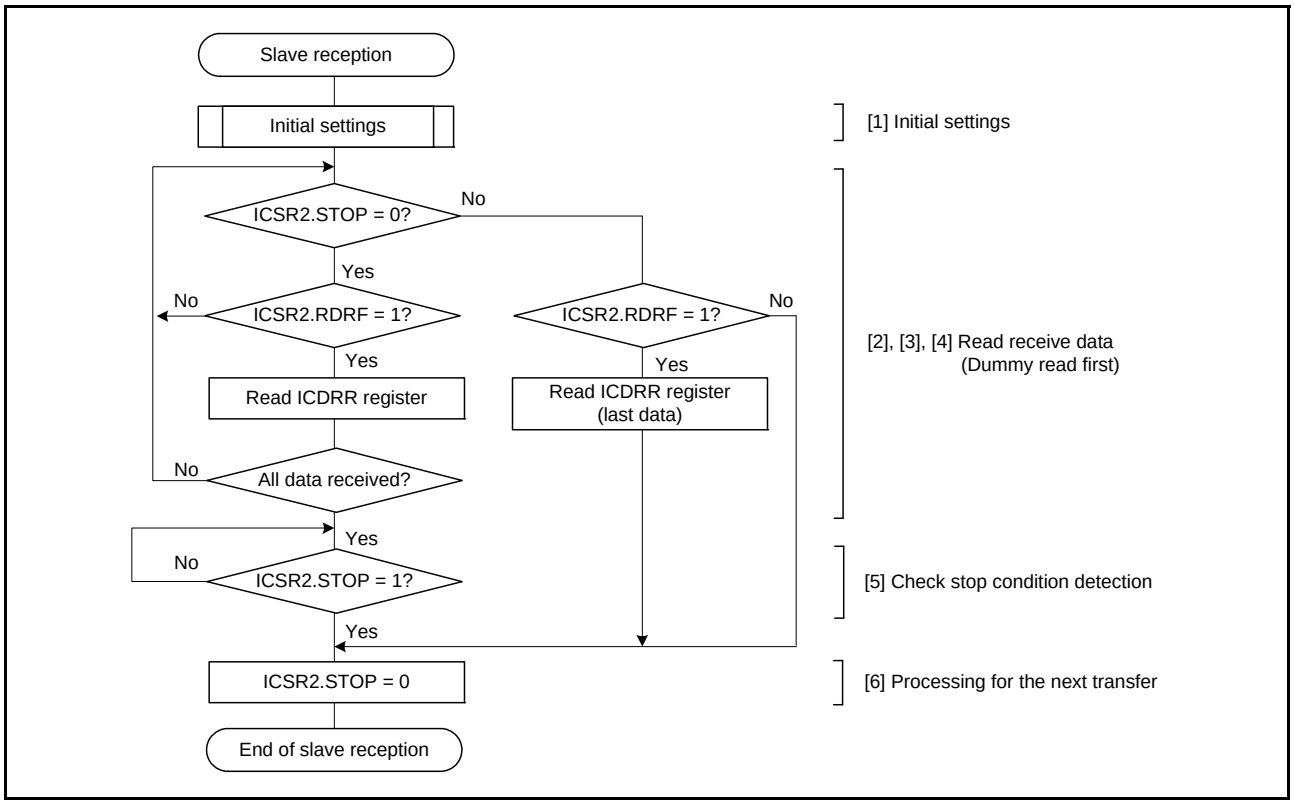

Figure 42.18 Example of Slave Reception Flowchart

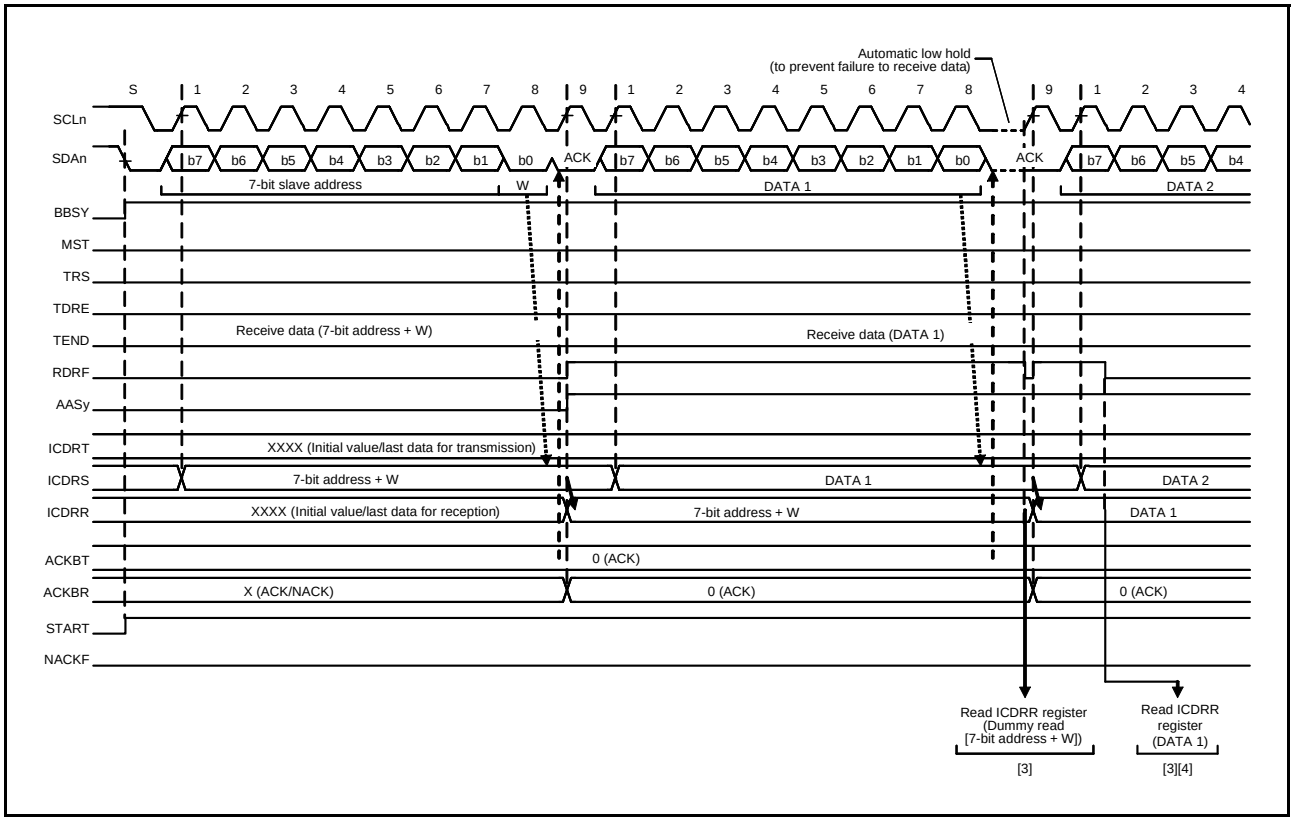

Figure 42.19 Slave Receive Operation Timing (1) (7-Bit Address Format, when RDRFS bit is 0)

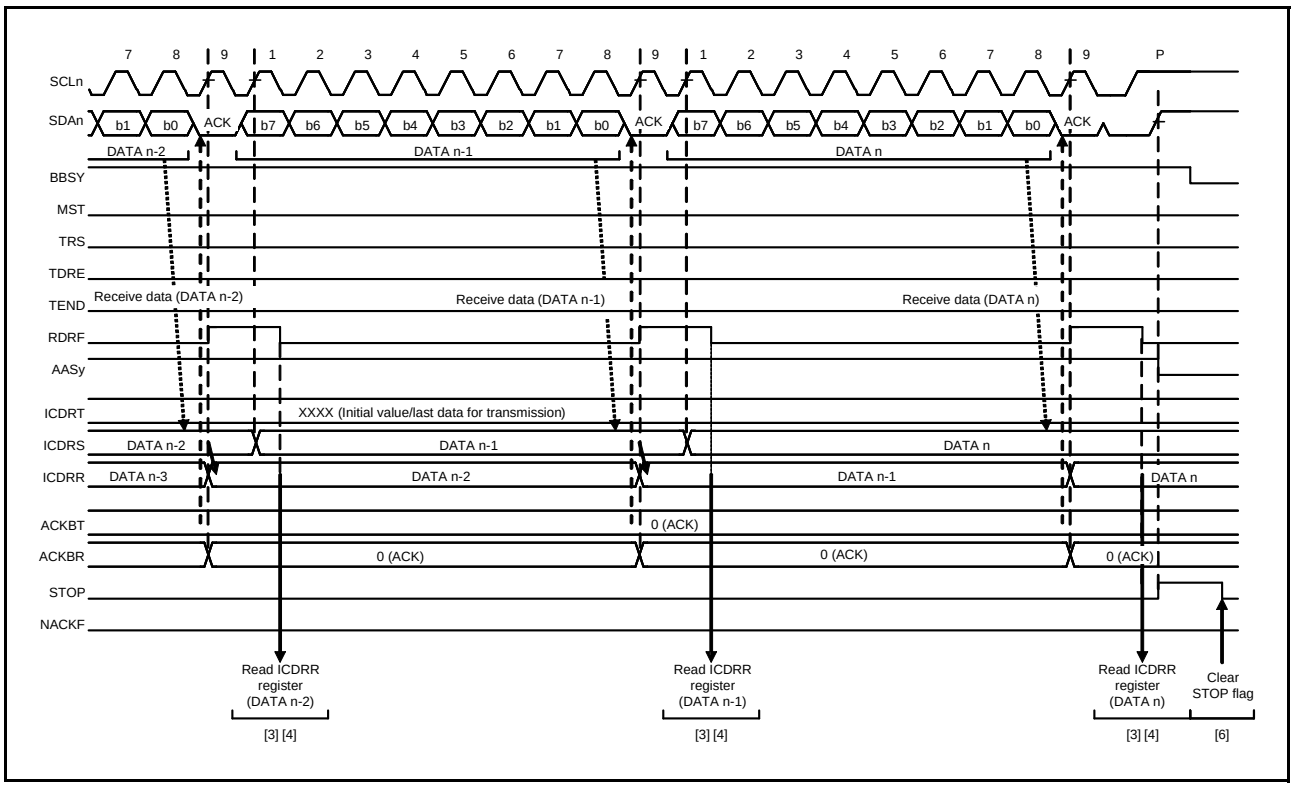

Figure 42.20 Slave Receive Operation Timing (2) (when RDRFS bit is 0)

42.4 SCL Synchronization Circuit

In generation of the SCL clock, the RIIC starts counting out the value for width at high level specified in the ICBRH register when it detects a rising edge on the SCLn line and drives the SCLn line low once counting of the width at high level is complete. When the RIIC detects the falling edge of the SCLn line, it starts counting out the width at low level period specified in the ICBRL register, and then stops driving the SCLn line (releases the line) once counting of the width at low level is complete. The SCL clock is thus generated.

If multiple master devices are connected to the I2C-bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Because this synchronization of SCL signals must be bit by bit, the RIIC is equipped with a facility (the SCL synchronization circuit) to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCLn line while in master mode.

When the RIIC has detected a rising edge on the SCLn line and thus started counting out the width at high level specified in the ICBRH register, and the level on the SCLn line falls because an SCL signal is being generated by another master device, the RIIC stops counting when it detects the falling edge, drives the level on the SCLn line low, and starts counting out the width at low level specified in the ICBRL register. When the RIIC finishes counting out the width at low level, it stops driving the SCLn line to the low level (i.e. releases the line). At this time, if the width at low level of the SCL clock signal from the other master device is longer than the width at low level set in the RIIC, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the SCLn line has been released. When the RIIC finishes outputting the low-level period of the SCL clock, the SCLn line is released and the SCL clock rises. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the ICFER.SCLE bit is set to 1.

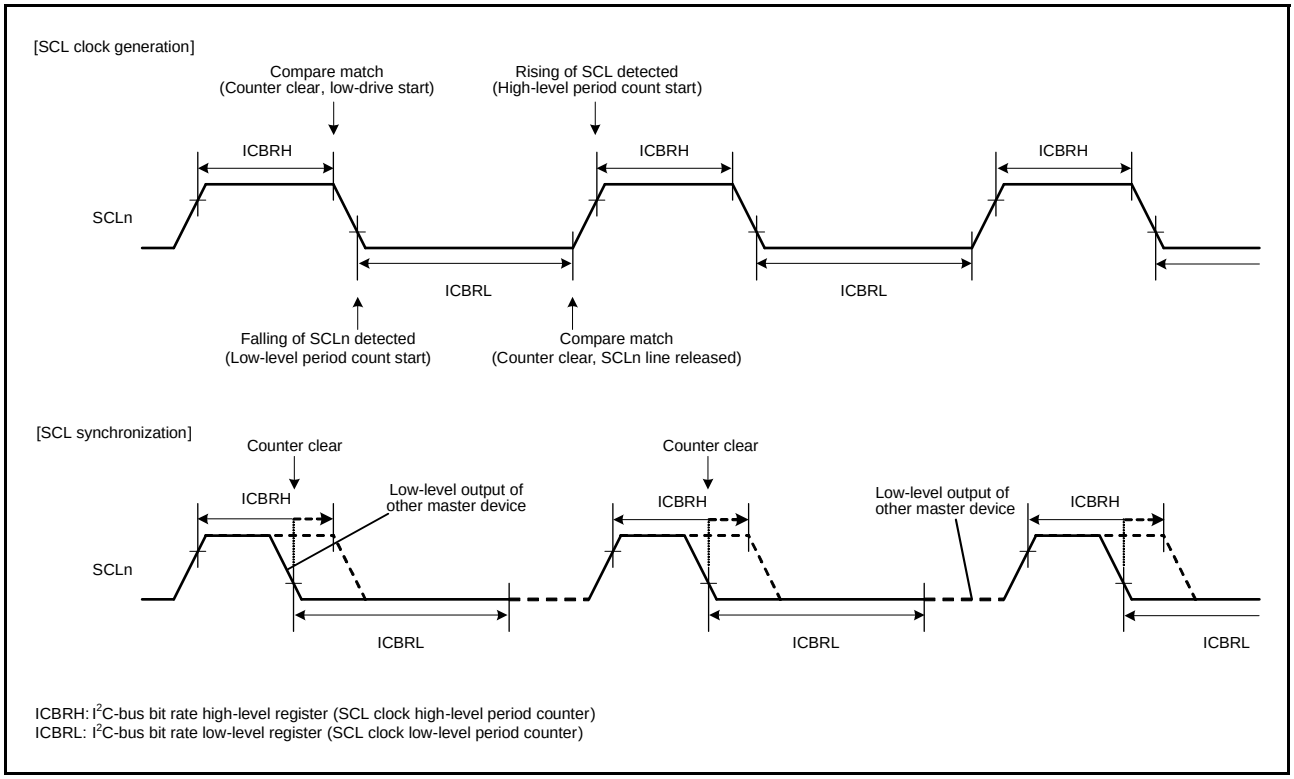

Figure 42.21 Generation and Synchronization of the SCL Signal from the RIIC

42.5 SDA Output Delay Function

The RIIC module incorporates a function for delaying output on the SDA line. The delay can be applied to all output (issuing of the start, restart, and stop conditions, data, and the ACK and NACK signals) on the SDA line.

With the SDA output delay function, SDA output is delayed from detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval over which the SCL clock is at the low level. Doing this leads to usage with the aim of preventing erroneous operation of communications devices, with the aim of satisfying the 300-ns (min.) data-hold time requirement of the SMBus specification.

The output delay function is enabled by setting the ICMR2.SDDL[2:0] bits to any value other than 000b, and disabled by setting the same bits to 000b.

While the SDA output delay function is enabled (i.e. while the ICMR2.SDDL[2:0] bits are set to any value other than 000b), the ICMR2.DLCS bit selects the clock source for counting by the SDA output delay counter as the internal base clock (IICφ) for the RIIC module or as a clock signal derived by dividing the frequency of the internal base clock by two (IICφ/2). The counter counts the number of cycles set in the ICMR2.SDDL[2:0] bits. After counting of the set number of cycles of delay is completed, the RIIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.

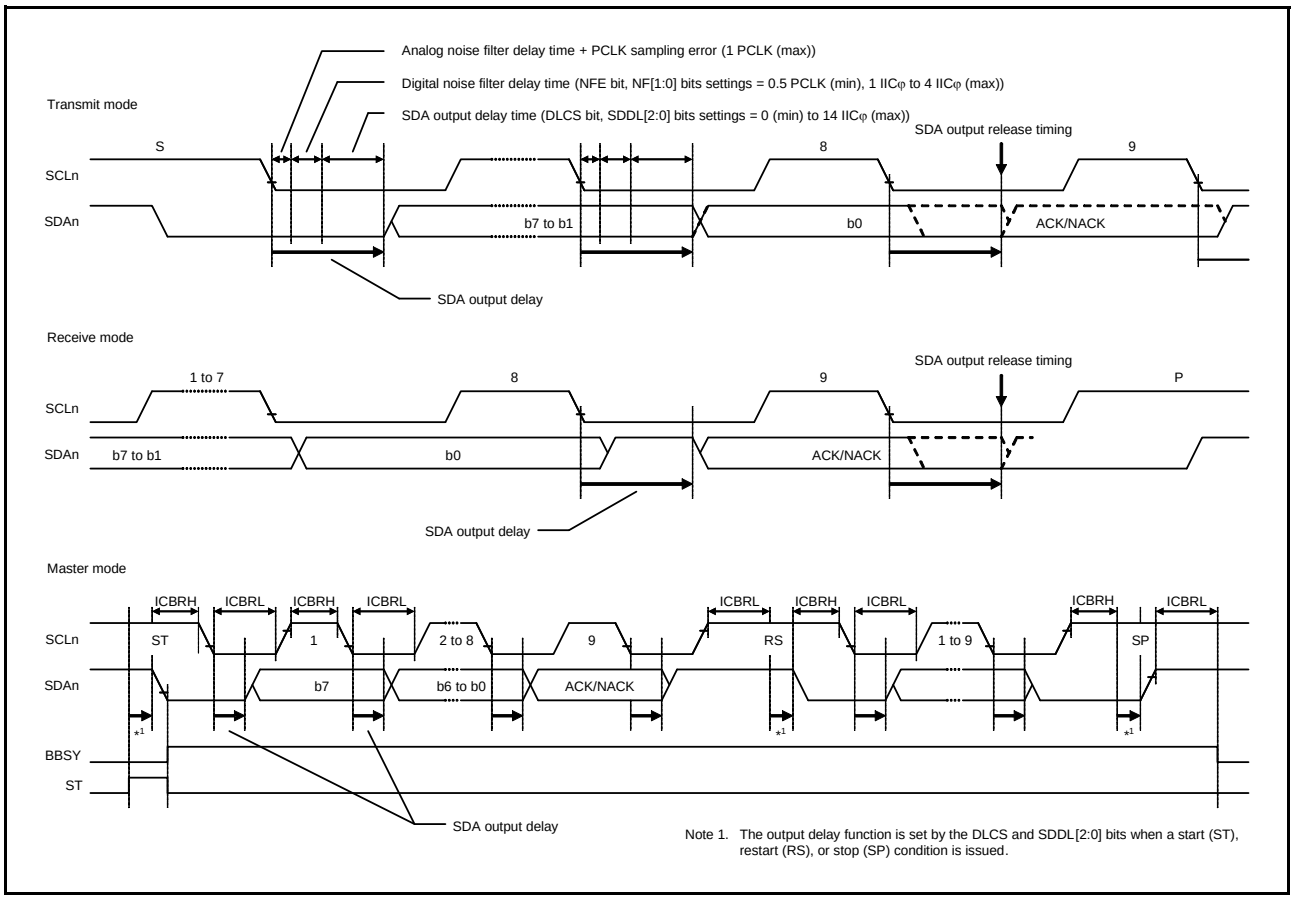

Figure 42.22 SDA Output Delay Function

42.6 Digital Noise Filter Circuit

The states of the SCLn and SDAn pins are conveyed to the internal circuitry through analog noise-filter and digital noise-filter circuits. Figure 42.23 is a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of the RIIC consists of four flip-flop circuit stages connected in series and a match-detection circuit.

The number of effective stages in the digital noise filter is selected by the ICMR3.NF[1:0] bits. The selected number of effective stages determines the noise-filtering capability as a period from one to four IICφ cycles.

The input signal to the SCLn pin (or SDAn pin) is sampled on falling edges of the IICφ signal. When the input signal level matches the output level of the number of effective flip-flop circuit stages as selected by the ICMR3.NF[1:0] bits, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is retained.

If the ratio between the frequency of the internal operating clock (PCLK) and the transfer rate is small (e.g. data transfer at 400 kbps with PCLK = 4 MHz), the characteristics of the digital noise filter may lead to the elimination of needed signals as noise. In such cases, it is possible to disable the digital noise-filter circuit (by setting the ICFER.NFE bit to 0) and use only the analog noise filter circuit.

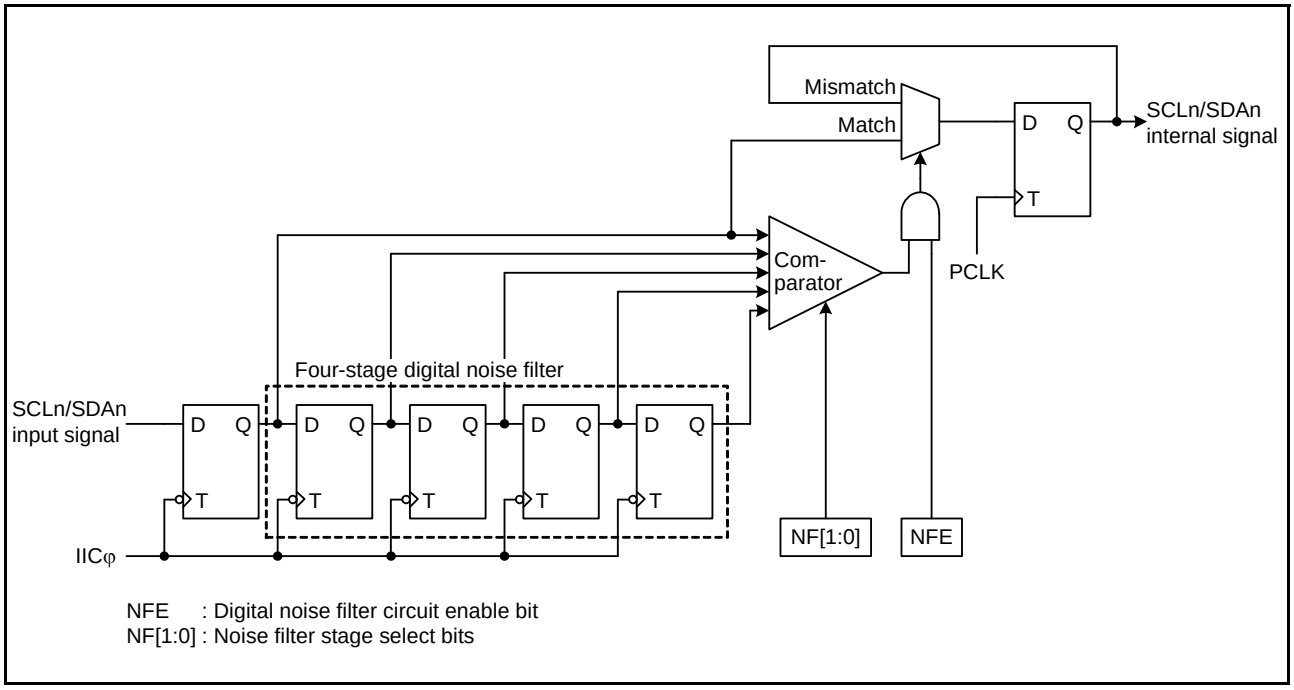

Figure 42.23 Block Diagram of Digital Noise Filter Circuit

42.7 Address Match Detection

The RIIC can set three unique slave addresses in addition to the general call address and host address, and also can set 7-bit or 10-bit slave addresses.

42.7.1 Slave-Address Match Detection

The RIIC can set three unique slave addresses, and has a slave address detection function for each unique slave address. When the ICSER.SARyE bit (y = 0 to 2) is set to 1, the slave addresses set in registers SARUy and SARLy (y = 0 to 2) can be detected.

When the RIIC detects a match of the set slave address, the corresponding ICSR1.AASy flag (y = 0 to 2) is set to 1 at the rising edge of the ninth SCL clock cycle, and the ICSR2.RDRF flag or the ICSR2.TDRE flag is set to 1 by the following R/W# bit. This causes a receive data full interrupt (RXI) or transmit data empty interrupt (TXI) to be generated. The AASy flag is used to identify which slave address has been specified.

Figure 42.24 to Figure 42.26 show the AASy flag set timing in three cases.

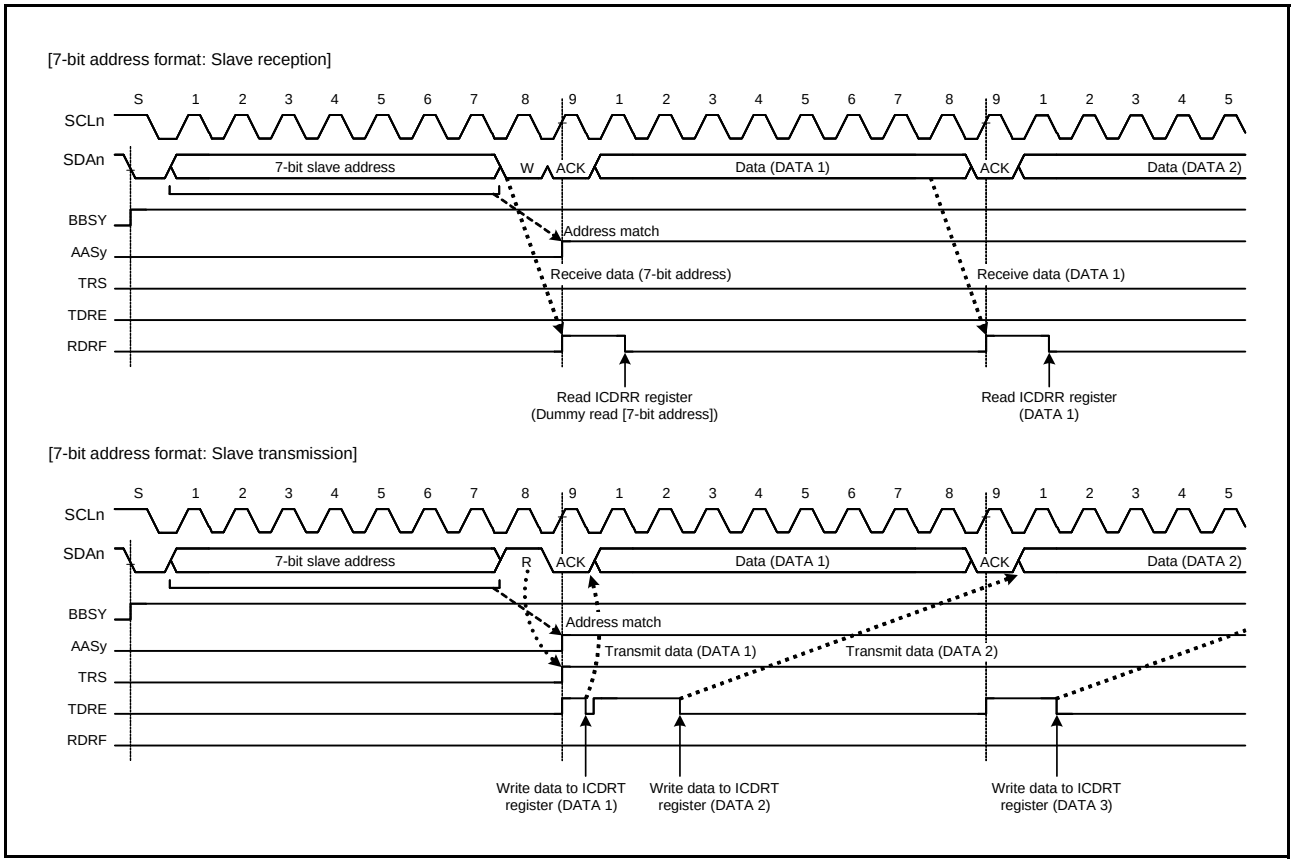

Figure 42.24 AASy Flag Set Timing with 7-Bit Address Format Selected

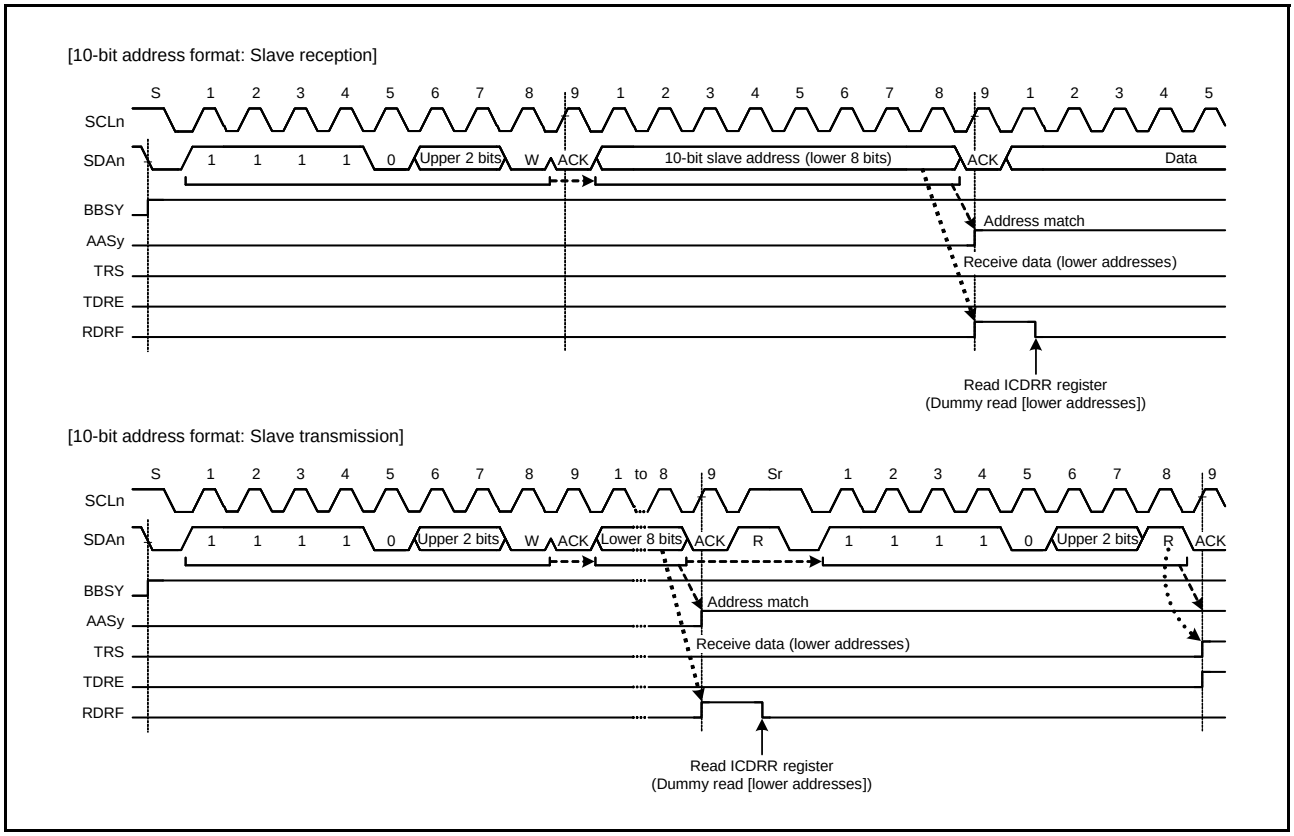

Figure 42.25 AASy Flag Set Timing with 10-Bit Address Format Selected

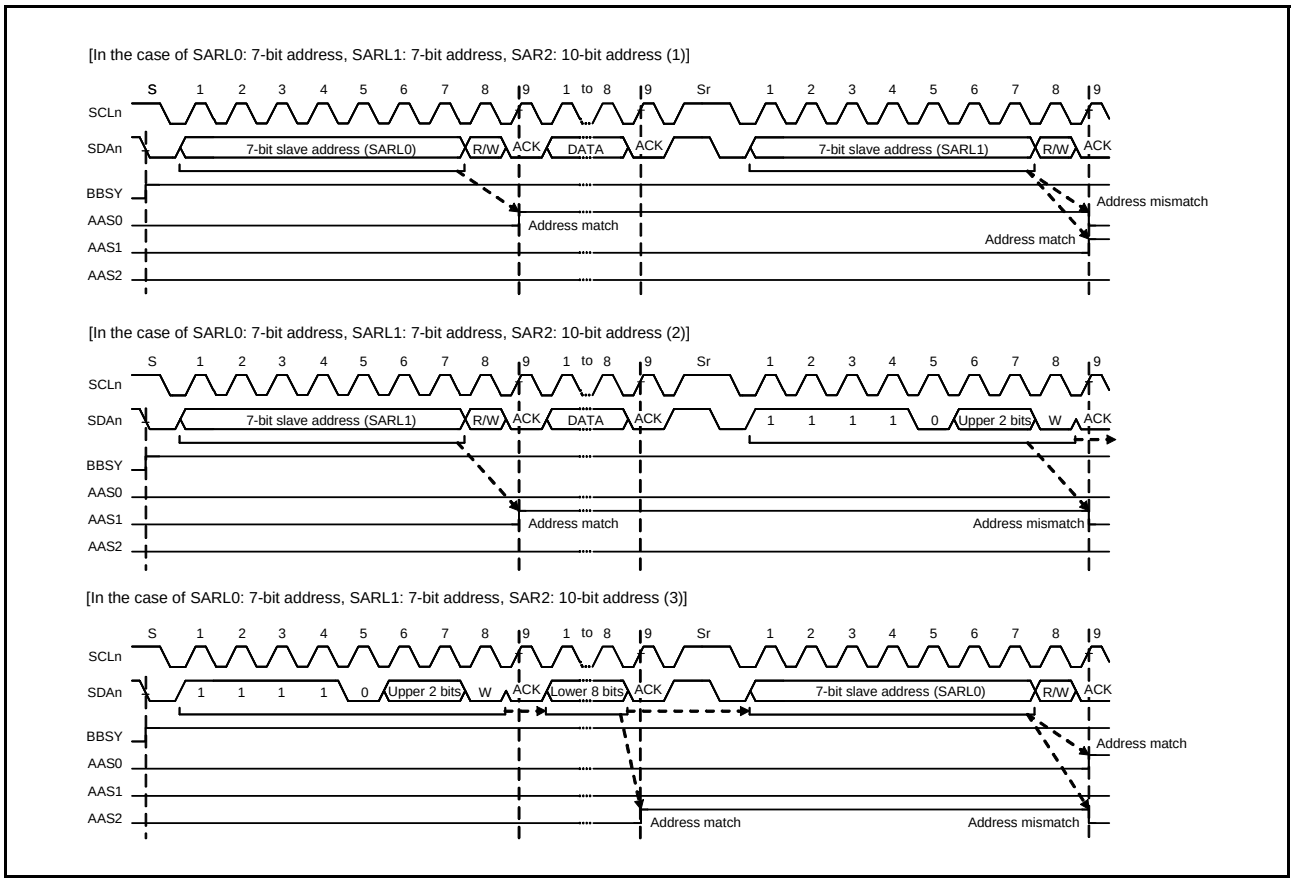

Figure 42.26 AASy Flag Set/Clear Timing with 7-Bit/10-Bit Address Formats Mixed

42.7.2 Detection of the General Call Address

The RIIC has a facility for detecting the general call address (0000 000b + 0 (write)). This is enabled by setting the ICSER.GCAE bit to 1.

If the address received after a start or restart condition is issued is 0000 000b + 1 (read) (start byte), the RIIC recognizes this as the address of a slave device with an “all-zero” address but not as the general call address.

When the RIIC detects the general call address, both the ICSR1.GCA flag and the ICSR2.RDRF flag are set to 1 on the rising edge of the ninth cycle of SCL clock. This leads to the generation of a receive data full interrupt (RXI). The value of the GCA flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

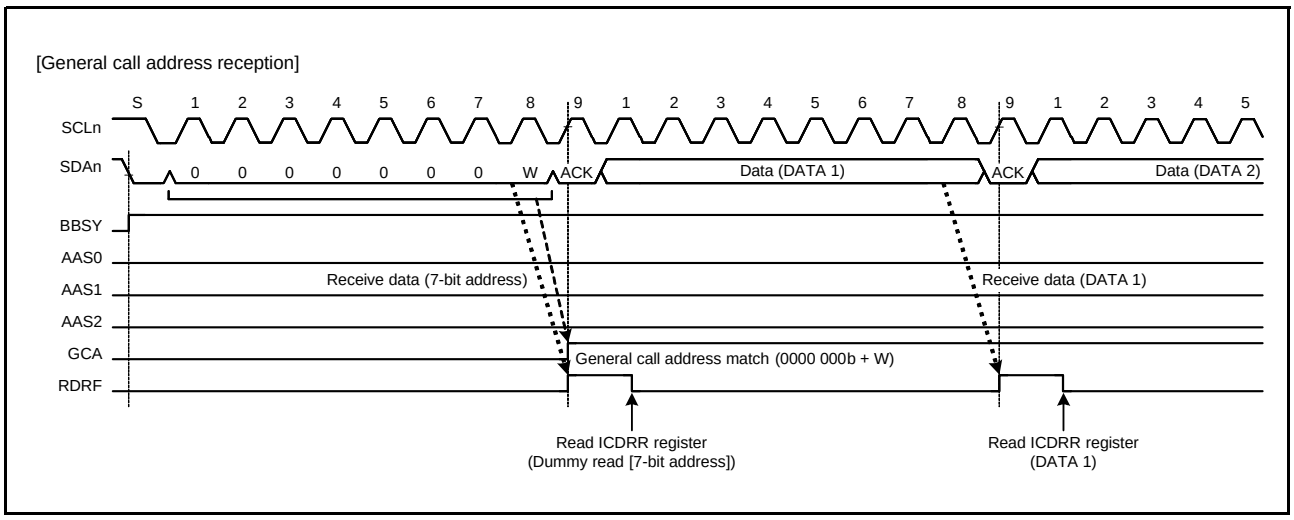

Figure 42.27 Timing of GCA Flag Setting during Reception of General Call Address

42.7.3 Device-ID Address Detection

The RIIC module has a facility for detecting device-ID addresses conformant with the I2C-bus specification (Rev. 03). When the RIIC receives 1111 100b as the first byte after a start condition or restart condition was issued with the ICSER.DIDE bit set to 1, the RIIC recognizes the address as a device ID, sets the ICSR1.DID flag to 1 on the rising edge of the eighth SCL clock cycle when the following R/W# bit is 0, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the RIIC sets the corresponding ICSR1.AASy flag (y = 0 to 2) to 1.

After that, when the first byte received after a start or restart condition is issued matches the device ID address (1111 100b) again and the following R/W# bit is 1, the RIIC does not compare the second and subsequent bytes and sets the ICSR2.TDRE flag to 1.

In the device-ID address detection function, the RIIC sets the DID flag to 0 if a match with the RIIC's own slave address is not obtained or a match with the device ID address is not obtained after a match with the RIIC's own slave address and the detection of a restart condition. If the first byte after detection of a start or restart condition matches the device ID address (1111 100b) and the R/W# bit is 0, the RIIC sets the DID flag to 1 and compares the second and subsequent bytes with the RIIC's slave address. If the R/W# bit is 1, the DID flag holds the previous value and the RIIC does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DID flag after confirming that TDRE flag is 1.

Furthermore, prepare the device-ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details of the information that must be included in device-ID fields, contact NXP Semiconductors.

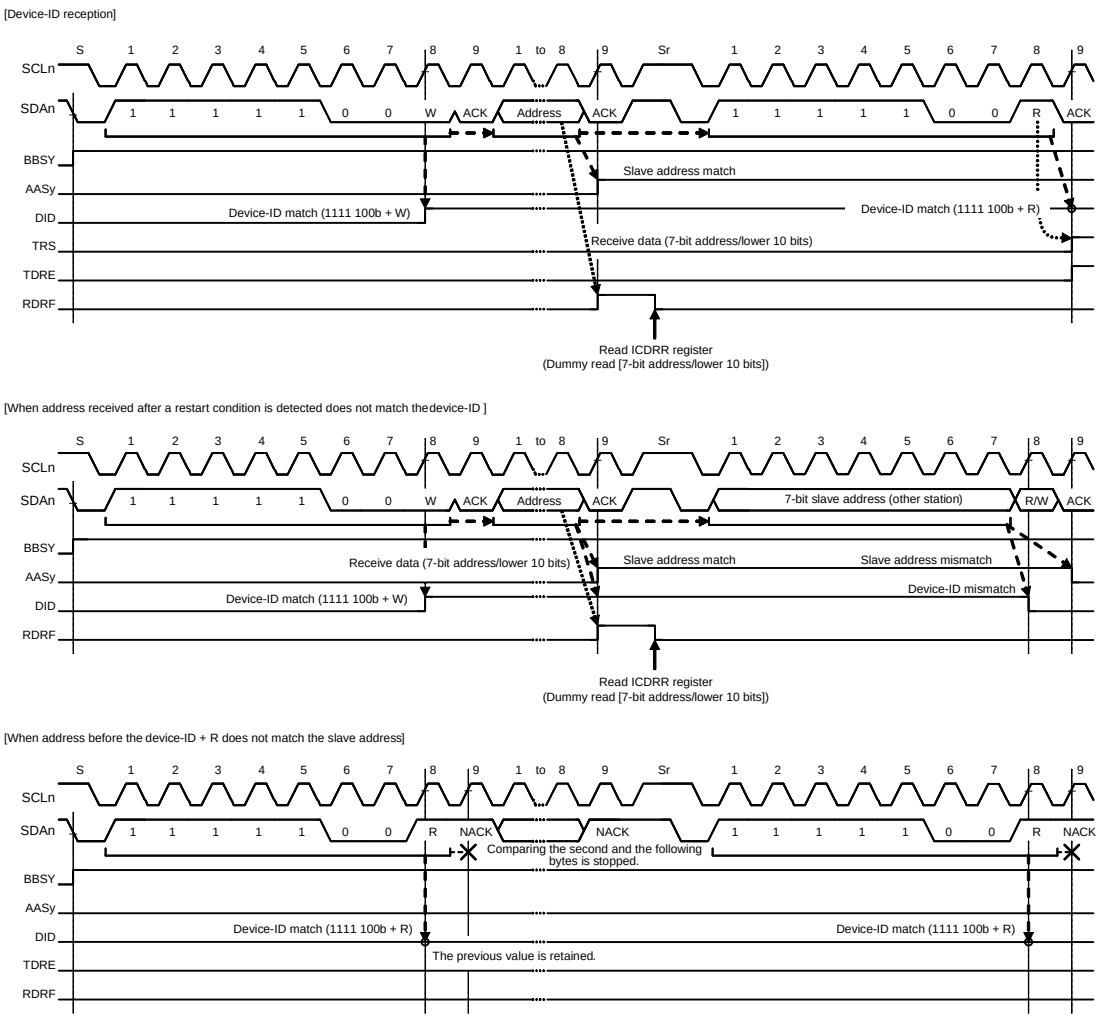

Figure 42.28 AASy/DID Flag Set/Clear Timing during Reception of Device-ID

42.7.4 Host Address Detection

The RIIC has a function to detect the host address while the SMBus is operating. When the ICSER.HOAE bit is set to 1 while the ICMR3.SMBS bit is 1, the RIIC can detect the host address (0001 000b) in slave receive mode (bits MST and TRS in the ICCR2 register are 00b).

When the RIIC detects the host address, the ICSR1.HOA flag is set to 1 at the rising edge of the ninth SCL clock cycle, and at the same time, the ICSR2.RDRF flag is set to 1 when the R/W# bit is 0 (Wr bit). This causes a receive data full interrupt (RXI) to be generated. The HOA flag is used to recognize that the host address was sent from the smart battery or other devices.

If the bit following the host address (0001 000b) is an Rd bit (R/W# bit is 1), the RIIC can also detect the host address. After the host address is detected, the RIIC operates in the same manner as normal slave operation.

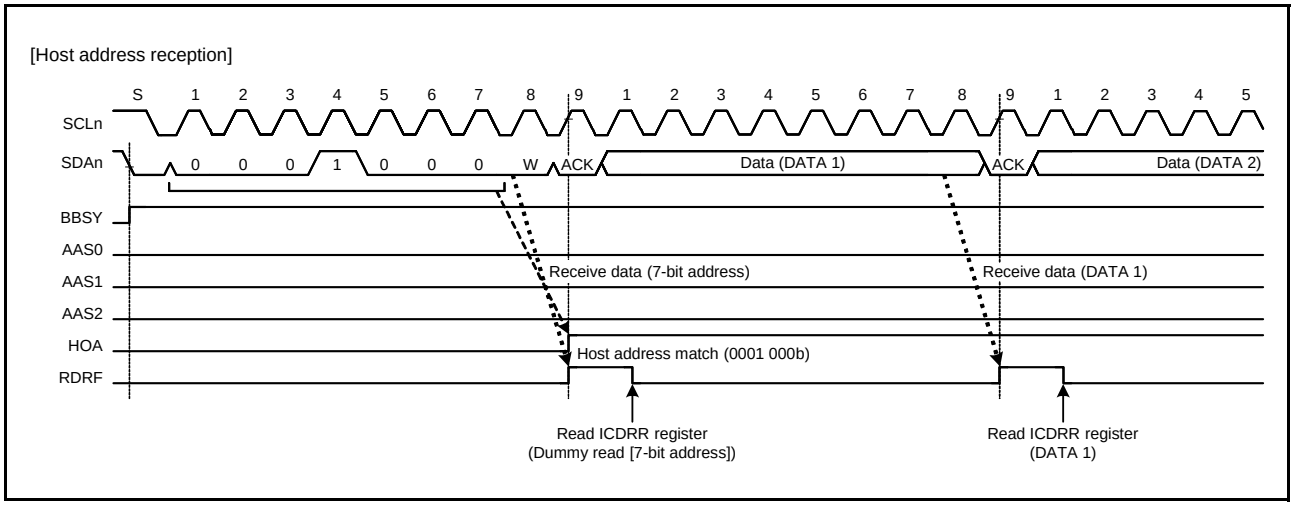

Figure 42.29 HOA Flag Set Timing during Reception of Host Address

42.8 Automatic Low-Hold Function for SCL

42.8.1 Function to Prevent Wrong Transmission of Transmit Data

If the shift register (ICDRS) is empty when data have not been written to the I2C-bus transmit data register (ICDRT) with the RIIC in transmission mode (ICCR2.TRS bit is 1), the SCLn line is automatically held at the low level over the intervals shown below. This low-hold period is extended until data for transmission have been written, which prevents the unintended transmission of erroneous data.

Master transmit mode

- Low-level interval after a start condition or restart condition is issued
- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

Slave transmit mode

- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

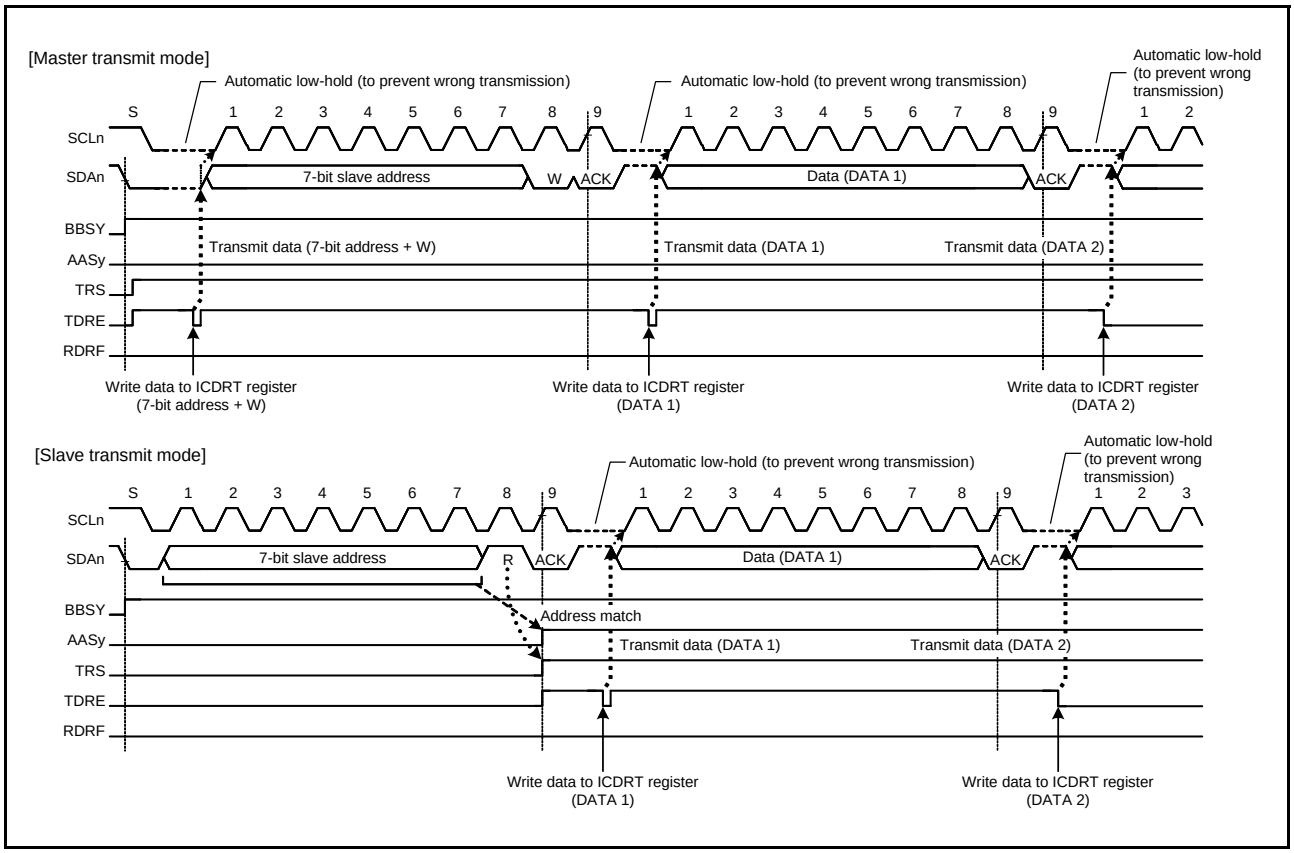

Figure 42.30 Automatic Low-Hold Operation in Transmit Mode

42.8.2 NACK Reception Transfer Suspension Function

The RIIC has a function to suspend transfer operation when NACK is received in transmit mode (ICCR2.TRS bit is 1). This function is enabled when the ICFER.NACKE bit is set to 1 (transfer suspension enabled). If the next transmit data has already been written (ICSR2.TDRE flag is 0) when NACK is received, next data transmission at the falling edge of the ninth SCL clock cycle is automatically suspended. This prevents the SDAn line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (ICSR2.NACKF flag is 1), transmit operation and receive operation are discontinued. To restore transmit/receive operation, be sure to set the NACKF flag to 0. In master transmit mode, after setting the NACKF flag to 0, issue a restart condition, or issue a stop condition and then issue a start condition again.

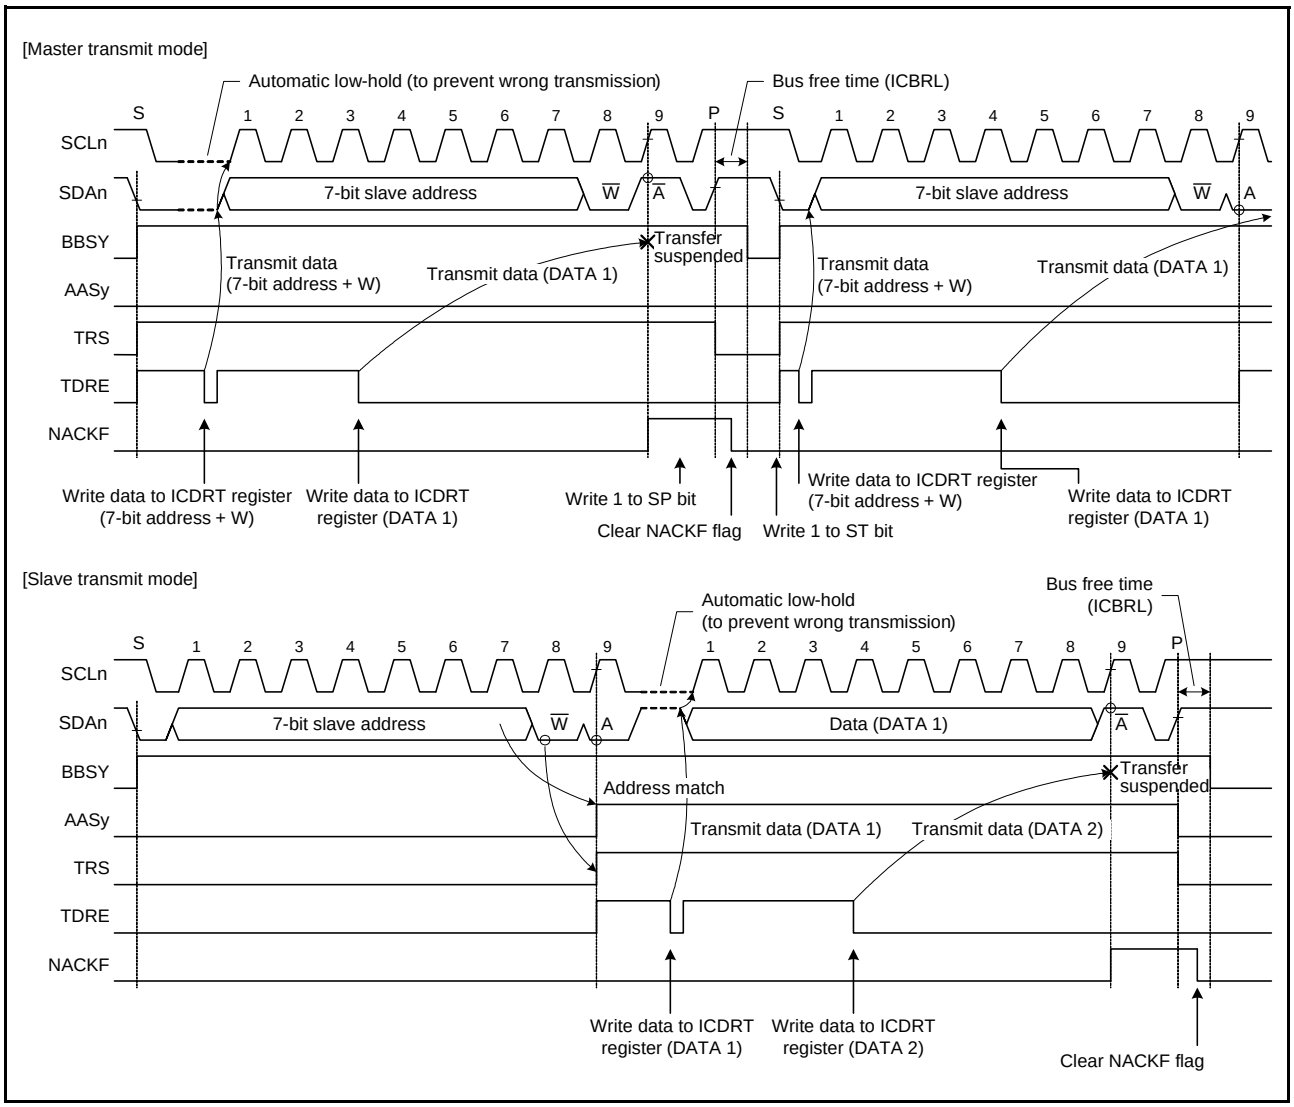

Figure 42.31 Suspension of Data Transfer When NACK is Received (NACKE = 1)

42.8.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (ICDRR) read is delayed for a period of one transfer byte or more with receive data full (ICSR2.RDRF flag is 1) in receive mode (ICCR2.TRS bit is 0), the RIIC holds the SCLn line low automatically immediately before the next data is received to prevent failure to receive data.

This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, the RIIC's own slave address is designated after a

stop condition is issued. This function does not disturb other communication because the RIIC does not hold the SCLn line low when a mismatch with its own slave address occurs after a stop condition is issued.
Sections in which the SCLn line is held low can be selected with a combination of the WAIT and RDRFS bits in the ICMR3 register.

(1) 1-Byte Receive Operation and Automatic Low-Hold Function Using the WAIT Bit

When the ICMR3.WAIT bit is set to 1, the RIIC performs 1-byte receive operation using the WAIT bit function. Furthermore, when the ICMR3.RDRFS bit is 0, the RIIC automatically sends the ICMR3.ACKBT bit value for the acknowledge bit in the period from the falling edge of the eighth SCL clock cycle to the falling edge of the ninth SCL clock cycle, and automatically holds the SCLn line low at the falling edge of the ninth SCL clock cycle using the WAIT bit function. This low-hold is released by reading data from the ICDRR register, which enables bytewise receive operation.

The WAIT bit function is enabled for receive bytes after a match with the RIIC's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

(2) 1-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the RDRFS Bit

When the ICMR3.RDRFS bit is set to 1, the RIIC performs 1-byte receive operation using the RDRFS bit function. When the RDRFS bit is set to 1, the ICSR2.RDRF flag (receive data full) is set to 1 at the rising edge of the eighth SCL clock cycle, and the SCLn line is automatically held low at the falling edge of the eighth SCL clock cycle. This low-hold is released by writing a value to the ICMR3.ACKBT bit, but cannot be released by reading data from the ICDRR register, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.

The RDRFS bit function is enabled for receive bytes after a match with the RIIC's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

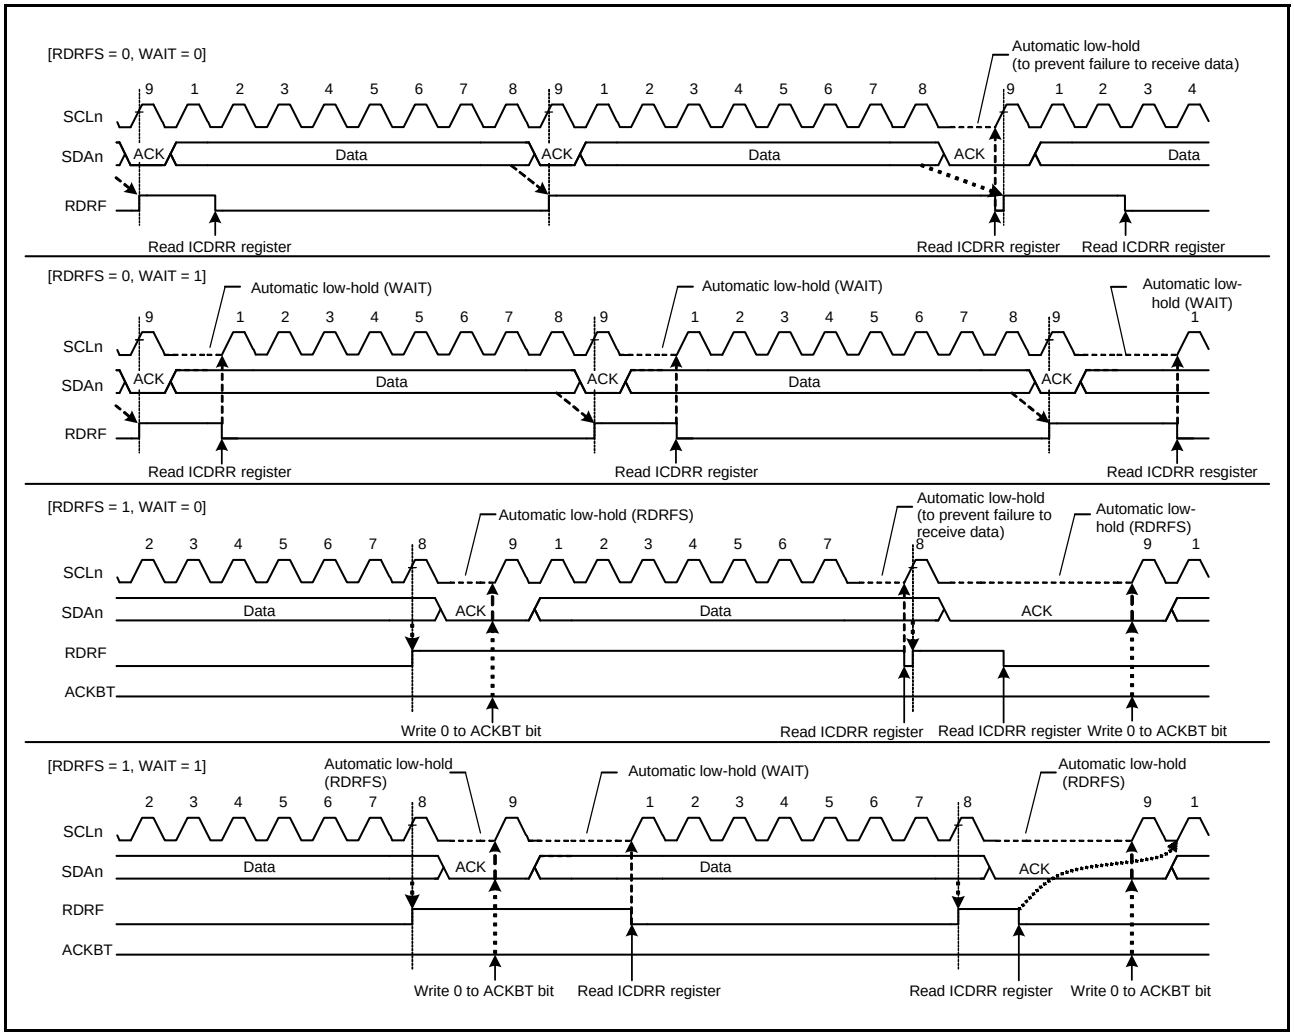

Figure 42.32 Automatic Low-Hold Operation in Receive Mode (Using RDRFS and WAIT Bits)

42.9 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I2C-bus specification, the RIIC has functions to prevent double-issue of a start condition, to detect arbitration-lost during transmission of NACK, and to detect arbitration-lost in slave transmit mode.

42.9.1 Master Arbitration-Lost Detection (MALE Bit)

The RIIC drives the SDAn line low to issue a start condition. However, if the SDAn line has already been driven low by another master device issuing a start condition, the RIIC causes arbitration to be lost, so priority is given to transfer by the other master device. Similarly, if the ICCR2.ST bit is set to 1 while the ICCR2.BBSY flag is 1 (bus busy state), arbitration is lost, so priority is given to transfer by the other master device. No start condition is issued in this case.
When a start condition is issued successfully, if the data for transmission including the address bits (i.e. the internal SDA output level) and the level on the SDAn line do not match (the high output as the internal SDA output; i.e. the SDAn pin is in the high-impedance state) and the low level is detected on the SDAn line, the RIIC loses in arbitration.
After a loss in arbitration of mastership, the RIIC immediately enters slave receive mode. If a slave address (including the general call address) matches its own address at this time, the RIIC continues in slave operation.
A loss in arbitration of mastership is detected when the following conditions are met while the ICFER.MALE bit is 1 (master arbitration-lost detection enabled).

Conditions for master arbitration-lost

- Non-matching of the internal level for output on SDA and the level on the SDAn line after a start condition was issued by setting the ICCR2.ST bit to 1 while the ICCR2.BBSY flag was set to 0 (erroneous issuing of a start condition)
- Setting of the ICCR2.ST bit to 1 (start condition double-issue error) while the BBSY flag is set to 1
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDAn line in master transmit mode (bits MST and TRS in the ICCR2 register = 11b)

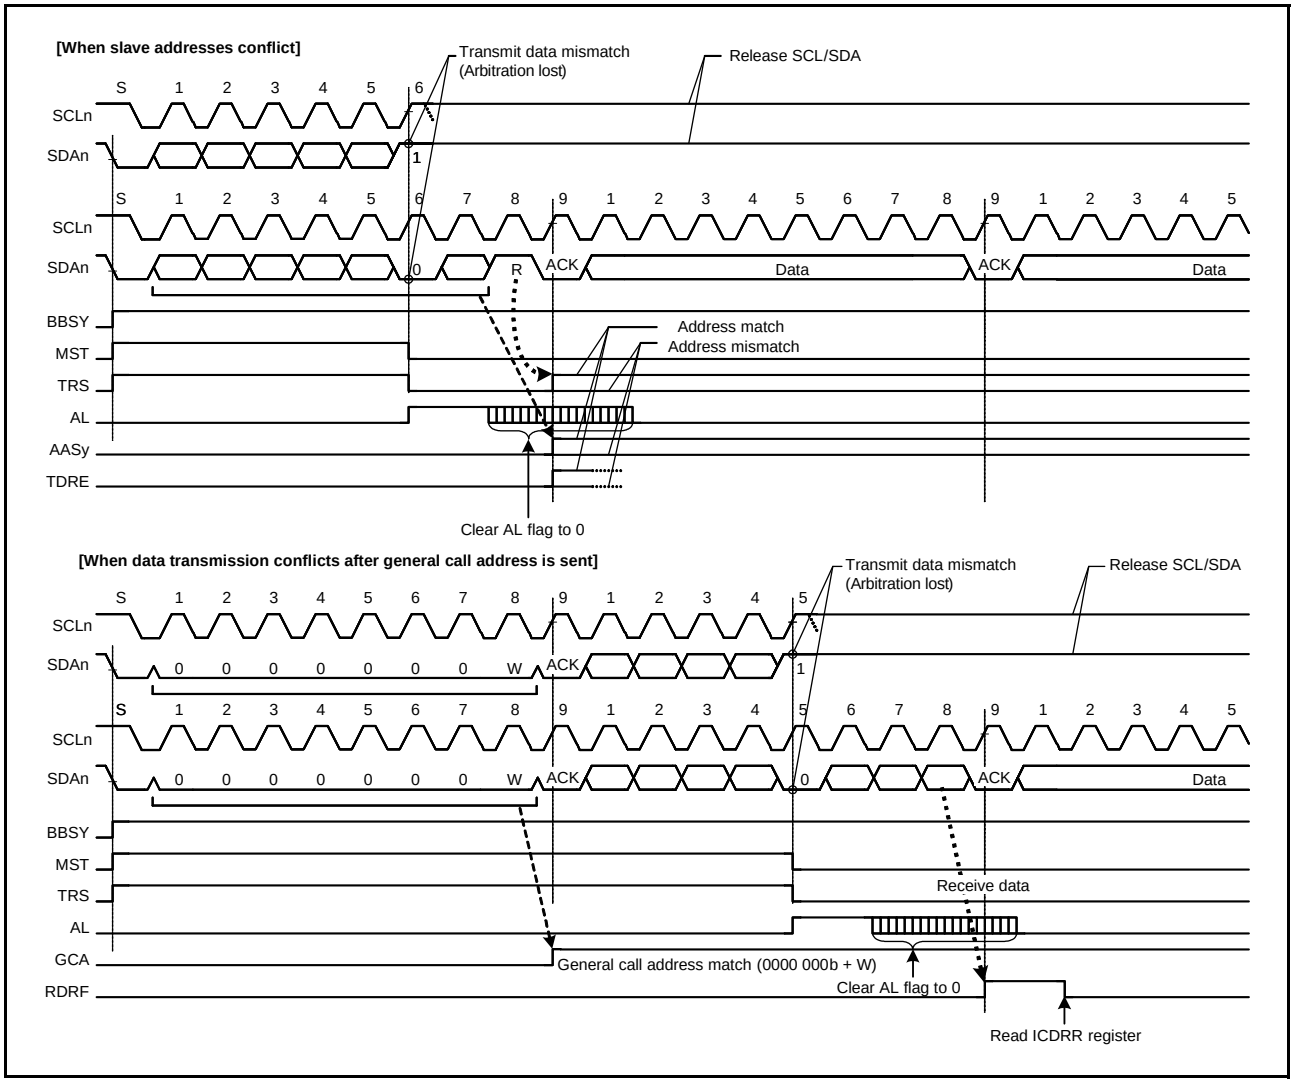

Figure 42.33 Examples of Master Arbitration-Lost Detection (MALE = 1)

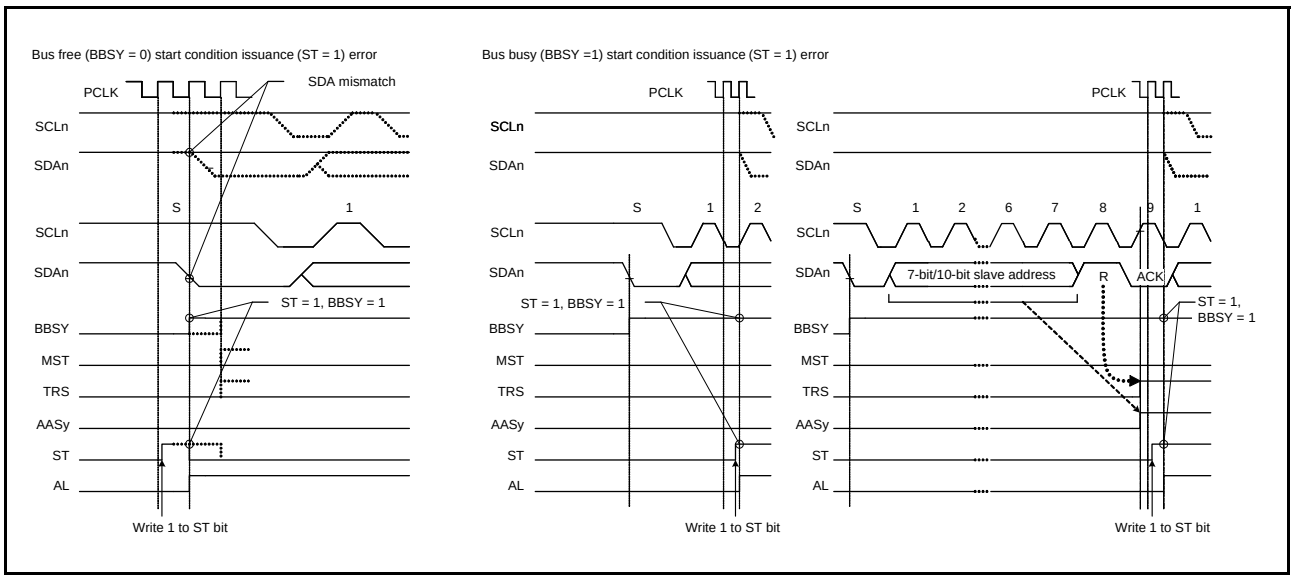

Figure 42.34 Arbitration-Lost When a Start Condition is Issued (MALE = 1)

42.9.2 Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit)

The RIIC has a function to cause arbitration to be lost if the internal SDA output level does not match the level on the SDAn line (the high output as the internal SDA output; i.e. the SDAn pin is in the high-impedance state) and the low level is detected on the SDAn line during transmission of NACK in receive mode. Arbitration is lost due to a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send/receive the same information through a single slave device. Figure 42.35 shows an example of arbitration-lost detection during transmission of NACK.

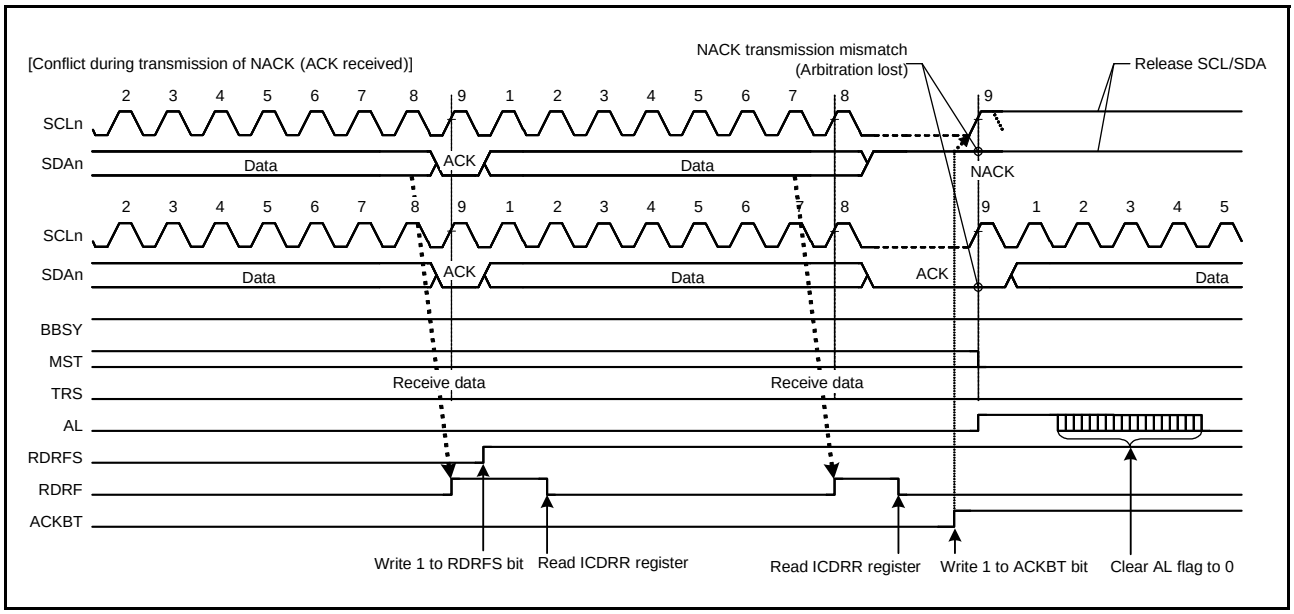

Figure 42.35 Example of Arbitration-Lost Detection during Transmission of NACK (NALE = 1)

The following explains arbitration-lost detection using an example where two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives 2 bytes of data from the slave device, and master B receives 4 bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in both master A and master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Here, master A sends NACK when it has received 2 final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received necessary 4 bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect ACK transmitted by master B and issues a stop condition. Therefore, the issuance of the stop condition conflicts with the SCL clock output of master B, which disturbs communication.

When the RIIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost.

If arbitration is lost during transmission of NACK, the RIIC immediately cancels the slave match condition and enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing (such as FFh transmission processing) necessary if the UDID (Unique Device Identifier) of assign address does not match in the Get UDID (general) processing after the Assign address command.

The RIIC detects arbitration-lost during transmission of NACK when the following condition is met with the ICFER.NALE bit set to 1 (arbitration-lost detection during NACK transmission enabled).

Condition for arbitration-lost during NACK transmission

- When the internal SDA output level does not match the SDAn line (ACK is received) during transmission of NACK (ICMR3.ACKBT bit = 1)

42.9.3 Slave Arbitration-Lost Detection (SALE Bit)

The RIIC has a function to cause arbitration to be lost if the data for transmission (i.e. the internal SDA output level) and the level on the SDAn line do not match (the high output as the internal SDA output; i.e. the SDAn pin is in the high-impedance state and the low level is detected on the SDAn line in slave transmit mode). This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.
When it loses slave arbitration, the RIIC is immediately released from the slave-matched state and enters slave receive mode. This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminate subsequent redundant processing (processing for the transmission of FFh).
The RIIC detects slave arbitration-lost when the following condition is met with the ICFER.SALE bit set to 1 (slave arbitration-lost detection enabled).

Condition for slave arbitration-lost

- When transmit data excluding acknowledge (internal SDA output level) does not match the SDAn line in slave transmit mode (bits MST and TRS in the ICCR2 register are 01b)

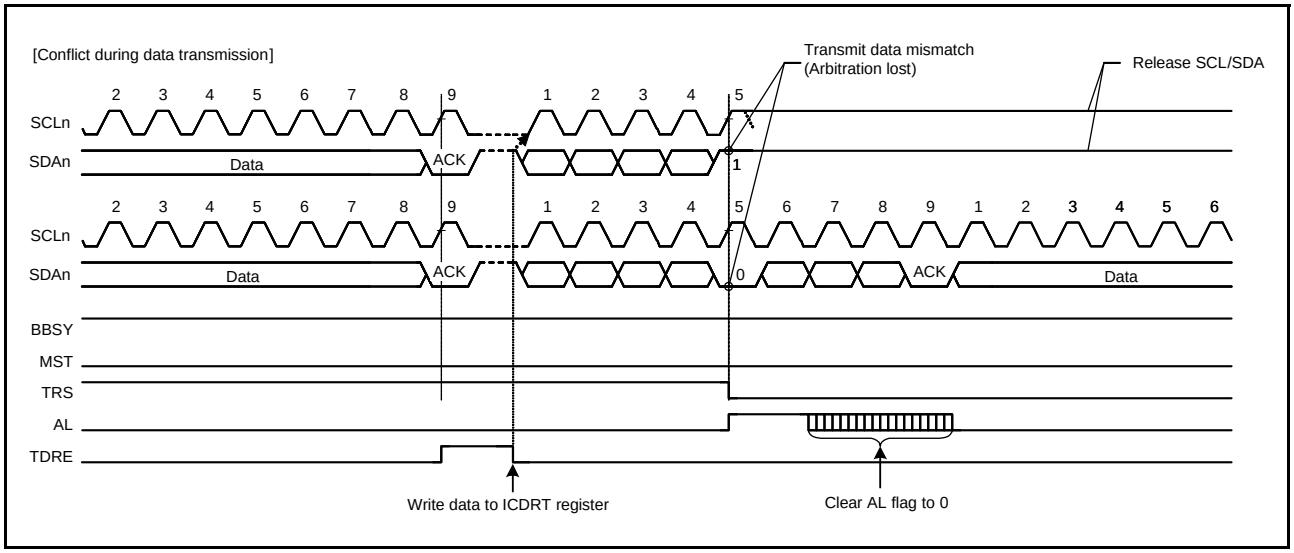

Figure 42.36 Example of Slave Arbitration-Lost Detection (SALE = 1)

42.10 Start Condition/Restart Condition/Stop Condition Issuing Function

42.10.1 Issuing a Start Condition

The RIIC issues a start condition when the ICCR2.ST bit is set to 1.
When the ST bit is set to 1, a start condition issuance request is made and the RIIC issues a start condition when the ICCR2.BBSY flag is 0 (bus free state). When a start condition is issued normally, the RIIC automatically shifts to the master transmit mode.
A start condition is issued in the following sequence.

Start condition issuance

(1) Drive the SDAn line low (high level to low level).
(2) Ensure the time set in the ICBRH register and the start condition hold time.
(3) Drive the SCLn line low (high level to low level).
(4) Detect low level of the SCLn line and ensure the low-level period of SCLn line set in the ICBRL register.

42.10.2 Issuing a Restart Condition

The RIIC issues a restart condition when the ICCR2.RS bit is set to 1.
When the RS bit is set to 1, a restart condition issuance request is made and the RIIC issues a restart condition when the ICCR2.BBSY flag is 1 (bus busy state) and the ICCR2.MST bit is 1 (master mode).
A restart condition is issued in the following sequence.

Restart condition issuance

(1) Release the SDAn line.
(2) Ensure the low-level period of SCLn line set in the ICBRL register.
(3) Release the SCLn line (low level to high level).
(4) Detect a high level of the SCLn line and ensure the time set in the ICBRL register and the restart condition setup time.
(5) Drive the SDAn line low (high level to low level).
(6) Ensure the time set in the ICBRH register and the restart condition hold time.
(7) Drive the SCLn line low (high level to low level).
(8) Detect a low level of the SCLn line and ensure the low-level period of SCLn line set in the ICBRL register.

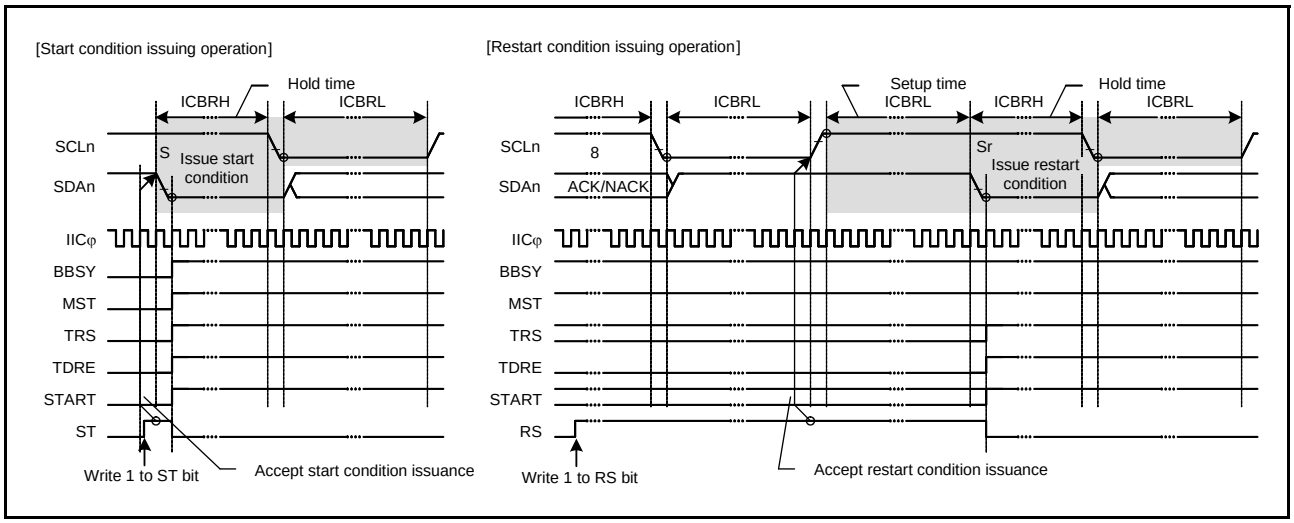

Figure 42.37 Start Condition/Restart Condition Issue Timing (ST and RS Bits)

42.10.3 Issuing a Stop Condition

The RIIC issues a stop condition when the ICCR2.SP bit is set to 1.
When the SP bit is set to 1, a stop condition issuance request is made and the RIIC issues a stop condition when the ICCR2.BBSY flag is 1 (bus busy state) and the ICCR2.MST bit is 1 (master mode).
A stop condition is issued in the following sequence.

Stop condition issuance

- Drive the SDAn line low (high level to low level).
- Ensure the low-level period of SCLn line set in the ICBRL register.
- Release the SCLn line (low level to high level).
- Detect a high level of the SCLn line and ensure the time set in the ICBRH register and the stop condition setup time.
- Release the SDAn line (low level to high level).
- Ensure the time set in the ICBRL register and the bus free time.
- Set the BBSY flag to 0 (to release the bus mastership).

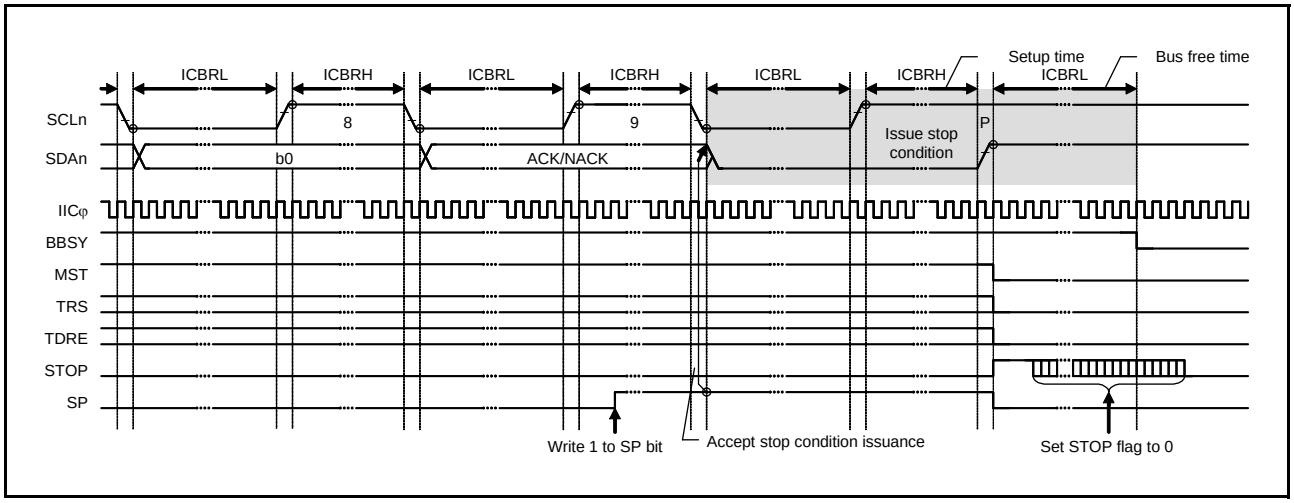

Figure 42.38 Stop Condition Issue Timing (SP Bit)

42.11 Bus Hanging

If the clock signals from the master and slave devices go out of synchronization due to noise or other factors, the I2C-bus might hang with a fixed level on the SCLn line and/or SDAn line.
As measures against the bus hanging, the RIIC has a timeout function to detect hanging by monitoring the SCLn line, a function for the output of an extra SCL clock cycle to release the bus from a hung state due to clock signals being out of synchronization, the RIIC reset function, and internal reset function.
By checking bits SCLO, SDAO, SCLI, and SDAI in the ICCR1 register, it is possible to see whether the RIIC or its partner in communications is placing the low level on the SCLn or SDAn lines.

42.11.1 Timeout Function

The RIIC includes a timeout function for detecting when the SCLn line has been stuck longer than the predetermined time. The RIIC can detect an abnormal bus state by monitoring that the SCLn line is stuck low or high for a predetermined time.
The timeout function monitors the SCLn line state and counts the low-level period or high-level period using the internal counter. The timeout function resets the internal counter each time the SCLn line changes (rising or falling), but continues to count unless the SCLn line changes. If the internal counter overflows due to no SCLn line change, the RIIC can detect the timeout and report the bus hung state.
This timeout function is enabled when the ICFER.TMOE bit is 1. It detects a hung state that the SCLn line is stuck low or high during the following conditions:

- The bus is busy (ICCR2.BBSY flag is 1) in master mode (ICCR2.MST bit is 1).
- The RIIC's own slave address is detected (ICSR1 register is not 00h) and the bus is busy (ICCR2.BBSY flag is 1) in slave mode (ICCR2.MST bit is 0).
- The bus is free (ICCR2.BBSY flag is 0) while generation of a start condition is requested (ICCR2.ST bit is 1).

The internal counter of the timeout function works using the internal reference clock (IICφ) set by the ICMR1.CKS[2:0] bits as a count source. It functions as a 16-bit counter when long mode is selected (ICMR2.TMOS bit is 0) or a 14-bit counter when short mode is selected (TMOS bit is 1).
The SCLn line level (low/high or both levels) during which this counter is activated can be selected by the setting of bits TMOH and TMOL in the ICMR2 register. If both bits TMOL and TMOH are set to 0, the internal counter does not work.

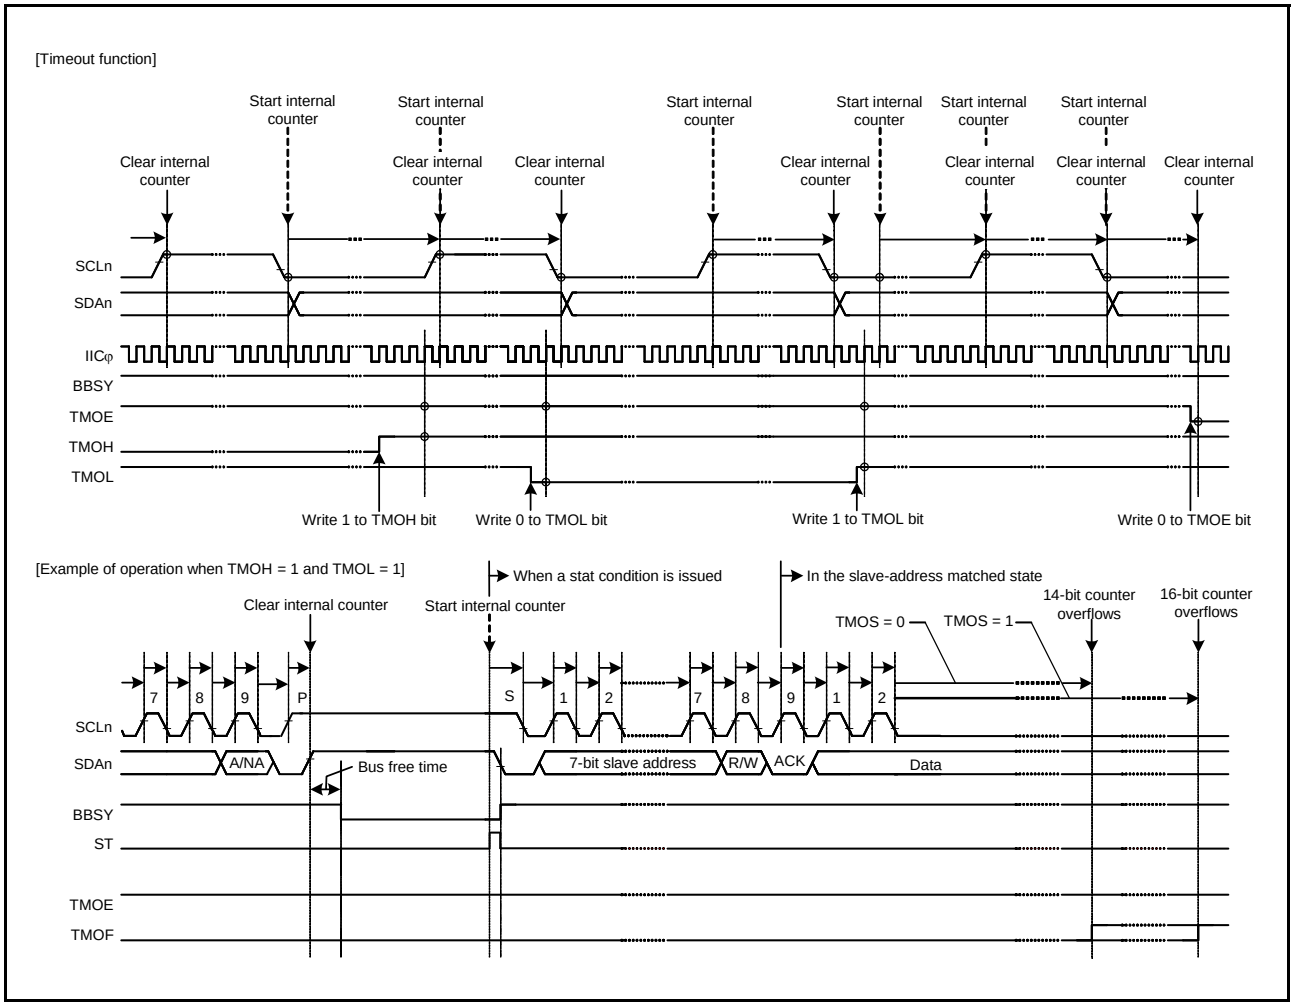

Figure 42.39 Timeout Function

42.11.2 Extra SCL Clock Cycle Output Function

In master mode, the RIIC module has a facility for the output of extra SCL clock cycles to release the SDAn line of the slave device from being held at the low level due to the master being out of synchronization with the slave device. This function is mainly used in master mode to release the SDAn line of the slave device from the state of being fixed to the low level by including extra cycles of SCL output from the RIIC with single cycles of the SCL clock as the unit if the RIIC cannot issue a stop condition because the slave device is holding the SDAn line at the low level. Do not use this facility in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.

When the ICCR1.CLO bit is set to 1 in master mode, a single cycle of the SCL clock at the frequency corresponding to the transfer rate settings (settings of the ICMR1.CKS[2:0] bits, and of registers ICBRH and ICBRL) is output as an extra clock cycle. After output of this single cycle of the SCL clock, the CLO bit is automatically set to 0. Therefore, further extra clock cycles can be output consecutively by writing 1 to the CLO bit after confirming the CLO bit to be 0.

When the RIIC module is in master mode and the slave device is holding the SDAn line at the low level because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a stop condition is not possible. The facility for output of an extra cycle of the SCL clock can be used to output extra cycles of SCL one by one to make the slave device release the SDAn line from being held at the low level, thus recovering the bus from an unusable state. Release of the SDAn line by the slave device can be monitored by reading the ICCR1.SDAI bit. After confirming release of the SDAn line by the slave device, complete communications by reissuing the stop condition.

Use this facility with the ICFER.MALE bit (master arbitration-lost detection disabled) set to 0. If the MALE bit is set to 1 (master arbitration-lost detection enabled), arbitration is lost when the value of the ICCR1.SDAO bit does not match the state of the SDAn line, so take care on this point.

Output conditions for using the ICCR1.CLO bit

- When the bus is free (ICCR2.BBSY flag is 0) or in master mode (ICCR2.MST bit is 1 and ICCR2.BBSY flag is 1)
- When the communication device does not hold the SCLn line low

Figure 42.40 shows the operation timing of the extra SCL clock cycle output function (CLO bit).

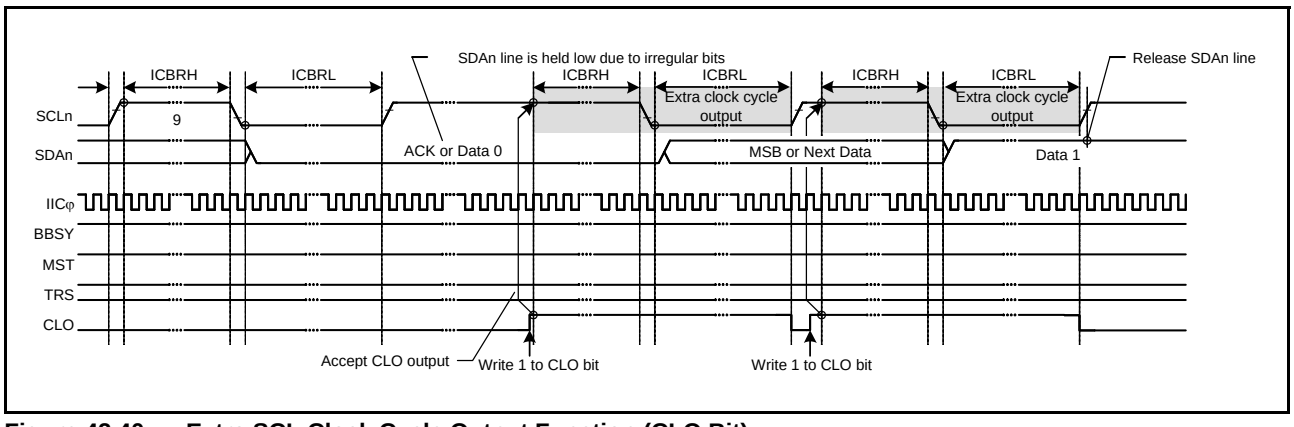

Figure 42.40 Extra SCL Clock Cycle Output Function (CLO Bit)

42.11.3 RIIC Reset and Internal Reset

The RIIC module incorporates a function for resetting itself. There are two types of reset. One is referred to as an RIIC reset; this initializes all registers including the ICCR2.BBSY flag. The other is referred to as an internal reset; this releases the RIIC from the slave-address matched state and initializes the internal counter while retaining other settings. After issuing a reset, be sure to set the ICCR1.IICRST bit to 0.

Both types of reset are effective for release from bus-hung states because both restore the output state of the SCLn and SDAn pins to the high-impedance state.

Issuing a reset during slave operation may lead to a loss of synchronization between the master device clock and the slave device clock, so avoided this where possible. Note that monitoring of the bus state, such as for the presence of a start condition, is not possible during an RIIC reset (bits ICE and IICRST in the ICCR1 register are 01b).

For a detailed description of the RIIC and internal resets, refer to section 42.14, Resets and Register and Function States When Issuing Each Condition.

42.12 SMBus Operation

The RIIC is available for data communication conforming to the SMBus (Version 2.0). To perform SMBus communication, set the ICMR3.SMBS bit to 1. To use the transfer rate within a range of 10 kbps to 100 kbps of the SMBus specification, set the ICMR1.CKS[2:0] bits, the ICBRH register, and the ICBRL register. In addition, determine the values of the ICMR2.DLCS bit and the ICMR2.SDDL[2:0] bits to meet the data hold time specification of 300 ns or more. If the RIIC is used only as a slave device, the transfer rate setting is not necessary, whereas the ICBRL register needs to be set to a value longer than the data setup time (250 ns).
For the SMBus device default address (1100 001b), use one of the slave address registers L0 to L2 (registers SARL0, SARL1, and SARL2), and set the corresponding SARUy.FS bit (7-bit/10-bit address format select) (y = 0 to 2) to 0 (7-bit address format).
When transmitting the UDID (Unique Device Identifier), set the ICFER.SALE bit to 1 to enable the slave arbitration-lost detection function.

42.12.1 SMBus Timeout Measurement

(1) Measuring timeout of slave device

The following period (timeout interval: $T_{LOW:SEXT}$) must be measured for slave devices in SMBus communication.

- From start condition to stop condition

To measure timeout for slave devices, measure the period from start condition detection to stop condition detection with the MTU or TMR timer using a start condition detection interrupt (STI) and stop condition detection interrupt (SPI) of the RIIC. The measured timeout period must be within the total clock low-level period [slave device] $T_{LOW:SEXT}$: 25 ms (max.) of the SMBus specification.
If the time measured with the MTU or TMR exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (min.) of the SMBus specification, the slave device must release the bus by writing 1 to the ICCR1.IICRST bit to issue an internal reset of the RIIC. When an internal reset is issued, the RIIC stops driving the bus for the SCLn pin and SDAn pin and make the SCLn/SDAn pin outputs high-impedance, which releases the bus.

(2) Measuring timeout of master device

The following periods (timeout interval: $T_{LOW:MEXT}$) must be measured for master devices in SMBus communication.

- From start condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to stop condition

To measure timeout for master devices, measure these periods with the MTU or TMR timer using a start condition detection interrupt (STI), stop condition detection interrupt (SPI), and transmit end interrupt (TEI) or receive data full interrupt (RXI) of the RIIC. The measured timeout period must be within the total clock low-level extended period (master device) $T_{LOW:MEXT}$: 10 ms (max.) of the SMBus specification, and the total of all $T_{LOW:MEXT}$ from start condition to stop condition must be within $T_{LOW:SEXT}$: 25 ms (max.).
For the ACK receive timing (rising edge of the ninth SCL clock cycle), monitor the ICSR2.TEND flag in master transmit mode (master transmitter) and the ICSR2.RDRF flag in master receive mode (master receiver). For this reason, perform bytewise transmit operation in master transmit mode, and hold the ICMR3.RDRFS bit 0 until the byte just before reception of the final byte in master receive mode. While the RDRFS bit is 0, the RDRF flag is set to 1 at the rising edge of the ninth SCL clock cycle.
If the period measured with the MTU or TMR exceeds the total clock low-level extended period (master device) $T_{LOW:MEXT}$: 10 ms (max.) of the SMBus specification or the total of measured periods exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (min.) of the SMBus specification, the master device must stop the transaction by issuing a stop condition. In master transmit mode, immediately stop the transmit operation (writing data to the ICDRT register).

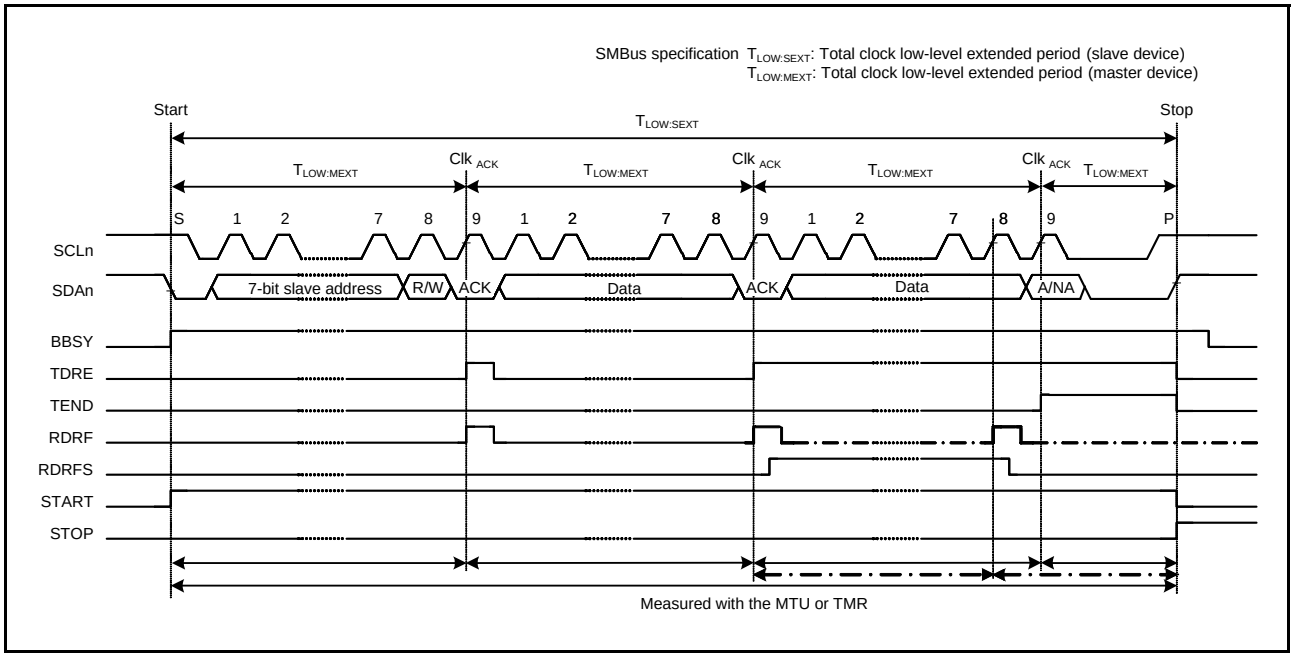

Figure 42.41 SMBus Timeout Measurement

42.12.2 Packet Error Code (PEC)

This MCU incorporates a CRC calculator. The CRC calculator enables transmission of a packet error code (PEC) or checking the received data of the SMBus in data communication of the RIIC. For the CRC generating polynomials of the CRC calculator, refer to section 46, CRC Calculator (CRC).

The PEC data in master transmit mode can be generated by writing all transmit data to the CRC data input register (CRCDIR) in the CRC calculator.

The PEC data in master receive mode can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC data output register (CRCDOR) with the received PEC data.

To send ACK or NACK according to the match or mismatch result when the final byte is received as a result of the PEC code check, set the ICMR3.RDRFS bit to 1 before the rising edge of the eighth SCL clock cycle during reception of the final byte, and hold the SCLn line low at the falling edge of the eighth clock cycle.

42.12.3 SMBus Host Notification Protocol (Notify ARP Master Command)

In communications over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of its own slave address or to request its own slave address from the SMBus host.

For a product of this MCU to operate as an SMBus host (or ARP master), the host address (0001 000b) sent from the slave device must be detected as a slave address, so the RIIC has a function for detecting the host address. To detect the host address as a slave address, set the ICMR3.SMBS bit and the ICSER.HOAE bit to 1. Operation after the host address has been detected is the same as normal slave operation.

42.13 Interrupt Sources

The RIIC issues four types of interrupt request: transfer error or event generation (arbitration-lost, NACK detection, timeout detection, start condition detection, and stop condition detection), receive data full, transmit data empty, and transmit end.

Table 42.6 lists details of the several interrupt requests. The receive data full and transmit data empty are both capable of activating data transfer by the DTC or DMAC.

Table 42.6 Interrupt Sources

Symbol	Interrupt Source	Interrupt Flag	DTC Activation	DMAC Activation	Priority	Interrupt Condition
EEI	Transfer error/ event generation	AL	Not possible	Not possible	High	AL = 1 • ALIE = 1
		NACKF				NACKF = 1 • NAKIE = 1
		TMOF				TMOF = 1 • TMOIE = 1
		START				START = 1 • STIE = 1
		STOP				STOP = 1 • SPIE = 1
RXI*2	Receive data full	RDRF	Possible	Possible		RDRF = 1 • RIE = 1
TXI*1	Transmit data empty	TDRE	Possible	Possible		TDRE = 1 • TIE = 1
TEI*3	Transmit end	TEND	Not possible	Not possible	Low	TEND = 1 • TEIE = 1

Note: There is a delay time between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. Thus, when an interrupt flag has been cleared or an interrupt request has been masked, read the relevant flag again to check whether clearing or masking has been completed, and then return from interrupt handling. Returning from interrupt handling without checking that writing to the module has been completed creates a possibility of repeated processing of the same interrupt.

Note 1. Because TXI is an edge-detected interrupted, it does not require clearing. Furthermore, the ICSR2.TDRE flag (a condition for TXI) is automatically set to 0 when data for transmission are written to the ICDRT register or a stop condition is detected (ICSR2.STOP flag is 1).

Note 2. Because RXI is an edge-detected interrupted, it does not require clearing. Furthermore, the ICSR2.RDRF flag (a condition for RXI) is automatically set to 0 when data are read from the ICDRR register.

Note 3. When using the TEI interrupt, clear the ICSR2.TEND flag in the TEI interrupt handling.
Note that the ICSR2.TEND flag is automatically set to 0 when data for transmission are written to the ICDRT register or a stop condition is detected (ICSR2.STOP flag is 1).

Clear the each flag or mask the interrupt request during interrupt handling.

42.13.1 Buffer Operation for TXI and RXI Interrupts

If the conditions for generating a TXI and RXI interrupt are satisfied while the corresponding IR flag is 1, the interrupt request is not output for the ICU but retained internally (the capacity for internal retention is one request per source). An interrupt request that was being retained internally is output to the ICU when the value of the ICU.IRn.IR flag becomes 0. Internally retained interrupt requests are automatically cleared under normal conditions of usage. Internally retained interrupt requests can also be cleared by writing 0 to the corresponding interrupt enable bit in the ICIER register.

42.14 Resets and Register and Function States When Issuing Each Condition

The RIIC can be reset by MCU reset, RIIC reset, and internal reset functions. Table 42.7 lists the register and function states when issuing each reset or condition.

Table 42.7 Register and Function States When Issuing Each Reset or Condition

		MCU Reset	RIIC Reset (ICE = 0, IICRST = 1)	Internal Reset (ICE = 1, IICRST = 1)	Start Condition/ Restart Condition Detection	Stop Condition Detection
ICCR1	ICE, IICRST	To be reset	Retained	Retained	Retained	Retained
	SCLO, SDAO		To be reset	To be reset		
	Others			Retained		
ICCR2	BBSY	To be reset	To be reset	Retained	Retained	Retained
	ST			To be reset	To be reset	Retained
	Others					To be reset
ICMR1	BC[2:0]	To be reset	To be reset	To be reset	To be reset	Retained
	Others			Retained	Retained	
ICMR2		To be reset	To be reset	Retained	Retained	Retained
ICMR3		To be reset	To be reset	Retained	Retained	Retained
ICFER		To be reset	To be reset	Retained	Retained	Retained
ICSER		To be reset	To be reset	Retained	Retained	Retained
ICIER		To be reset	To be reset	Retained	Retained	Retained
ICSR1		To be reset	To be reset	To be reset	Retained	To be reset
ICSR2	TDRE, TEND	To be reset	To be reset	To be reset	Retained	To be reset
	START				Retained	
	STOP				Retained	Retained
	Others				Retained	Retained
SARL0, SARL1, SARL2, SARU0, SARU1, SARU2		To be reset	To be reset	Retained	Retained	Retained

ICDRT		To be reset	To be reset	Retained	Retained	Retained
ICDRR		To be reset	To be reset	Retained	Retained	Retained
ICDRS		To be reset	To be reset	To be reset	Retained	Retained
Timeout function		To be reset	To be reset	Operation	Operation	Operation
Bus free time measurement		To be reset	To be reset	Operation	Operation	Operation

42.15 Event Link Function (Output)

The RIIC0 handles event output for the event link controller (ELC) corresponding to the following sources.

- Communication error/ communication event
- Receive data full
- Transmit data empty
- Transmit end

42.15.1 Interrupt Handling and Event Linking

The RIIC module produces four kinds of interrupt: transfer error (arbitration-lost detection, detection of NACK, detection of timeout, or detection of a stop condition) event, receive data full, transmit data empty, and transmit end interrupts detection of a start condition. Each of these has an enable bit to control enabling and disabling of the interrupt signal. An interrupt request signal is output for the CPU when an interrupt source condition is satisfied while the setting of the corresponding enable bit is enabled.
The corresponding event signals are sent to other modules via the ELC when the interrupt source conditions are satisfied, regardless of the settings of the interrupt enable bits.
For details on interrupt sources, see Table 42.6.

42.16 Usage Notes

42.16.1 Setting Module Stop Function

Module stop state can be entered or released using module stop control register B (MSTPCRB) or module stop control register C (MSTPCRC). The initial setting is for operation of the RIIC to be stopped. RIIC register access is enabled by releasing the module stop state.
For details on module stop control registers B and C, refer to section 11, Low Power Consumption.

42.16.2 Notes on Starting Transfer

If the IR flag corresponding to the RIIC interrupt is 1 when transfer is started (ICCR1.ICE bit is 1), follow the procedure below to clear interrupts before enabling operations. Starting transfer with the IR flag set to 1 while the ICCR1.ICE bit is 1 leads to an interrupt request being internally retained after transfer starts, and this can lead to unanticipated behavior of the IR flag.

1. Confirm that the ICCR1.ICE bit is 0.
2. Set the relevant interrupt enable bits (ICIER.TIE, etc.) on the peripheral function side to 0.
3. Read the relevant interrupt enable bits (ICIER.TIE, etc.) on the peripheral function side and confirm that its value is 0.
4. Set the IR flag to 0.

43. CAN Module (CAN)

43.1 Overview

This MCU implements three channels of the CAN (Controller Area Network) module that complies with the ISO 11898-1 Standards. The CAN module transmits and receives both formats of messages, namely the standard identifier (11 bits) (identifier is hereafter referred to as ID) and extended ID (29 bits).

Table 43.1 lists the specifications of the CAN module, and Figure 43.1 shows a block diagram of the CAN module (i = 0 to 2).

Connect the CAN bus transceiver externally.

Table 43.1 Specifications of CAN Module

Item	Description
Protocol	• ISO 11898-1 compliant (standard and extended frames)
Bit rate	• Programmable bit rate up to 1 Mbps (fCAN ≥ 8 MHz) fCAN: CAN clock source
Message box	• 32 mailboxes: Two selectable mailbox modes Normal mailbox mode: 32 mailboxes can be configured for either transmission or reception. FIFO mailbox mode: 24 mailboxes can be configured for either transmission or reception. Of the other mailboxes, four FIFO stages can be configured for transmission and four FIFO stages for reception.
Reception	• Data frame and remote frame can be received. • Selectable receiving ID format (only standard ID, only extended ID, or both IDs) • Programmable one-shot reception function • Selectable from overwrite mode (message overwritten) and overrun mode (message discarded) • The reception complete interrupt can be individually enabled or disabled for each mailbox.
Acceptance filter	• Eight acceptance masks (one mask for every four mailboxes) • The mask can be individually enabled or disabled for each mailbox.
Transmission	• Data frame and remote frame can be transmitted. • Selectable transmitting ID format (only standard ID, only extended ID, or both IDs) • Programmable one-shot transmission function • Selectable from ID priority mode and mailbox number priority mode • Transmission request can be aborted (the completion of abort can be confirmed with a flag) • The transmission complete interrupt can be individually enabled or disabled for each mailbox.
Mode transition for bus-off recovery	• Mode transition for the recovery from the bus-off state can be selected: ISO 11898-1 Standards compliant Automatic entry to CAN halt mode at bus-off entry Automatic entry to CAN halt mode at bus-off end Entry to CAN halt mode by a program Transition into error-active state by a program
Error status monitoring	• CAN bus errors (stuff error, form error, ACK error, CRC error, bit error, and ACK delimiter error) can be monitored. • Transition to error states can be detected (error-warning, error-passive, bus-off entry, and bus-off recovery). • The error counters can be read.
Time stamp function	• Time stamp function using a 16-bit counter • The reference clock can be selected from 1-, 2-, 4- and 8-bit time periods.
Interrupt function	• Five types of interrupt sources (reception complete, transmission complete, receive FIFO, transmit FIFO, and error interrupts)
CAN sleep mode	• Current consumption can be reduced by stopping the CAN clock.
Software support unit	• Three software support units: Acceptance filter support Mailbox search support (receive mailbox search, transmit mailbox search, and message lost search) Channel search support
CAN clock source	Peripheral module clock (PCLKB) or CANMCLK
Test mode	• Three test modes available for user evaluation Listen-only mode Self-test mode 0 (external loopback) Self-test mode 1 (internal loopback)
Power consumption reducing function	Module-stop state can be set.

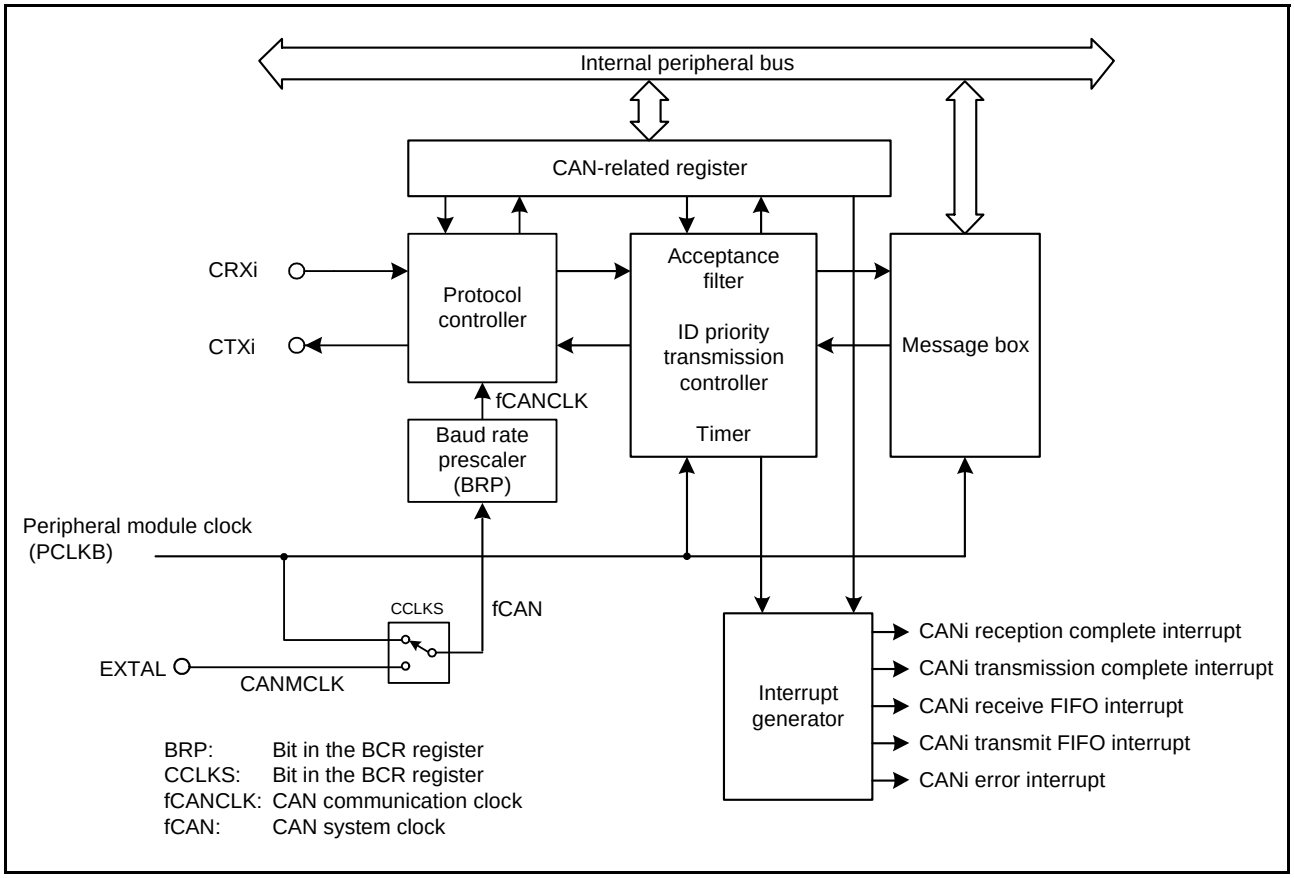

Figure 43.1 Block Diagram of CAN Module (i = 0 to 2)

- CRXi and CTXi (i = 0 to 2)
  CAN input and output pins
- Protocol controller
  Handles CAN protocol processing such as bus arbitration, bit timing at transmission and reception, stuffing, and error handling, etc.
- Message box
  Consists of 32 mailboxes which can be configured as either transmit or receive mailboxes. Each mailbox has an individual ID, data length code, a data field (8 bytes), and a time stamp.
- Acceptance filter
  Performs filtering of received messages. MKR0 to MKR7 are used for the filtering process.
- Timer
  Used for the time stamp function. The timer value when a message is stored into the mailbox is written as the time stamp value.
- Interrupt generator:
  Generates the following five types of interrupts:
  CANi reception complete interrupt
  CANi transmission complete interrupt
  CANi receive FIFO interrupt
  CANi transmit FIFO interrupt
  CANi error interrupt

Table 43.2 lists the CAN module pins.
The CAN functions should be selected for the pins multiplexed with other signals. For details, see section 22, I/O Ports.

Table 43.2 Pin Configuration

Pin Name	I/O	Function
CRX0	Input	Pin for receiving data
CTX0	Output	Pin for transmitting data
CRX1	Input	Pin for receiving data
CTX1	Output	Pin for transmitting data
CRX2	Input	Pin for receiving data
CTX2	Output	Pin for transmitting data

43.2 Register Descriptions

43.2.1 Control Register (CTLR)

Address(es): CAN0.CTLR 0009 0840h, CAN1.CTLR 0009 1840h, CAN2.CTLR 0009 2840h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	RBOC	BOM[1:0]		SLPM	CANM[1:0]		TSPS[1:0]		TSRC	TPM	MLM	IDFM[1:0]		MBM
Value after reset:	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MBM	CAN Mailbox Mode Select *1	0: Normal mailbox mode 1: FIFO mailbox mode	R/W
b2, b1	IDFM[1:0]	ID Format Mode Select*1	b2 b1 0 0: Standard ID mode All mailboxes (including FIFO mailboxes) handle only standard Ids. 0 1: Extended ID mode All mailboxes (including FIFO mailboxes) handle only extended IDs. 1 0: Mixed ID mode All mailboxes (including FIFO mailboxes) handle both standard IDs and extended IDs. Standard IDs or extended IDs are specified by using the IDE bit in the corresponding mailbox in normal mailbox mode. In FIFO mailbox mode, the IDE bit in the corresponding mailbox is used for mailboxes [0] to [23], the IDE bits in FIDCR0 and FIDCR1 are used for the receive FIFO, and the IDE bit in mailbox [24] is used for the transmit FIFO. 1 1: Do not use this combination	R/W
b3	MLM	Message Lost Mode Select*2	0: Overwrite mode 1: Overrun mode	R/W
b4	TPM	Transmission Priority Mode Select*2	0: ID priority transmit mode 1: Mailbox number priority transmit mode	R/W
b5	TSRC	Time Stamp Counter Reset Command*4	0: Nothing occurred 1: Reset*3	R/W
b7, b6	TSPS[1:0]	Time Stamp Prescaler Select*1	b7 b6 0 0: Every bit time 0 1: Every 2-bit time 1 0: Every 4-bit time 1 1: Every 8-bit time	R/W
b9, b8	CANM[1:0]	CAN Operating Mode Select*5	b9 b8 0 0: CAN operation mode 0 1: CAN reset mode 1 0: CAN halt mode 1 1: CAN reset mode (forcible transition)	R/W
b10	SLPM	CAN Sleep Mode*5,*6	0: Other than CAN sleep mode 1: CAN sleep mode	R/W
b12, b11	BOM[1:0]	Bus-Off Recovery Mode *1	b12 b11 0 0: Normal mode (ISO 11898-1 compliant) 0 1: Entry to CAN halt mode automatically at bus-off entry 1 0: Entry to CAN halt mode automatically at bus-off end 1 1: Entry to CAN halt mode (during bus-off recovery period) by a program request	R/W
b13	RBOC	Forcible Return From Bus-Off*2	0: Nothing occurred 1: Forcible return from bus-off*3	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Write to the BOM[1:0], TSPS[1:0], TPM, MLM, IDFM[1:0], and MBM bits in CAN reset mode.
Note 2. Set the RBOC bit to 1 in the bus-off state.
Note 3. This bit is automatically set back to 0 after being set to 1. It should be read as 0.
Note 4. Set the TSRC bit to 1 in CAN operation mode.
Note 5. When the CANM[1:0] and SLPM bits are changed, check STR to ensure that the mode has been switched. Do not change the CANM[1:0] bits or SLPM bit until the mode has been switched.

Note 6. Write to the SLPM bit in CAN reset mode or CAN halt mode. When changing the SLPM bit, write 0 or 1 to only the SLPM bit.

MBM Bit (CAN Mailbox Mode Select)

When the MBM bit is 0 (normal mailbox mode), mailboxes [0] to [31] are configured as transmit or receive mailboxes.
When the MBM bit is 1 (FIFO mailbox mode), mailboxes [0] to [23] are configured as transmit or receive mailboxes. Mailboxes [24] to [27] are configured as a transmit FIFO and mailboxes [28] to [31] as a receive FIFO.
Transmit data is written into mailbox [24] (mailbox [24] is a window mailbox for the transmit FIFO). Receive data is read from mailbox [28] (mailbox [28] is a window mailbox for the receive FIFO).
Table 43.3 lists the mailbox configuration.

IDFM[1:0] Bits (ID Format Mode Select)

The IDFM[1:0] bits specify the ID format.

MLM Bit (Message Lost Mode Select)

The MLM bit specifies the operation when a new message is captured in the unread mailbox. Overwrite mode or overrun mode can be selected. All mailboxes (including the receive FIFO) are set to either overwrite mode or overrun mode.
When the MLM bit is 0, all mailboxes are set to overwrite mode and the new message is overwriting the old message.
When the MLM bit is 1, all mailboxes are set to overrun mode and the new message is discarded.

TPM Bit (Transmission Priority Mode Select)

The TPM bit specifies the priority of modes when transmitting messages.
ID priority transmit mode or mailbox number transmit mode can be selected. All mailboxes are set for either ID priority transmission or mailbox number priority transmission.
When the TPM bit is 0, ID priority transmit mode is selected and transmission priority complies with the CAN bus arbitration rule, as defined in the ISO 11898-1 Standards. In ID priority transmit mode, mailboxes [0] to [31] (in normal mailbox mode), and mailboxes [0] to [23] (in FIFO mailbox mode), and the transmit FIFO are compared for the IDs of mailboxes configured for transmission. If two or more mailbox IDs are the same, the mailbox with the smaller number has higher priority.
Only the next message to be transmitted from the transmit FIFO is included in the transmission arbitration. If a transmit FIFO message is being transmitted, the next pending message within the transmit FIFO is included in the transmission arbitration.
When the TPM bit is 1, mailbox number transmit mode is selected and the transmit mailbox with the smallest mailbox number has the highest priority. In FIFO mailbox mode, the transmit FIFO has lower priority than normal mailboxes (mailboxes [0] to [23]).

TSRC Bit (Time Stamp Counter Reset Command)

The TSRC bit is used to reset the time stamp counter. When the TSRC bit is set to 1, TSR is set to 0000h. This bit is automatically set to 0.

TSPS[1:0] Bits (Time Stamp Prescaler Select)

The TSPS[1:0] bits select the prescaler for the time stamp. The reference clock for the time stamp can be selected to be either 1-, 2-, 4- or 8-bit time periods.

CANM[1:0] Bits (CAN Operating Mode Select)

The CANM[1:0] bits select one of the following modes for the CAN module: CAN operation mode, CAN reset mode, or CAN halt mode. CAN sleep mode is set by the SLPM bit. For details, refer to section 43.3, Operating Mode.
When the CAN module enters CAN halt mode according to the setting of the BOM[1:0] bits, the CANM[1:0] bits are automatically set to 10b.

SLPM Bit (CAN Sleep Mode)

When the SLPM bit is set to 1, the CAN module enters CAN sleep mode. When the SLPM bit is set to 0, the CAN module exits CAN sleep mode. For details, refer to section 43.3, Operating Mode.

BOM[1:0] Bits (Bus-Off Recovery Mode)

The BOM[1:0] bits are used to select bus-off recovery mode for the CAN module.
When the BOM[1:0] bits are 00b, the recovery from bus-off is compliant with the ISO 11898-1 Standards, i.e. the CAN module reenters CAN communication (error-active state) after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request is generated when recovering from bus-off.
When the BOM[1:0] bits are 01b and the CAN module reaches the bus-off state, the CANM[1:0] bits in CTLR are set to 10b (CAN halt mode) to enter CAN halt mode. No bus-off recovery interrupt request is generated when recovering from bus-off, and TECR and RECR are set to 00h.
When the BOM[1:0] bits are 10b, the CANM[1:0] bits are set to 10b as soon as the CAN module reaches the bus-off state. The CAN module enters CAN halt mode after the recovery from the bus-off state, i.e. after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request is generated when recovering from bus-off, and TECR and RECR are set to 00h.
When the BOM[1:0] bits are 11b, the CAN module enters CAN halt mode by setting the CANM[1:0] bits to 10b while the CAN module is still in the bus-off state. No bus-off recovery interrupt request is generated when recovering from bus-off and TECR and RECR are set to 00h. However, if the CAN module recovers from bus-off after detecting 11 consecutive recessive bits 128 times before the CANM[1:0] bits are set to 10b, a bus-off recovery interrupt request is generated.
If the CPU requests an entry to CAN reset mode at the same time as the CAN module attempts to enter CAN halt mode (at bus-off entry when the BOM[1:0] bits are 01b, or at bus-off end when the BOM[1:0] bits are 10b), then the CPU request to enter CAN reset mode has higher priority.

RBOC Bit (Forcible Return From Bus-Off)

When the RBOC bit is set to 1 (force return from bus-off) in the bus-off state, the CAN module forcibly returns from the bus-off state. This bit is automatically set to 0. The error state changes from bus-off to error-active. When the RBOC bit is set to 1, RECR and TECR are set to 00h and the BOST bit in STR is set to 0 (the CAN module is not in bus-off state). The other registers remain unchanged even when the RBOC bit is set to 1. No bus-off recovery interrupt request is generated by this recovery from the bus-off state. Use the RBOC bit only when the BOM[1:0] bits are 00b (normal mode).

Table 43.3 Mailbox Configuration

Mailbox	MBM Bit = 0 (Normal Mailbox Mode)	MBM Bit = 1 (FIFO Mailbox Mode)
Mailboxes [0] to [23]	Normal mailbox	Normal mailbox
Mailboxes [24] to [27]		Transmit FIFO
Mailboxes [28] to [31]		Receive FIFO

Points 1 to 5 below should be considered when the CTLR.MBM bit is set to 1.
Note 1. Transmit FIFO is controlled by TFCR. MCTLj of mailboxes [24] to [27] is disabled.
MCTL24 to MCTL27 cannot be used by the transmit FIFO.
Note 2. Receive FIFO is controlled by RFCR. MCTLj of mailboxes [28] to [31] is disabled.
MCTL28 to MCTL31 cannot be used by the receive FIFO.
Note 3. Refer to MIER about the FIFO interrupts.
Note 4. The corresponding bits in MKIVLR for mailboxes [24] to [31] are disabled. Set 0 to these bits.
Note 5. Transmit/receive FIFOs can be used for both data frames and remote frames.

43.2.2 Bit Configuration Register (BCR)

Address(es): CAN0.BCR 0009 0844h, CAN1.BCR 0009 1844h, CAN2.BCR 0009 2844h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25 to b16	BRP[9:0]	Prescaler Division Ratio Select*1	These bits set the frequency of the CAN communication clock (fCANCLK).	R/W
b26	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b27	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b31 to b28	TSEG1[3:0]	Time Segment 1 Control	b31 b28 0 0 0 0: Setting prohibited 0 0 0 1: Setting prohibited 0 0 1 0: Setting prohibited 0 0 1 1: 4 Tq 0 1 0 0: 5 Tq 0 1 0 1: 6 Tq 0 1 1 0: 7 Tq 0 1 1 1: 8 Tq 1 0 0 0: 9 Tq 1 0 0 1: 10 Tq 1 0 1 0: 11 Tq 1 0 1 1: 12 Tq 1 1 0 0: 13 Tq 1 1 0 1: 14 Tq 1 1 1 0: 15 Tq 1 1 1 1: 16 Tq	R/W

Tq: Time Quantum

Note 1. Do not select the value less than 1 while the SCKCR3.CKSEL[2:0] bits are 010b (selecting the main clock oscillator).

For bit timing setting, refer to section 43.4, CAN Communication Speed Setting.
Set BCR before entering CAN halt mode or CAN operation mode from CAN reset mode. After the setting is made once, this register can be written to in CAN reset mode or CAN halt mode.
BCR consists of 24 bits. A 32-bit read/write access should be performed carefully not to rewrite bits b0 to b7.

CCLKS Bit (CAN Clock Source Selection)

When the CCLKS bit is 0, the peripheral module clock (PCLKB) produced by the PLL frequency synthesizer is used as the CAN clock source (fCAN).
When the CCLKS bit is 1, CANMCLK produced externally by the EXTAL pins is used as the CAN clock source (fCAN).

TSEG2[2:0] Bits (Time Segment 2 Control)

The TSEG2[2:0] bits are used to specify the length of the phase buffer segment 2 (PHASE_SEG2) with a Tq value. A value from 2 to 8 Tq can be set. Set a value smaller than that of the TSEG1[3:0] bits.

SJW[1:0] Bits (Resynchronization Jump Width Control)

The SJW[1:0] bits are used to specify the resynchronization jump width with a Tq value. A value from 1 to 4 Tq can be set. Set a value smaller than or equal to that of the TSEG2[2:0] bits.

BRP[9:0] Bits (Prescaler Division Ratio Select)

The BRP[9:0] bits are used to set the frequency of the CAN communication clock (fCANCLK). The fCANCLK cycle is 1 Tq. If the setting is P (0 to 1023), the baud rate prescaler divides fCAN by P + 1.

TSEG1[3:0] Bits (Time Segment 1 Control)

The TSEG1[3:0] bits are used to specify the total length of the propagation time segment (PROP_SEG) and phase buffer segment 1 (PHASE_SEG1) with a time quantum (Tq) value.
A value from 4 to 16 Tq can be set.

43.2.3 Mask Register k (MKRk) (k = 0 to 7)

Address(es): CAN0.MKR0 0009 0400h, CAN0.MKR1 0009 0404h, CAN0.MKR2 0009 0408h, CAN0.MKR3 0009 040Ch, CAN0.MKR4 0009 0410h, CAN0.MKR5 0009 0414h, CAN0.MKR6 0009 0418h, CAN0.MKR7 0009 041Ch, CAN1.MKR0 0009 1400h, CAN1.MKR1 0009 1404h, CAN1.MKR2 0009 1408h, CAN1.MKR3 0009 140Ch, CAN1.MKR4 0009 1410h, CAN1.MKR5 0009 1414h, CAN1.MKR6 0009 1418h, CAN1.MKR7 0009 141Ch, CAN2.MKR0 0009 2400h, CAN2.MKR1 0009 2404h, CAN2.MKR2 0009 2408h, CAN2.MKR3 0009 240Ch, CAN2.MKR4 0009 2410h, CAN2.MKR5 0009 2414h, CAN2.MKR6 0009 2418h, CAN2.MKR7 0009 241Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	SID[10:0]											EID[17:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	EID[17:0]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b17 to b0	EID[17:0]	Extended ID	0: Corresponding EID[17:0] bit is not compared 1: Corresponding EID[17:0] bit is compared	R/W
b28 to b18	SID[10:0]	Standard ID	0: Corresponding SID[10:0] bit is not compared 1: Corresponding SID[10:0] bit is compared	R/W
b31 to b29	—	Reserved	The read value is undefined. The write value should be 0.	R/W

For the mask function in FIFO mailbox mode, refer to section 43.6, Acceptance Filtering and Masking Functions.
Write to MKR0 to MKR7 in CAN reset mode or CAN halt mode.

EID[17:0] Bits (Extended ID)

The EID[17:0] bits are the filter mask bits for the CAN extended ID bits.
These bits are used to receive extended ID messages.
When the EID[17:0] bit is set to 0, the received ID is not compared with the mailbox ID for the corresponding EID[17:0] bit.
When the EID[17:0] bit is set to 1, the received ID is compared with the mailbox ID for the corresponding EID[17:0] bit.

SID[10:0] Bits (Standard ID)

The SID[10:0] bits are the filter mask bits corresponding to the CAN standard ID bits.
These bits are used to receive both standard ID and extended ID messages.
When the SID[10:0] bit is set to 0, the received ID is not compared with the mailbox ID for the corresponding SID[10:0] bit.
When the SID[10:0] bit is set to 1, the received ID is compared with the mailbox ID for the corresponding SID[10:0] bit.

43.2.4 FIFO Received ID Compare Registers 0 and 1 (FIDCR0 and FIDCR1)

Address(es): CAN0.FIDCR0 0009 0420h, CAN0.FIDCR1 0009 0424h, CAN1.FIDCR0 0009 1420h, CAN1.FIDCR1 0009 1424h, CAN2.FIDCR0 0009 2420h, CAN2.FIDCR1 0009 2424h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	IDE	RTR	—	SID[10:0]											EID[17:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	EID[17:0]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b17 to b0	EID[17:0]	Extended ID	0: Corresponding EID[17:0] bits are 0 1: Corresponding EID[17:0] bits are 1	R/W
b28 to b18	SID[10:0]	Standard ID	0: Corresponding SID[10:0] bits are 0 1: Corresponding SID[10:0] bits are 1	R/W
b29	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b30	RTR	Remote Transmission Request	0: Data frame 1: Remote frame	R/W
b31	IDE	ID Extension*1	0: Standard ID 1: Extended ID	R/W

Note 1. When the IDFM[1:0] bits are not 10b, the IDE bit should be written with 0 and read as 0.

FIDCR0 and FIDCR1 are enabled when the MBM bit in CTLR is set to 1 (FIFO mailbox mode). Bits EID[17:0], SID[10:0], RTR, and IDE in MB28 to MB31 are disabled.
For the usage of FIDCR0 and FIDCR1, refer to section 43.6, Acceptance Filtering and Masking Functions.
Write to FIDCR0 and FIDCR1 in CAN reset mode or CAN halt mode.

EID[17:0] Bits (Extended ID)

The EID[17:0] bits set the extended ID of data frames and remote frames.
These bits are used to receive extended ID messages.

SID[10:0] Bits (Standard ID)

The SID[10:0] bits set the standard ID of data frames and remote frames.
These bits are used to receive both standard ID and extended ID messages.

RTR Bit (Remote Transmission Request)

The RTR bit sets the specified frame format of data frames or remote frames.

- When both RTR bits in FIDCR0 and FIDCR1 are set to 0, only data frames can be received.
- When both RTR bits in FIDCR0 and FIDCR1 are set to 1, only remote frames can be received.
- When the RTR bits in FIDCR0 and FIDCR1 are set to 0 or 1 individually, both data frames and remote frames can be received.

IDE Bit (ID Extension)

The IDE bit sets the ID format to standard ID or extended ID. The IDE bit is enabled when the IDFM[1:0] bits in CTLR are 10b (mixed ID mode).

- When both IDE bits in FIDCR0 and FIDCR1 are set to 0, only standard ID frames can be received.
- When both IDE bits in FIDCR0 and FIDCR1 are set to 1, only extended ID frames can be received.
- When the IDE bits in FIDCR0 and FIDCR1 are set to 0 or 1 individually, both standard ID and extended ID frames can be received.

43.2.5 Mask Invalid Register (MKIVLR)

Address(es): CAN0.MKIVLR 0009 0428h, CAN1.MKIVLR 0009 1428h, CAN2.MKIVLR 0009 2428h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MB31	MB30	MB29	MB28	MB27	MB26	MB25	MB24	MB23	MB22	MB21	MB20	MB19	MB18	MB17	MB16
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MB15	MB14	MB13	MB12	MB11	MB10	MB9	MB8	MB7	MB6	MB5	MB4	MB3	MB2	MB1	MB0
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	MB31 to MB0	Mask Invalid	0: Mask valid 1: Mask invalid	R/W

Each bit in MKIVLR corresponds to a mailbox.
The correspondence between the bits and mailboxes is shown below.
Bit 0 in MKIVLR corresponds to mailbox 0 (MB0) and bit 31 corresponds to mailbox 31 (MB31).*1
When a bit is set to 1, the relevant acceptance mask register becomes invalid for the corresponding mailbox. When a mask invalid bit is set to 1, a message is received by the corresponding mailbox only if the receive message ID matches the mailbox ID exactly.
Write to MKIVLR in CAN reset mode or CAN halt mode.

Note 1. Set bits 31 to 24 to 0 in FIFO mailbox mode.

43.2.6 Mailbox Register j (MBj) (j = 0 to 31)

Table 43.4 lists the CANi mailbox memory mapping, and Table 43.5 lists the CAN data frame configuration.
The value after reset of the CANi mailbox is undefined.
Write to MBj only when the related MCTLj (j = 0 to 31) is 00h and the corresponding mailbox is not processing an abort request.
See Table 43.4 for detailed register addresses.

Table 43.4 CANi Mailbox Memory Mapping

Address			Message Content
CAN0	**CAN1**	**CAN2**	**Memory Mapping**
0009 0200h + 16 × j + 0	0009 1200h + 16 × j + 0	0009 2200h + 16 × j + 0	IDE, RTR, SID10 to SID6
0009 0200h + 16 × j + 1	0009 1200h + 16 × j + 1	0009 2200h + 16 × j + 1	SID5 to SID0, EID17, EID16
0009 0200h + 16 × j + 2	0009 1200h + 16 × j + 2	0009 2200h + 16 × j + 2	EID15 to EID8
0009 0200h + 16 × j + 3	0009 1200h + 16 × j + 3	0009 2200h + 16 × j + 3	EID7 to EID0
0009 0200h + 16 × j + 4	0009 1200h + 16 × j + 4	0009 2200h + 16 × j + 4	—
0009 0200h + 16 × j + 5	0009 1200h + 16 × j + 5	0009 2200h + 16 × j + 5	Data length code (DLC[3:0])
0009 0200h + 16 × j + 6	0009 1200h + 16 × j + 6	0009 2200h + 16 × j + 6	Data byte 0
0009 0200h + 16 × j + 7	0009 1200h + 16 × j + 7	0009 2200h + 16 × j + 7	Data byte 1
0009 0200h + 16 × j + 8	0009 1200h + 16 × j + 8	0009 2200h + 16 × j + 8	Data byte 2
0009 0200h + 16 × j + 9	0009 1200h + 16 × j + 9	0009 2200h + 16 × j + 9	Data byte 3
0009 0200h + 16 × j + 10	0009 1200h + 16 × j + 10	0009 2200h + 16 × j + 10	Data byte 4
0009 0200h + 16 × j + 11	0009 1200h + 16 × j + 11	0009 2200h + 16 × j + 11	Data byte 5
0009 0200h + 16 × j + 12	0009 1200h + 16 × j + 12	0009 2200h + 16 × j + 12	Data byte 6
0009 0200h + 16 × j + 13	0009 1200h + 16 × j + 13	0009 2200h + 16 × j + 13	Data byte 7
0009 0200h + 16 × j + 14	0009 1200h + 16 × j + 14	0009 2200h + 16 × j + 14	Time stamp upper byte
0009 0200h + 16 × j + 15	0009 1200h + 16 × j + 15	0009 2200h + 16 × j + 15	Time stamp lower byte

Note: When accessing to the content of the MBj register, access to an address of a multiple of 4 (the suffix of the address is 0h, 4h, 8h, or Ch) in 32-bit units and to an even address in 16-bit units.

Table 43.5 CAN Data Frame Configuration

SID10 to SID6	SID5 to SID0	EID17 to EID16	EID15 to EID8	EID7 to EID0	DLC3 to DLC1	DATA0	DATA1	…	DATA7

The previous value of each mailbox is retained unless a new message is received.

Address(es): CAN0.MB0 to CAN0.MB31 0009 0200h to 0009 03FFh, CAN1.MB0 to CAN1.MB31 0009 1200h to 0009 13FFh, CAN2.MB0 to CAN2.MB31 0009 2200h to 0009 23FFh

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b17 to b0	EID[17:0]	Extended ID*1	0: Corresponding EID[17:0] bits are 0 1: Corresponding EID[17:0] bits are 1	R/W
b28 to b18	SID[10:0]	Standard ID	0: Corresponding SID[10:0] bits are 0 1: Corresponding SID[10:0] bits are 1	R/W
b29	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b30	RTR	Remote Frame Request	0: Data frame 1: Remote frame	R/W
b31	IDE	ID Extension*2	0: Standard ID 1: Extended ID	R/W

Note 1. If the mailbox has received a standard ID message, the EID bits in the mailbox are undefined.
Note 2. The IDE bit is enabled when the IDFM[1:0] bits in CTLR are 10b (mixed ID mode). When the IDFM[1:0] bits are not 10b, it should be written with 0 and read as 0.

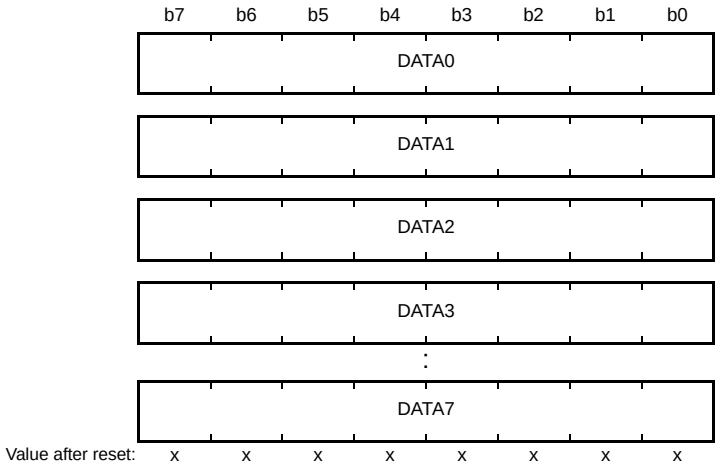
	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	DLC[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	DLC[3:0]	Data Length Code*1	b3 b0 0 0 0 0: Data length = 0 byte 0 0 0 1: Data length = 1 byte 0 0 1 0: Data length = 2 bytes 0 0 1 1: Data length = 3 bytes 0 1 0 0: Data length = 4 bytes 0 1 0 1: Data length = 5 bytes 0 1 1 0: Data length = 6 bytes 0 1 1 1: Data length = 7 bytes 1 x x x: Data length = 8 bytes	R/W
b15 to b4	—	Reserved	The read value is undefined. The write value should be 0.	R/W

x: Don't care

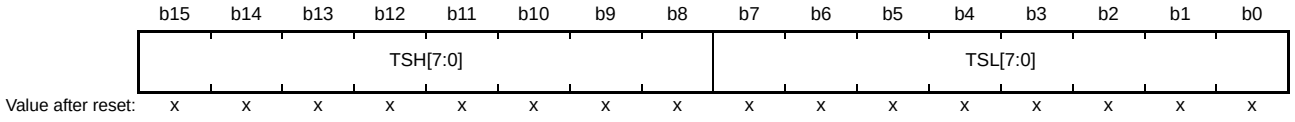
Note 1. If the mailbox has received a message whose data length set by the DLC[3:0] bits is less than 8 bytes, the values of DATA larger than the data length set by the DLC[3:0] bits in the mailbox are undefined.



x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	DATA0 to DATA7	Data Bytes 0 to 7*1, *2, *3	DATA0 to DATA7 store the transmitted or received CAN message data. Transmission or reception starts from DATA0. The bit order on the CAN bus is MSB first, and transmission or reception starts from bit 7.	R/W

Note 1. If the mailbox has received a message with n bytes less than 8 bytes, the values of DATAn to DATA7 in the mailbox are undefined.
Note 2. If the mailbox has received a remote frame, the previous values of DATA0 to DATA7 in the mailbox are retained.
Note 3. DATA0 to DATA3 or DATA4 to DATA7 cannot be accessed in 32-bit units at one time. The access must be divided into 3 times: DATA0 to DATA1, DATA2 to DATA5, and DATA6 to DATA7, or 4 times: DATA0 to DATA1, DATA2 to DATA3, DATA4 to DATA5, and DATA6 to DATA7.



x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TSL[7:0]	Time Stamp Lower Byte	Bits TSH[7:0] and TSL[7:0] store the counter value of the time stamp when received messages are stored in the mailbox.	R/W
b15 to b8	TSH[7:0]	Time Stamp Higher Byte		R/W

EID[17:0] Bits (Extended ID)

The EID[17:0] bits set the extended ID of data frames and remote frames.
These bits are used to transmit or receive extended ID messages.

SID[10:0] Bits (Standard ID)

The SID[10:0] bits set the standard ID of data frames and remote frames.
These bits are used to transmit or receive both standard ID and extended ID messages.

RTR Bit (Remote Frame Request)

The RTR bit sets the frame format of data frames or remote frames.

- Receive mailbox receives only frames with the format specified by the RTR bit.
- Transmit mailbox transmits according to the frame format specified by the RTR bit.
- Receive FIFO mailbox receives the data frame, remote frame, or both frames specified by the RTR bit in FIDCR0 and FIDCR1.
- Transmit FIFO mailbox transmits the data frame or remote frame specified by the RTR bit in the relevant transmit message.

IDE Bit (ID Extension)

The IDE bit sets the ID format of standard IDs or extended IDs. The IDE bit is enabled when the IDFM[1:0] bits in CTLR is 10b (mixed ID mode).

- Receive mailbox receives only the ID format specified by the IDE bit.
- Transmit mailbox transmits with the ID format specified by the IDE bit.
- Receive FIFO mailbox receives messages with the standard ID and extended ID specified by the IDE bit in FIDCR0 and FIDCR1.
- Transmit FIFO mailbox transmits messages with the standard ID or extended ID specified by the IDE bit in the relevant transmit message.

DLC[3:0] Bits (Data Length Code)

The DLC[3:0] bits specify the number of bytes of data to be transmitted in data frames. When a remote frame is used to request data, this field specifies the requested number of bytes of data.
When a data frame is received, the number of bytes received is stored in this field. When a remote frame is received, this field is used to store the number requested by the frame.

43.2.7 Mailbox Interrupt Enable Register (MIER)

Address(es): CAN0.MIER 0009 042Ch, CAN1.MIER 0009 142Ch, CAN2.MIER 0009 242Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MB31	MB30	MB29	MB28	MB27	MB26	MB25	MB24	MB23	MB22	MB21	MB20	MB19	MB18	MB17	MB16
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MB15	MB14	MB13	MB12	MB11	MB10	MB9	MB8	MB7	MB6	MB5	MB4	MB3	MB2	MB1	MB0
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

- Normal mailbox mode

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	MB31 to MB0	Interrupt Enable	0: Interrupt disabled 1: Interrupt enabled Bit 31 corresponds to mailbox 31 (MB31), and bit 0 corresponds to mailbox 0 (MB0).	R/W

- FIFO mailbox mode

Bit	Symbol	Bit Name	Description	R/W
b23 to b0	MB23 to MB0	Interrupt Enable	0: Interrupt disabled 1: Interrupt enabled Bit 23 corresponds to mailbox 23 (MB23), and bit 0 corresponds to mailbox 0 (MB0).	R/W
b24	MB24	Transmit FIFO Interrupt Enable	0: Interrupt disabled 1: Interrupt enabled	R/W
b25	MB25	Transmit FIFO Interrupt Generation Timing Control	0: Every time transmission is completed 1: When the transmit FIFO becomes empty due to completion of transmission	R/W
b27, b26	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b28	MB28	Receive FIFO Interrupt Enable	0: Interrupt disabled 1: Interrupt enabled	R/W
b29	MB29	Receive FIFO Interrupt Generation Timing Control*1	0: Every time reception is completed 1: When the receive FIFO becomes buffer warning by completion of reception	R/W
b31, b30	—	Reserved	The read value is undefined. The write value should be 0.	R/W

Note 1. No interrupt request is generated when the receive FIFO becomes buffer warning from full. “Buffer warning” indicates a state in which the third message is stored in the receive FIFO.

MIER can individually enable interrupts for each mailbox.
In normal mailbox mode (all bits) and in FIFO mailbox mode (bits 24 to 0 in MIER), each bit corresponds to the mailbox with the related number. These bits enable or disable transmission/reception complete interrupts for the corresponding mailboxes.

- Bit 0 in MIER corresponds to mailbox 0 (MB0).
- Bit 31 in MIER corresponds to mailbox 31 (MB31).

In FIFO mailbox mode, bits 29, 28, 25, and 24 of MIER specify whether transmit/receive FIFO interrupts are enabled/disabled and the timing when interrupt requests are generated.
Write to MIER only when the related MCTLj (j = 0 to 31) is 00h and the corresponding mailbox is not processing a transmission or reception abort request. In FIFO mailbox mode, change the bits in MIER for the related FIFO only when the TFE bit in TFCR is 0 and the TFEST flag is 1, and the RFE bit in RFCR is 0 and the RFEST flag in RFCR is 1.

43.2.8 Message Control Register j (MCTLj) (j = 0 to 31)

Address(es): CAN0.MCTL0 to CAN0.MCTL31 0009 0820h to 0009 083Fh, CAN1.MCTL0 to CAN1.MCTL31 0009 1820h to 0009 183Fh, CAN2.MCTL0 to CAN2.MCTL31 0009 2820h to 0009 283Fh

- Transmit mode (when the TRMREQ bit is 1 and the RECREQ bit is 0)

	b7	b6	b5	b4	b3	b2	b1	b0
	TRMREQ	RECREQ	—	ONESHOT	—	TRMABT	TRMACTIVE	SENTDATA
Value after reset:	0	0	0	0	0	0	0	0

- Receive mode (when the TRMREQ bit is 0 and the RECREQ bit is 1)

	b7	b6	b5	b4	b3	b2	b1	b0
	TRMREQ	RECREQ	—	ONESHOT	—	MSGLOST	INVALDATA	NEWDATA
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SENTDATA	Transmission Complete Flag *1,*2	0: Transmission is not completed 1: Transmission is completed	R/W
	NEWDATA	Reception Complete Flag *1,*2	0: No data has been received or 0 is written to the NEWDATA flag 1: A new message is being stored or has been stored to the mailbox	R/W
b1	TRMACTIVE	Transmission-in-Progress Status Flag	(Transmit mailbox setting enabled) 0: Transmission is pending or transmission is not requested 1: From acceptance of transmission request to completion of transmission, or error/arbitration-lost	R
	INVALDATA	Reception-in-Progress Status Flag	(Receive mailbox setting enabled) 0: Message valid 1: Message being updated	R
b2	TRMABT	Transmission Abort Complete Flag*1,*2	(Transmit mailbox setting enabled) 0: Transmission has started, transmission abort failed because transmission is completed, or transmission abort is not requested 1: Transmission abort is completed	R/W
	MSGLOST	Message Lost Flag*1,*2	(Receive mailbox setting enabled) 0: Message is not overwritten or overrun 1: Message is overwritten or overrun	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	ONESHOT	One-Shot Enable*3	0: One-shot reception or one-shot transmission disabled 1: One-shot reception or one-shot transmission enabled	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	RECREQ	Receive Mailbox Request *2,*3,*4,*5	0: Not configured for reception 1: Configured for reception	R/W
b7	TRMREQ	Transmit Mailbox Request *2,*4	0: Not configured for transmission 1: Configured for transmission	R/W

Note 1. Write 0 only. Writing 1 has no effect.
Note 2. When writing 0 to bits NEWDATA, SENTDATA, MSGLOST, TRMABT, RECREQ, and TRMREQ by a program, do not use the logic operation instruction (AND). Write 0 to only the specified bit and write 1 to the other bits before using the transfer (MOV) instruction.
Note 3. To enter one-shot receive mode, write 1 to the ONESHOT bit at the same time as setting the RECREQ bit to 1.
To exit one-shot receive mode, write 0 to the ONESHOT bit after writing 0 to the RECREQ bit and confirming that it has been set to 0.
To enter one-shot transmit mode, write 1 to the ONESHOT bit at the same time as setting the TRMREQ bit to 1.
To exit one-shot transmit mode, write 0 to the ONESHOT bit after the message has been transmitted or aborted.
Note 4. Do not set both the RECREQ and TRMREQ bits to 1.
Note 5. When setting the RECREQ bit to 0, set bits MSGLOST, NEWDATA, and RECREQ to 0 simultaneously.

Write to the MCTLj in CAN operation mode or CAN halt mode.
Do not use MCTL24 to MCTL31 in FIFO mailbox mode.

SENTDATA Flag (Transmission Complete Flag)

The SENTDATA flag is set to 1 when data transmission from the corresponding mailbox is completed. The SENTDATA flag is set to 0 by writing 0 by a program.
To set the SENTDATA flag to 0, first set the TRMREQ bit to 0. Bits SENTDATA and TRMREQ cannot be set to 0 simultaneously. To transmit a new message from the corresponding mailbox, set the SENTDATA flag to 0.

NEWDATA Flag (Reception Complete Flag)

The NEWDATA flag is set to 1 when a new message is being stored or has been stored to the mailbox. The timing for setting this bit to 1 is simultaneous with the INVALDATA flag. The NEWDATA flag is set to 0 by writing 0 by a program. The NEWDATA flag cannot be set to 0 by writing 0 by a program while the related INVALDATA flag is 1.

TRMACTIVE Flag (Transmission-in-Progress Status Flag)

The TRMACTIVE flag is set to 1 when the corresponding mailbox of the CAN module begins transmitting a message. The TRMACTIVE flag is set to 0 when the CAN module has lost CAN bus arbitration, a CAN bus error occurs, or data transmission is completed.

INVALDATA Flag (Reception-in-Progress Status Flag)

After the completion of a message reception, the INVALDATA flag is set to 1 while the received message is being updated into the corresponding mailbox. The INVALDATA flag is set to 0 immediately after the message has been stored. If the mailbox is read while the INVALDATA flag is 1, the data is undefined.

TRMABT Flag (Transmission Abort Complete Flag)

The TRMABT flag is set to 1 in the following cases:

- Following a transmission abort request, when the transmission abort is completed before starting transmission.
- Following a transmission abort request, when the CAN module detects CAN bus arbitration-lost or a CAN bus error.
- In one-shot transmission mode (RECREQ bit = 0, TRMREQ bit = 1, and ONESHOT bit = 1), when the CAN module detects CAN bus arbitration-lost or a CAN bus error.

The TRMABT flag is not set to 1 when data transmission is completed. In this case, the SENTDATA flag is set to 1. The TRMABT flag is set to 0 by writing 0 by a program.

MSGLOST Flag (Message Lost Flag)

The MSGLOST flag is set to 1 when the mailbox is overwritten or overrun by a new received message while the NEWDATA flag is 1. The MSGLOST flag is set to 1 at the end of the 6th bit of EOF. The MSGLOST flag is set to 0 by writing 0 by a program.
In both overwrite and overrun modes, the MSGLOST flag cannot be set to 0 by writing 0 by a program during five peripheral module clock (PCLKB) cycles following the sixth bit of EOF.

ONESHOT Bit (One-Shot Enable)

The ONESHOT bit can be used in the following two ways, receive mode and transmit mode.

- One-shot receive mode
  When the ONESHOT bit is set to 1 in receive mode (RECREQ bit = 1 and TRMREQ bit = 0), the mailbox receives a message only one time. (The mailbox does not behave as a receive mailbox after having received a message one time.) The behavior of flags NEWDATA and INVALDATA is the same as in normal receive mode. In one-shot receive mode, the MSGLOST flag is not set to 1. To set the ONESHOT bit to 0, first write 0 to the RECREQ bit and ensure that it has been set to 0.
- One-shot transmit mode
  When the ONESHOT bit is set to 1 in transmit mode (RECREQ bit = 0 and TRMREQ bit = 1), the CAN module transmits a message only one time. (The CAN module does not transmit the message again if a CAN bus error or CAN bus arbitration-lost occurs.) When transmission is completed, the SENTDATA flag is set to 1. If transmission is not completed due to a CAN bus error or CAN bus arbitration-lost, the TRMABT flag is set to 1. Set the ONESHOT bit to 0 after the SENTDATA or TRMABT flag is set to 1.

RECREQ Bit (Receive Mailbox Request)

The RECREQ bit selects receive modes listed in Table 43.10.
When the RECREQ bit is set to 1, the corresponding mailbox is configured for reception of a data frame or a remote frame.
When the RECREQ bit is set to 0, the corresponding mailbox is not configured for reception of a data frame or a remote frame.
Due to hardware protection, the RECREQ bit cannot be set to 0 by writing 0 by a program during the following period.

- Hardware protection is started
  From the acceptance filter processing (the beginning of CRC field)

- Hardware protection is released
  – For the mailbox that is specified to receive the incoming message, after the received data is stored into the mailbox or a CAN bus error occurs (i.e. maximum period of hardware protection is from the beginning of CRC field to the end of the 7th bit of EOF)
  – For the other mailboxes, after the acceptance filter processing
  – If no mailbox is specified to receive the message, after the acceptance filter processing
  When setting the RECREQ bit to 1, do not set the TRMREQ bit to 1. To change the configuration of a mailbox from transmission to reception, first abort the transmission and then set flags SENTDATA and TRMABT to 0 before changing to reception.

TRMREQ Bit (Transmit Mailbox Request)

The TRMREQ bit selects transmit modes listed in Table 43.10.
When the TRMREQ bit is set to 1, the corresponding mailbox is configured for transmission of a data frame or a remote frame.
When the TRMREQ bit is set to 0, the corresponding mailbox is not configured for transmission of a data frame or a remote frame.
If the TRMREQ bit is changed from 1 to 0 to cancel the corresponding transmission request, either the TRMABT or SENTDATA flag is set to 1. When setting the TRMREQ bit to 1, do not set the RECREQ bit to 1. To change the configuration of a mailbox from reception to transmission, first abort the reception and then set flags NEWDATA and MSGLOST to 0 before changing to transmission.

43.2.9 Receive FIFO Control Register (RFCR)

Address(es): CAN0.RFCR 0009 0848h, CAN1.RFCR 0009 1848h, CAN2.RFCR 0009 2848h

	b7	b6	b5	b4	b3	b2	b1	b0
	RFEST	RFWST	RFFST	RFMLF	RFUST[2:0]			RFE
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFE	Receive FIFO Enable	0: Receive FIFO disabled 1: Receive FIFO enabled	R/W
b3 to b1	RFUST[2:0]	Receive FIFO Unread Message Number Status Flag	b3 b1 0 0 0: No unread message 0 0 1: 1 unread message 0 1 0: 2 unread messages 0 1 1: 3 unread messages 1 0 0: 4 unread messages 1 0 1: Reserved 1 1 0: Reserved 1 1 1: Reserved	R
b4	RFMLF	Receive FIFO Message Lost Flag	0: No receive FIFO message lost has occurred 1: Receive FIFO message lost has occurred	R/W
b5	RFFST	Receive FIFO Full Status Flag	0: Receive FIFO is not full 1: Receive FIFO is full (4 unread messages)	R
b6	RFWST	Receive FIFO Buffer Warning Status Flag	0: Receive FIFO is not buffer warning 1: Receive FIFO is buffer warning (3 unread messages)	R
b7	RFEST	Receive FIFO Empty Status Flag	0: Unread message in receive FIFO 1: No unread message in receive FIFO	R

Write to RFCR in CAN operation mode or CAN halt mode.

RFE Bit (Receive FIFO Enable)

When the RFE bit is set to 1, the receive FIFO is enabled.

When the RFE bit is set to 0, the receive FIFO is disabled for reception and becomes empty (RFEST flag = 1). Write 0 to the RFE bit simultaneously with setting the RFMLF flag.

Do not set this bit to 1 in normal mailbox mode (MBM bit in CTLR = 0). Due to hardware protection, the RFE bit is not set to 0 by writing 0 by a program during the following period.

- Hardware protection is started
  - From the acceptance filter processing (the beginning of CRC field)
- Hardware protection is released
  - If the receive FIFO is specified to receive the incoming message, after the received data is stored into the receive FIFO or a CAN bus error occurs (i.e. maximum period of hardware protection is from the beginning of CRC field to the end of 7th bit of EOF)
  - If the receive FIFO is not specified to receive the message, after the acceptance filter processing

RFUST[2:0] Flags (Receive FIFO Unread Message Number Status Flag)

The RFUST[2:0] flags indicate the number of unread messages in the receive FIFO.

The value of the RFUST[2:0] flags is initialized to 000b when the RFE bit is set to 0.

RFMLF Flag (Receive FIFO Message Lost Flag)

The RFMLF flag is set to 1 (receive FIFO message lost has occurred) when the receive FIFO receives a new message and the receive FIFO is full. The timing for setting this bit to 1 is at the end of the 6th bit of EOF.
The RFMLF flag is set to 0 by writing 0 by a program (writing 1 has no effect). In both overwrite and overrun modes, the RFMLF flag cannot be set to 0 (receive FIFO message lost has not occurred) by writing 0 by a program due to hardware protection during five peripheral module clock (PCLKB) cycles following the sixth bit of EOF, if the receive FIFO is full and determined to receive a message.

RFFST Flag (Receive FIFO Full Status Flag)

The RFFST flag is set to 1 (receive FIFO is full) when the number of unread messages in the receive FIFO is 4. The RFFST flag is 0 (receive FIFO is not full) when the number of unread messages in the receive FIFO is less than 4. The RFFST flag is set to 0 when the RFE bit is 0.

RFWST Flag (Receive FIFO Buffer Warning Status Flag)

The RFWST flag is set to 1 (receive FIFO is buffer warning) when the number of unread messages in the receive FIFO is 3. The RFWST flag is 0 (receive FIFO is not buffer warning) when the number of unread messages in the receive FIFO is less than 3 or equal to 4. The RFWST flag is set to 0 when the RFE bit is 0.

RFEST Flag (Receive FIFO Empty Status Flag)

The RFEST flag is set to 1 (no unread message in receive FIFO) when the number of unread messages in the receive FIFO is 0. The RFEST flag is set to 1 when the RFE bit is set to 0. The RFEST flag is set to 0 (unread message in receive FIFO) when the number of unread messages in the receive FIFO is one or more.

Figure 43.2 shows the receive FIFO mailbox operation.

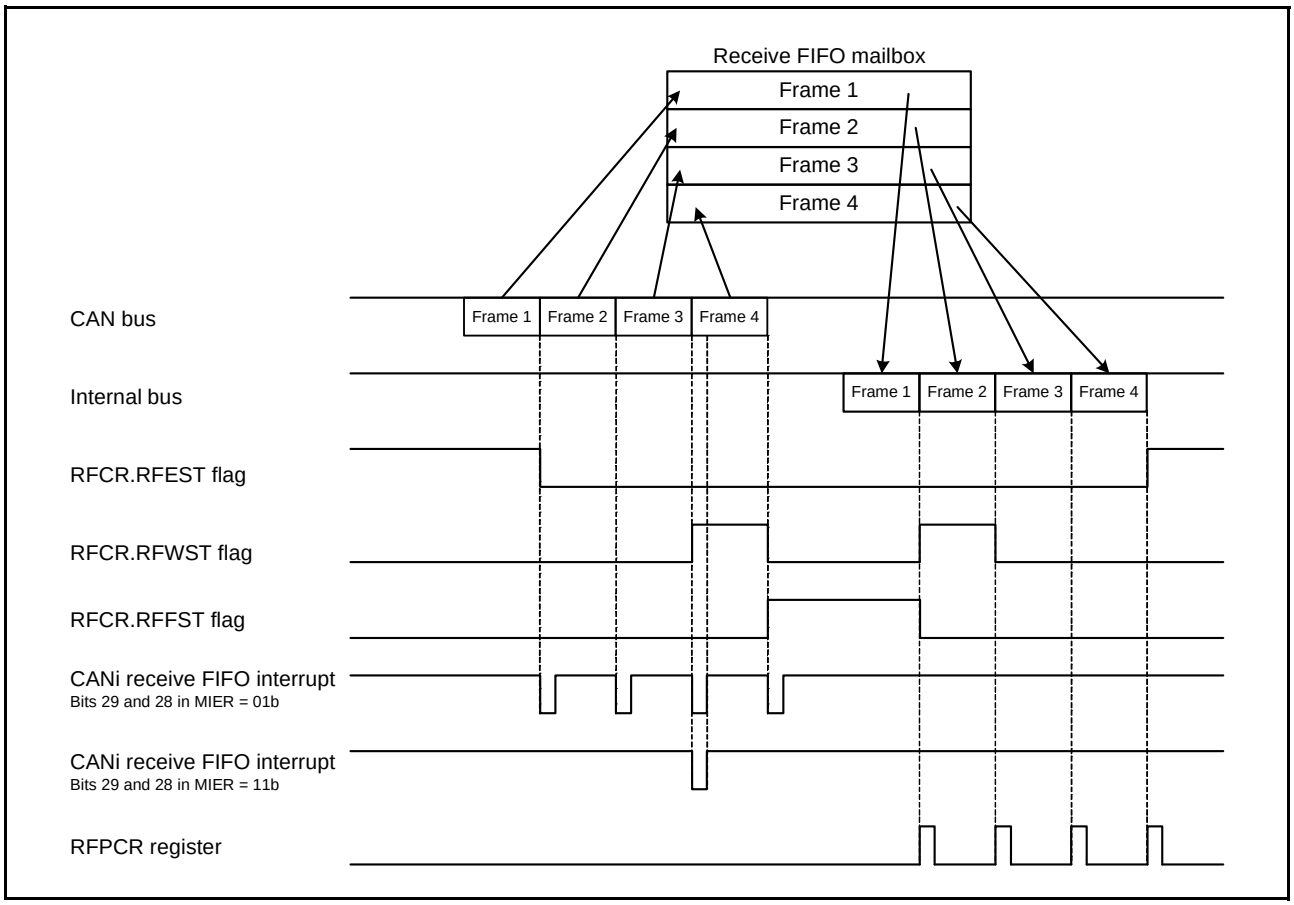


Figure 43.2 Receive FIFO Mailbox Operation (Bits 29 and 28 in MIER = 01b or 11b)

43.2.10 Receive FIFO Pointer Control Register (RFPCR)

Address(es): CAN0.RFPCR 0009 0849h, CAN1.RFPCR 0009 1849h, CAN2.RFPCR 0009 2849h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

Bit	Description	R/W
b7 to b0	The CPU-side pointer for the receive FIFO is incremented by writing FFh to RFPCR.	W

When the receive FIFO is not empty, write FFh to RFPCR by a program to increment the CPU-side pointer for the receive FIFO to the next mailbox location.
Do not write to RFPCR when the RFE bit in RFCR is 0 (receive FIFO disabled).
Both the CAN-side pointer and the CPU-side pointer are incremented when a new message is received and the RFFST flag is 1 (receive FIFO is full) in overwrite mode. When the RFMLF flag is 1 in this condition, the CPU-side pointer cannot be incremented by writing to RFPCR by a program.

43.2.11 Transmit FIFO Control Register (TFCR)

Address(es): CAN0.TFCR 0009 084Ah, CAN1.TFCR 0009 184Ah, CAN2.TFCR 0009 284Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	TFEST	TFFST	—	—	TFUST[2:0]			TFE
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TFE	Transmit FIFO Enable	0: Transmit FIFO disabled 1: Transmit FIFO enabled	R/W
b3 to b1	TFUST[2:0]	Transmit FIFO Unsent Message Number Status Flag	b3 b2 b1 0 0 0: No unsent message 0 0 1: 1 unsent message 0 1 0: 2 unsent messages 0 1 1: 3 unsent messages 1 0 0: 4 unsent messages 1 0 1: Reserved 1 1 0: Reserved 1 1 1: Reserved	R
b5, b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	TFFST	Transmit FIFO Full Status Flag	0: Transmit FIFO is not full 1: Transmit FIFO is full (4 unsent messages)	R
b7	TFEST	Transmit FIFO Empty Status Flag	0: Unsent message in transmit FIFO 1: No unsent message in transmit FIFO	R

Write to TFCR in CAN operation mode or CAN halt mode.

TFE Bit (Transmit FIFO Enable)

When the TFE bit is set to 1, the transmit FIFO is enabled.
When the TFE bit is set to 0, the transmit FIFO becomes empty (TFEST flag = 1) and then unsent messages from the transmit FIFO are lost as described below:

- Immediately if a message from the transmit FIFO is not scheduled for the next transmission or during transmission
- Following the completion of transmission, a CAN bus error, CAN bus arbitration-lost, or entry to CAN halt mode if a message from the transmit FIFO is scheduled for the next transmission or already during transmission

Before setting the TFE bit to 1 again, ensure that the TFEST flag has been set to 1. After setting the TFE bit to 1, write transmit data into MB24.
Do not set the TFE bit to 1 in normal mailbox mode (MBM bit in CTLR = 0).

TFUST[2:0] Flags (Transmit FIFO Unsent Message Number Status Flag)

The TFUST[2:0] flags indicate the number of unsent messages in the transmit FIFO.
The TFUST[2:0] flags are set to 000b after TFE bit is cleared to 0 and transmission is aborted or completed.

TFFST Flag (Transmit FIFO Full Status Flag)

The TFFST flag is set to 1 (transmit FIFO is full) when the number of unsent messages in the transmit FIFO is 4. The TFFST flag is set to 0 (transmit FIFO is not full) when the number of unsent messages in the transmit FIFO is less than 4. The TFFST flag is set to 0 when transmission from the transmit FIFO has been aborted.

TFEST Flag (Transmit FIFO Empty Status Flag)

The TFEST flag is set to 1 (no message in transmit FIFO) when the number of unsent messages in the transmit FIFO is 0. The TFEST flag is set to 1 when transmission from the transmit FIFO has been aborted. The TFEST flag is set to 0 (message in transmit FIFO) when the number of unsent messages in the transmit FIFO is not 0.

Figure 43.3 shows the transmit FIFO mailbox operation.

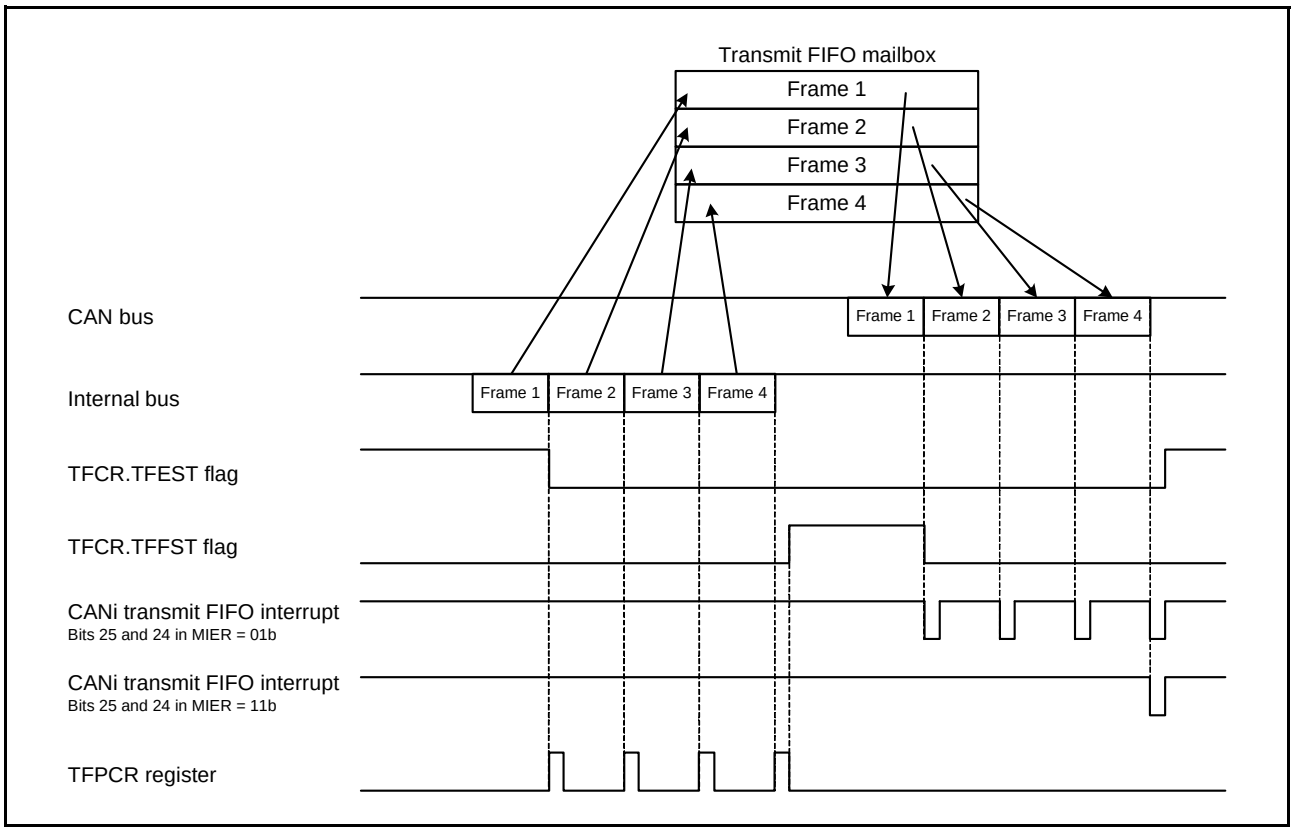

Figure 43.3 Transmit FIFO Mailbox Operation (Bits 25 and 24 in MIER = 01b or 11b)

43.2.12 Transmit FIFO Pointer Control Register (TFPCR)

Address(es): CAN0.TFPCR 0009 084Bh, CAN1.TFPCR 0009 184Bh, CAN2.TFPCR 0009 284Bh

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

Bit	Description	R/W
b7 to b0	The CPU-side pointer for the transmit FIFO is incremented by writing FFh to TFPCR.	W

When the transmit FIFO is not full, write FFh to TFPCR by a program to increment the CPU-side pointer for the transmit FIFO to the next mailbox location.
Do not write to TFPCR when the TFE bit in TFCR is 0 (transmit FIFO disabled).

43.2.13 Status Register (STR)

Address(es): CAN0.STR 0009 0842h, CAN1.STR 0009 1842h, CAN2.STR 0009 2842h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	RECST	TRMST	BOST	EPST	SLPST	HLTST	RSTST	EST	TABST	FMLST	NMLST	TFST	RFST	SDST	NDST
Value after reset:	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	NDST	NEWDATA Status Flag	0: No mailbox with NEWDATA flag = 1 1: Mailbox(es) with NEWDATA flag = 1	R
b1	SDST	SENTDATA Status Flag	0: No mailbox with SENTDATA flag = 1 1: Mailbox(es) with SENTDATA flag = 1	R
b2	RFST	Receive FIFO Status Flag	0: No message in receive FIFO (empty) 1: Message in receive FIFO	R
b3	TFST	Transmit FIFO Status Flag	0: Transmit FIFO is full 1: Transmit FIFO is not full	R
b4	NMLST	Normal Mailbox Message Lost Status Flag	0: No mailbox with MSGLOST flag = 1 1: Mailbox(es) with MSGLOST flag = 1	R
b5	FMLST	FIFO Mailbox Message Lost Status Flag	0: RFMLF flag = 0 1: RFMLF flag = 1	R
b6	TABST	Transmission Abort Status Flag	0: No mailbox with TRMABT flag = 1 1: Mailbox(es) with TRMABT flag = 1	R

b8	RSTST	CAN Reset Status Flag	0: Not in CAN reset mode 1: In CAN reset mode	R
b9	HLTST	CAN Halt Status Flag	0: Not in CAN halt mode 1: In CAN halt mode	R
b10	SLPST	CAN Sleep Status Flag	0: Not in CAN sleep mode 1: In CAN sleep mode	R
b11	EPST	Error-Passive Status Flag	0: Not in error-passive state 1: In error-passive state	R
b12	BOST	Bus-Off Status Flag	0: Not in bus-off state 1: In bus-off state	R
b13	TRMST	Transmit Status Flag (transmitter)	0: Bus idle or reception in progress 1: Transmission in progress or in bus-off state	R
b14	RECST	Receive Status Flag (receiver)	0: Bus idle or transmission in progress 1: Reception in progress	R
b15	—	Reserved	The read value is 0.	R

NDST Flag (NEWDATA Status Flag)

The NDST flag is set to 1 when at least one NEWDATA flag in MCTLj (j = 0 to 31) is 1 regardless of the value of MIER. The NDST flag is set to 0 when all NEWDATA flags are 0.

SDST Flag (SENTDATA Status Flag)

The SDST flag is set to 1 when at least one SENTDATA flag in MCTLj (j = 0 to 31) is 1 regardless of the value of MIER. The SDST flag is set to 0 when all SENTDATA flags are 0.

RFST Flag (Receive FIFO Status Flag)

The RFST flag is set to 1 when the receive FIFO is not empty. The RFST flag is set to 0 when the receive FIFO is empty or normal mailbox mode is selected.

TFST Flag (Transmit FIFO Status Flag)

The TFST flag is set to 1 when the transmit FIFO is not full. The TFST flag is set to 0 when the transmit FIFO is full or normal mailbox mode is selected.

NMLST Flag (Normal Mailbox Message Lost Status Flag)

The NMLST flag is set to 1 when at least one MSGLOST flag in MCTLj (j = 0 to 31) is 1 regardless of the value of MIER. The NMLST flag is set to 0 when all MSGLOST flags are 0.

FMLST Flag (FIFO Mailbox Message Lost Status Flag)

The FMLST flag is set to 1 when the RFMLF flag in RFCR is 1 regardless of the value of MIER. The FMLST flag is set to 0 when the RFMLF flag is 0.

TABST Flag (Transmission Abort Status Flag)

The TABST flag is set to 1 when at least one TRMABT flag in MCTLj (j = 0 to 31) is 1 regardless of the value of MIER. The TABST flag is set to 0 when all TRMABT flags are 0.

EST Flag (Error Status Flag)

The EST flag is set to 1 when at least one error is detected by EIFR regardless of the value of EIER. The EST flag is set to 0 when no error is detected by EIFR.

RSTST Flag (CAN Reset Status Flag)

The RSTST flag is set to 1 when the CAN module is in CAN reset mode. The RSTST flag is 0 when the CAN module is not in CAN reset mode. Even when the state is changed from CAN reset mode to CAN sleep mode, the RSTST flag remains 1.

HLTST Flag (CAN Halt Status Flag)

The HLTST flag is set to 1 when the CAN module is in CAN halt mode. The HLTST flag is set to 0 when the CAN module is not in CAN halt mode. Even when the state is changed from CAN halt mode to CAN sleep mode, the HLTST flag remains 1.

SLPST Flag (CAN Sleep Status Flag)

The SLPST flag is set to 1 when the CAN module is in CAN sleep mode. The SLPST flag is set to 0 when the CAN module is not in CAN sleep mode.

EPST Flag (Error-Passive Status Flag)

The EPST flag is set to 1 when the value of TECR or RECR exceeds 127 and the CAN module is in the error-passive state ($128 \leq TEC < 256$ or $128 \leq REC < 256$). The EPST flag is set to 0 when the CAN module is not in the error-passive state.

BOST Flag (Bus-Off Status Flag)

The BOST flag is set to 1 when the value of TECR exceeds 255 and the CAN module is in the bus-off state ($TEC \geq 256$). The BOST flag is set to 0 when the CAN module is not in the bus-off state.

TRMST Flag (Transmit Status Flag (transmitter))

The TRMST flag is set to 1 when the CAN module performs as a transmitter node or is in the bus-off state. The TRMST flag is set to 0 when the CAN module performs as a receiver node or is in the bus-idle state.

RECST Flag (Receive Status Flag (receiver))

The RECST flag is set to 1 when the CAN module performs as a receiver node. The RECST flag is set to 0 when the CAN module performs as a transmitter node or is in the bus-idle state.

43.2.14 Mailbox Search Mode Register (MSMR)

Address(es): CAN0.MSMR 0009 0853h, CAN1.MSMR 0009 1853h, CAN2.MSMR 0009 2853h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	MBSM[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	MBSM[1:0]	Mailbox Search Mode Select	b1 b0 0 0: Receive mailbox search mode 0 1: Transmit mailbox search mode 1 0: Message lost search mode 1 1: Channel search mode	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Write to MSMR in CAN operation mode or CAN halt mode.

MBSM[1:0] Bits (Mailbox Search Mode Select)

The MBSM[1:0] bits select the search mode for the mailbox search function.

When the MBSM[1:0] bits are 00b, receive mailbox search mode is selected. In this mode, the search targets are the NEWDATA flag in MCTLj (j = 0 to 31) for the normal mailbox and the RFEST flag in RFCR.

When the MBSM[1:0] bits are 01b, transmit mailbox search mode is selected. In this mode, the search target is the SENTDATA flag in MCTLj.

When the MBSM[1:0] bits are 10b, message lost search mode is selected. In this mode, the search targets are the MSGLOST flag in MCTLj for the normal mailbox and the RFMLF flag in RFCR.

When the MBSM[1:0] bits are 11b, channel search mode is selected. In this mode, the search target is CSSR. Refer to section 43.2.16, Channel Search Support Register (CSSR).

43.2.15 Mailbox Search Status Register (MSSR)

Address(es): CAN0.MSSR 0009 0852h, CAN1.MSSR 0009 1852h, CAN2.MSSR 0009 2852h

	b7	b6	b5	b4	b3	b2	b1	b0
	SEST	—	—	MBNST[4:0]				
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	MBNST[4:0]	Search Result Mailbox Number Status Flag	These bits output the smallest mailbox number that is searched in each mode of MSMR.	R
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	SEST	Search Result Status Flag	0: Search result found 1: No search result	R

MBNST[4:0] Flags (Search Result Mailbox Number Status Flag)

The MBNST[4:0] flags output the smallest mailbox number that is searched in each mode of MSMR. In receive mailbox search mode, transmit mailbox search mode, and message lost search mode, the value of the mailbox i.e., the search result to be output, is updated as described below:

- When the NEWDATA, SENTDATA or MSGLOST flag for the output mailbox is set to 0
- When the NEWDATA, SENTDATA or MSGLOST flag for a higher-priority mailbox is set to 1

If the MBSM[1:0] bits are set to 00b (receive mailbox search mode) or 10b (message lost search mode), the receive FIFO (mailbox [28]) is output when the receive FIFO is not empty and there are no unread received messages or no lost messages in any of the normal mailboxes (mailboxes [0] to [23]). If the MBSM[1:0] bits are set to 01b (transmit mailbox search mode), the transmit FIFO (mailbox [24]) is not output. Table 43.6 lists the behavior of the MBNST[4:0] flags in FIFO mailbox mode.

In channel search mode, the MBNST[4:0] flags output the corresponding channel number. After MSSR is read by a program, the next target channel number is output.

SEST Flag (Search Result Status Flag)

The SEST flag is set to 1 (no search result) when no corresponding mailbox is found after searching all mailboxes. For example, in transmit mailbox search mode, the SEST flag is set to 1 when no SENTDATA flag for mailboxes is 1. The SEST flag is set to 0 when at least one SENTDATA flag is 1. When the SEST flag is 1, the value of the MBNST[4:0] flags is undefined.

Table 43.6 Behavior of MBNST[4:0] Flags in FIFO Mailbox Mode

MBSM[1:0] Bits	Mailbox [24] (Transmit FIFO)	Mailbox [28] (Receive FIFO)
00b	Mailbox [24] is not output.	Mailbox [28] is output when no MCTLj.NEWDATA flag for the normal mailboxes is set to 1 (new message is being stored or has been stored to the mailbox) and the receive FIFO is not empty.
01b		Mailbox [28] is not output.
10b		Mailbox [28] is output when no MCTLj.MSGLOST flag for the normal mailboxes is set to 1 (message is overwritten or overrun) and the RFCR.RFMLF bit is set to 1 (receive FIFO message lost has occurred) in the receive FIFO.
11b		Mailbox [28] is not output.

43.2.16 Channel Search Support Register (CSSR)

Address(es): CAN0.CSSR 0009 0851h, CAN1.CSSR 0009 1851h, CAN2.CSSR 0009 2851h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

Bit	Description	R/W
b7 to b0	When the value for the channel search is input, the channel number is output to MSSR.	R/W

The bits in CSSR, which are set to 1, are encoded by an 8/3 encoder (the LSB position has the higher priority) and output to the MBNST[4:0] flags in MSSR.
MSSR outputs the updated value whenever MSSR is read by a program.
Write to CSSR only when the MSMR.MBSM[1:0] bits are 11b (channel search mode). Write to CSSR in CAN operation mode or CAN halt mode.

Figure 43.4 shows the write and read of CSSR and MSSR.

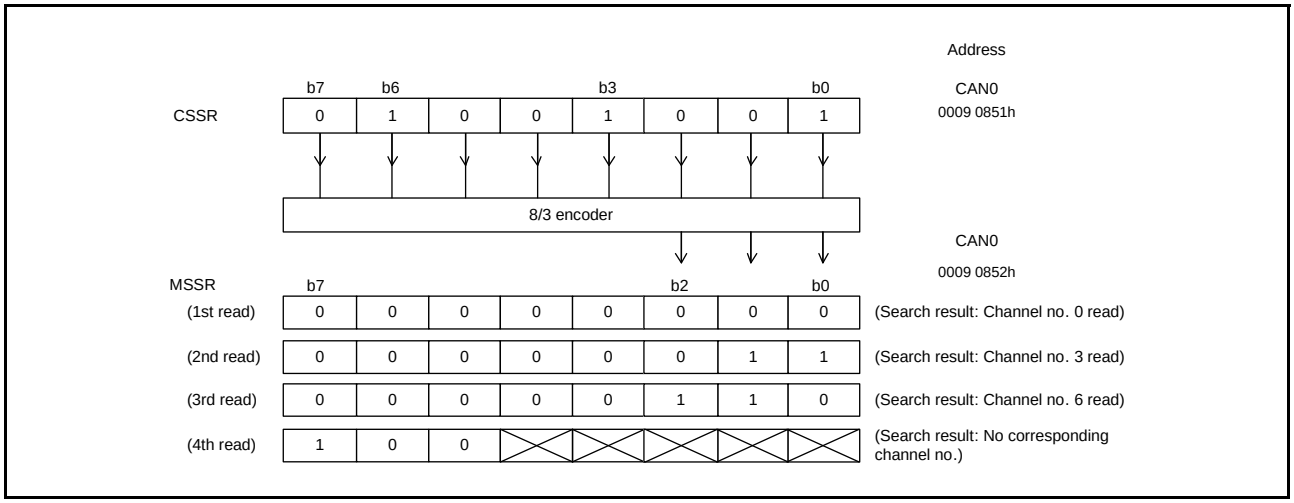

Figure 43.4 Write and Read of CSSR and MSSR

The value of CSSR is also updated whenever MSSR is read. When read, the value prior to conversion by the 8/3 encoder can be read.

43.2.17 Acceptance Filter Support Register (AFSR)

Address(es): CAN0.AFSR 0009 0856h, CAN1.AFSR 0009 1856h, CAN2.AFSR 0009 2856h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Description	R/W
b15 to b0	After the standard ID of a received message is written, the value converted for data table search can be read.	R/W

Note: Write to AFSR in CAN operation mode or CAN halt mode.

The acceptance filter support unit (ASU) can be used for data table (8 bits × 256) search. In the data table, all standard IDs created by the user are set to be valid/invalid in bit units. When AFSR is written with data in 16-bit units including the SID[10:0] bit in MBj (j = 0 to 31), in which a received standard ID is stored, a decoded row (byte offset) position and column (bit) position for data table search can be read. The ASU can be used for standard (11-bit) IDs only.
The ASU is enabled in the following cases:

- When the ID to receive cannot be masked by the acceptance filter
  (Example) IDs to receive: 078h, 087h, and 111h
- When there are too many IDs to receive and software filtering time is expected to be shortened
  It should be noted that AFSR cannot be set in CAN reset mode.

Figure 43.5 shows the write and read of AFSR.

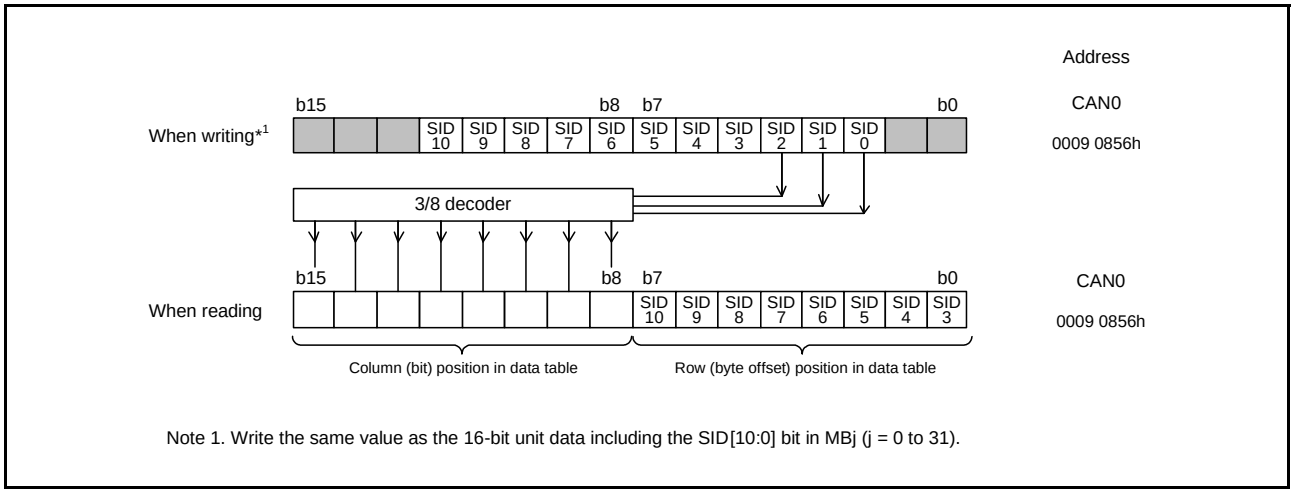

Figure 43.5 Write and Read of AFSR

43.2.18 Error Interrupt Enable Register (EIER)

Address(es): CAN0.EIER 0009 084Ch, CAN1.EIER 0009 184Ch, CAN2.EIER 0009 284Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	BLIE	OLIE	ORIE	BORIE	BOEIE	EPIE	EWIE	BEIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BEIE	Bus Error Interrupt Enable	0: Bus error interrupt disabled 1: Bus error interrupt enabled	R/W
b1	EWIE	Error-Warning Interrupt Enable	0: Error-warning interrupt disabled 1: Error-warning interrupt enabled	R/W
b2	EPIE	Error-Passive Interrupt Enable	0: Error-passive interrupt disabled 1: Error-passive interrupt enabled	R/W
b3	BOEIE	Bus-Off Entry Interrupt Enable	0: Bus-off entry interrupt disabled 1: Bus-off entry interrupt enabled	R/W
b4	BORIE	Bus-Off Recovery Interrupt Enable	0: Bus-off recovery interrupt disabled 1: Bus-off recovery interrupt enabled	R/W
b5	ORIE	Overrun Interrupt Enable	0: Receive overrun interrupt disabled 1: Receive overrun interrupt enabled	R/W
b6	OLIE	Overload Frame Transmit Interrupt Enable	0: Overload frame transmit interrupt disabled 1: Overload frame transmit interrupt enabled	R/W
b7	BLIE	Bus Lock Interrupt Enable	0: Bus lock interrupt disabled 1: Bus lock interrupt enabled	R/W

EIER is used to enable or disable the error interrupt individually for each error interrupt source in EIFR.
Write to EIER in CAN reset mode.

BEIE Bit (Bus Error Interrupt Enable)

When the BEIE bit is 0, no error interrupt request is generated even if the BEIF flag in EIFR is set to 1. When the BEIE bit is 1, an error interrupt request is generated if the BEIF flag is set to 1.

EWIE Bit (Error-Warning Interrupt Enable)

When the EWIE bit is 0, no error interrupt request is generated even if the EWIF flag in EIFR is set to 1. When the EWIE bit is 1, an error interrupt request is generated if the EWIF flag is set to 1.

EPIE Bit (Error-Passive Interrupt Enable)

When the EPIE bit is 0, no error interrupt request is generated even if the EPIF flag in EIFR is set to 1. When the EPIE bit is 1, an error interrupt request is generated if the EPIF flag is set to 1.

BOEIE Bit (Bus-Off Entry Interrupt Enable)

When the BOEIE bit is 0, no error interrupt request is generated even if the BOEIF flag in EIFR is set to 1. When the BOEIE bit is 1, an error interrupt request is generated if the BOEIF flag is set to 1.

BORIE Bit (Bus-Off Recovery Interrupt Enable)

When the BORIE bit is 0, an error interrupt request is not generated even if the BORIF flag in EIFR is set to 1. When the BORIE bit is set to 1, an error interrupt request is generated if the BORIF flag is set to 1.

ORIE Bit (Overrun Interrupt Enable)

When the ORIE bit is 0, an error interrupt request is not generated even if the ORIF flag in EIFR is set to 1. When the ORIE bit is 1, an error interrupt request is generated if the ORIF flag is set to 1.

OLIE Bit (Overload Frame Transmit Interrupt Enable)

When the OLIE bit is 0, no error interrupt request is generated even if the OLIF flag in EIFR is set to 1. When the OLIE bit is 1, an error interrupt request is generated if the OLIF flag is set to 1.

BLIE Bit (Bus Lock Interrupt Enable)

When the BLIE bit is 0, no error interrupt request is generated even if the BLIF flag in EIFR is set to 1. When the BLIE bit is 1, an error interrupt request is generated if the BLIF flag is set to 1.

43.2.19 Error Interrupt Factor Judge Register (EIFR)

Address(es): CAN0.EIFR 0009 084Dh, CAN1.EIFR 0009 184Dh, CAN2.EIFR 0009 284Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	BLIF	OLIF	ORIF	BORIF	BOEIF	EPIF	EWIF	BEIF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BEIF	Bus Error Detect Flag	0: No bus error detected 1: Bus error detected	R/W
b1	EWIF	Error-Warning Detect Flag	0: No error-warning detected 1: Error-warning detected	R/W
b2	EPIF	Error-Passive Detect Flag	0: No error-passive detected 1: Error-passive detected	R/W
b3	BOEIF	Bus-Off Entry Detect Flag	0: No bus-off entry detected 1: Bus-off entry detected	R/W
b4	BORIF	Bus-Off Recovery Detect Flag	0: No bus-off recovery detected 1: Bus-off recovery detected	R/W
b5	ORIF	Receive Overrun Detect Flag	0: No receive overrun detected 1: Receive overrun detected	R/W
b6	OLIF	Overload Frame Transmission Detect Flag	0: No overload frame transmission detected 1: Overload frame transmission detected	R/W
b7	BLIF	Bus Lock Detect Flag	0: No bus lock detected 1: Bus lock detected	R/W

If an event corresponding to each bit occurs, the corresponding bit in EIFR is set to 1 regardless of the setting of EIER. To set each bit to 0, write 0 by a program. If the set timing occurs simultaneously with the clear timing by the program, the bit becomes 1.

When a single bit is set to 0 by a program, do not use the logic operation instruction (AND) – use the transfer instruction (MOV) to ensure that only the specified bit is set to 0 and the other bits are set to 1. Writing 1 has no effect to these bit values.

BEIF Flag (Bus Error Detect Flag)

The BEIF flag is set to 1 when a bus error is detected.

EWIF Flag (Error-Warning Detect Flag)

The EWIF flag is set to 1 when the value of the receive error counter (REC) or transmit error counter (TEC) exceeds 95. The EWIF flag is set to 1 only when the REC or TEC initially exceeds 95. Thus, if 0 is written to the EWIF flag by a program while the REC or TEC remains greater than 95, the EWIF flag is not set to 1 until the REC and TEC go below 95 and then REC or TEC exceeds 95 again.

EPIF Flag (Error-Passive Detect Flag)

The EPIF flag is set to 1 when the CAN error state becomes error-passive (the REC (receive error counter) or TEC (transmit error counter) value exceeds 127).
The EPIF flag is set to 1 only when the REC or TEC initially exceeds 127. Thus, if 0 is written by a program while the REC or TEC remains greater than 127, the EPIF flag is not set to 1 until the REC and TEC go below 127 and then REC or TEC exceeds 127 again.

BOEIF Flag (Bus-Off Entry Detect Flag)

The BOEIF flag is set to 1 when the CAN error state becomes bus-off (the TEC (transmit error counter) value exceeds 255). The BOEIF flag is also set to 1 when the BOM[1:0] bits in CTLR are 01b (entry to CAN halt mode automatically at bus-off entry) and the CAN module becomes the bus-off state.

BORIF Flag (Bus-Off Recovery Detect Flag)

The BORIF flag is set to 1 when the CAN module recovers from the bus-off state normally by detecting 11 consecutive bits 128 times in the following conditions:

- When the BOM[1:0] bits in CTLR are 00b
- When the BOM[1:0] bits in CTLR are 10b
- When the BOM[1:0] bits in CTLR are 11b

However, the BORIF flag is not set to 1 if the CAN module recovers from the bus-off state in the following conditions:

- When the CANM[1:0] bits in CTLR are set to 01b or 11b (CAN reset mode)
- When the RBOC bit in CTLR is set to 1 (forcible return from bus-off)
- When the BOM[1:0] bits in CTLR are set to 01b
- When the BOM[1:0] bits in CTLR are set to 11b and the CANM[1:0] bits in CTLR are set to 10b (CAN halt mode) before normal recovery occurs

Table 43.7 lists the behavior of BOEIF and BORIF flags according to the CTLR.BOM[1:0] bit setting.

Table 43.7 Behavior of BOEIF and BORIF Flags according to CTLR.BOM[1:0] Bit Setting

BOM[1:0] Bits	BOEIF Flag	BORIF Flag
00b	Set to 1 on entry to the bus-off state.	Set to 1 on exit from the bus-off state.
01b		Do not set to 1.
10b		Set to 1 on exit from the bus-off state.
11b		Set to 1 if normal bus-off recovery occurs before the CANM[1:0] bits are set to 10b (CAN halt mode).

ORIF Flag (Receive Overrun Detect Flag)

The ORIF flag is set to 1 when a receive overrun occurs. This flag is not to set to 1 in overwrite mode.
In overwrite mode, a reception complete interrupt request is generated if an overwrite condition occurs and the ORIF flag is not set to 1.
In normal mailbox mode, if an overrun occurs in any of mailboxes [0] to [31] in overrun mode, this flag is set to 1. In

FIFO mailbox mode, if an overrun occurs in any of mailboxes [0] to [23] or the receive FIFO in overrun mode, this flag is set to 1.

OLIF Flag (Overload Frame Transmission Detect Flag)

The OLIF flag is set to 1 if the transmitting condition of an overload frame is detected when the CAN module performs transmission or reception.

BLIF Flag (Bus Lock Detect Flag)

The BLIF flag is set to 1 if 32 consecutive dominant bits are detected on the CAN bus while the CAN module is in CAN operation mode.

After the BLIF flag is set to 1, a bus lock is detected again under either of the following conditions:

- After this flag is set to 0 from 1, recessive bits are detected
- After this flag is set to 0 from 1, the CAN module enters CAN reset mode or CAN halt mode and then enters CAN operation mode again (internal reset).

43.2.20 Receive Error Count Register (RECR)

Address(es): CAN0.RECR 0009 084Eh, CAN1.RECR 0009 184Eh, CAN2.RECR 0009 284Eh

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Description	R/W
b7 to b0	Receive error count function RECR increments or decrements the counter value according to the error status of the CAN module during reception.	R

RECR indicates the value of the receive error counter.

Refer to the ISO 11898-1 Standards about the increment/decrement conditions of the receive error counter.

The value of RECR in the bus-off state is undefined.

43.2.21 Transmit Error Count Register (TECR)

Address(es): CAN0.TECR 0009 084Fh, CAN1.TECR 0009 184Fh, CAN2.TECR 0009 284Fh

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Description	R/W
b7 to b0	Transmit error count function TECR increments or decrements the counter value according to the error status of the CAN module during transmission.	R

TECR indicates the value of the transmit error counter.
Refer to the ISO 11898-1 Standards about the increment/decrement conditions of the transmit error counter.
The value of TECR in the bus-off state is undefined.

43.2.22 Error Code Store Register (ECSR)

Address(es): CAN0.ECSR 0009 0850h, CAN1.ECSR 0009 1850h, CAN2.ECSR 0009 2850h

	b7	b6	b5	b4	b3	b2	b1	b0
	EDPM	ADEF	BE0F	BE1F	CEF	AEF	FEF	SEF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SEF	Stuff Error Flag*1,*2	0: No stuff error detected 1: Stuff error detected	R/W
b1	FEF	Form Error Flag*1,*2	0: No form error detected 1: Form error detected	R/W
b2	AEF	ACK Error Flag*1,*2	0: No ACK error detected 1: ACK error detected	R/W
b3	CEF	CRC Error Flag*1,*2	0: No CRC error detected 1: CRC error detected	R/W
b4	BE1F	Bit Error (recessive) Flag*1,*2	0: No bit error (recessive) detected 1: Bit error (recessive) detected	R/W
b5	BE0F	Bit Error (dominant) Flag*1,*2	0: No bit error (dominant) detected 1: Bit error (dominant) detected	R/W
b6	ADEF	ACK Delimiter Error Flag*1,*2	0: No ACK delimiter error detected 1: ACK delimiter error detected	R/W
b7	EDPM	Error Display Mode Select*3,*4	0: Output of first detected error code 1: Output of accumulated error code	R/W

Note 1. Writing 1 has no effect to these flag values.
Note 2. To write 0 to SEF, FEF, AEF, CEF, BE1F, BE0F, and ADEF flags, do not use the logic operation instruction (AND). Use the transfer (MOV) instruction to ensure that only the specified flag is set to 0 and the other flags are set to 1.
Note 3. Write to the EDPM bit in CAN reset mode or CAN halt mode.
Note 4. If more than one error condition is detected simultaneously, all related flags are set to 1.

ECSR can be used to monitor whether an error has occurred on the CAN bus.
Refer to the ISO 11898-1 Standards to check the generation conditions of each error.

To set each flag except for the EDPM bit to 0, write 0 by a program. If the timing at which each flag is set to 1 and the timing at which 0 is written by a program are the same, the relevant flag is set to 1.

SEF Flag (Stuff Error Flag)

The SEF flag is set to 1 when a stuff error is detected.

FEF Flag (Form Error Flag)

The FEF flag is set to 1 when a form error is detected.

AEF Flag (ACK Error Flag)

The AEF flag is set to 1 when an ACK error is detected.

CEF Flag (CRC Error Flag)

The CEF flag is set to 1 when a CRC error is detected.

BE1F Flag (Bit Error (recessive) Flag)

The BE1F flag is set to 1 when a recessive bit error is detected.

BE0F Flag (Bit Error (dominant) Flag)

The BE0F flag is set to 1 when a dominant bit error is detected.

ADEF Flag (ACK Delimiter Error Flag)

The ADEF flag is set to 1 when a form error is detected with the ACK delimiter during transmission.

EDPM Bit (Error Display Mode Select)

The EDPM bit selects the output mode of ECSR. When the EDPM bit is set to 0, ECSR outputs the first error code. When the EDPM bit is set to 1, ECSR outputs the accumulated error code.

43.2.23 Time Stamp Register (TSR)

Address(es): CAN0.TSR 0009 0854h, CAN1.TSR 0009 1854h, CAN2.TSR 0009 2854h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Description	R/W
b15 to b0	Free-running counter value for the time stamp function	R

Note: Read TSR in 16-bit units.

When TSR is read, the value of the time stamp counter (16-bit free-running counter) at that moment is read.
The value of the time stamp counter reference clock is a multiple of 1 bit time, as configured by the TSPS[1:0] bits in CTLR.
The time stamp counter stops in CAN sleep mode and CAN halt mode, and is initialized in CAN reset mode.
The time stamp counter value is stored to bits TSL[7:0] and TSH[7:0] in MBj when a received message is stored in a receive mailbox.

43.2.24 Test Control Register (TCR)

Address(es): CAN0.TCR 0009 0858h, CAN1.TCR 0009 1858h, CAN2.TCR 0009 2858h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	TSTM[1:0]		TSTE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TSTE	CAN Test Mode Enable	0: CAN test mode disabled 1: CAN test mode enabled	R/W
b2, b1	TSTM[1:0]	CAN Test Mode Select	b2 b1 0 0: Other than CAN test mode 0 1: Listen-only mode 1 0: Self-test mode 0 (external loopback) 1 1: Self-test mode 1 (internal loopback)	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

TCR controls the CAN test mode. Write to TCR in CAN halt mode only.

(1) Listen-Only Mode

The ISO 11898-1 Standards recommend an optional bus monitoring mode. In listen-only mode, valid data frames and valid remote frames can be received. However, only recessive bits can be sent on the CAN bus, and the ACK bit, overload flag, and active error flag cannot be sent.

Listen-only mode can be used for baud rate detection.

Do not request transmission from any mailboxes in listen-only mode.

Figure 43.6 shows the connection when listen-only mode is selected (i = 0 to 2).

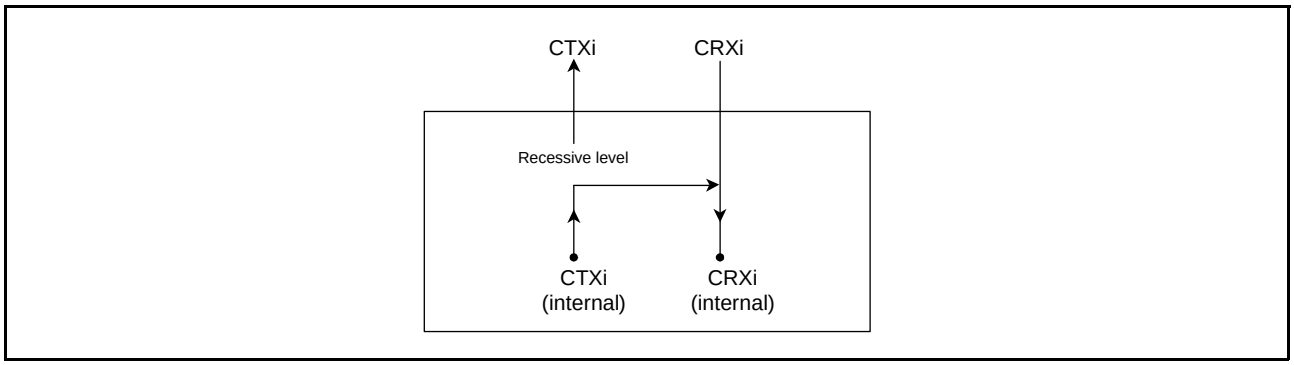

Figure 43.6 Connection when Listen-Only Mode is Selected (i = 0 to 2)

(2) Self-Test Mode 0 (External Loopback))

Self-test mode 0 is provided for CAN transceiver tests.
In self-test mode 0, the protocol controller treats its own transmitted messages as messages received via the CAN transceiver and stores them into the receive mailbox. To be independent from external stimulation, the protocol controller generates the ACK bit.
Connect the CTXi and CRXi pins to the transceiver.
Figure 43.7 shows the connection when self-test mode 0 is selected (i = 0 to 2).

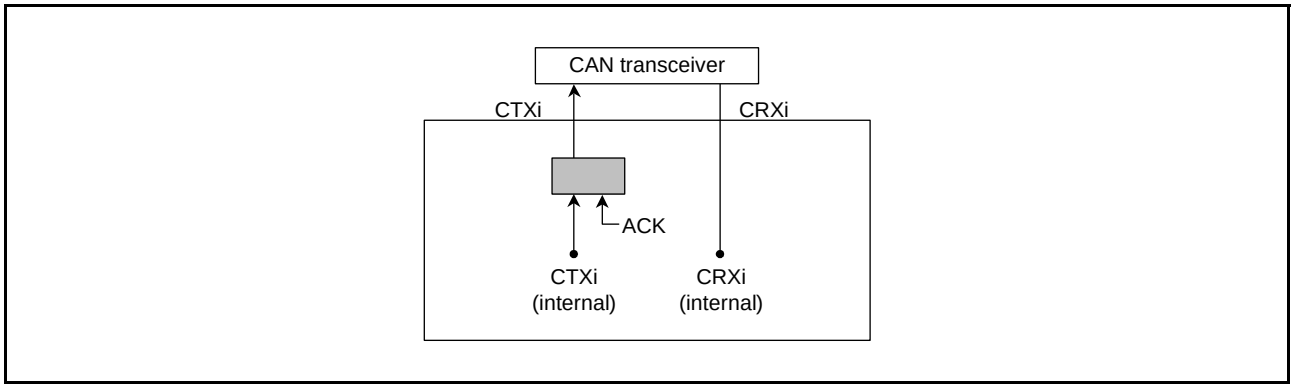

Figure 43.7 Connection when Self-Test Mode 0 is Selected (i = 0 to 2)

(3) Self-Test Mode 1 (Internal Loopback)

Self-test mode 1 is provided for self-test functions.
In self-test mode 1, the protocol controller treats its transmitted messages as received messages and stores them into the receive mailbox. To be independent from external stimulation, the protocol controller generates the ACK bit.
In self-test mode 1, the protocol controller performs an internal feedback from the internal CTXi pin to the internal CRXi pin. The input value of the external CRXi pin is ignored. The external CTXi pin outputs only recessive bits. The CTXi and CRXi pins do not need to be connected to the CAN bus or any external device.
Figure 43.8 shows the connection when self-test mode 1 is selected (i = 0 to 2).

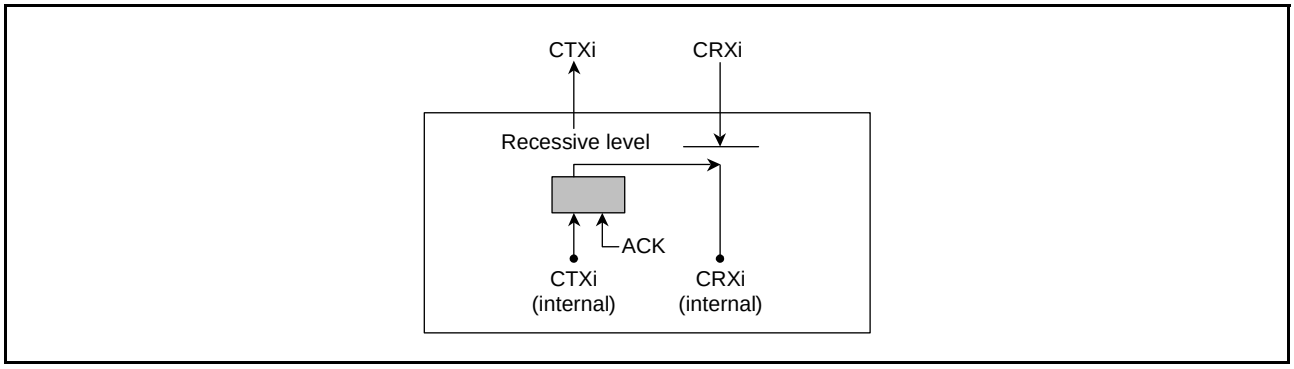

Figure 43.8 Connection when Self-Test Mode 1 is Selected (i = 0 to 2)

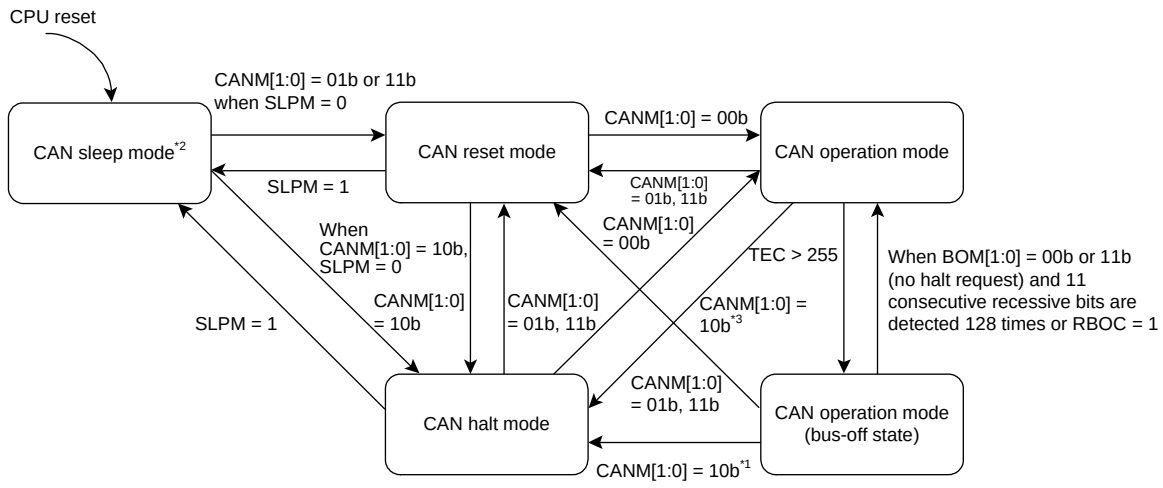
43.3 Operating Mode

The CAN module has the following four operating modes.

- CAN reset mode
- CAN halt mode
- CAN operation mode
- CAN sleep mode

Figure 43.9 shows the transition between CAN operating modes.



CANM, SLPM, BOM, RBOC: Bits in CTLR

Note 1. The transition timing from the bus-off state to CAN halt mode depends on the setting of the CTLR.BOM[1:0] bits.
When the CTLR.BOM[1:0] bits are 01b, the state transition timing is immediately after entering the bus-off state.
When the CTLR.BOM[1:0] bits are 10b, the state transition timing is at the end of the bus-off state.
When the CTLR.BOM[1:0] bits are 11b, the state transition timing is at the setting of the CTLR.CANM[1:0] bits to 10b (CAN halt mode).
Note 2. Change the CTLR.SLPM bit to set or cancel CAN sleep mode.
Note 3. While the CAN bus is locked at the dominant level, the CAN module does not enter CAN halt mode. In that case, enter CAN reset mode.

Figure 43.9 Transition between CAN Operating Modes

43.3.1 CAN Reset Mode

CAN reset mode is provided for CAN communication configuration.
When the CTLR.CANM[1:0] bits are set to 01b or 11b, the CAN module enters CAN reset mode. Then, the STR.RSTST flag is set to 1. Do not change the CTLR.CANM[1:0] bits until the RSTST flag is set to 1. Set BCR before exiting CAN reset mode to any other modes.
The following registers are initialized to their reset values after entering CAN reset mode, and their initial values are retained during CAN reset mode:

- MCTLj
- STR (except for the SLPST and TFST flags)
- EIFR
- RECR
- TECR
- TSR
- MSSR
- MSMR
- RFCR
- TFCR
- TCR
- ECSR (except for the EDPM bit)

The following registers retain their previous values even after entering CAN reset mode.

- CTLR
- STR (only the SLPST and TFST flags)
- MIER
- EIER
- BCR
- CSSR
- ECSR (only the EDPM bit)
- MBj
- MKR0 to MKR7
- FIDCR0 and FIDCR1
- MKIVLR
- AFSR
- RFPCR
- TFPCR

43.3.2 CAN Halt Mode

CAN halt mode is used for mailbox configuration and test mode setting.
When the CTLR.CANM[1:0] bits are set to 10b, CAN halt mode is selected. Then the STR.HLTST flag is set to 1. Do not change the CTLR.CANM[1:0] bits until the HLTST flag is set to 1.
See Table 43.8 for the state transition conditions when transmitting or receiving.
All registers except for RSTST, HLTST, and SLPST flags in STR remain unchanged when the CAN enters CAN halt mode.
Do not change CTLR (except for bits CANM[1:0] and SLPM) and EIER in CAN halt mode. BCR can be changed in CAN halt mode only when listen-only mode is selected for automatic baud rate detection.

Table 43.8 Operation in CAN Reset Mode and CAN Halt Mode

Mode	Receiver	Transmitter	Bus-Off
CAN reset mode (forcible transition) CANM[1:0] = 11b	CAN module enters CAN reset mode without waiting for the end of message reception.	CAN module enters CAN reset mode without waiting for the end of message transmission.	CAN module enters CAN reset mode without waiting for the end of bus-off recovery.
CAN reset mode CANM[1:0] = 01b	CAN module enters CAN reset mode without waiting for the end of message reception.	CAN module enters CAN reset mode after waiting for the end of message transmission.*1,*4	CAN module enters CAN reset mode without waiting for the end of bus-off recovery.
CAN halt mode	CAN module enters CAN halt mode after waiting for the end of message reception.*2,*3	CAN module enters CAN halt mode after waiting for the end of message transmission.*1,*2,*4	[When the BOM[1:0] bits are 00b] A halt request from a program will be accepted only after bus-off recovery. [When the BOM[1:0] bits are 01b] CAN module automatically enters CAN halt mode without waiting for the end of bus-off recovery (regardless of a halt request from a program). [When the BOM[1:0] bits are 10b] CAN module automatically enters CAN halt mode after waiting for the end of bus-off recovery (regardless of a halt request from a program). [When the BOM[1:0] bits are 11b] CAN module enters CAN halt mode (without waiting for the end of bus-off recovery) if a halt is requested by a program during bus-off.

CANM[1:0], BOM[1:0]: Bits in CTLR

Note 1. If several messages are requested to be transmitted, mode transition occurs after the completion of the first message transmission. In a case that the CAN reset mode is being requested during suspend transmission, mode transition occurs when the bus is idle, the next transmission ends, or the CAN module becomes a receiver.

Note 2. If the CAN bus is locked at the dominant level, the program can detect this state by monitoring the EIFR.BLIF flag. While the CAN bus is locked at the dominant level, the CAN module does not enter CAN halt mode. In that case, enter CAN reset mode.

Note 3. If a CAN bus error occurs during reception after CAN halt mode is requested, the CAN module transits to CAN halt mode. However, while the CAN bus is locked at the dominant level, the CAN module does not enter CAN halt mode.

Note 4. If a CAN bus error or arbitration-lost occurs during transmission after CAN reset mode or CAN halt mode is requested, the CAN module transits to the requested operating mode. However, while the CAN bus is locked at the dominant level, the CAN module does not enter CAN halt mode.

43.3.3 CAN Sleep Mode

CAN sleep mode is used for reducing current consumption by stopping the clock supply to the CAN module. After a reset from an MCU pin or software reset, the CAN module starts from CAN sleep mode.
When the SLPM bit in CTLR is set to 1, the CAN module enters CAN sleep mode. Then, the SLPST flag in STR is set to 1. Do not change the value of the SLPM bit until the SLPST flag is set to 1. The other registers remain unchanged when the CAN module enters CAN sleep mode.
Write to the SLPM bit in CAN reset mode and CAN halt mode. Do not change any registers (except for the SLPM bit) during CAN sleep mode. Read operation is still allowed.
When the SLPM bit is set to 0, the CAN module is released from CAN sleep mode. When the CAN module exits CAN sleep mode, the other registers remain unchanged.

43.3.4 CAN Operation Mode (Excluding Bus-Off State)

CAN operation mode is used for CAN communication.
When the CANM[1:0] bits in CTLR are set to 00b, the CAN module enters CAN operation mode.
Then RSTST and HLTST flags in STR are set to 0. Do not change the value of the CANM[1:0] until bits RSTST and HLTST flags are set to 0.
If 11 consecutive recessive bits are detected after entering CAN operation mode, the CAN module is in the following states:

- The CAN module becomes an active node on the network, thus enabling transmission and reception of CAN messages.
- Error monitoring of the CAN bus, such as receive and transmit error counters, is performed.

During CAN operation mode, the CAN module may be in one of the following three sub-modes, depending on the status of the CAN bus.

- Idle mode: Transmission or reception is not being performed.
- Receive mode: A CAN message sent by another node is being received.
- Transmit mode:A CAN message is being transmitted. The CAN module receives a message transmitted by the local node simultaneously when self-test mode 0 (TSTM[1:0] bits in TCR = 10b) or self-test mode 1 (TSTM[1:0] bits = 11b) is selected.

Figure 43.10 shows the sub-modes of CAN operation mode.

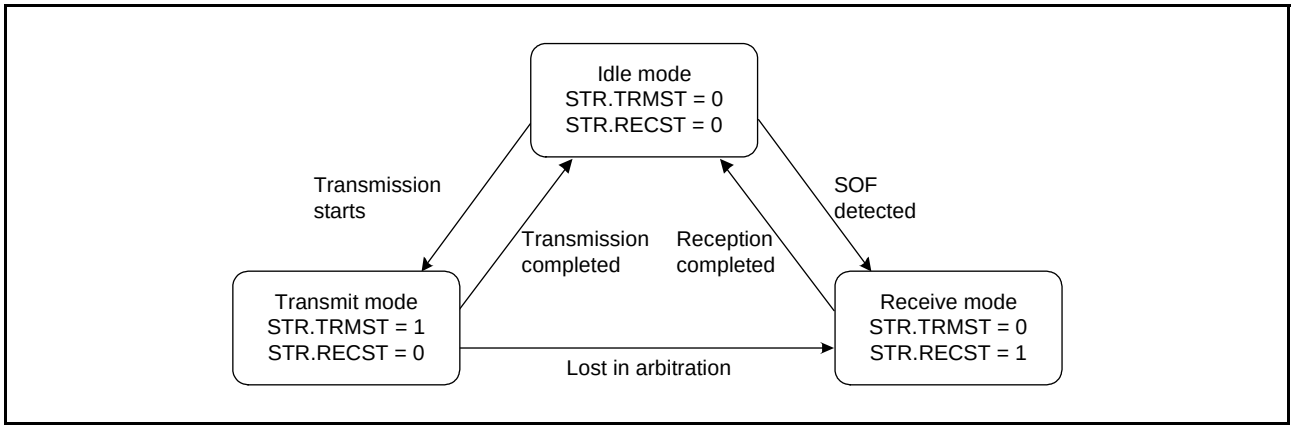


Figure 43.10 Sub-Modes of CAN Operation Mode

43.3.5 CAN Operation Mode (Bus-Off State)

The CAN module enters the bus-off state according to the increment/decrement rules for the transmit/error counters in the CAN Specifications.
The following cases apply when the CAN module is recovering from the bus-off state. When the CAN module is in the bus-off state, the values of the CAN-related registers, except for STR, EIFR, RECR, TECR and TSR, remain unchanged.

(1) When bits BOM[1:0] in CTLR are 00b (normal mode)

The CAN module enters the error-active state after it has completed the recovery from the bus-off state and CAN communication is enabled. The BORIF flag in EIFR is set to 1 (bus-off recovery detected) at this time.

(2) When bit RBOC in CTLR is set to 1 (forcible return from bus-off)

The CAN module enters the error-active state when it is in the bus-off state and the RBOC bit is set to 1. CAN communication is enabled again after 11b consecutive recessive bits are detected. The BORIF flag is not set to 1 at this time.

(3) When bits BOM[1:0] are 01b (automatic transition to CAN halt mode at bus-off entry)

The CAN module enters CAN halt mode when it reaches the bus-off state. The BORIF flag is not set to 1 at this time.

(4) When bits BOM[1:0] are 10b (automatic transition to CAN halt mode at bus-off end)

The CAN module enters CAN halt mode when it has completed the recovery from bus-off. The BORIF flag is set to 1 at this time.

(5) When bits BOM[1:0] are 11b (automatic transition to CAN halt mode by a program) and bits CANM[1:0] in CTLR are set to 10b (CAN halt mode) during bus-off state

The CAN module enters CAN halt mode when it is in the bus-off state and the CANM[1:0] bits are set to 10b (CAN halt mode). The BORIF flag is not set to 1 at this time.
If the CANM[1:0] bits are not set to 10b during bus-off, the same behavior as (1) applies.

43.4 CAN Communication Speed Setting

The following description explains about CAN communication speed setting.

43.4.1 CAN Clock Setting

The CAN module has a CAN clock selector.
The CAN clock can be set by the CCLKS bit and the BRP[9:0] bits in BCR.
Figure 43.11 shows a block diagram of the CAN clock generator.

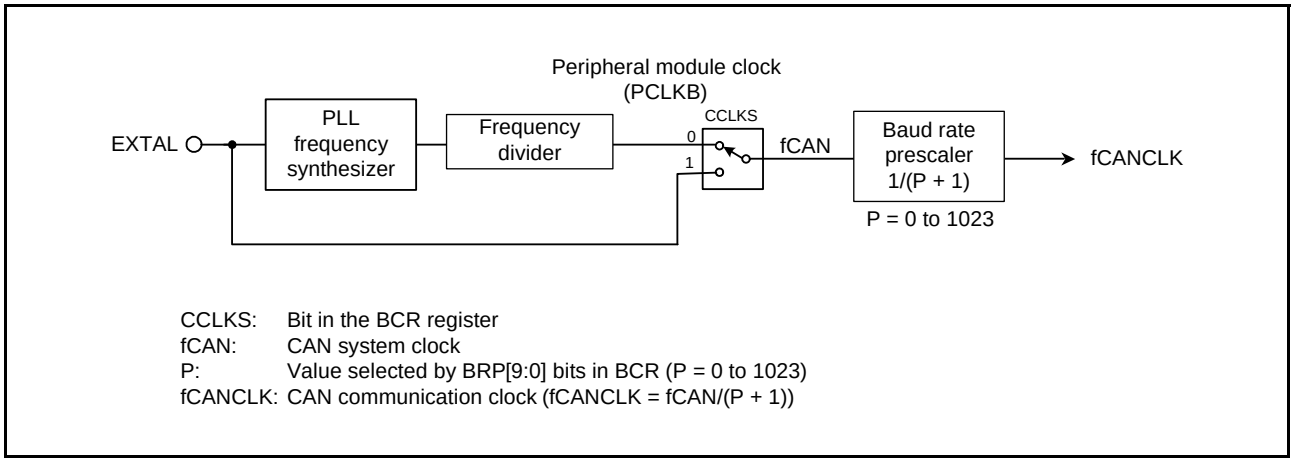

Figure 43.11 Block Diagram of CAN Clock Generator

43.4.2 Bit Timing Setting

The bit time consists of the following three segments.
Figure 43.12 shows the bit timing.

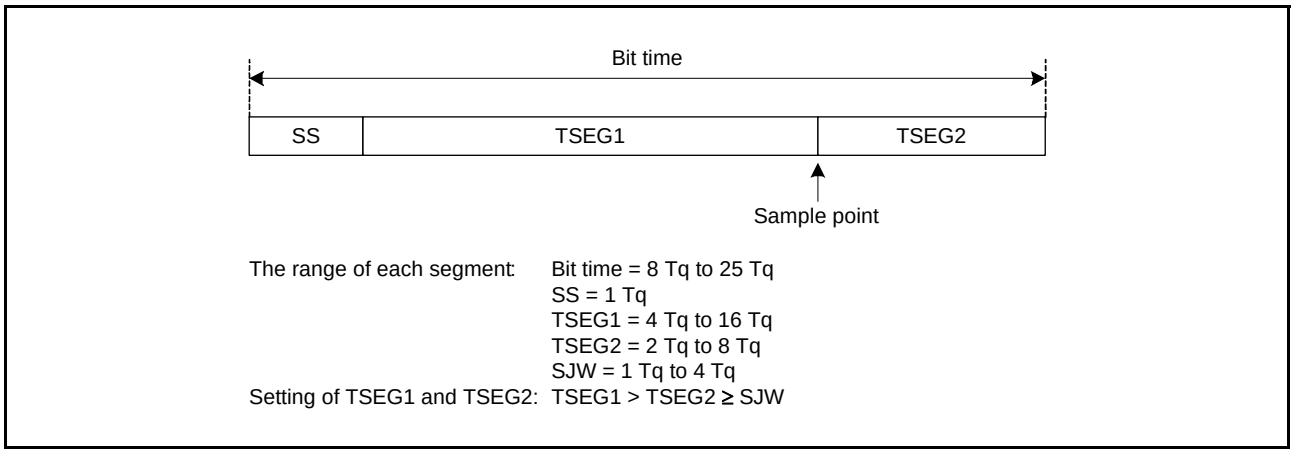

Figure 43.12 Bit Timing

43.4.3 Bit Rate

The bit rate depends on the division value of fCAN (CAN clock), the division value of the baud rate prescaler, and the number of Tq of 1 bit time.

$$\text{Bit rate [bps]} = \frac{\text{fCAN}}{\text{Baud rate prescaler division value}^{*1} \times \text{number of Tq of 1 bit time}} = \frac{\text{fCANCLK}}{\text{Number of Tq of 1 bit time}}$$

Note 1. Division value of baud rate prescaler = P + 1 (P: 0 to 1023)
P: Setting of the BRP[9:0] bits in BCR

Table 43.9 lists bit rate examples.

Table 43.9 Bit Rate Examples

fCAN	50 MHz		48 MHz		40 MHz		32 MHz	
Bit Rate	Number of Tq	P + 1	Number of Tq	P + 1	Number of Tq	P + 1	Number of Tq	P + 1
1 Mbps	10Tq 25Tq	5 2	8Tq 12Tq 16Tq	6 4 3	10Tq 20Tq	4 2	8Tq 16Tq	4 2
500 kbps	10Tq 25Tq	10 4	8Tq 12Tq 16Tq	12 8 6	10Tq 20Tq	8 4	8Tq 16Tq	8 4

33.3 kbps	10Tq 25Tq	150 60	8Tq 12Tq 16Tq	180 120 90	8Tq 10Tq 20Tq	150 120 60	8Tq 10Tq 16Tq 20Tq	120 96 60 48

43.5 Mailbox and Mask Register Structure

Figure 43.13 shows the structure of MBj.
There are 32 mailboxes with the same structure.

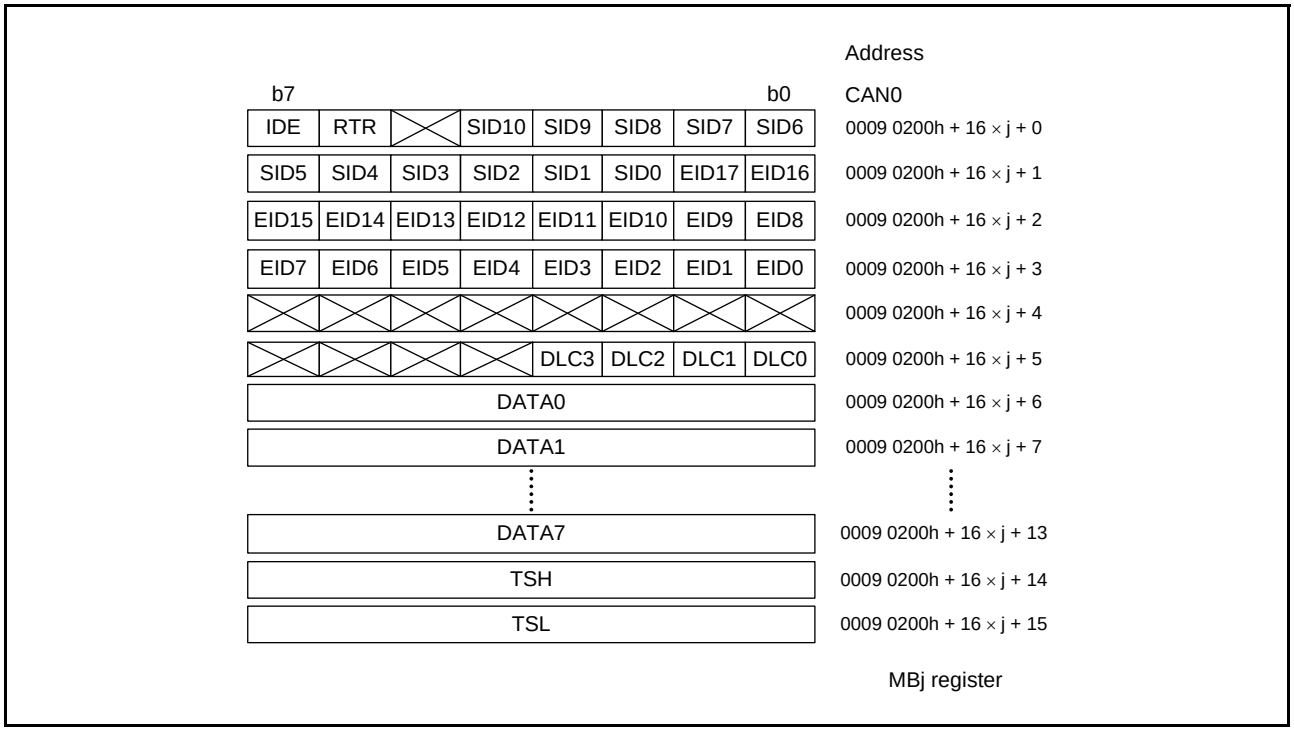

Figure 43.13 Structure of MBj (j = 0 to 31)

Figure 43.14 shows the structure of MKRk.
There are eight mask registers with the same structure.

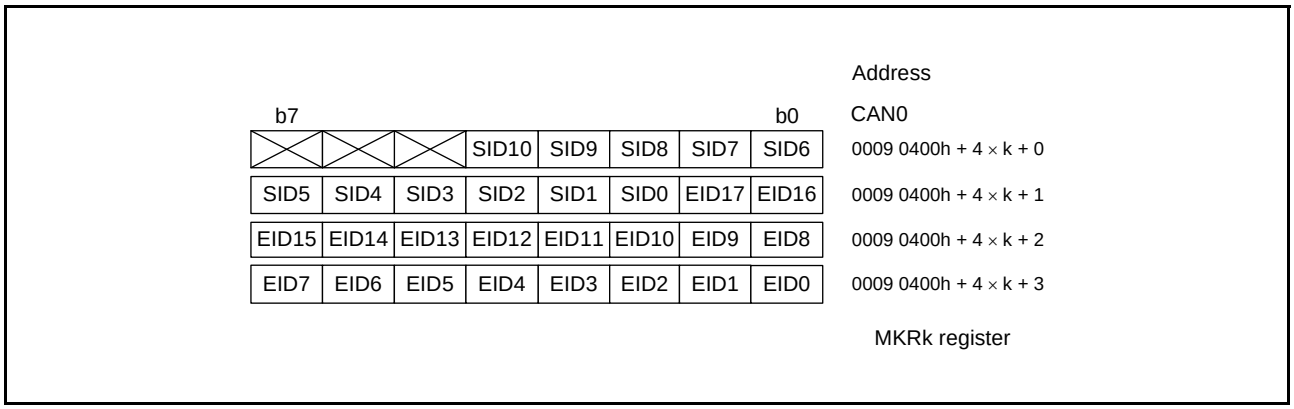

Figure 43.14 Structure of MKRk (k = 0 to 7)

Figure 43.15 shows the structure of FIDCR0 and FIDCR1.
There are two FIFO received ID compare registers with the same structure.

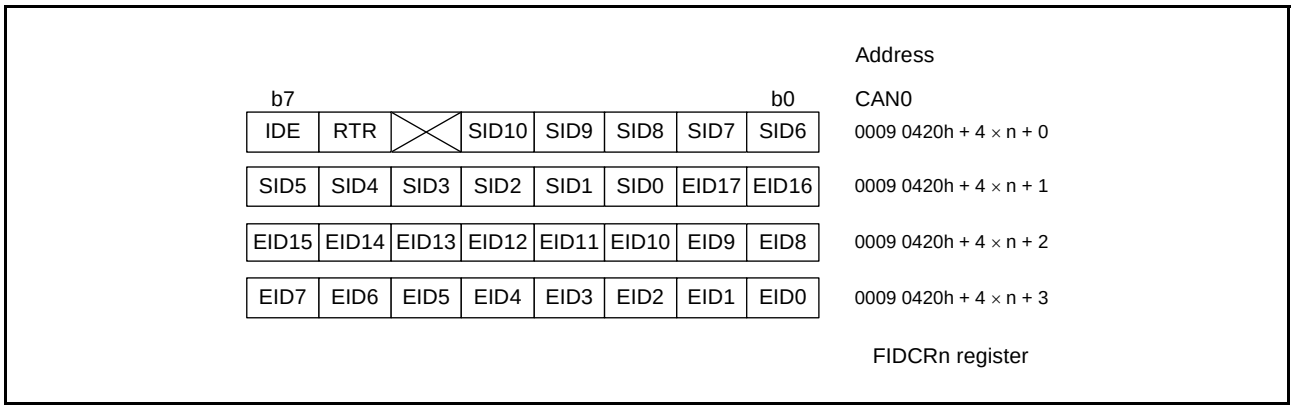

Figure 43.15 Structure of FIDCRn (n = 0, 1)

43.6 Acceptance Filtering and Masking Functions

The acceptance filtering function and masking function allows the user to select and receive messages with a specified range of multiple IDs for mailboxes.
Registers MKR0 to MKR7 can perform masking of the standard ID and the extended ID of 29 bits.

- MKR0 corresponds to mailboxes [0] to [3]
- MKR1 corresponds to mailboxes [4] to [7]
- MKR2 corresponds to mailboxes [8] to [11]
- MKR3 corresponds to mailboxes [12] to [15]
- MKR4 corresponds to mailboxes [16] to [19]
- MKR5 corresponds to mailboxes [20] to [23]
- MKR6 corresponds to mailboxes [24] to [27] in normal mailbox mode and the receive FIFO mailboxes [28] to [31] in FIFO mailbox mode.
- MKR7 corresponds to mailboxes [28] to [31] in normal mailbox mode and the receive FIFO mailboxes [28] to [31] in FIFO mailbox mode.

MKIVLR disables acceptance filtering individually for each mailbox.
The IDE bit in MBj is valid when the IDFM[1:0] bits in CTLR are 10b (mixed ID mode).
The RTR bit in MBj selects a data frame or a remote frame.

In FIFO mailbox mode, normal mailboxes (mailboxes [0] to [23]) use the single corresponding register among MKR0 to MKR5 for acceptance filtering. Receive FIFO mailboxes (mailboxes [28] to [31]) use two registers MKR6 and MKR7 for acceptance filtering.
Also, the receive FIFO uses two registers FIDCR0 and FIDCR1 for ID comparison. Bits EID[17:0], SID[10:0], RTR, and IDE in MB28 to MB31 for the receive FIFO are disabled. As acceptance filtering depends on the result of two logic AND operations, two ranges of IDs can be received into the receive FIFO.
MKIVLR is disabled for the receive FIFO.

If both the standard ID and extended ID are set in the IDE bits in FIDCR0 and FIDCR1 individually, both ID formats are received.
If both the data frame and remote frame are set in the RTR bits in FIDCR0 and FIDCR1 individually, both data and remote frames are received.
When combination with two ranges of IDs is not necessary, set the same mask value and the same ID into both the FIFO ID and mask register.
Figure 43.16 shows the correspondence between mask registers and mailboxes. Figure 43.17 shows acceptance filtering.

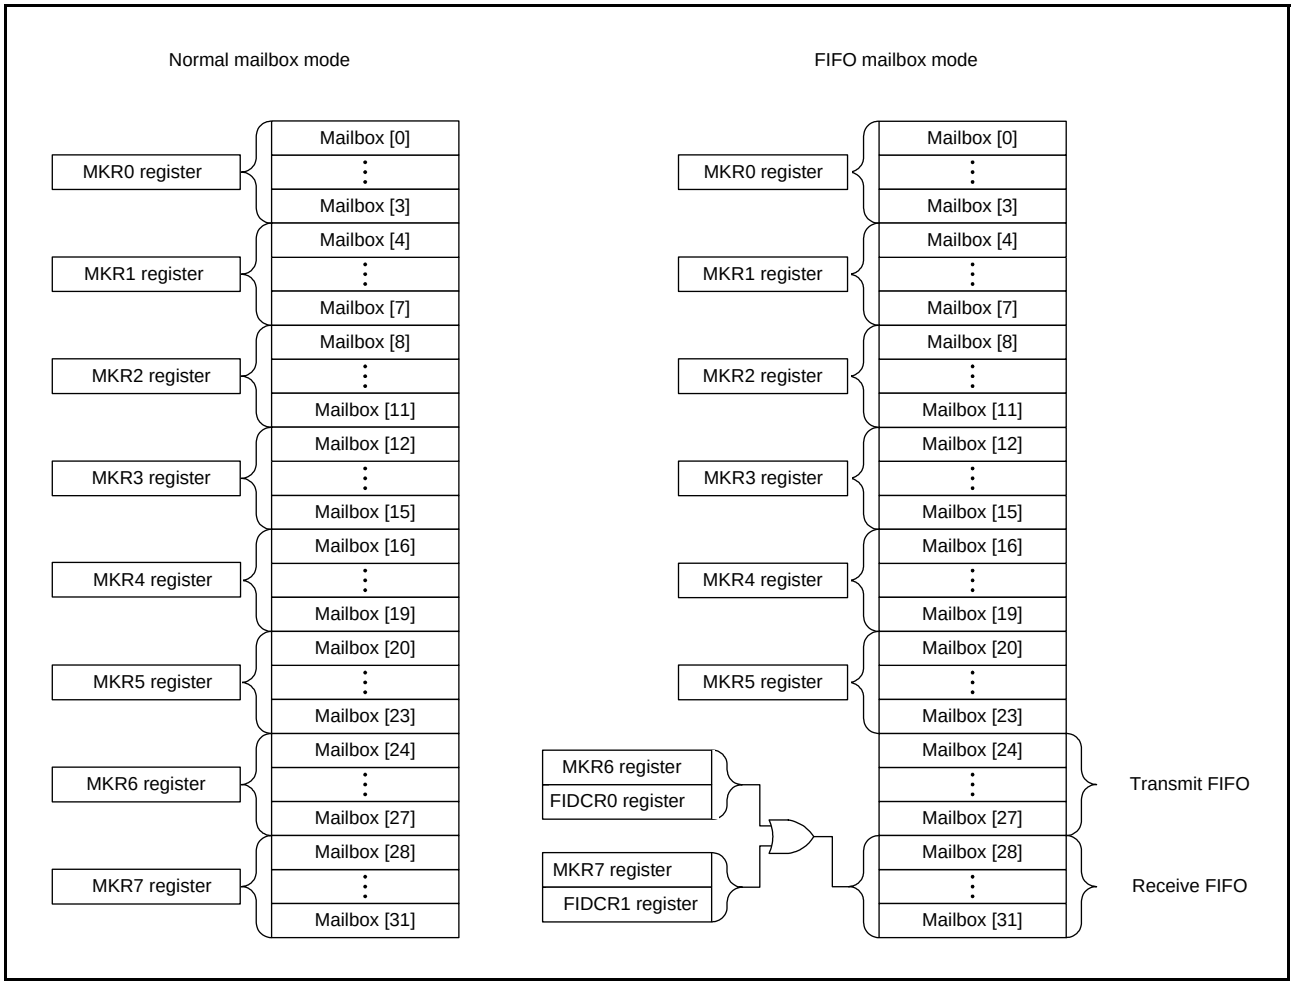

Figure 43.16 Correspondence between Mask Registers and Mailboxes

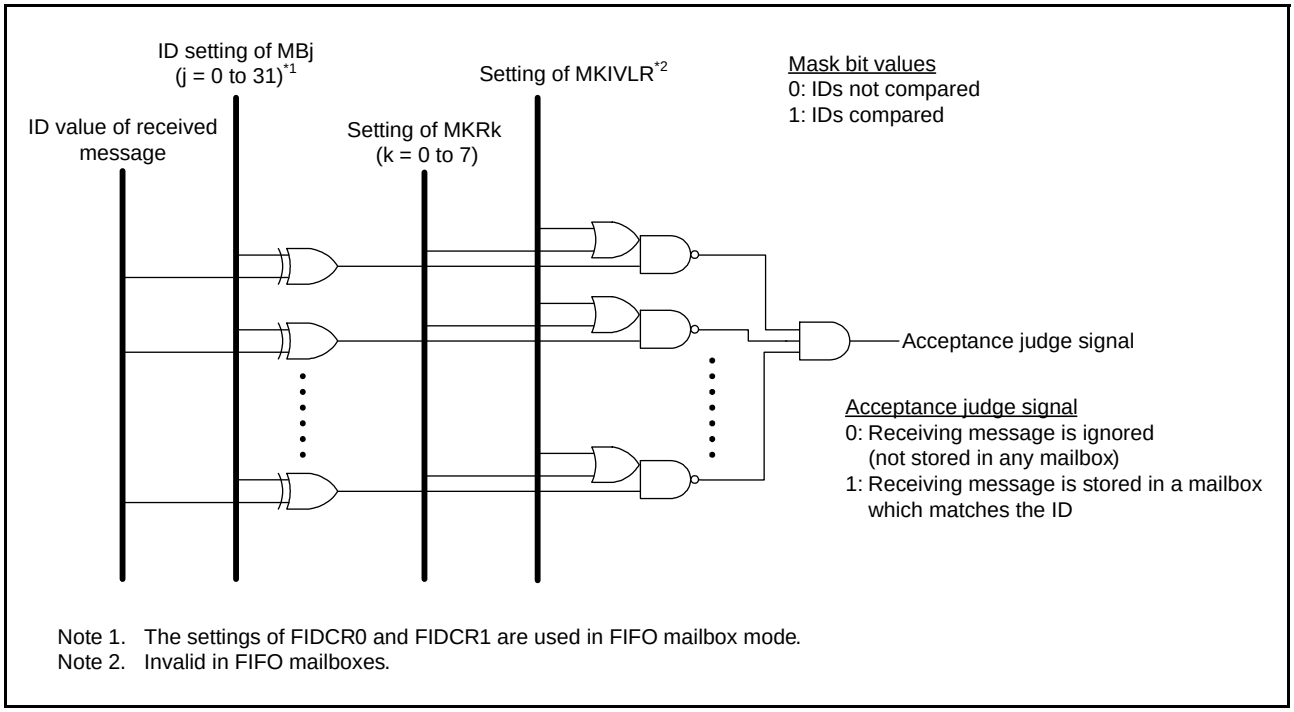

Note 1. The settings of FIDCR0 and FIDCR1 are used in FIFO mailbox mode.
Note 2. Invalid in FIFO mailboxes.

Figure 43.17 Acceptance Filtering

43.7 Reception and Transmission

Table 43.10 lists how to make the CAN communication mode settings.

Table 43.10 Setting of CAN Receive Mode and CAN Transmit Mode

MCTLj. TRMREQ	MCTLj. RECREQ	MCTLj. ONESHOT	Communication Mode of Mailbox
0	0	0	Mailbox disabled or transmission being aborted.
0	0	1	Can be configured only when transmission or reception from a mailbox programmed in one-shot mode is aborted.
0	1	0	Configured as a receive mailbox for a data frame or a remote frame.
0	1	1	Configured as a one-shot receive mailbox for a data frame or a remote frame.
1	0	0	Configured as a transmit mailbox for a data frame or a remote frame.
1	0	1	Configured as a one-shot transmit mailbox for a data frame or a remote frame.
1	1	0	Do not set.
1	1	1	Do not set.

j = 0 to 31

When a mailbox is configured as a receive mailbox or a one-shot receive mailbox, note the following:

1. Before a mailbox is configured as a receive mailbox or a one-shot receive mailbox, set MCTLj to 00h.
2. A received message is stored into the first mailbox that matches the condition according to the result of receive mode setting and acceptance filtering. Upon deciding the mailbox to store the received message, the mailbox with the smaller number has higher priority.
3. In CAN operation mode, when the CAN module transmits a message whose ID matches with the ID/mask set of a mailbox configured to receive messages, the CAN module never receives the transmitted data. In self-test mode, however, the CAN module will receive its transmitted data. In this case, the CAN module returns ACK.

When configuring a mailbox as a transmit mailbox or a one-shot transmit mailbox, note the following:

4. Before a mailbox is configured as a transmit mailbox or a one-shot transmit mailbox, ensure that MCTLj is 00h and that there is no pending abort process.

43.7.1 Reception

Figure 43.18 shows an operation example of data frame reception in overwrite mode.
This example shows the operation of overwriting the first message when the CAN module receives two consecutive CAN messages which match the receiving conditions of MCTLj (j = 0 to 31).

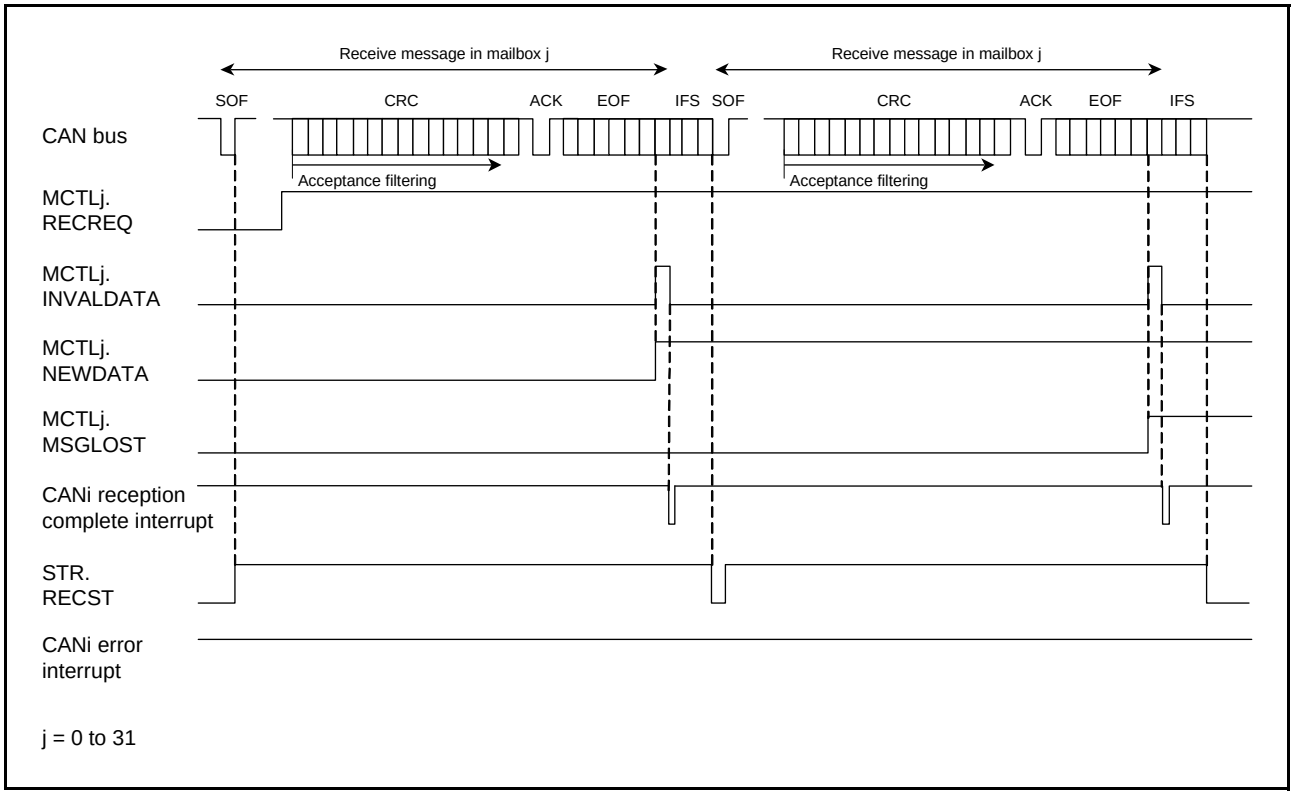

Figure 43.18 Operation Example of Data Frame Reception in Overwrite Mode

1. When an SOF is detected on the CAN bus, the RECST flag in STR is set to 1 (reception in progress) if the CAN module has no message ready to start transmission.
2. The acceptance filter processing starts at the beginning of the CRC field to select the receive mailbox.
3. After a message has been received, the NEWDATA flag in MCTLj for the receive mailbox is set to 1 (new message is being stored or has been stored to the mailbox). The INVALDATA flag in MCTLj is set to 1 (message is being updated) at the same time, and then the INVALDATA flag is set to 0 (message valid) again after the complete message is transferred to the mailbox.
4. When the interrupt enable bit in MIER for the receive mailbox is 1 (interrupt enabled), the CANi reception complete interrupt request is generated. This interrupt (CANi reception complete interrupt) is generated when the INVALDATA flag is set to 0.
5. After reading the message from the mailbox, the NEWDATA flag needs to be set to 0 by a program.
6. In overwrite mode, if the next CAN message has been received into a mailbox whose NEWDATA flag is still set to 1, the MSGLOST flag in MCTLj is set to 1 (message has been overwritten). The new received message is transferred to the mailbox. The CANi reception complete interrupt request is generated the same as in 4.

Figure 43.19 shows the operation example of data frame reception in overrun mode.
This example shows the operation of overrunning the second message when the CAN module receives two consecutive CAN messages which match the receiving conditions of MCTLj (j = 0 to 31).

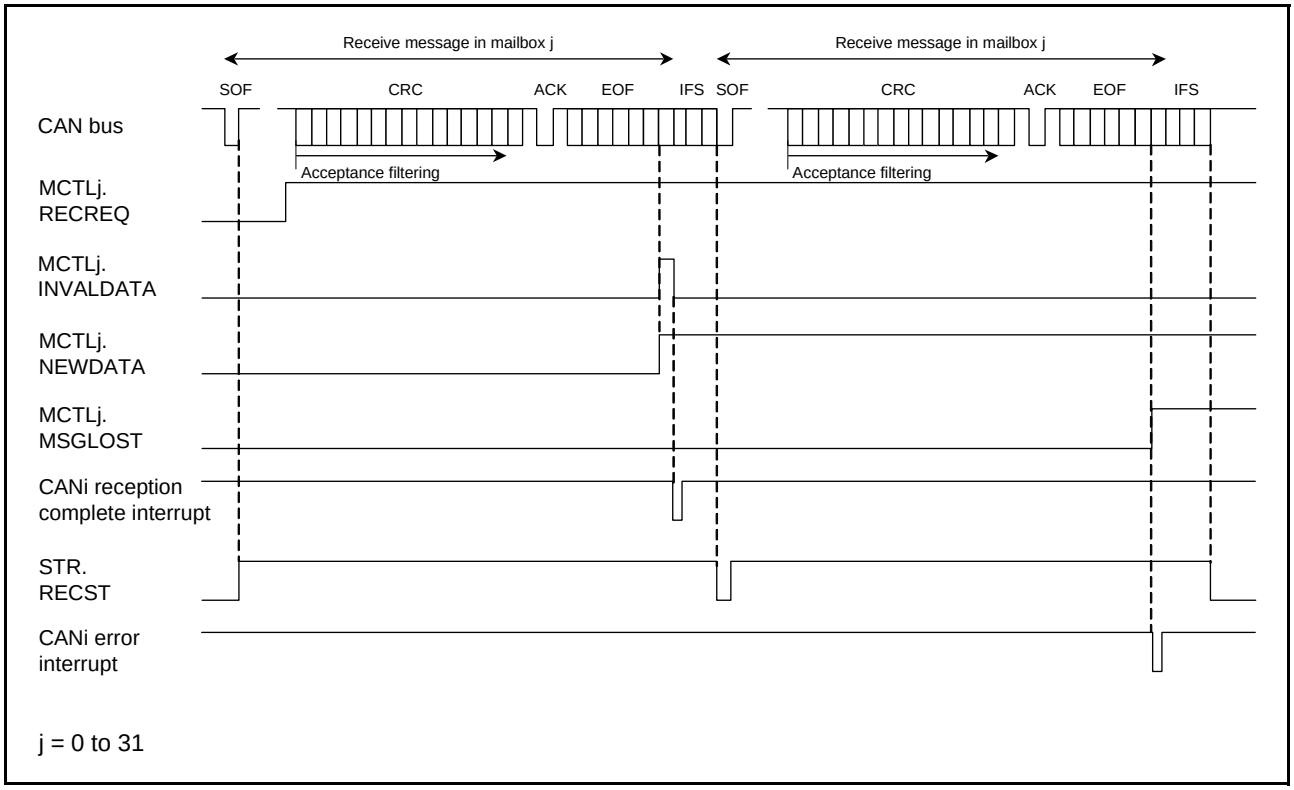

Figure 43.19 Operation Example of Data Frame Reception in Overrun Mode

1. to 5. are the same as in overwrite mode.

6. In overrun mode, if the next CAN message has been received before the NEWDATA flag in MCTLj is set to 0, the MSGLOST flag in MCTLj is set to 1 (message has been overrun). The new received message is discarded and a CANi error interrupt request is generated if the corresponding interrupt enable bit in EIER is set to 1 (interrupt enabled).

43.7.2 Transmission

Figure 43.20 shows an operation example of data frame transmission.

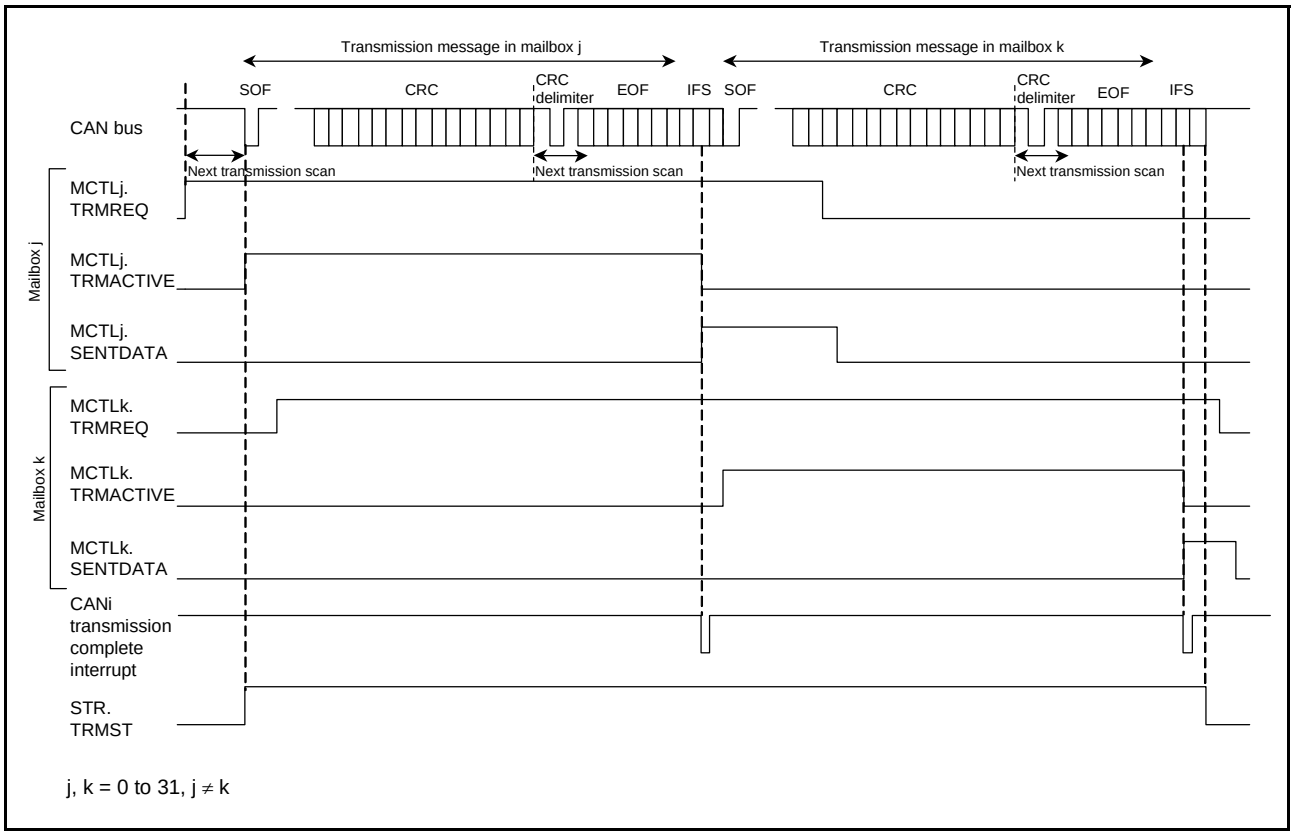

Figure 43.20 Operation Example of Data Frame Transmission

1. When a TRMREQ bit in MCTLj (j = 0 to 31) is set to 1 (transmit mailbox) in the bus-idle state, the mailbox scan processing starts to decide the highest-priority mailbox for transmission. Once the transmit mailbox is decided, the TRMACTIVE flag in MCTLj is set to 1 (from acceptance of transmission request to completion of transmission, or error/arbitration-lost), the TRMST flag in STR is set to 1 (transmission in progress), and the CAN module starts transmission.*1
2. If other TRMREQ bits are set, the transmission scan processing starts with the CRC delimiter for the next transmission.
3. If transmission is completed without losing arbitration, the SENTDATA flag in MCTLj is set to 1 (transmission completed) and the TRMACTIVE flag is set to 0 (transmission is pending or transmission is not requested). If the interrupt enable bit in MIER is 1 (interrupt enabled), the CANi transmission complete interrupt request is generated.
4. When requesting the next transmission from the same mailbox, set SENTDATA flag and TRMREQ bit to 0, then set the TRMREQ bit to 1 after checking that SENTDATA flag and TRMREQ bit have been set to 0.

Note 1. If arbitration is lost after the CAN module starts transmission, the TRMACTIVE flag is set to 0. The transmission scan processing is performed again to search for the highest-priority transmit mailbox from the beginning of the CRC delimiter. If an error occurs either during transmission or following the arbitration-lost, the transmission scan processing is performed again to search for the highest-priority transmit mailbox from the start of the error delimiter.

43.8 CAN Interrupt

The CAN module provides the following CAN interrupts for each channel. Table 43.11 lists CAN interrupts.

- CANi reception complete interrupt (mailboxes 0 to 31) [RXMi]
- CANi transmission complete interrupt (mailboxes 0 to 31) [TXMi]
- CANi receive FIFO interrupt [RXFi]
- CANi transmit FIFO interrupt [TXFi]
- CANi error interrupt [ERSi]

There are eight types of interrupt sources for the CANi error interrupts. These sources can be determined by checking EIFR.

- Bus error
- Error-warning
- Error-passive
- Bus-off entry
- Bus-off recovery
- Receive overrun
- Overload frame transmission
- Bus lock

Table 43.11 CAN Interrupts

Module	Interrupt Symbol	Interrupt Source	Source Flag
CANi	ERSi	Bus lock detected	EIFR.BLIF
		Overload frame transmission detected	EIFR.OLIF
		Overrun detected	EIFR.ORIF
		Bus-off recovery detected	EIFR.BORIF
		Bus-off entry detected	EIFR.BOEIF
		Error-passive detected	EIFR.EPIF
		Error-warning detected	EIFR.EWIF
		Bus error detected	EIFR.BEIF
	RXFi	Receive FIFO message received (MIER[29] = 0)	RFCR.RFUST[2:0]
		Receive FIFO warning (MIER[29] = 1)	
	TXFi	Transmit FIFO message transmission completed (MIER[25] = 0)	TFCR.TFUST[2:0]
		FIFO last message transmission completed (MIER[25] = 1)	
	RXMi	Mailbox 0 to 31 message received	MCTL0.NEWDATA to MCTL31.NEWDATA
	TXMi	Mailbox 0 to 31 message transmission completed	MCTL0.SENTDATA to MCTL31.SENTDATA

i = 0 to 2

43.9 Usage Notes

43.9.1 Setting for the Module-Stop State

Module stop control register B (MSTPCRB) can be used to enable or disable operation of the CAN module. The CAN module is stopped after a reset. The registers become accessible on release from the module-stop state. For details, refer to section 11, Low Power Consumption.

44. Serial Peripheral Interface (RSPIa)

In this section, “PCLK” is used to refer to PCLKA.

44.1 Overview

This MCU includes one channel of Serial Peripheral Interface (RSPI).
The RSPI channels are capable of high-speed, full-duplex synchronous serial communications with multiple processors and peripheral devices.
Table 44.1 lists the specifications of the RSPI, and Figure 44.1 shows a block diagram of the RSPI.
In this section, m as used with the RSPI command registers (SPCMDm) indicates 0 to 7.

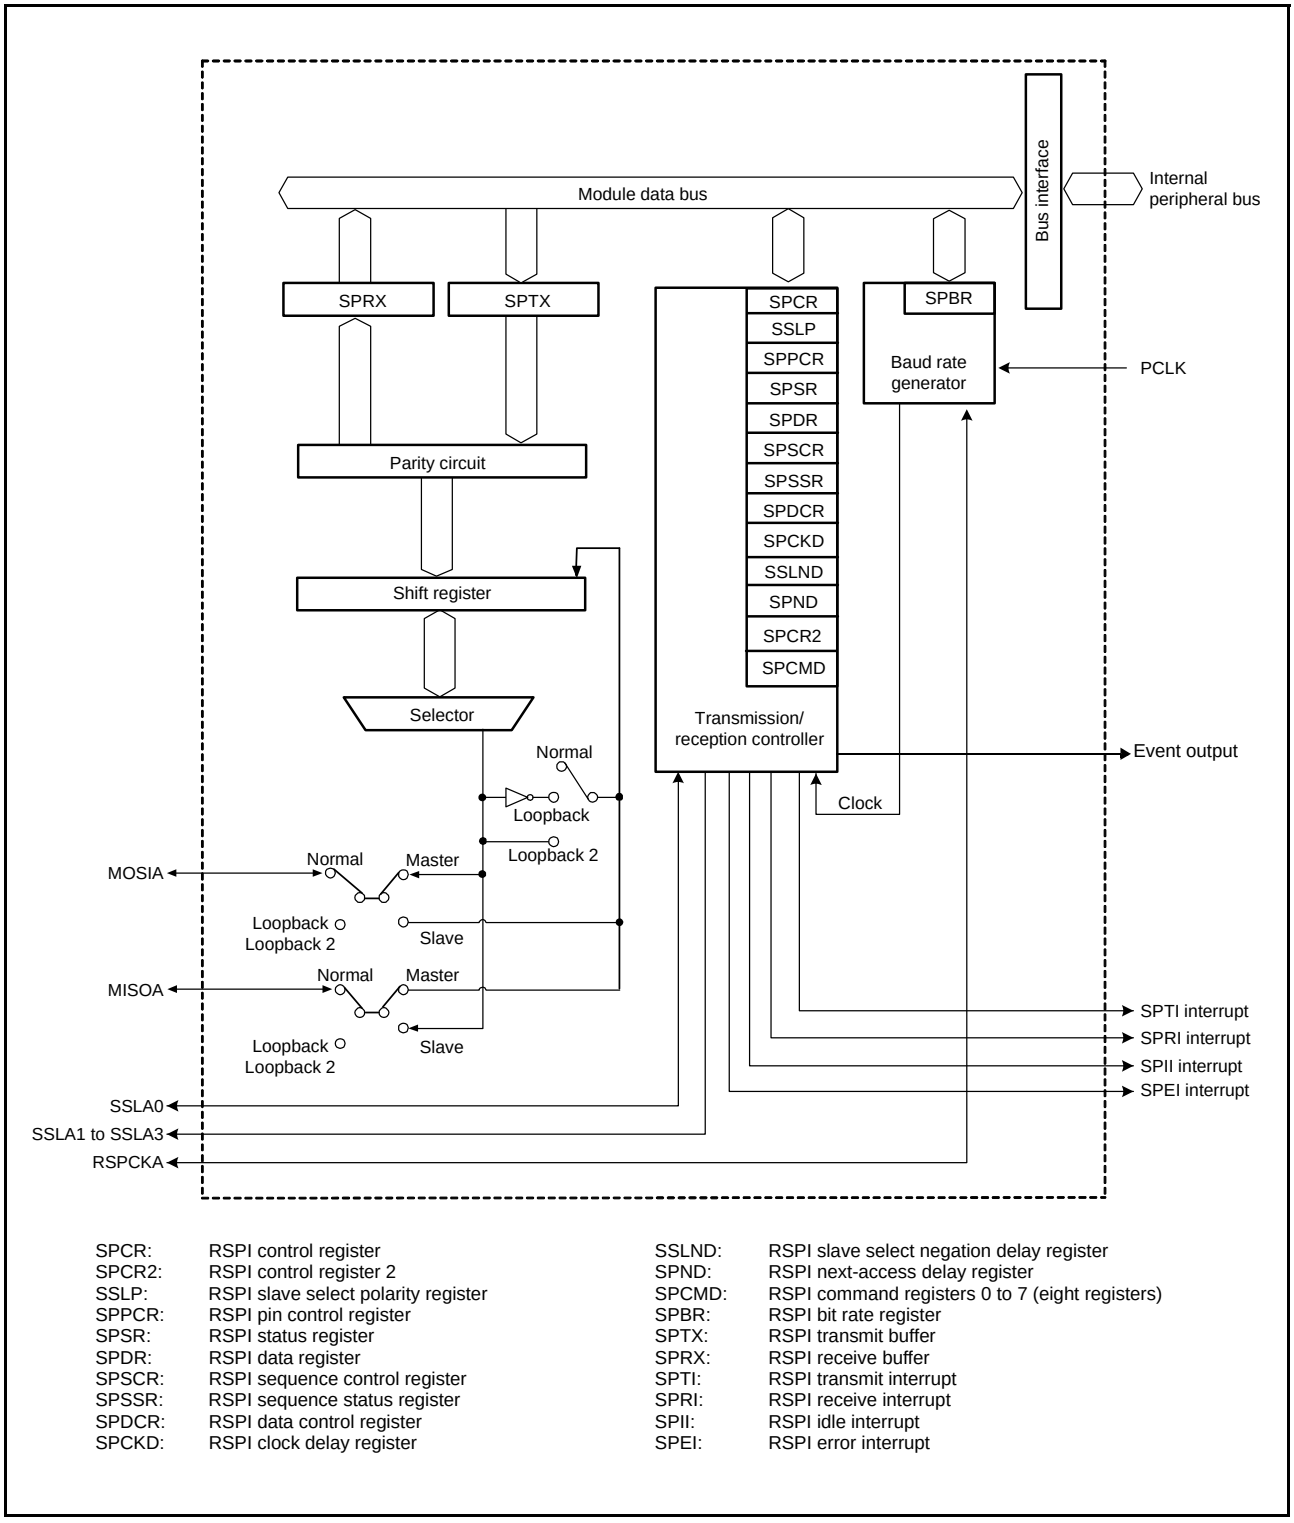
Table 44.1 RSPI Specifications (1/2)

Item	Description
Number of channels	One channel
RSPI transfer functions	• Use of MOSI (master out/slave in), MISO (master in/slave out), SSL (slave select), and RSPCK (RSPI clock) signals allows serial communications through SPI operation (4-wire method) or clock synchronous operation (3-wire method). • Transmit-only operation is available. • Communication mode: Full-duplex or transmit-only can be selected. • Switching of the polarity of RSPCK • Switching of the phase of RSPCK
Data format	• MSB first/LSB first selectable • Transfer bit length is selectable as 8, 9, 10, 11, 12, 13, 14, 15, 16, 20, 24, or 32 bits. • 128-bit transmit/receive buffers • Up to four frames can be transferred in one round of transmission/reception (each frame consisting of up to 32 bits).
Bit rate	• In master mode, the on-chip baud rate generator generates RSPCK by frequency-dividing PCLK (the division ratio ranges from divided by 2 to divided by 4096). • In slave mode, the minimum PCLK clock divided by 8 can be input as RSPCK (the maximum frequency of RSPCK is that of PCLK divided by 8). Width at high level: 4 cycles of PCLK; width at low level: 4 cycles of PCLK
Buffer configuration	• Double buffer configuration for the transmit/receive buffers • 128 bits for the transmit/receive buffers
Error detection	• Mode fault error detection • Overrun error detection*1 • Parity error detection
SSL control function	• Four SSL pins (SSLA0 to SSLA3) for each channel • In single-master mode, SSLA0 to SSLA3 pins are output. • In multi-master mode: SSLA0 pin for input, and SSLA1 to SSLA3 pins for either output or unused. • In slave mode: SSLA0 pin for input, and SSLA1 to SSLA3 pins for unused. • Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable delay from RSPCK stop to SSL output negation (SSL negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Function for changing SSL polarity
Control in master transfer	• A transfer of up to eight commands can be executed sequentially in looped execution. • For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity/phase, transfer data length, MSB/LSB first, burst, RSPCK delay, SSL negation delay, and next-access delay • A transfer can be initiated by writing to the transmit buffer. • MOSI signal value specifiable in SSL negation • RSPCK auto-stop function

Table 44.1 RSPI Specifications (2/2)

Item	Description
Interrupt sources	• Interrupt sources Receive buffer full interrupt Transmit buffer empty interrupt RSPI error interrupt (mode fault, overrun, or parity error) RSPI idle interrupt (RSPI idle)
Event link function (output)	• The following events can be output to the event link controller. (RSPI0) Receive buffer full signal Transmit buffer empty signal Mode fault, overrun, or parity error signal RSPI idle signal Transmission-completed signal
Others	• Function for switching between CMOS output and open-drain output • Function for initializing the RSPI • Loopback mode
Low power consumption function	Module stop state can be set.

Note 1. In master reception and when the RSPCK auto-stop function is enabled, an overrun error does not occur because the transfer clock is stopped at the timing of overrun error detection.



SPCR:	RSPI control register	SSLND:	RSPI slave select negation delay register
SPCR2:	RSPI control register 2	SPND:	RSPI next-access delay register
SSLP:	RSPI slave select polarity register	SPCMD:	RSPI command registers 0 to 7 (eight registers)
SPPCR:	RSPI pin control register	SPBR:	RSPI bit rate register
SPSR:	RSPI status register	SPTX:	RSPI transmit buffer
SPDR:	RSPI data register	SPRX:	RSPI receive buffer
SPSCR:	RSPI sequence control register	SPTI:	RSPI transmit interrupt
SPSSR:	RSPI sequence status register	SPRI:	RSPI receive interrupt
SPDCR:	RSPI data control register	SPII:	RSPI idle interrupt
SPCKD:	RSPI clock delay register	SPEI:	RSPI error interrupt

Figure 44.1 RSPI Block Diagram

Table 44.2 lists the I/O pins used in the RSPI.
The RSPI automatically switches the I/O direction of the SSLA0 pin. SSLA0 is set as an output when the RSPI is a single master and as an input when the RSPI is a multi-master or a slave. Pins RSPCKA, MOSIA, and MISOA are automatically set as inputs or outputs according to the setting of master or slave and the level input on the SSLA0 pin. Refer to section 44.3.2, Controlling RSPI Pins for details.

Table 44.2 RSPI Pin Configuration

Channel	Pin Name	I/O	Function
RSPI0	RSPCKA	I/O	Clock I/O
	MOSIA	I/O	Master transmit data I/O
	MISOA	I/O	Slave transmit data I/O
	SSLA0	I/O	Slave selection I/O
	SSLA1	Output	Slave selection output
	SSLA2	Output	Slave selection output
	SSLA3	Output	Slave selection output

44.2 Register Descriptions

44.2.1 RSPI Control Register (SPCR)

Address(es): RSPI0.SPCR 000D 0100h

	b7	b6	b5	b4	b3	b2	b1	b0
	SPRIE	SPE	SPTIE	SPEIE	MSTR	MODFEN	TXMD	SPMS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SPMS	RSPI Mode Select	0: SPI operation (4-wire method) 1: Clock synchronous operation (3-wire method)	R/W
b1	TXMD	Communications Operating Mode Select	0: Full-duplex synchronous serial communications 1: Serial communications consisting of only transmit operations	R/W
b2	MODFEN	Mode Fault Error Detection Enable	0: Disables the detection of mode fault error 1: Enables the detection of mode fault error	R/W
b3	MSTR	RSPI Master/Slave Mode Select	0: Slave mode 1: Master mode	R/W
b4	SPEIE	RSPI Error Interrupt Enable	0: Disables the generation of RSPI error interrupt requests 1: Enables the generation of RSPI error interrupt requests	R/W
b5	SPTIE	Transmit Buffer Empty Interrupt Enable	0: Disables the generation of transmit buffer empty interrupt requests 1: Enables the generation of transmit buffer empty interrupt requests	R/W
b6	SPE	RSPI Function Enable	0: Disables the RSPI function 1: Enables the RSPI function	R/W
b7	SPRIE	RSPI Receive Buffer Full Interrupt Enable	0: Disables the generation of RSPI receive buffer full interrupt requests 1: Enables the generation of RSPI receive buffer full interrupt requests	R/W

If the SPCR.MSTR, SPCR.MODFEN, or SPCR.TXMD bit is changed while the SPCR.SPE bit is 1, subsequent operations should not be performed.

SPMS Bit (RSPI Mode Select)

The SPMS bit selects SPI operation (4-wire method) or clock synchronous operation (3-wire method).
The SSLA0 to SSLA3 pins are not used in clock synchronous operation. The RSPCKA, MOSIA, and MISOA pins handle communications. If clock synchronous operation is to proceed in master mode (SPCR.MSTR = 1), the SPCMDm.CPHA bit can be set to either 0 or 1. Set the CPHA bit to 1 if clock synchronous operation is to proceed in slave mode (SPCR.MSTR = 0). Operation should not be performed if the CPHA bit is set to 0 when clock synchronous operation is to proceed in slave mode (SPCR.MSTR = 0).

TXMD Bit (Communications Operating Mode Select)

The TXMD bit selects full-duplex synchronous serial communications or transmit operations only.
When performing communications with the TXMD bit set to 1, the RSPI performs only transmit operations and not receive operations (refer to section 44.3.6, Communications Operating Mode).
When the TXMD bit is set to 1, receive buffer full interrupt requests cannot be used.

MODFEN Bit (Mode Fault Error Detection Enable)

The MODFEN bit enables or disables the detection of mode fault error (refer to section 44.3.8, Error Detection). In addition, the RSPI determines the I/O direction of the SSLA0 to SSLA3 pins based on combinations of the MODFEN and MSTR bits (refer to section 44.3.2, Controlling RSPI Pins).

MSTR Bit (RSPI Master/Slave Mode Select)

The MSTR bit selects master/slave mode of the RSPI. According to MSTR bit settings, the RSPI determines the direction of pins RSPCKA, MOSIA, MISOA, and SSLA0 to SSLA3.

SPEIE Bit (RSPI Error Interrupt Enable)

The SPEIE bit enables or disables the generation of RSPI error interrupt requests when the RSPI detects a mode fault error and sets the SPSR.MODF flag to 1, when the RSPI detects an overrun error and sets the SPSR.OVRF flag to 1, or when the RSPI detects a parity error and sets the SPSR.PERF flag to 1 (refer to section 44.3.8, Error Detection).

SPTIE Bit (Transmit Buffer Empty Interrupt Enable)

The SPTIE bit enables or disables the generation of transmit buffer empty interrupt requests when the RSPI detects when the transmit buffer is empty.
